Work-family enrichment has emerged as a positive way to test the work-family interface and its influence on outcomes. However, there has been little study of enrichment on indigenous populations, and furthermore, there has been little attention paid to outcomes associated with cultural elements. The present study tests work-family enrichment (WFE) and family-work enrichment (FWE) towards Maori cultural outcomes as a way to explore the importance of Maori culture in the New Zealand workplace. In addition, collectivism was tested as a potential moderator of these relationships due to Maori having strong collectivistic notions. Data were collected from 172 Maori employees, with data collected in two time periods, separating predictors (time 1) from outcomes (time 2), with a four week gap. Two distinct factors were found regarding cultural values in the workplace: work cultural enjoyment and work cultural satisfaction. Regression analysis was conducted with WFE and FWE predicting outcomes with collectivism included as a potential moderator. WFE was significantly linked to cultural work enjoyment while FWE was significantly linked to cultural work satisfaction. Enrichment accounted for sizeable amounts of variance towards cultural work enjoyment (15%) and cultural work satisfaction (29%). In addition, collectivism was tested as a potential moderator and was found to significantly interact with FWE towards cultural work enjoyment and with both WFE and FWE towards cultural work satisfaction. The interaction effects accounted for minor additional variance of 3% to cultural work enjoyment and 2% towards cultural work satisfaction. Regarding cultural work enjoyment, interactions showed that high collectivism was most advantageous at low levels of FWE only, leading to higher levels of cultural work enjoyment. Regarding cultural work satisfaction, high collectivism leads to greater satisfaction at all levels of WFE, and similarly, towards satisfaction at all levels of FWE. These significant interaction effects highlight the importance of collectivism for indigenous employees and the way it can interact with enriching aspects of the work-family interface and how indigenous workers may view culture in the workplace. Overall, there is strong support for enrichment influencing cultural workplace outcomes, especially FWE which aligns well with Maori and their focus on whanau or extended family.

Abstracts of the 27th International Congress of Applied Psychology

**Work-life balance: A longitudinal analyses of the mediating effects of conflict and enrichment processes across Australian and Chinese samples**

KALLIATH, T. (Australian National University), MARMEN, J. (Australian National University), BROUGH, P. (Griffith University), SIU, O. (Lingnan University), O'DRISCOLL, M. (Waikato University), TIMMS, C. (Griffith University), LO, D. (Shue Yan University)

The aim of the current study was to address some theoretical and methodological gaps in work-life balance (WLB) literature by evaluating the longitudinal nexus between WLB and its antecedents and outcomes within the framework of Conservation of Resources (COR) theory and Job Demand-Resources (JD-R) model across Australian and Chinese samples. The study used two-wave longitudinal data collected from two different cultural settings, Australia, \(n=846\) and China, \(n=854\). The estimation of relevant parameters, test for the hypothesized coefficients, and assessment of stability and cross-lagged paths were based on longitudinal structural equation modeling. In the mediating process, time-based WFCT was the most influential mediator revealing that the mediating effect was stronger in the Australian sample than in the Chinese sample. The direct effect of supervisor support on WLB was significant in Chinese sample and the direct effect of work demands on WLB was significant in the Australian sample. The impact on psychological strain was significantly higher in the Australian sample, than in the Chinese sample, confirming cultural effects in the tested models. The variance explained in WLB by explanatory variables was higher in the Australian sample than in the Chinese sample. First, it was found that an overall work-life balance construct that is independent of conflict and enrichment processes make a useful contribution to advance theory and improve practice. Second, the cross-lagged modeling of the effects of demands (work and home) and resources (work and home) on work-life balance through two underlying psychological processes (‘health impairment pathway’ and ‘motivation pathway’) confirm the key tenants of JD-R model and COR theory. Third, the cross-lagged modeling uncovered the mediating role of conflict and enrichment processes in the relationship between demands and resources and work-life balance, the conflict processes were clearly more dominant than enrichment processes in the tested models. Finally, there is evidence to support cultural differences in the dynamics of WLB in Australian and Chinese samples.

**Workspace, employees’ territoriality and affective consequences: A critical review**

AYOKO, O. (University of Queensland), JEHN, K. (The University of Melbourne), ASHKANASY, N. (The University of Queensland)

In this presentation, we discuss research connecting office space, emotions, attitudes and acts through the lens of employee territoriality, its effect on team affective processes and the consequences that follow. Literature suggests that office size and features drive employees’ territoriality of marking and defending. Moreover, the consequences of workplace territoriality are paradoxical. Office size influences employees’ health status, while open space offices reduce costs, improve communication and foster relationships. Likewise, control of territory leads to identity, security and stimulation, which increase productivity. In contrast, territoriality holds potential to increase conflict, aggression, frustration, turnover, noise, and loss of privacy leading to inefficiency. Studies also show that workspace features connect affectivity. For example, physical aesthetic features affect employees’ mood and behaviours. Similarly, open-plan office leads to poor satisfaction and motivation while the interaction between noise and light collocates with the recall of negative emotional words. Nevertheless, the development of instruments designed to study territoriality at work is in its infancy. In our presentation, we discuss two critical questions: How can we reduce the negative and promote the positive affective consequences of employees’ territoriality? How can we study the connection between workspace, territoriality and team affective outcomes? Further research should explore three phenomena related to...
territoriality and affectivity. First, time is crucial; the same territorial behaviours initially provoking conflict may later reduce conflict because of more defined boundaries. Second, team composition should moderate overtime the impact of territorial affective products (conflict, emotions) on team outcomes. Thirdly, training could ameliorate the negative effects of workplace territoriality. We recommend that researchers use a multi-method design to study workplace territoriality and team affective interactions qualitatively (e.g., experience sampling method) and quantitatively (physiological data) over time. Results hold potential to further our understanding of the role of time, team composition and training in the association between workspace behaviours and affectivity to improve managers’ territorial management skills. Our review expands the literature on territoriality and team affectivity with a potential to improve personal and managerial skills in this area.

"How did this happen? What can we do?"
Comparing family members' beliefs about adolescents' medically unexplained somatic symptoms

BIBBY, H. (Adolescent Medicine, The Children’s Hospital at Westmead), SAMPSON, S. (The Children’s Hospital at Westmead), BENNETT, D. (The Children’s Hospital at Westmead), HOFFMAN, R. (The Children’s Hospital at Westmead), TOWNS, S. (The Children’s Hospital at Westmead)

This study involved 50 adolescents (aged 12 to 17 years) with medically unexplained somatic symptoms and their families. They received a multi-disciplinary, rehabilitative treatment program which attempts to help them gradually draw a link between somatic and psychological aspects of the adolescent’s condition. The aim of this study was to compare family members’ health beliefs over the course of treatment. Thirty-six percent of the adolescents met criteria for Chronic Fatigue Syndrome, and the remaining 64% received a DSM-IV diagnosis of one of the Somatoform Disorders. Participants and their parents completed questionnaires measuring physical and psychosocial functioning (the Child Health Questionnaire) and health beliefs (the Illness Perception Questionnaire) at recruitment, four months into treatment, and 12 months later. Analyses of variance (ANOVAs) were conducted to examine how adolescent functioning and family health beliefs changed over the 12-month period, and to compare family members’ health beliefs over time. There were significant improvements in adolescent physical and psychosocial functioning over the first four months of treatment, and these were maintained at 12 months. In terms of beliefs about what caused the adolescent’s condition, significant interaction effects were obtained such that parents became increasingly open to the role of psychosocial causes, while adolescents did not. In terms of beliefs about what might cure/control the condition, significant main effects for time and family member were obtained, as well as a significant interaction effect. Follow-up contrasts revealed that fathers placed greater importance on the adolescent’s role in cure/control (relative to the role of treatment) than other family members, and that this difference became more marked over time. This study provides support for a family-based approach to adolescents with medically unexplained somatic symptoms. It illustrates that parental health beliefs may be more amenable to change than those of the adolescent.

'Dokic is not an Australian name': Constructions of identity, culture and nation in Australian perspectives on multiculturalism

DANDY, J. (Edith Cowen University)

The Australian multicultural ‘experiment’ has often been described as highly successful, resulting in the “peaceful co-existence” of diverse groups (Borowski, 2000, p. 461). Whilst there is some evidence to support this, there remains considerable racial and ethnic discrimination in Australia as well as continued ambivalence in Australians’ attitudes toward multiculturalism and acceptance of ‘outgroups’. In this paper I will discuss these attitudes, their features and their possible foundations. In so doing, I will draw upon interview and survey data collected over the past five years, including the Australian Pilot for the International Study of Attitudes Toward Immigration and Settlement (ISATIS; Dandy & Pe-Pua, 2009). I will argue that there are competing discourses in Australian multiculturalism that echo concerns in other diverse contexts and nations. Australians’ support for multiculturalism is connected with beliefs in social equality and egalitarianism but these are in tension with fears of threats to Australian national identity and social cohesion. These fears can be linked to essentialist discourses of race and ethnicity, as well as beliefs that cultural homogeneity is necessary for strong communities (Dunn, Forrest, Burnley, & McDonald, 2004). I will propose that these discourses serve to reinforce white multiculturalism in Australia, in which Australian identity remains centred around a white, British cultural heritage (Dandy, in press; Forrest & Dunn, 2006; Hage, 1998). The paper will conclude by opening for discussion of ways that researchers and policymakers can contribute to the development of a more inclusive
construction of national identity in Australia and other diverse contexts.

'Making sense' of climate change response: Reframing the applied challenge of climate change mitigation and adaptation.

O'NEILL, G. (Griffith University)

Climate change (CC) constitutes the most significant challenge facing humanity and the natural environment this century. Substantial debate continues in the media as to whether CC is real, and if it is, whether the prime causes are anthropogenic, natural cyclical patterns of the earth’s climate, or some combination of these. These social representations of CC have resulted in a confusion of beliefs and concerns. A substantial proportion of the public is reported as believing that the risks of CC and its likely impact on their life are low, to be skeptical about any immediate direct threat to themselves, and as not feeling personally vulnerable or responsible for CC. For others, apocalyptic predictions and media doom-saying are arguably resulting in feelings of despair and hopelessness. Research into public understandings of CC can be usefully informed by conceptual frameworks such as ‘sense making’ (SM) and the ‘social amplification and attenuation of risk’ (SAAR). Such models can assist in identifying key factors influencing risk perception and appraisal, and in designing effective messages and strategies to foster appropriate behaviour change. Inter alia, empirical research based on SM and SAAR could provide valuable insights into how individuals deal with and respond to CC. For example, SM is a framework and an approach in psychology and the social sciences which addresses how individuals and societies make sense of their world and their experiences from the myriad of cues in their external (social, physical, etcetera) and internal (cognitive, affective, etcetera) environments. Sense making is also the underlying process that individuals use to make sense of a threat and phenomenon such as climate change. Social amplification of risk is a phenomenon in which risk events or perceived threats become heightened through collective information processing and sense making. Public perceptions of risk are influenced by such sources as news media, scientists, private networks, public agencies, other institutions and personal experience. Risk is also amplified by intra-individual information processing and sense making biases. Factors that appear to contribute to risk attenuation include protection motivation, level of trust and credibility in information sources, and the extent of disagreement or debate. This paper assesses the extent to which selected theories, models and conceptual frameworks provide a useful basis for exploring important psychological aspects of how individuals and societies perceive, appraise and make sense of climate change.

‘NIMBYism’ and public participation in electricity network change

DEVINE-WRIGHT, P. (University of Exeter)

The United Kingdom Government plans to implement greater low-carbon electricity generation from both nuclear and renewable energy sources in response to the problem of climate change. These changes lead to a need to extend and reinforce the existing electricity network to connect new generating sources and balance electricity demand and supply. New overhead line proposals, often in rural areas, are problematic due to public reactions to proposed routes, reactions often dubbed ‘NIMBYism’. Public opposition has emerged around issues such as potential health risks from electric and magnetic fields, damage to visual amenity and household property values. As such, the rationales and methods of engagement between network operators such as National Grid and local communities affected by line proposals are of critical importance for understanding how individuals’ respond to technology proposals. This paper draws together the results of two ongoing qualitative studies: interviews with key actors in the networks industry around issues of public roles and engagement methods (n = 25) and an investigation of representations of public

Abstracts of the 27th International Congress of Applied Psychology

1031 Brief Oral Presentations
participation in network planning using the Q-method with a diverse sample of local actors in affected line proposal communities \((n = 28)\). The findings show how recent regulatory change has encouraged greater levels of engagement by network operators with members of the public. However, this typically occurs at a level ‘downstream’ of the decision-making process. We conclude that industry engagement practices lack a clear rationale and means to incorporate citizen perspectives ‘upstream’ in network planning. If these factors could be resolved, then this may mitigate public opposition and foster mutual trust between network organisations and citizen groups.

"All my hurts my garden spade can heal": The meaning of domestic gardens in the lives of community-dwelling older adults

SCOTT, T. (University of Queensland), PANCHANA, N. (University of Queensland)

Human attraction to gardens and green-spaces goes beyond mere aesthetics. According to Biophilia theory, we are not only genetically programmed to respond positively to natural environments, our emotional, intellectual, and physical well-being depends upon having access to nature. The extant literature supports the therapeutic value of gardens, plants and horticultural activities for a variety of populations; however few studies have systematically explored the importance of the domestic garden in the lives of community-dwelling older adults. A gardening survey, developed for this study, included an activity inventory; several open and closed questions about involvement in, and feelings about, gardens; Attitudes to Ageing Questionnaire (AAQ); demographic information; and subjective health and quality of life. The survey was distributed to a large sample (approximately 300-plus) of community-dwelling older adults across Australia. Participants reported numerous benefits associated with their gardens and gardening activities, which could be summed up as tangible, physiological or psychological rewards. For some participants, active pursuit of their gardening activities, despite experiencing physical limitations since first gardening, was extremely important, while for others, simply ‘being’ in the garden was of value. Participants reported reminiscence of childhood gardens, and the desire to pass on the benefits of experiences to younger people; this latter effect increased with age. Other benefits included a sense of purpose from cultivating plants; having an outlet for physical activity and exercise; and social benefits, which were significantly increased for those members of a gardening club. Participants overwhelmingly agreed that if they had to leave their gardens, it would be important to continue gardening elsewhere. Encouraging continued participation in gardening activities may be one way to support older adults’ ageing in place. Home gardens and related activities afforded older adults the opportunity for increased well-being, meaningful engagement and manageable physical activity. The results also have implications for the establishment of community gardening programs as a means of providing a common shared interest with other older adults and with future generations, through mentoring younger participants; and for the establishment of gardening activities in residential care facilities as gardens provide a link to the past and a connection to the outside world, according to this sample.

"Dynamic sequences of behaviour" (DSB): Development of an inventory for the analysis of processes which can lead to burnout and inner emigration

JIMENEZ, P. (University of Graz), SEILINGER, B. (University of Graz), HASIBEDER, J. (University of Graz)

Dynamic processes and behaviours which can increase the risk for burnout and inner emigration are mentioned in the literature. The processes themselves are studied very seldomly in individual and organizational analyses. The newly developed questionnaire is based on a system analytic approach and allows detecting self-reinforcing dynamic circles of behaviour in
critical person-situation interactions. The questionnaire was tested together with additional instruments (CSESd, RESTQ-Work, EDEM, HOM-scale of HAKEMP-90, MBI-GS-D) with 900 employees of a non-profit-organization. The consistency of the scales and subscales is presented; the scales prove to have good values. Validity was tested with structural equation modeling. The items of the Dynamic Sequences of Behaviour inventory (DSB) refer to concrete behaviour of persons in situations at work. These situational sequences are based on models of burnout and also inner emigration and allow detection of critical self-reinforcing cause-effect circles. The important aspect of the questionnaire is to use it for prevention purposes in an organizational diagnosis. The use of the questionnaire helps to derive interventions for individuals for changing their behaviour and also for the work environment in the organizations in a differentiated way.

Keywords: burnout, person-situation interactions, work environment, behaviour change

"Narativizing" a vocal tic: The use of narrative therapy in the ridding of "Mr Squeaky in a single session"

FERNANDEZ, M. (Northcentral University)

Using the well known philosophical approach of externalising the problem (Fernandez, 2001; White & Epston, 1990) in Narrative Therapy, the technique of “interviewing the problem” was used in extinguishing an ubiquitous vocal tic, “Mr Squeaky”, that had afflicted a 9-year old girl for over two weeks. The vocal tic was not only interfering with her social network at school and at home but also with her sleep. “Interviewing the problem” involved a series of externalising questions that separated the problem from the person and created space to “see the problem” for what it was. In mapping out the influence of the tic, several questions were asked that focused on the reasons for the tic; how it happened to choose this child; what its plans were for her; whether it saw itself leaving the child; whether there was a possibility of it having a “holiday” so it could allow the child to sleep etc. All questions were addressed to the child, with the therapist facing the “problem” while asking the questions. This is an approach that is not often used for behaviours of this nature. Carr, Taylor, Wallander, & Reiss (1996), among others, have noted that a functional treatment of habit forming behaviours has been the usual mode of treatment for tics. Over 90% of the tic had disappeared from her person by the second session (a gap of a week between the first and second sessions), with the remaining expressions of it extinguished by the beginning of the third session (a gap of a week between the second and third sessions). At the third session the tic was brought into the session in an airtight container labelled “Squeaky lives here.” In this age of brief therapies, Narrative Therapy represents a novel way of extinguishing dysfunctional behaviours or habits. The use of a story metaphor is very attractive to children, and allows children to experiment with behavioural control in a way that empowers them.

Keywords: externalising the problem, narrative therapy, interviewing the problem, habit development, tics

“Their system, our crisis!” A French study of the social representations, personal involvement and behavioral responses to the financial crisis of 2008

ERNST-VINTILA, A. (Universite de la Mediterranee Aix-Marseille II), DELOUVEE, S. (Universite Europeenne Rennes 2)

This empirical study focused on laypeople’s thinking about the financial crisis of 2008 in France, and shows how established practices and personal involvement affected the social representations of the crisis, and the subsequent behaviors. The originality of this study consists in completing an analysis of laypeople’s thinking about the financial crisis at the positional level of explanation, a complement to the ideological level often used in sociology, and to the intra- and inter-individual levels often adopted in psychology. Previous studies showed that established practices are a determinant factor in shaping social representations, and suggested personal involvement as a major explanatory variable. Personal involvement (Flament and Rouquette, 2003) corresponds to an individual’s relationship to a social object, such as the financial crisis, and is a combination of three
The study was run in France in the first month of the financial crisis (October 2008). It was conducted within the structural approach to the Theory of Social Representations (TSR), which enables formal comparisons among representations with the aid of its specific methodologies (cf. infra). To compare the social representations of the financial crisis among participants (N = 30) who had different levels of practice we questioned senior executives of the financial sector, and lay participants. Participants’ personal involvement was measured as a selection variable on six-point Likert scales. The structure of the social representations of the financial crisis was analysed through a standard procedure developed within the structural approach of the TSR: prototypicality analysis (Vergès, 1992). Results showed that, relatively to the executives, lay participants reported significantly lower personal involvement (lower valuation of, exposure to, and also perceived capacity to act on the crisis). However, all participants perceived collective action as more effective than individual action. This finding may be an explanation of the high expectations of French for institutionalised (as opposed to individual) action (though other explanations, such as the French culture’s relatively high uncertainty avoidance (cf. Hofstede), should be considered, too). In both groups, the social representation of the financial crisis displayed salient normative aspects and, especially for lay participants, low functional orientation. This structure explains the social representations’ low efficiency in prescribing behaviors (inertia). Indeed, little change in consumer behavior was reported by lay participants. In contrast, all executives in the sample reported immediate behavioral change of at least one consuming behavior (individual action), and having additional intentions of behavioral change if the crisis continues. The TSR predicts that the behavioral change reported by executives is temporary and conditional (“if” the crisis continues), unless the change brought by the crisis in the general context is perceived as irreversible (Rouquette and Rateau, 1998). A study in progress should tell if this is the case, or if the crisis contributed to a sustainable behavioral change, that is, a change in consuming habits, especially knowing that the end of the crisis (reversibility of context) is predicted for 2010 to 2011.

**Keywords:** financial crisis, social representations, behaviour change

### 2D:4D Digit ratio and close following

LEWIS-EVANS, B. (Traffic and Environmental Psychology Group, University of Groningen), DE WAARD, D. Y. (University of Groningen), ALBERDA, R. H. (University of Groningen), TALAROVICOVA, S. A. (Comenius University Bratislava)

The 2D:4D digit ratio, the ratio of finger length between the index and ring finger, has been linked to exposure to testosterone at a specific point in the development of the fetus. Higher levels of testosterone at this point in development result in lower 2D:4D ratios, and in turn digit ratios have been correlated with a range of behavioural outcomes, such as sexual orientation, sensation seeking, stock trading and risk taking. This experiment set out to use a driving simulator to examine the relationship between 2D:4D digit ratio, close following, sensation seeking and risk perception. Digit ratios were measured using a scanner and the GIMP software for windows. Participants were then required to follow a car at 50 kilometers per hour over several different distances, ranging from 7.9 meters to 56.1 meters, as well as being able to select their own following distance. Ratings of risk, task difficulty, effort and comfort were collected after each drive and analysed. Participants also filled in the Sensation Seeking Scale. The lateral displacement and following distance of participants (in the free following condition) were also recorded. The results are in the final stages of being collected, and will be analysed and fully available at the time of the conference. The findings of this study will be discussed in terms of their relevance to driver safety, and the usefulness of the 2D:4D ratio to indicate a propensity for producing risky driving behaviours.

**Keywords:** digit (finger) ratios, driving simulation, sensation seeking, risky driving behaviours, risk perception
Abstracts of the 27th International Congress of Applied Psychology

A classroom intervention to facilitate students’ asking questions

NGUYEN, H. H. (California State University, Long Beach), LEWIS, M. (California State University)

What can be done to increase the frequency of question asking and broaden the types of questions that individuals may ask in the classroom? The researchers hypothesized (a) that students would ask more questions if they could ask the questions anonymously and receive feedback from educators, (b) that the quality of questions would change from lower cognitive types of questions to higher cognitive ones during the intervention, and (c) that students’ learning approaches would change from surface-learning to deep-learning. This study used a mixed design of natural observation and pretest-posttest, two-group intervention. The first author sat in two sections of the same course (introduction to industrial-organizational psychology) taught by the second author, and observed students’ target behavior (asking questions verbally) in their natural setting (classroom) for 12 class periods per section (N = 51). Both frequency of question asking, question content, and types of questions asked were recorded. On the 7th class observation, the researchers recruited voluntary participants to respond to two pretest and posttest surveys for extra credits. The experimental group (participants in one course section; n = 23) additionally received the intervention: (a) they were asked to anonymously submit in writing any questions that they had not verbally asked in class, and (b) they received the researchers’ answers to their questions at the beginning of a following class period. The surveys consisted of a measure of student’s learning process (deep versus surface learning) and demographic questionnaire. The qualitative data (students’ verbal and written questions asked) were coded according to Bloom’s (1956) taxonomy of educational objectives, and the quantitative data were analyzed to detect group mean differences. As predicted, students in the experimental group asked significantly more questions (both verbally in class and in writing) than the control group because of the intervention. Further, some students in the experimental group reported a significant shift from baseline surface-learning approach to deep learning approach at the end of the study. However, the types of questions asked did not change: students were still more likely to ask procedural questions than questions about materials presented. This study has several practical implications for both teachers and employers: an environment of anonymously submitted questions may encourage students’ or employees’ question-asking behavior because individuals do not want to feel embarrassed or look incompetent by asking questions in the open. Also, individuals tend to ask more procedural questions than explanation questions, which may be beneficial for organizations that require their employees to know how to do something, even if they do not know why they should do it. Last, teachers or employers should not expect that students/new hires know how to apply or evaluate classroom information into the real-world setting, or that they would be willing to admit their ignorance by asking clarifying questions. Therefore, students or staff should be given proper training or orientation to perform their tasks correctly.

Keywords: classroom questions, students, surface versus deep learning, learning approaches

A comparison investigation of episodic memory in schizophrenic patients, their biological relatives and normal people

NIKPOUR, G. (Applied & Science University of Behzisti, Ghaemshahr Branch), HOMAYOUNI, A. (Islamic Azad University)

This study aimed to investigate episodic memory in schizophrenic patients, their biological relatives and comparison with normal people. Twenty schizophrenic patients, 20 their biological relatives and 20 normal people were randomly selected and William’s Individual Episodic Memory Test (WIEMT) was administered on them. In the research, the participants were presented 15 target words (five pleasant, five unpleasant, five neutral words). The participants were asked to recall a past memory associated with target words. An ANOVA test was used to analyze the data. Findings showed significant differences among groups. The majority of schizophrenics were oriented to choose neutral and somewhat unpleasant stimuli (words) and recall their past...
memory with a depressive and unpleasant matter and their relatives too. However the majority of normal people chose the better and pleasant words with good and pleasant past memories. Our results reveal that deficits in episodic memory can be regarded one of the most prominent cognitive deficits in schizophrenia and should thus be taken seriously in both its diagnosis and treatment. It stresses the importance of assessing memory function impairments in clinical settings. Also, choosing the neutral (and not pleasant) stimuli (words) may cause a tendency to depressed mood and can impair social cognition in schizophrenia that may be an important predictor of social dysfunction.

Keywords: schizophrenia, memory function, assessment of schizophrenia, episodic memory, social dysfunction

A comparison of international and local students on fear of external threats and fearfulness: A cognitive behavioural perspective

XIONG, L. (RMIT University), SMYRNIOS, S. (RMIT University), SMYRNIOS, K. (RMIT University)

Two inter-related studies compared international with local students on their specific fears of external threats (e.g., crime and public places) and on fearfulness. Mass media reports of crimes against international students have emphasised external threats, while Culture Shock Theory proposes that international students are more likely to report feeling fearful than their local counterparts due to internal processes of adjustment. A cognitive behavioural theoretically based model of fear of crime underpinned this investigation. Quantitative studies utilised nonclinical and clinical participants respectively. Study 1 surveyed 591 international and 579 local students across four universities regarding victimisation, perceptions of social disorder, perceived risk and fears of specific crimes, and avoidance behaviors. Study 2 compared 640 international and 2252 local students presenting at a university counselling center on a range of clinical variables, including fearfulness and feeling afraid of public places. Data analysis utilised Structural Equation Modelling. Study 1 found that compared with local counterparts, international students express higher levels of fear of crime. Testing of the cognitive behavioural model showed a nonrecursive relationship between cognitions, emotions, and behaviours associated with fear of crime. All three factors are significantly related to participants’ perceptions of social disorder and their levels of social integration. However, experiences of victimisation have a nonsignificant impact on avoidance behavior. For clinical participants in Study 2, comparisons of cohorts on fearfulness and feeling afraid of public places are nonsignificant. Depression and somatisation are significantly related to both fears for both groups. However, depression is more strongly related to fearfulness whereas somatisation is the strongest predictor of feeling afraid of public places. Separate comparisons of international and local students on other clinical variables showed different patterns of relationships to the two types of fear. Implications arising from Study 1 suggest the importance of addressing issues relating to social integration and engagement of international students in influencing perceived risk, fears of crime and avoidance behaviors. Study 2 highlights the role of the depression and other clinical issues in fears for both international and local students.

Keywords: international students, victimization, culture shock theory, fearfulness, threat

A cross-cultural study of computer games and internet addictions in middle schools

YE, R. (Houston Independent School District, Research), GU, H. (Shanghai Normal University), LU, J. (Shanghai Normal University)

This study explores and analyzes middle school students’ computer games and Internet addictions and the relationships of these two addictions with factors regarding students’ backgrounds, interests, activities, associations and academic studies in nine countries: Australia, Canada, England, Hungary, Israel, Japan, Korea, Russia, and the United States. International database was used: TIMSS 1995, 1999, 2003, and 2007. The sample was from the eighth grade and a Student Questionnaire was used. Tables, figures, descriptive methods and
correlation were used. Middle school students’ computer game addictions increased from 1995 to 2003 but these rates decreased in 2007 in some countries; for the current four years, Internet addiction rates have quickly increased in all participating countries except Korea. Male students play computer games significantly more than females do, but gender differences in using the Internet are very different among the countries; home study conditions are also positively related to Internet addictions but are negatively related to computer game addictions in some countries; the numbers of books in a student’s homes has similar results as the home study condition with two addictions; and in a general, parents’ education levels have negative relationships with the addictions. The results also reveal that students being bullied in schools, hurt by others or made to do things they do not want was also related with their addictions. These two addictions also influence students’ learning habits for outside-of-school reading and doing homework greatly, but results have large differences among the countries. Finally, the relationships between the addictions of computer games or Internet and students’ academic achievement, interests, feelings regarding school and expectations for education are identical: all relationships are negative and almost all of them are significant. In conclusion, computer games and Internet addictions are have developed quickly in middle and high schools in all countries, and there are many resulting negative influences on students’ study, life, attitudes and activities. It is necessary to find effective testing, find preventing methods and the first step is to analyze current situations and related factors, and summarize and develop practical experiences for all students in the world.

Keywords: internet addiction, computer game addiction, student addiction, video games and students

A cross-cultural study of instrumental motivation towards school science learning: Findings from PISA

Li, Z. (Education College of Shanghai Normal University), LI, Z. (Shanghai Normal University), GU, H. (Shanghai Normal University), YE, R. (Houston Independent School District)

This study explores and analyzes 15-year-old students’ instrumental motivation towards school science learning and its gender difference, the relationships between instrumental motivation and students’ social, economic and cultural status, and their school science academic achievements in nine countries (regions): United States, Japan, United Kingdom, Germany, France, Hong Kong-China, Macao-China, Chinese Taipei, and China. An international database was used and Student Questionnaire of PISA 2006 was answered by the 15-year-old students. The five indices of instrumental motivation towards school science learning were “help later work”, “learn need later”, “useful to me”, “improve my career”, and “get a job”. Descriptive methods, figures and tables, ANOVA, t-test, Pearson correlation and multiple linear regression were used. On average, 15-year-olds from all the nine countries (regions) were more likely to value school science as an instrument that could “help later work” and “useful to them” and Chinese students’ instrumental motivation towards school science learning was the strongest. The situation of gender differences of instrumental motivation is very different among all the countries (regions). Parents’ education level influenced the five aspects of students’ instrumental motivation in very different ways among all the nine countries (regions), but in general, it was positively related to the instrumental motivation. Educational resources such as education software and cultural possessions such as art works at home both had significant positive effects on students’ instrumental motivation in most countries (regions). However, family wealth such as cars was a less effective influencing factor on students’ instrumental motivation. We also found the index that school science is “useful to me” was a good predictor of students’ science achievement in school. In general, instrumental motivation was very important for 15-year-olds in their school science learning. Since students who believe science is useful to them would be more likely to make an effort on learning science and gain a higher achievement on it we believe that improving students’ instrumental motivation could guarantee students put their time and attention into learning science, transforming it into a genuine interest.
Keywords: student’s interest in science, instrumental motivation, science learning, students

A cross-culture study on aesthetic preference for traditional Chinese and western paintings

BAO, Y. (Peking University), LEI, Q. (Peking University), FANG, Y. (Peking University), WANG, Y. (Peking University)

Western and Chinese artists have different traditions in representing the world in their paintings. While western artists since the Renaissance period represent the world with a geometric perspective and focus on salient objects in a scene, Chinese artists since before the mid-nineteenth century continue to apply a reversed geometric perspective and concentrate more on context information in traditional Chinese paintings. The present study aimed to find out whether these different ways of representation influence the aesthetic preference for traditional Chinese and western paintings in different cultural groups. Forty-six Peking University students, of whom half were Chinese and half were westerners, participated in the study. Eighty traditional Chinese paintings and 80 western paintings were presented randomly on a computer screen for an aesthetic evaluation. Both Chinese and western paintings included two categories: landscapes and people in a scene, with 40 paintings in each category. All paintings were selected for their culturally different ways of representation according to a theoretical analysis. Students were asked to evaluate the beautifulness of each painting by pressing a corresponding number key from one to eight. Number one represented the ugliest painting and number eight - the most beautiful painting. Results showed a significant interaction between source of painting and cultural group. For typically represented Chinese and western paintings, a pattern of aesthetic preference was observed. Chinese students gave higher aesthetic scores to traditional Chinese paintings than western paintings, and foreign students from western countries tended to give lower aesthetic scores to traditional Chinese paintings than western paintings. These results suggest that the way artists represent the world in their paintings influences how culturally embedded viewers perceive and appreciate paintings. The clear cultural difference in aesthetic preference for traditional Chinese and western paintings might be correlated to culturally different perceptual habits and social practices in every life of the different cultures.

Keywords: cross-cultural, aesthetic preference, Chinese painting, western painting

A cross-level perspective on employee voice: Goal orientation and team psychological safety

DENG, J. (Zhejiang University), WANG, Z. (Zhejiang University)

Relevant academic research showed that employees with specific personality traits are more willing to speak up than others and the relationship between individual goal orientation, team climate and employee voice with people of Chinese cultural background still remained unclear. Based on self-motivation and person-situation interactions theories, this study developed a cross-level model of individual goal orientation, team psychological safety and employee voice, and tried to gain a better understanding about individual behavior and context. The sample constituted 27 sale-teams comprising 201 employees recruited from a large chemical company in China. Based on hierarchical linear modeling, we explored three models to test individual-level effects, team-level effects, and cross-level interaction effects on employee voice respectively. We also computed the proportion of variance in employee voice explained by individual-level factors as well as by team-level factors. The results showed that, individual-level, employee developing orientation and approach orientation are positively related to employee voice, while avoidance orientation is negatively related. In team-level, the team psychological safety has not only directly impacted on employee voice but also has positively moderating effects between individual approach orientation and employee voice — the team’s psychological safety strengthened the positive relationship between approach orientation and employee voice. However, cross-level interaction effects of team psychological safety with developing orientation and avoidance orientation were not significant. From an achievement motivation and
person-situation interactions perspective, this study adds further evidence to explain employee voice behavior. Our research extends the existing theory of employee voice through understanding how the team context may interact with individual motivation to affect individual voice with a cross-level framework. The cross-level interaction hypotheses based on the theory of situational strength were supported, and the situation and individual motivation seemed to play an important role in shaping individual voice behavior, so the substantial implications of this study are as follows: first, the study highlights that not only the individual but also the individual in his/her context should be considered. Secondly, the findings of this study show that fostering a safe climate in a team would be an effective way to encourage employees speaking up.

**Keywords:** employees, team psychological safety, individual goal orientation, achievement motivation, person-situation interactions

**A grounded theory study on civil servants’ psychological contract**

YAO, R. (Beijing Normal University), HUAI-BIN, J. (Sun Yat-Sen University), HONG, Z. (Beijing Normal University)

Civil servants’ mental state can affect not only an individual’s job satisfaction and job stress, but also can influence the government performance and government’s image. However, few on-going research studies focusing on it in have been done in China’s academic world. The Civil servants’ mental state is comprehended from the perspective of Psychological Contract in this study. The study intends to explore the content of the Civil servants’ Psychological Contract on the one hand, and to explore if Psychological Contract Violation happens in government. A qualitative method is used in this study. The data were collected by open-ended individual interviews with 33 Civil servants who work for the government and were analyzed by using grounded theory. The study establishes two models to understand Civil servants’ Psychological Contract, which include the model of Civil servants’ Psychological Contract content and the model of Civil servants’ perceptions of Psychological Contract fulfillment. The Contract Content Model shows that the Civil servants conceive that the obligations they should take for the government are from five aspects: work responsibility, peer responsibility, underling responsibility, public responsibility, and self-aware responsibility. The Contract Content Model also shows that the Civil servants conceive that the obligations the government should take for them are from twelve aspects: basic insurance, supporting working environment, working payments, rewards upon performance review, vocational development, advice adoption, outstanding leader, healthy networking, value appreciation, social status, job stability, and fairness. The Contract Fulfillment Model shows that Contract Violation does happen in government. When the violation happens, Civil servants will adjust the Psychological Contract content and take several behaviors such as to being slack in work for a reply, which can affect an individual’s job satisfaction, job stress and the government performance and government’s image. From the perspective of Psychological Contract the researcher found Civil servants have a strong will to take public responsibility, see themselves as representatives of government and have strong obedience. When performing the Psychological Contract, the government department leader, Civil servants’ regime, culture background, and servants’ individual status all become import factors that influence the direction of the whole process.

**Keywords:** civil servants, job satisfaction, job stress, government performance, government image

**A job-demands resources model for promoting worker wellbeing: A randomised controlled trial**

TODD, C. (Flinders University), ROCHE, A. (Flinders University), BOND, M. (Flinders University), PIDD, K. (Flinders University)

The aim of this study was to determine the effectiveness of a theoretically-driven online worker wellbeing program for employees in the Australian alcohol and other drug (AOD) sector. A randomised controlled trial involving Australian drug and alcohol sector employees (N = 243) was conducted. Participants were allocated to an intervention group (n = 118)
involving five online cognitive behavioural sessions or a wait-list control group (n = 125). Intervention content was tailored to address key identified AOD work environment demands (client, workload and work-life demands). Work engagement (UWES-9), burnout (MBI and CBI), psychological distress (GHQ-12), coping (Brief COPE), job satisfaction (MOAQ), and turnover intention (MOAQ) were assessed pre- and post-intervention and at 12-weeks follow-up. Preliminary analysis indicated that the online worker wellbeing program had some beneficial effects. Differences between the intervention group relative to the control neared significance on the CBI work burnout subscale at post-intervention (intervention: $M = 40.52$, $SD = 16.41$; control: $M = 46.34$, $SD = 16.30$, $p = .053$), and reached significance at 12-weeks follow-up (intervention: $M = 37.46$, $SD = 13.82$; control: $M = 47.15$; $SD = 16.25$, $p = .001$). However no changes attributable to the intervention were observed at post-intervention or follow-up on the MBI burnout scales, work engagement, or psychological distress. There were no significant group differences over time in job satisfaction or turnover intention. Attrition, despite being significantly higher in the intervention group (post-intervention: 42.4%; 12-week follow-up: 57.6%) compared to the control group (post-intervention: 22.4%; 12-week follow-up: 28.0%), was comparable or lower than rates reported for similar online interventions. This study has important theoretical and practical contributions. A Job-Demands Resources model of burnout and work engagement is provided for the AOD workforce. Additionally, some psychological benefits of a tailored cognitive behavioural intervention were demonstrated. Online psychological interventions are a viable cost-effective strategy to promote the wellbeing of employees in high demand/low resource work environments.

**A longitudinal investigation of perceived peer influence, body dissatisfaction, and eating problems in early adolescent females**

RAYNER, K. (Macquarie University), SCHNIERING, C. (Macquarie University), RAPEE, R. (Macquarie University), HUTCHINSON, D. (National Drug and Alcohol Research Centre)

The aim of this research was to examine the role of perceived peer influence on the development of body image and eating problems in young adolescent girls over time. Specifically, this research will investigate (1) whether perceived peer influence is longitudinally associated with the development of eating problems (restrictive dieting or bulimic behaviours), and (2) whether this relationship is mediated by body dissatisfaction. Participants were 1094 female students from ten girls’ high schools in New South Wales who completed a battery of questionnaires at three time points, each one-year apart (Grades Seven, Eight and Nine). The battery included measures of perceived peer influence, body dissatisfaction, bulimic behaviours, dietary restraint, body mass index, and demographic information. Missing data were imputed using multiple imputation methods. A longitudinal mediational model was then developed in order to examine the relationship between the variables of interest across the three time points. The collected measures served as indicators for the following latent variables: perceived peer influence, body dissatisfaction, bulimic behaviours, dietary restraint, body mass index, and demographic information. Missing data were imputed using multiple imputation methods. A longitudinal mediational model was then developed in order to examine the relationship between the variables of interest across the three time points. The collected measures served as indicators for the following latent variables: perceived peer influence, body dissatisfaction, dieting and bulimic behaviours. Preliminary analyses showed that the observed variables related to the latent variables as anticipated (that is, the measurement model was a good fit to the data). A comprehensive structural equation modeling approach based on statistical recommendations from the literature will be used to examine pathways between the key variables. Final results will be presented at the conference. Given that early adolescence is a high risk period for the development of body image and eating problems, and that peers become an increasingly important source of influence during this time, studying these factors in concert may provide further insight into how the development of body image and eating problems may be interrupted. If perceived peer influence contributes significantly to the development of body dissatisfaction, and, in turn, eating problems, then it is important that the peer environment is addressed in prevention and intervention programs.
A longitudinal mediation model of the mechanisms of change within a mindfulness-based stress reduction program

DAVIS, K. (Macquarie University), BAILLIE, A. (Macquarie University), FOLEY, E. (University of Sydney), CAIRNS, D. (Macquarie University), TAYLOR, A. (Macquarie University), GODDARD, T. (Openground: Training and Consultation)

This study aimed to develop a model of the mechanisms by which the cultivation of mindfulness skills leads to improvements in quality of life. Recent studies have shown another outcome of the mindfulness-based stress reduction (MBSR) program is increased self-compassion (Shapiro et al., 2005), therefore another aim of this study was to examine the relationship between self-compassion and the development of mindfulness. One hundred and sixty-five adult participants in an 8-week MBSR program responded to questionnaires at four time points: before, during and after the course, and 3 months following course completion. Measures used were: Five Facet Mindfulness Questionnaire (Baer et al., 2006), Toronto Mindfulness Scale (Davis et al., 2009), Self-Compassion Scale (Neff, 2003), DASS-21 (Lovibond & Lovibond, 1995), SF-12 Health Survey (Ware et al., 1995), and Credibility Expectancy Questionnaire (Devilly & Borkovec, 2000). Preliminary data analysis revealed significant increases across time for Observe, Act with Awareness, Nonjudge, Nonreact, Decenter and Self-compassion. In addition, there were significant improvements in symptoms of anxiety, depression and stress, and increases in physical and mental wellbeing. Curiosity and Describe factors did not change significantly. A model of the mechanisms of mindfulness will be developed in using a longitudinal mediational model showing pathways between increases in aspects of mindfulness and self-compassion, and improvements in wellbeing. A number of researchers have highlighted a need for future mindfulness research to determine the mechanisms of change (Brown et al., 2007; Shapiro et al., 2006). This empirical model provides preliminary evidence of these mechanisms of change. Instructions given during MBSR classes emphasise cultivating curiosity toward the nature of one’s experiences, therefore it is surprising that the Curiosity factor did not change across time. MBSR instruction does not emphasise labeling experiences, therefore the lack of significant change for the Describe factor is to be expected. Final results and conclusions will be presented at the conference.

Keywords: mindfulness-based stress reduction, mechanisms of change, quality of life, self-compassion

A means-ends chain analysis of a successful implementation of an information system

VELLA, S. (University of Wollongong), CAPUTI, P. (University of Wollongong)

With organisations investing heavily in new information systems (IS) and a significant number of these implementations not succeeding, it is fundamental to investigate factors that contribute to the successful implementation of an IS. It is known that employees’ behaviours are pertinent to the success of an implementation; however there is a limited understanding of employees’ behaviours and how they contribute to the success of an implementation. It is for this reason that this case study utilising the personal construct psychology technique of laddering within a means-end chain analysis framework investigates the relationship between employees’ perceptions of a successful implementation, the related consequences, and values. Three employees of a large Australian manufacturing organisation: two females and one male with a mean age of 46 years participated in this case study. Laddering is an in-depth interview that facilitates an understanding of the relationship between certain attributes and the individuals associations to higher level values. The participants were asked “what for you constitutes a successful and unsuccessful implementation?” Then laddering begins by selecting a set of attributes (one for successful and one for unsuccessful) for the individual and...
then they are asked which pole they prefer. Laddering continues by asking “why is that attribute important to you?” This process continues with the participants responses until it is apparent that the participant is having trouble responding indicating that the top of the ladder has been reached. The laddering responses were analysed in accordance with Reynolds and Gutman’s (1988) means-end chain analysis theory and a hierarchical value map displaying the relationship between the attributes, consequences, and values of the aggregate coded responses was constructed. The results indicated that the personal values of altruism and living to the fullest were associated with employees’ perceptions of a successful implementation. The results also indicated important attributes and consequences pertaining to the employees that are related to the success of an implementation. These results suggest a need to further expand the critical success factors prominent in the literature to include more factors pertaining to “people”, not just systems and processes.

Keywords: information systems, employee perceptions, means-ends chain analysis, laddering

A model for perceived social belongingness in the context of executive business and elite sport: A qualitative study

MUeller, M. (University of the Sunshine Coast)

Social belongingness has been referred to as a fundamental human need, and anthropology research has considered belonging to a small group as a human survival mechanism. The aim of this study was to explore constituents of social belongingness and propose a model of perceived social belonging in the context of executive business and elite sport. Individual semi-structured interviews were conducted upon 30 business executives and athletes; both elite and amateur. The interviews were transcribed and common themes were extracted. Participants did not perceive social belongingness in terms of individual relationships but instead as small groups, for example, “parents”, “friends”, “club members”, “team” or “neighbors”, clustered into three domains: family, work/occupation and social life. All participants emphasized the self-regulatory aspect of social belongingness: “contributing” to be “supported”. Furthermore, participants reported feeling “energized” or “drained” depending on how they perceived their level of social belonging. Belongingness to one group could supply energy for operating in others. Senior executives and elite athletes were focused on generating sufficient energy for the work/occupation domain and reported significant situational fluctuations in perceived belongingness levels based on their perception of situational performance in high pressure environments. In contrast, employees and amateur participants were more concerned with “work-life-balance”. Proposed is a model of perceived social belongingness as a hierarchy of inter-connected small group related energy reserves providing resources for self-regulation, motivation and effort regarding that specific group, other groups within the same domain or other domains, and being re-energized by perceived social belongingness to that specific group. This proposed model furthers our understanding of perceived social belongingness, may be useful for the understanding of dysfunctional and self-defeating behavior, and additionally suggests a theoretical platform for applied interventions attempting to enhance motivation and performance in areas such as business and sport.

Keywords: social belongingness in elite sports, executive business, group relationships, situational performance, self-regulation

A new framework for understanding contested policy innovations designed to produce behaviour change

YOUNG, D. (Cancer Council Victoria), BORLAND, R. (Cancer Council Victoria)

The major determinants of behaviour change lie in the system and environment within which the person is embedded. Reshaping the environment to facilitate desirable behaviour patterns is an important area of cultural adaptation. Understanding the way people can act to collectively change their environment is critical to facilitating this process. This paper presents a framework for understanding and
supporting such changes. This was an analytical study applying concepts from Open Systems Theory (OST) and Actor-Network Theory (ANT). ANT organises the contest for change around four processes: mobilising evidence, building alliances, public positioning and institutionalising the changes. Supporting interviews concerning successes and failures in achieving smoke-free regulations, and any lessons learned for future tobacco control issues, were carried out with tobacco control experts from Ireland, United States of America, Germany, Australia, Canada, and the United Kingdom. OST was used to construct a model of a Tobacco Use Management System with four sub-systems (the tobacco industry, forces acting to reduce use, regulators, and tobacco users), acting in a broader environment that the System has to adapt with. This highlighted several endemic problems with the System that it cannot resolve from within. However, ANT proved useful in describing how such problems had been confronted in the past, and how to address future changes to more rapidly reduce tobacco-related harms. In conclusion, our models of population level behaviour change need rethinking. Such change is a contest of social forces, as well as ideas. While OST offers the best approach to problem definition, and the changes required, it cannot elaborate the kinds of environmental (especially social) interventions necessary to change the nature of a system and the behaviour of those within it. A theoretical framework combining analysis of the system, and of the changes required (OST), with a model of how change can be enacted (ANT), produces a comprehensive guide to future action where behaviour change is sought.

Keywords: open systems theory, actor-network theory, change processes, tobacco control, population level behaviour change

A new method of personal integration: Simultaneous audio-presentation of person-changing memories (SAPM)

NOURKOVA, V. (Lomonosov Moscow State University), NIKTIN, K. (Lomonosov Moscow State University)

This paper introduces a totally innovative technique of Simultaneous Audio-presentation of Person-changing Memories (SAPM), the application of which results in a subjective manifestation of personal uniqueness, unity and integrity. SAPM comprises three stages. At the first stage, the subject verbally recollects person-changing episodes from one’s personal past. Each story is recorded by an audio-carrier. To achieve the effect of “the internal voice”, we change the characteristics of frequency for each record with a sound editor on computer. At the second stage, the audio records are imposed against one other in computer musical editor. As a result all stories can be perceived by the listener simultaneously. SAPM is most efficient when seven to nine stories are imposed for each person. At the third stage, the subject listens to the audio record through ear-phones as many times as he or she deems necessary. While listening to the record, the subject sits in a soundproof dark room. Such listening sessions can be run as a one-time event or regularly. Forty-five subjects participated in the study of the psychological effect produced by the SAPM technique. The majority of the participants reported experiencing an unusual state of mind when listening to SAPM. They reported that their experiences included the feeling as if being out of their body, inner mobilization, time transformation and a panoramic representation of memories pertaining to different ages. We have noticed a significant increase in self-reported personal integrity and a decrease in symptoms of post-traumatic stress disorder and depression resulting from the SAPM method application. Losing a feeling of personal continuity through one’s life span is considered to be one of the core symptoms of various psychological disorders. It is associated with the inability to rely on the resource of a personal past in daily routines and when planning the future. The essence of the new technique is that of generating a stereoscopic and momentary overview of the personal past employing memories of turning points in personal development. The technique may be used in psychotherapeutic counseling as a concise and very efficient treatment procedure.

Keywords: simultaneous audio-presentation of person-changing memories, feeling of personal continuity, post-traumatic stress disorder, depression, lifespan
A positive perception of workload makes us engaged and less burned-out at work: A cross-cultural study of the role of positive perception of stressors at work

KOZUSZNIK, M. (University of Valencia), RODRIGUEZ, I. (University of Valencia), CARBONELL, S. (University of Valencia)

This study aims to identify the relationship between a positive perception of workload and its outcomes: work engagement and burnout. Given that cultural variables influence the investigated aspects (Chiu & Kosinski, 1995; Bliese & Jex, 2002), a comparative exploratory analysis was conducted in two European countries (Spain and Poland). The focus of the study was placed on the transactional perspective, the cognitive nature of stressful experiences (Lazarus & Folkman, 1984) and the Positive Psychology approach (Seligman & Csikszentmihalyi, 2000). It was proposed that when employees see workload as a challenge rather than a threat, they should be psychologically engaged in their work and less burned-out. The Maslach Burnout Inventory-General Survey (Schaufeli, Leiter, Maslach & Jackson, 1996), the Well-Being and Work Survey – a reduced version of the Utrecht Work Engagement Scale (Schaufeli, Bakker and Salanova, 2006); and a scale based on the Pressure Management Inventory (Williams & Cooper, 1998) were administered to the 751 social care employees who participated in the study (603 Spanish and 148 Polish). Hierarchical regression, moderated by country, and ANOVA techniques were applied. The main hypotheses were confirmed. Work engagement is predicted in both countries by the perception of workload as a challenge. Lower work engagement is triggered by the perception of workload as a threat. Burnout diminishes if a person perceives their workload as challenging whereas burnout correlates positively with the perception of workload as a threat. Workload perceived as a challenge (both in Poland and in Spain) was related positively to work engagement, and in Poland this relationship was stronger. Spanish employees had a lower level of burnout, a higher level of work engagement, and perceived workload as a threat more than Polish employees. Perception of stressors is crucial in the process of stress, and positive perception of workload has beneficial outcomes on psychological health. In both European countries investigated, a similar process takes place but it is important to be sensitive to nuances. There may be some additional stress factors that influence the level of burnout and work engagement that were not measured in this study. It is important to emphasise positive work aspects and human strengths, and to teach employees how to perceive work in a positive way to assure healthier work and organisational efficacy.

Keywords: workload, burnout, stressors, cross-cultural, work engagement

A qualitative analysis on clients’ perceptions of problems treated through psychotherapy

AOKI, M. (Japan Women’s University)

A person seeks therapy when he/she perceives something as a problem. Perceptions of problems constitute a subjective experience that differs among people. Treating this sensitive issue in an appropriate manner is vital for administering effective psychotherapy. The purpose of this study is to explore clients’ individual perceptions of problems. A total of nine subjects (three male and six female) participated in three-session therapy based on a solution-focused approach. Before and after the therapy, each subject was asked to describe his/her perception of the problem. The data obtained was analyzed through the Modified Grounded Theory Approach (M-GTA), a qualitative analysis, to compare pre- and post-perceptions and to examine the change in perceptions. Here, we will present only the results obtained through the analysis of the pre-therapy perceptions to discuss how the problems are perceived by the subjects prior to psychotherapy. The results were: 1. Negative emotions result from a person’s perception of a problem; 2. He/she then begins to consider the nature of the problem and worries about its possible outcomes; 3. Negative emotions elicit various reactions in a person: (a) inability to do anything; (b) a tendency to escape from or avoid the problem altogether, which sometimes creates new problems; (c) an attempt to cope...
with the perceived problem, during which the person might worry because things are not going well or his/her emotions mediate between hope and despair. It was suggested that the tendency to cope relates to perceived positive factors such as support from other people, aims, and preferences. In conclusion: 1. The results showed that an individual’s perceptions of problems are not stable. Instead, they are dynamic with respect to processes including the influence of the problems on individuals, their reaction to problems, and perceived support; 2. The perceptions of problems include positive factors that influence tendencies to cope with the problems. Therefore, we should utilize positive factors to support those who suffer from psychological illnesses; 3. We should also provide support in keeping with the mental status of the individual, as seen in points (a) to (c).

A randomised clinical trial of a meridian-based intervention for food cravings: Treatment versus waitlist

STAPLETON, P. (Griffith University), SHELDON, T. (The Lakeside Rooms Robina), PORTER, B. (The Lakeside Rooms Robina), WHITTY, J. (Griffith University)

Food craving was hypothesised to be an important intervening causal variable in the development of obesity. This randomised, single-blind, clinical trial tested whether The Emotional Freedom Technique (EFT) reduced food cravings in participants under laboratory-controlled conditions. The study involved 96 overweight or obese adults who were allocated to the EFT treatment or the four-week waitlist condition. The waitlist condition received treatment after completion of the test period. Degree of food craving, perceived power of food, restraint capabilities and psychological symptoms were assessed pre- and post- a four week EFT treatment program (mixed method ANOVA comparative analysis), and at six-month follow-up (repeated measure ANOVA with group data collapsed). EFT was associated with a significantly greater improvement in food cravings, subjective power of food, and craving restraint, than waitlist from pre- to immediately post-test (p < 0.05). Across collapsed groups, an improvement in food cravings and subjective power of food after treatment was maintained at six-months, and a delayed effect was seen for restraint. Although there was a significant reduction in measures of psychological distress immediately after treatment (p < 0.05), there was no between group difference and significance was not maintained at six-months. There was no difference in weight or body mass index across all time points, but this may change with longer treatment programs. EFT can have an immediate effect on reducing food cravings, results in maintaining reduced cravings over time and, when added to weight loss/dietary programs, may result in assisting people to achieve and maintain reduced food cravings.

Keywords: food craving, emotional freedom techniques, perceived power of food, craving restraint, body mass index

A sense of field reality that makes a group situation real

KAKIMOTO, T. (Gunma University)

A new concept to evaluate an experimental situation is developed for the experimental study of intergroup relations: a sense of field reality. Methodological importance of experimental reality has long been appreciated for any experimental study, but its theoretical importance has not been recognized fully for the experimental study of intergroup relations. The present study demonstrates that a subjective sense of reality of an experimental situation is necessary for a group situation to be a “real” group situation. In two experiments, two conditions, with high and low in the subjective sense of reality of the situation, were compared in terms of theoretically important criteria for a “real” (group) situation: participants’ group identification and “seriousness” about the situation. First, 47 university students participated in a simulated international society (SIMINSOC) game, where the sense of the reality of the situation was measured at an “opinion poll” in the game, using a scale called the Sense of Field Reality (SFR) scale, which has been developed on the basis of a series of theoretical
and empirical studies (e.g. Kakimoto, 2005, 2006, 2008). Second, a revised version of the scale was administered to the 67 respondents in a university lecture. In the SIMINSOC game, the participants with high in the scale score showed significantly more identification with the group (“area” in the game), than those with low in the score, in two self-reported measures out of three. The same pattern was also observed in the remaining measure though statistically marginal. The degrees of group identification by the highs were quite large (means were 4.4~4.6 in the five point scale) whereas those by the lows were moderate (3.1~3.8). In the respondents from the university lecture, those with low in the scale score showed marginally less seriousness about the situation (in the item “engaged in this lecture quite seriously”) than those with high in the score. The results in the first experiment clearly showed importance of a subjective sense of reality of the situation for an experimental study of groups. Even in a SIMINSOC game, known as a reality provoking situation, participants identified with the group only to a moderate degree when a subjective sense of reality of the situation was low. This may be due to a relative lack of seriousness, along with other relevant variables, about the situation among participants with low in the sense of reality, implied by the second experiment. Future research is needed to clarify the factors that create the sense of reality of the situation.

Keywords: intergroup relations, experimental reality, group identification, subjective reality, field reality

A strength-based approach to assessment and treatment of children and adolescents

RAWANA, E. (Centre of Excellence for Children and Adolescents with Special Needs, Thunder Bay), BRAZEAU, J. (Centre for Excellence for Children and Adolescents With Special Needs)

In recent years, a number of researchers have advocated for a more holistic understanding of human development that includes positive aspects of the individual and their environment. This has been championed by the positive psychology movement and the strength-based approach that emphasize the need to draw upon positive aspects of functioning in order to overcome adversity. The purpose of this presentation is to provide an overview of the strength-based approach to treatment for children and adolescents that we have applied to diverse clinical populations. The overview will focus on both the theory of strength development and descriptions of studies that have used the strength-based approach in both educational and mental health settings. The presentation will provide a theoretical review of our approach to strength-based treatment for children and adolescents. In addition, the author will introduce the Strength Assessment Inventory, a measure that can be used to assess children’s strengths across various domains, and describes how this information can be integrated into assessments and treatment planning. There is strong preliminary evidence that indicates that a strength-based approach to assessment and treatment provides additional information about the client and may be related to improved outcomes when integrated into interventions. The strength-based approach provides a method to engage youths in working towards solving their problems in a collaborative manner. The strength-based approach draws on personal strengths and interests and uses these to overcome adversity. Our research has provided some preliminary evidence for the efficacy of this approach and future studies will be necessary to further clarify the role of strengths in overcoming psychological problems.

Keywords: positive psychology, strength-based approach, Strength Assessment Inventory, treatment of children and adolescents, children’s strengths

A study of burnout among French firefighters

MARIEN, P. (Université Victor Segalen), AUVERT, L. (Service Départemental d’Incendie et de Secours de la Gironde), PORRAS, J. (Service Départemental d’Incendie et de Secours de la Gironde), MICHEL, G. (Université Victor Segalen)

Burnout (BO) is an international phenomenon studied but remains largely unexplored among firefighters (Lavillunière et al. 2007; Lourel et al., 2008). Most studies have tried to apprehend the
BO or through individual characteristics or through the environmental requirements but neglecting the relationship that both could maintain. The objective was to investigate predictors of BO among French firefighters. Two hundred firefighters mean age of 37.87 years (SD = 10.95) completed: the Temperamental and Character Inventory (TCI-56; Rigozzi & Rossier, 2005), Survey of Professional Stress adapted to SP (JSS-F, Marien, Auvert & Michel, 2009), the Maslach Burnout Inventory (MBI; Dion & Teissier, 1994). After multiple linear regression, predictors of symptomatology of BO would mostly be rank and personality patterns (p < 0.05). Thus, emotional exhaustion was predicted by demographic characteristics (marital status (β = .175), rank (β = .205), years of service (β = −.189)) and certain personality traits such as temperamental pattern "Persistence" (β = .195) and character traits "Determination" (β = −.356) and "Cooperation" (β = -.157). For depersonalization, the predictors are rank (β = −.238), family status (β = .155) and the temperamental pattern "reward dependence" (β = .213) For the reduction of self-accomplishment, predictors were rank (β = −.225), the temperamental patterns "novelty seeking" (β = −.210), "harm avoidance" (β = −.196), "reward dependence" (β = .203) and the trait "Transcendence" (β = .136). Thus, these results show both the presence of vulnerability factors but also protective factors that protect individuals from BO. These findings are particularly interesting because i) they emphasize the importance of differentiating these individuals according to their job requirements and by rank; and ii) they focus on the importance of subjective dimensions in this syndrome. Indeed, according to findings, individuals suffering from these symptoms seem to have particularly high standards. Requirements that are too high can have deleterious effects on psychological well-being. This results in an imbalance between the expectations of the subject and environmental constraints. This can orient some intervention approaches that can access the motivational aspect. In this case, the job could be for a redefinition of goals but also on expanding the flexibility and skills to both business and personal life given the opportunity to respond optimally to environmental constraints.

A study of implicit knowledge of creativity in China

CHOE, I. S. (Sungkyunkwan University), LEE, H. J. (Sungkyunkwan University), PYO, J. M. (Sungkyunkwan University), CAO, D. (Sungkyunkwan University)

The authors investigated the implicit knowledge of creativity in China. One hundred and twenty eight Chinese (63 men and 65 women) completed open-ended questionnaires on two questions. Two questions were as follows: ‘what do you think are the characteristics and behaviors of creative people?’ and ‘Who is the most creative people in China?’ The results showed that, firstly, Chinese people in general have positive perception on the concept of creativity. Smart was listed as the most salient character of creativity. It means that intelligence counts most in Chinese implicit knowledge of creativity. Other traits such as “positive”, “daring”, “having lot of ideas”, “kind”, “having lots of knowledge”, “original”, “weird”, “imaginative”, and “active” were the ten most cited ones. Males and females had almost the same implicit knowledge of creativity. But differences were found by generations. New generation expressed more negative factors. Regarding the second question, artists/entertainers and politicians were nominated as most creative in the list followed by scientists/inventors, businessmen, writers, philosophers/educators. Artists/entertainers were nominated mostly by new generation and politicians were nominated mostly by old generation. It seems that with the increasing interaction with western countries via international events such as the Beijing Olympics, Chinese people are naturally exposed to the concept of creativity.

A study of psychological side-effects of abortion on mothers' general health and depression
BASTEH HOSSEINI, S. (Azad University), KHUSHABIB, 
(University of Rehabilitation and Welfare)

Due to various side-effects, abortion could put mothers’ mental and physical health in danger. These side-effects may occur during the abortion, after the expected time or even during the next pregnancy. Among pregnant women who referred to health centers in Tehran, we randomly ask 30 persons who had induced abortion and 20 persons who had experienced spontaneous (unwilling) abortion and also 30 women who experienced their first pregnancy, to participate in this research. After controlling for several socio-demographic factors, results from the Beck Depression Questionnaire indicated the highest range of depression was among mothers who experienced induced abortion and then in mothers who had unwilling abortion and at last on pregnant women. Also, the General Health Questionnaire showed highest rate of general health in pregnant mothers than in mothers who experienced induced abortion and the least in mothers who had unwilling abortion. In conclusion, the findings showed that the highest rate of depression and lowest rate of general health occurs among mothers who experienced abortion and thus this needs to be considered as one of main factors that can influence on their recovery.

Keywords: abortion side-effects, mothers’ depression, General Health Questionnaire, pregnancy

A study on the relationship between leader-member exchange and organizational justice under the circumstance of communication openness

LIU, Y. (Renmin University of China), DING, G. (Renmin University of China), YAN, S. A. (The University of Warwick)

Based in Chinese context, this essay explores the relationship between Leader Membership Exchange (LMX), organizational justice and communication openness. This essay will focus on the following three variables: communication openness, LMX and organizational justice, and will probe into the moderating effect of communication openness between LMX and organizational justice. All the variables were measured by scales developed in western researchers, including the Organizational Justice Scale (Nehoff & Moonman, 1993), Communication Openness Measure (Rogers, 1987), and LMX Scale (Bhal & Ansari, 1998, 2006). Responses were made on a five-point scale ranging from one (strongly disagree) to five (strongly agree). This essay proves the hypothesis model via regression analysis, and the results are: LMX-contribution is positively related to distributive justice; LMX-affect is positively related to distributive justice; LMX-contribution is positively related to procedural justice; LMX-affect is positively related to procedural justice; LMX-contribution is positively related to interaction justice; and LMX-affect is positively related to interaction justice. In addition, Communication Openness is positively related to distributive justice, procedural justice, and interaction justice. Communication Openness negatively moderates the relationship between LMX-affect and distributive justice. Communication Openness negatively moderates the relationship between LMX-contribution and procedural justice. Communication Openness negatively moderates the relationship between LMX-affect and interaction justice. Communication Openness negatively moderates the relationship between LMX-contribution and interaction justice. In this research, we can see that in-group employees have higher organizational justice than out-group ones. This reminds us that the improvement of organizational justice is one of the essential ways to decrease negative effect of low quality LMX. Our research also shows that communication openness has a significant effect on the relationship between LMX and organizational justice, so organizations should be more open so as to decrease the negative influence of organizational justice resulted from low quality LMX. Communication openness may release pressure via free expression and improve productivity by identification with organization goals.

Keywords: leader-member exchange, procedural justice, distributive justice, organisational justice, communication openness
A surveillance study for a street crime prevention intervention

KOSUGI, K. (Yamaguchi University), OKIBAYASHI, Y. (Yamaguchi University), FUKUDA, H. (Yamaguchi University)

In this surveillance study of anxiety about crime in one’s daily life - commissioned by the National Police Agency of Japan in 2004 - street crime, especially the ‘bag-snatch’, ranked highly, placing just after the ‘break-in’ and the ‘holdup’. Risk perception is defined as the multiplication of a fear by the expectation of the probability of its occurrence. Kosugi, et al. (2008) revealed how the risk of the street crime was positioned among other risks encountered in the course of life. Although all respondents were students of psychology at various universities, their attitude to risk differed appreciably depending on their sex and their area of habitation. The first purpose of this study was to create segments among respondents with respect to certain categories. The second purpose was to clarify the differences in attitude between the estimated reaction and the crime prevention action of the respondents. The third purpose was to investigate what points of view respondents had, by asking for their impressions of a photograph of the street where a crime had actually taken place. The participants were university students and other people who were part of the citizens’ anticrime movement. The questionnaire administered contained a scale to measure farness to crime, a scale to determine usual crime prevention action, and impressions of some street photographs. It was judged that it was appropriate to divide the respondents into three segments as a result of the latent class analysis. In addition, correspondence analysis was conducted based on the photograph × answer cross-tabulation table, in accordance with the latent classes. This analysis clarified how the view points on the street incidents were different in each latent class. By following these results, we aim to construct a civic education program to strengthen crime prevention actions.

Keywords: street crime, crime prevention, crime education program, risk perception, latent class analysis

ABLE mental health screening of young children: Validity and reliability

BARBARIN, O. (Tulane University)

This paper analyzes the psychometric properties of ABLE, a mental health screening tool for young children. The purpose of ABLE is to evaluate the prevalence and severity of concerns parents and teachers have about children’s adjustment to school and to identify children who might benefit from early intervention. The paper describes the prevalence of language, behavior and emotional problems in representative and large samples of rural and urban children in the United States of America. Parents and teachers and children were randomly selected from public pre-kindergarten classrooms in six states (N = 415) and from a mental health screening of rural and urban children ages 2.5 to 6 (N = 5,577) and they completed the ABLE, a two level instrument consisting of a five-minute screening and standardised clinical scales assessing Attention, Behavior, Language and Emotions. ABLE scales had high internal consistencies and strong evidence of construct validity. ABLE identified severe problems in 18.4% of children from parental reports and in 10.5% from reports of pre-kindergarten teachers. By kindergarten, the proportion of children identified by their teachers with serious problems more than doubled to 23%. Inattention/over-activity and behavior problems were identified most often. Children identified as having a serious problem typically had more than one. These children were 3.4 times more likely to be certified for special education services by kindergarten than children not identified with problems by ABLE. However, fewer than 14% of children in public pre-kindergarten identified with serious problems in pre-kindergarten had received the needed mental health services by the end of kindergarten. ABLE is a brief valid and reliable tool that can be helpful in screening early onset language, behavioral and emotional problems which, when undetected, can present significant challenges to children’s school adjustment. Unlike many widely used tests of behavior and emotional problems, ABLE does not over-identify poor and ethnic minority children as having adjustment difficulties. Moreover the results of this study provide incontrovertible
evidence of the need for preventative mental health services in early childhood and confirm the value of ABLE as part of a system of mental health service delivery to young children.

**Abstract and concrete sentences, embodiment and languages**

SCOROLLI, C., BINKOFSKI, F. (University of Lübeck), BUCCINO, G. (University of Catanzaro), NICOLETTI, R. (University of Bologna), RIGGIO, L. (University of Parma), BORGHI, A. (University of Bologna)

One of the main challenges of embodied theories is accounting for meanings of abstract words. The most common explanation is that abstract words, like concrete ones, are grounded in the sensorimotor system and activate situations and introspection; alternatively, they are explained through metaphoric mapping. However, evidence provided so far pertains to specific domains. To be able to account for abstract words in their variety it could be necessary to take into account not only the fact that language is grounded in the sensorimotor system, but also that language represents a linguistic-social experience. Cross-linguistic comparisons is a promising way to investigate the role played by the linguistic experience. We examined different combinations of a transitive verb and a concept noun, both abstract and concrete, focusing on two syntactically different languages: German and Italian. Thirty-eight students of the University of Hamburg and 38 students of the University of Bologna were required to judge the sensibility of 192 word pairs, selected based on familiarity and probability of use. Compatible combinations (Concrete Verb plus Concrete Noun; Abstract Verb plus Abstract Noun) were processed faster than mixed combinations (Concrete Verb plus Abstract Noun; Abstract Verb plus Concrete Noun). Moreover, with mixed combinations, when the concrete word preceded the abstract one, participants were faster, regardless of the specific grammatical class and the spoken language. The first result is in line with the idea that abstract and concrete words are processed in parallel systems (Dove, 2009; Barsalou, Santos, Simmons & Wilson, 2008, Borghi & Cimatti, 2009) – abstract in the language system and more concrete in the motor system, making the costs of processing within one system the lowest. The advantage of the first concrete word is probably due to the fact that, when running a simulation, abstract words require more time as a consequence of their peculiar acquisition modality. Results confirm embodied theories which assign a crucial role to both sensorimotor and linguistic experience for abstract words (Barsalou, et al, 2008; Borghi & Cimatti, 2009, submitted).

**Accountability can improve support for organizational change: Perspective from interest-relatedness**

HUANG, X. (Zhejiang University), WANG, Z. (Zhejiang University)

Along with dynamics of outside surroundings and updating of an organization, research on organizational change has become a hot topic in the field of strategic management, which can determine the existence and development of organization. However, employees always resist organizational change. Studies showed employees’ participation in change can make employees support change. It is true that employees’ participation of change can bring many benefits for development of organization, but negative effects are also obvious. Some researchers indicated accountability can solve the problem. Based on the social contingency model, the accountability effect and its psychological mechanism under organizational change were explored. With undergraduates as subjects and change of university’s mental health education as experimental materials, two experiments were conducted. In Experiment One, 161 subjects including 97 psychological committee members were divided into four groups using a between-subject design, which had accountability and interest-relatedness as independent variables and support for change as dependent variable. In Experiment Two, with accountability and change agents as independent variables and support for change as
dependent variable, 124 psychological committee members were divided into four groups under between-subject design. Experiment one showed that subjects with low interest-relatedness supported change to a significantly higher extent than ones with high interest-relatedness; and accountable subjects supported change to a significantly higher extent than unaccountable subjects under high interest-relatedness, but there were no significant differences under low interest-relatedness. Experiment Two revealed no significant interaction between accountability and change agents on support for change. It is concluded that the social contingency model should add a contingent factor — interest-relatedness between context and accountable entity, and the mechanism of attitude shifting under accountability was cognitive alignment.

**Accounting selfishness in donation? From the perspective of evolutionism**

**WEI, W. (Peking University), WANG, L. (Peking University), LI, C. (Peking University)**

Generally speaking, donation is considered to be an altruistic behavior. However, some researchers argue that there may also be a part of selfishness in donation. The present paper aimed to give evidence to support the idea that people show selfishness in donation through two empirical studies. Study One aimed to find the selfishness across individuals and Study Two aimed to find the selfishness across race. In Study One, participants \( (n = 879) \) were randomly assigned to one of six conditions in a 3 (position: supervisor, colleague or subordinate) \( \times \) 2 (money: 100 Renminbi (RMB) or 500RMB) between-participants design. Participants were told that their supervisor (or colleague or subordinate) had donated either 100RMB or 500RMB for earthquake relief in China, and then they were required to make a decision about how much money they wanted to donate. In Study Two, participants \( (n = 246) \) were randomly assigned to one of six conditions in a 3 (position: supervisor, colleague or subordinate) \( \times \) 2 (race of donation target: native or foreigner) between-participants design. Participants were told that their supervisor (or colleague or subordinate) had donated 500RMB for either a fire in their hometown or an earthquake in Italy, and then were required to make a decision about how much money they wanted to donate. The key findings were that when given the information about how much one’s supervisor, colleague or subordinate had donated, the participants decided to donate less money than their colleagues, reflecting selfishness across the individual (Study 1), and participants were willing to donate more money for natives than for foreigners, reflecting selfishness across race (Study 2). We didn’t find any interaction effect between position and money (Study 1) or position and race (Study 2). Overall, when people do a pro-social behavior such as donation, they also show a piece of selfishness, for the sake of themselves or their own race.

**Keywords:** selfishness, donation behaviours, pro-social behaviour, selfishness in donation

**Adapting languages tests from analytical languages such as English into an agglutinative tonal language of the Bantu family: Rasch modeling results**

**KOCH, E. (University of the Western Cape and Nelson Mandela Metropolitan University)**

This paper will present and discuss the Rasch modeling results of the Verbal Analogies and Letter Word Identification subscales of the Woodcock Munoz Language Survey that were adapted into an indigenous South African language, Xhosa. The data were collected using a monolingual two group design (English \( n = 186; \) Xhosa \( n = 189, \) grade six and seven South African learners). Rasch modeling was deemed fit for the analysis because of the need to derive sample and test-free item and person estimates for the comparison of the two language versions of the test. The results of the English and Xhosa versions of the subscales will be presented. The results will include the results of a Differential Item Functioning (DIF) analysis. Evidence of scalar equivalence across the two language versions exists. The challenges of adapting language tests from analytical languages such as English into Xhosa as an example of an agglutinative tonal language of the Bantu family, and the strategies that were followed in
Adapting the subscales will be briefly presented. The linguistic differences between the two languages and a theoretical understanding of the development of verbal reasoning and letter word identification in reading, across the two languages and language groups, will be used as a framework for the interpretation of the psychometric results. The implications of these results for the adaptation of tests from English to indigenous African languages will be discussed.

**Keywords:** Rasch modeling, adapting language tests, verbal reasoning, letter word identification, language surveys

**Adolescent creativity and its subjective representations**

BABAeva, J. (Lomonosov MSU), Sabadosh, P. (Lomonosov MSU)

The aim of this study was to find interrelations of adolescents’ creativity, their opinions about its nature and value, and its self-assessment. Russian scholars aged 13-15 years of both sexes completed the adapted Rokeach Value Survey (RVS) and Torrance Test of Creative Thinking (TTCT). Scholars and their teachers were questioned about their implicit theories of creativity: is it inborn or can be nurtured, and what creative work is. Adolescents self-assessed their creativity level and giftedness in various domains; teachers also assessed scholars. Total number of participants was approximately 250. Significant correlations (Spearman’s $r$) were found between TTCT originality scores and RVS ratings: Creativity ($r = 0.31$), Active life ($r = -0.40$), and (in the female sample) Family life ($r = 0.47$). Implicit theory of creativity nurturance also significantly correlated with TTCT originality ($r = 0.60$) and (in the female sample) Flexibility scores ($r = 0.55$). In the male sample implicit theory of creativity nurturance correlated with Development ($r = 0.43$), self-assessed creativity level correlated with the RVS ratings of Wisdom ($r = 0.46$) and Inner harmony ($r = -0.54$). Creativity took a relatively low average place in RVS rates, while creative work is thought of as essentially artistic, not scientific, technical nor social. Adolescents often consider truly creative behaviour as a risky one, vulnerable to criticism and inducing social disapproval; a number of them perceived school as a place “designed to getting knowledge”, and one which “doesn’t dispose you to be creative”. There was no correlation found between TTCT scores and self-assessed creative giftedness. Adolescents’ creative giftedness self-assessment differed from its assessment by teachers, while scholars and teachers did not view creativity in the same way. Actual adolescent creativity level is related to its implicit theories and subjective value (to participants’ value orientations, in a more general context). Some gender differences in these relations were found. Creativity value is probably underrated due to expected high social risk and insufficient knowledge of a real demand for it. Test-measured creativity level, a self-assessed one, and those assessed by teacher, do not match. This is apparently because corresponding creativity conceptions vary resulting in use of different creativity criteria.

**Keywords:** adolescent creativity, creative giftedness

**Advantageous social inequity for sustainable social motivation: Possible consequences for service organizations**

Sinha, A. (Indian Institute of Technology, Kanpur)

This study attempted to understand the relevance of “Advantageous social inequity” for sustained effectiveness in service organizations. The equity theory of motivation takes the position that individuals tend to compare their job inputs and outcomes with those of relevant others, and this comparison might result in consequences that could affect quantity and quality of organizationally relevant outcomes. Under the backdrop of Indian culture and some cherished values, the need for affiliation and (higher level) recognition, experimental evidence was obtained on undergraduate student samples, and also on some real life working individuals in service organizations (banks). The data showed that, apart from material gains, there could be other gains for which the phenomenon of equity motivation needs to be understood, and that a perception of over-reward (called advantageous inequity) might be related to a behavior pattern that is conducive to the satisfied existence of the person and quality contribution to the lives of the relevant
others. Further, such “advantageous inequity” may contribute to a heritage of sustained effective behaviour for others to follow and perpetuate. The results were discussed and an elementary theoretical framework of advantageous social inequity based model of sustainable effective behavior in service organizations proposed.

Keywords: advantageous inequity, service organizations, motivation, sustainable effective behaviour, Indian culture

Adverse events in psychotherapy

MUNRO, B. (Edith Cowan University)

Since April 2008 health practitioners, including psychologists, working in health care facilities have to implement the National Open Disclosure Standard. Clinical psychologists working in health care facilities, both private and public, therefore have to disclose adverse events to their clients. The Standard defines an adverse event as an incident that results in unintended harm to a person receiving health care. Whilst the Standard is basically a restatement of the ethical principles of veracity and autonomy, the practical implication of it for psychologists is not clear and it is important that guidance should be given to local psychologists in this regard. There is currently no Australian literature on the topic and overseas research is dated and based mainly on anecdotal case study analysis. There is therefore a need to determine how Australian clinical psychologists perceive adverse events in psychotherapy, when they believe they should disclose such events, and how they would disclose such events if they choose to. The participants were psychologists eligible for membership of the APS College of Clinical Psychologists. Working within a phenomenological framework, semi-structured interviews were conducted. Thematic analysis was used to uncover dominant themes. Four dominant themes were identified. The first is that unintended harm is perceived to occur as a result of lapses in clinical technique. The second dominant theme is that unintended harm in psychotherapy is unavoidable. The third theme is that adverse events should always be disclosed. A final theme is that it is inherent in the psychotherapeutic process that unintended harm should be addressed with the client and that this is a usual part of psychotherapy. The process is also thought to be therapeutically beneficial for the client. Clinical psychologists perceive that adverse events occur in psychotherapy as a result of their practices. They rely on the therapeutic process as a mechanism to work through unintended harm with their clients as soon as it is possible to do so in therapy. The process is still highly individualistic, and guidelines to improve consistency to ensure that adverse events do not go undetected and harm the client should prove to be useful.

Keywords: adverse events, psychotherapy, open disclosure, clinical psychologists, Australian psychologists

Affective responses, emotional intelligence and examination performance of university undergraduates

HULME, R. (University of Southern Queensland), TERRY, P. (University of Southern Queensland), REVIEWS 2, ICAP (Brief Oral Presentation)

The aim of the research was to examine the link between emotional intelligence abilities, psychological distress levels and mood states among university undergraduates over the duration of a semester of study. The research also focused on the ability to predict student exam performance utilising the constructs of emotional intelligence, psychological distress and mood. This was accomplished through two related studies, both involving data collected from first year students. A sample of 218 undergraduate students from an Australian university completed the Trait Meta Mood Scale (TMMS) to establish their emotional intelligence abilities. They then completed the Brunel Mood Scale (BRUMS) and the Depression, Anxiety and Stress Scale (DASS-21) on three occasions during a university semester to monitor affective responses. Examination performance at the end of semester was recorded. Emotional intelligence was found to influence affective responses, showing a stronger influence on psychological distress than mood states. However, clarity, a component of emotional
intelligence, was more closely related to mood states than psychological distress. Of the psychological distress variables, stress scores showed the strongest influence on mood responses. Psychological distress and mood responses both predicted examination performance whereas emotional intelligence did not. High emotional intelligence among students is conducive to a more pleasant and less distressing university experience but does not appear to benefit examination performance. Further, negative affective responses are not necessarily an indication that students will underperform academically. Indeed high negative affect during the beginning of semester and mid-semester is an indicator of success in end of semester examinations. It appears to be important that negative affect abates during the period from mid-semester to the end of semester. Rising negative affect from mid-semester to end of semester may be an indication that a student is facing difficulties and could potentially fail their examinations.

**Keywords:** emotional intelligence, psychological distress, mood states, exam performance

### African Diaspora Dialogue Project

TINT, B. (Portland State University)

This paper explores dialogue and reconciliation work designed specifically for African Diaspora populations in the U.S., specifically, those from Somalia and the Great Lakes Region of Burundi, Congo and Rwanda. The paper will explore culturally coherent models of dialogue and reconciliation that incorporate historical issues, current resettlement issues and the integration of traditional peacemaking processes. A capacity building framework where participants become trained in facilitating conversations with their own communities was adopted. Coming from an ethnically diverse continent with a long history of conflict based in colonialism, tribalism, and religious differences, newly arrived African refugees carry these tensions into the U.S. These identity-based conflicts are fuelled by the traumas facing refugee populations and the challenges of transition and resettlement, making successful integration extremely difficult. The result of the challenges just described has been that groups separate themselves from each other and avoid contact whenever possible. In identity-based conflicts, one of the core elements that contributes to the entrenchment and polarization impeding reconciliation is the manifestation of a zero-sum perception of identity on the part of social groups - parties often feel that the very survival of their own group or identity is inextricably tied up with the negation of the other – that the two literally cannot co-exist. Reconciliation work is deeply rooted around issues of identity and the emergence of new identities developed through the process.

### Age differences in work motives

YEUNG, D. (City University of Hong Kong), FUNG, H. (The Chinese University of Hong Kong), CHAN, D. (The Chinese University of Hong Kong)

With an increasing number of older employees in the workforce, there is an increasing need to investigate whether older workers differ from their younger counterparts in work motives. This study examined whether there were age differences in work motives and their impacts on job performance. The sample consisted of 295 Chinese employees aged between 23 and 60 years. Among them, over 60% were managers and the remaining were professionals; and 57% of them were male. They were invited to fill in a set of questionnaires on work motives and job performance. Preliminary results showed that as compared with younger workers, older workers reported a higher level of intrinsic motivation \( t(293) = -3.11, p < .01 \) but less internally imposed motivation \( t(293) = 2.24, p < .05 \). Multiple regression analysis demonstrated that the positive relationship between intrinsic motivation and job performance was stronger among older workers than among younger workers (age by intrinsic motivation interaction, \( \beta = 1.479, p < .001 \)). The present study reveals age differences in work motives. In particular, older workers tend to have higher level of intrinsic motivation than their younger counterparts. The positive impact of intrinsic motivation on work was found to be stronger...
Abstracts of the 27th International Congress of Applied Psychology

among older employees than among younger employees. These findings provide significant implications to employers to understand work motivation and job performance of older workers.

Aggressive tendencies assessed through a stroop-like discrimination task among combat elite juvenile athletes

HERNANDEZ-POZO, R. (UNAM, National Autonomous University of Mexico), OLIVA, J. (Sports National Comission), HERNANDEZ-POZO, R. (National Autonomous University of Mexico)

This study was designed to assess whether athletes engaging in combat sports have increased probability of aggression, compared to people not involved in competitive sports. Juvenile elite athletes (N = 30; 12 to 18 years old) trained in one of five disciplines (boxing, Olympic wrestling, judo, karate, and tae-kwon-do) participated in the study, along with a control group of sedentary boys from the same age group. Proneness to aggressive behavior was measured by three methods: verbal, behavioral and physiological. A 28-item modified version of Spielberger’s STAXI-2 self-report for anger was used, validated for Spanish speakers. Behavioral bias for anger was measured through a computerized emotional Stroop task, using aggressive and neutral word stimuli (matched for word length and lexical probability) derived from a data base of words used in the sports’ jargon and presented in six different colors. Physiological reactivity to the computerized task was also monitored. Behavioral and physiological measures were recorded before and after a 90" video clip of a professional fight from the athlete’s discipline. Expression of internal aggression increased with age. Martial art practitioners (judo, karate and tae-kwon-do) showed higher interference for neutral thematic words than the rest of the athletes. Boxers exhibited a higher level of self-reported aggression than other sportsmen. Internal control of anger varied with behavioral scores on the Stroop test and with physiological reactivity. The use of three indexes to measure proneness to aggression highlights small differences among athletes engaging in combat sports that could be overlooked if only one of these procedures was used. Guidelines in training of boxing and martial arts might be responsible for some of the findings.

Keywords: aggression, combat sports, sport psychology, competitive sports, martial arts

Alcohol expectancies and self-efficacy beliefs predict drinking in young adolescents: A prospective study

CONNOR, J. (The University of Queensland), GEORGE, S. (The University of Queensland), GULLO, M. (The University of Queensland), KELLY, A. (The University of Queensland), YOUNG, R. (Queensland University of Technology)

Social Learning Theory (Bandura, 1969; 1977) has been effectively applied to substance use disorders (Bandura, 1999). According to this theory, the acquisition and maintenance of dysfunctional human behaviours derive from two related but independently operating expectations, outcome expectancies and self-efficacy expectancies. Alcohol expectancies and drinking refusal-self-efficacy beliefs are learnt at a very early age, often before drinking commences. Few early adolescent studies have prospectively examined both constructs to assess their impact on problem drinking. One hundred and ninety-two year nine students (Mean age = 13.8 years, SD = .51) were administered the Drinking Expectancy Questionnaire - Adolescent Version (Oei, et al. 2009) and the Drinking Refusal Self-Efficacy Questionnaire (Young, et al., 2007), as well as measures of quantity and frequency of alcohol consumption, and harmful alcohol usage (Alcohol Use Disorders Identification Test; Saunders, et al., 1993). Students were tracked for 12 months, with a follow-up rate of 88.5%. Data were analysed using structural equation modeling (SEM). As expected, lower drinking refusal-self-efficacy predicted more problematic drinking, after controlling for baseline alcohol use. Similarly, higher alcohol expectancies were associated with significantly lower self-efficacy and higher alcohol use. However, the effect of alcohol expectancies on future drinking was fully mediated by its strong negative association with self-efficacy, suggesting a more indirect role for
this cognitive construct. Previous research that has only included alcohol expectancies in their designs may have overestimated the role of this construct. Consistent with Social Learning Theory, the pattern of results from the current study suggests drinking refusal self-efficacy may act as a “gatekeeper”, mediating the influence of other risk factors.

Keywords: social learning theory, alcohol use, adolescence, self-efficacy, expectancies

‘Am I meant to have seen that?’ Why are consumer participation rates in mental health so low?

SCARIA, M. (Queensland Health)

The introduction of standardised outcomes measurement in mental health services has been an important recent development in Australia. However, consumer participation rates remain low, regardless of the brevity of the measurement tool used. In Queensland, the 36-item Mental Health Inventory (Viet & Ware, 1973) is the self-report measure used for consumer participation. Despite its use being mandatory, the statewide average consumer participation rate remains around 16-19 per cent. The rate varies widely across the state and within health service districts and their individual teams. Given the importance of consumer input into individual care, and into mental health service delivery, these figures remain disappointingly low. This research sought to examine the complex interplay of organisational and instrument factors contributing to ongoing low usage rates. Queensland Health staff from mental health services completed a series of questionnaires designed to examine their knowledge, skills and attitudes towards factors predicted to contribute to low consumer participation rates. These included personal factors such as knowledge of professional and ethical practices in psychological test usage, personal experience of psychological assessment, computer literacy skills, and attitudes towards mental health consumers. Organisational factors were also examined including management attitudes towards psychological assessment, consumer participation, the need for initial and ongoing staff training and supervision, provision of computer and support resources, and the clinical utility of the Mental Health Inventory itself. An evidence-based understanding of why consumer participation rates remain low is essential so that appropriate changes in current mental health service delivery, staff training, test development and organisational support can occur that will improve the quality of health care provided to mental health consumers and their families.

An analysis of research trends on career and vocational counseling in South Korea

YI, J. (Seoul National University), KIM, K. H. (Seoul National University), JO, H. (Seoul National University)

The purpose of this study was to provide information about the research trends and topics in career and vocational counseling in South Korea and to compare the Korean trends to those in the United States of America. Publications in two major journals were analysed, the Korean Journal of Counseling (KJC, 90 papers) and the Korean Journal of Counseling and Psychotherapy (KJCP, 63 papers). The papers were classified in terms of the fifteen categories developed by Fitzgerald and Rounds (1989) and this classification was compared to the analysis performed by Loveland, Buboltz, Schwartz, and Gibson (2006). In addition, issues such as research methodology were examined. The main samples were college students (46.4%), high school students (15.6%), and adults (15.6%). The number of articles within the special field of career and vocational counseling has increased since 2000, but the proportion of career and vocational counseling research amongst the “total” counseling research remained stable at 10~20%. In most of the studies analyzed, assessment tools related to career decision making, career development, interests and aptitudes were applied and the quantitative data were analyzed with inferential statistics. Qualitative research methods were seldom applied in the field. The principal topics of career and vocational counseling research were...

Brief Oral Presentations

‘vocational choice’, ‘decision-making process’, ‘career development’, ‘career development interventions’, and ‘assessment of vocational behavior’. These five categories accounted for 88.0% of the papers analyzed. In the US study, the order appeared to be different: career development, women’s careers, multicultural career counseling and programs.

An applied study of massed and distributed practice trials in the learning of a discrete and continuous soccer skill

MCNEIL, D. (University of Ballarat), SPITTLE, M. (Deakin University), MESAGNO, C. (University of Ballarat)

The distribution of practice trials has an important application in skill learning. Research has primarily focused on continuous motor skills with results indicating that distributed practice leads to better performance and learning than massed practice. The limited research on discrete skills has indicated that massed practice is more effective than distributed practice. Researchers, however, have not directly compared skills from one sport and have only used simple motor tasks rather than sports specific skills. Therefore, this study aimed to compare massed and distributed practice on the learning of a discrete or a continuous sport skill. The participants (N = 155, M_age = 19.69, SD = 1.76) practiced a discrete (passing) or continuous (dribbling) soccer skill in either a massed (one second inter-trial interval) or distributed practice condition (inter-trial interval of 30 seconds). Participants completed 20 practice trials, five immediate retention trials (after ten minutes), and five delayed retention trials (after two weeks). Preliminary analysis of the continuous skill indicated a skill improvement across the practice trials, with greater performance changes for the distributed than the massed practice condition. This difference was sustained throughout the immediate retention, with higher practice performance for the distributed than the massed practice condition. At delayed retention, there was no difference between massed and distributed practice conditions. For the discrete skill, there were no significant differences between the massed and distributed practice conditions during practice, immediate retention, or delayed retention. From the current results, distributed practice leads to better practice performance of the continuous sport skill; however, this did not result in better long-term learning. For the discrete skill, no differences were evident between the massed and distributed practice conditions for performance or learning. We would argue, then, that massed practice is as effective as distributed practice for learning a continuous and discrete sport skill. For applied sport settings, massing practice trials may be more effective than distributing trials because more trials can be completed in a shorter time period. The findings have application in the design of practice schedules for sport specific skills, which will be discussed.

Keywords: sports skills, sport, massed practice versus distributed practice, long-term learning, practice performance

An empirical study of the characteristics of salsa dancers and the impact on mental health and job stress

LIU, X. (Peking University), WANG, L. (Peking University)

The aim of this study is to examine the characteristics of Chinese SALSA dancers, and to conduct empirical studies on the impact of SALSA dancing on individual emotion and job stress. Online surveys and interviews were conducted to develop the item pool of the hobby characteristics of SALSA dancers, and then, exploratory factor analysis was employed based on a pretest of 116 participants, which yielded the final version of the questionnaire. Confirmatory factor analysis, reliability and validity tests were adopted on 257 participants. We compared SALSA dancers and 30 participants involved in other sports in terms of PANAS, subjective well-being and work stress, and measured the pre-and post-effect of SALSA learning. Results showed that Chinese dancers dance SALSA for four reasons, self presentation, self promotion, social restoration and easiness to learn. The subscales and the overall scale displayed acceptable reliability, validity and
fitness to data. Different hobby characteristics were correlated differentially with Big-Five factors; self presentation was positively related with positive affectivity and subjective well-being; those who scored high in self presentation had the highest levels of passion for dancing, followed by self promotion, and easiness to learn; social restoration was not correlated with passion for SALSA dance; self promotion was negatively correlated with education, and positively with dancing frequency. When frequency was controlled for, SALSA dancers of different lengths of time displayed a higher level of positive affectivity than participants engaged in other exercises. Long-term SALSA dancing (three-and-a-half weeks) significantly promoted positive affectivity and lowered participants’ negative affectivity and job stress, while short-term SALSA dancing (one-and-a-half hours) significantly lowered participants’ negative affectivity and promoted positive affectivity other than job stress. The conclusion is that Chinese dancers dance SALSA for self presentation, self promotion, social restoration and easiness to learn, and SALSA dancing can positively promote mental health and relieve job stress. The practical implication of the findings and directions for future research were discussed.

Keywords: salsa dancing, job stress, self promotion, well-being, social restoration

An examination of the relationship between psychological capital and performance in Chinese offshore oil workers

YAN, G. (Beijing Normal University), YUE, G. A. (Nankai University), LU, X. (China National Offshore Oil Company)

Psychological capital, a new construct coined by positive psychologists in the last decade, plays a more and more important role in domain of Human Resource Management and is credited to be a key for the talent war in the worldwide. The present study aims to investigate the relationship between psychological capital and job-related outcomes, such as task performance, engagement and satisfaction. Two-hundred and sixty two offshore oil workers and their supervisor from seven platforms in China responded to the mailed questionnaires anonymously when they were on duty, with an 87% response rate. All of the workers were male and age ranged from 20 to 50 years old. They needed to stay and work at the platform on the sea for 28 days in a session. Psychological capital questionnaire (PCQ), designed by Luthans, Youssef and Avolio (2007) and job performance measures, defined by Borman and Motowildlo, were mailed to the workers and their supervisors respectively. The workers’ demographic variables were controlled in the statistical analysis. The results indicate that (1) Workers’ psychological capital significantly correlated with their task performance and engagement rated by their supervisor respectively ($r = 0.21$ and $r = .27$). (2) The correlations between the Hope factor in PCQ with task performance, engagement and satisfaction were higher than the correlation of three other factors correspondingly. (3) The relationship between psychological capital and task performance was mediated by engagement. Two main conclusions were made in this study. First, psychological capital is a useful and valid construct and can be used in predicting job performance in the extreme work environment. Second, Hope plays a much important role when workers face a challenging job.

Keywords: psychological capital, human resources, job-related outcomes, job performance, task engagement and satisfaction

An exploration of individual differences involved in susceptibility to false memories

MONDS, L. (University of Sydney)

Individuals with Post Traumatic Stress Disorder (PTSD) may be more susceptible to developing false memories, compared to those without the disorder. The aim of this study is to examine trait dissociation and underlying cognitive biases related to threat, as vulnerability factors in the development of false memories for neutral and trauma-related words in a non-clinical population. Eighty-five undergraduate students completed the Deese-Roediger-McDermott (DRM) task for neutral and trauma-related word lists. The DRM is a common false memory procedure where participants are instructed to
remember semantically related word-lists and upon recall often produce a critical lure – a word that wasn’t originally presented but is strongly related to the studied words. Following this, participants filled out the questionnaires of interest (Dissociative Experiences Scale-Comparative, Looming Maladaptive Style Questionnaire-Revised, Post Traumatic Cognitions Inventory, Beck Depression Inventory-II), and a word recognition task. The cognitive bias and dissociation scales were all significantly correlated to the reporting of critical lures in either the free-recall or recognition conditions. Regression analyses also supported these findings, whereby those participants scoring high on dissociation, depression or post-traumatic cognitions were more likely to report trauma-related critical lures in the free-recall condition; whereas the looming cognitive style was related to traumatic lure recognition. Cognitive biases related to threat and trait dissociation may be predisposing factors that make an individual more susceptible to taking on false memories in traumatic situations. This study has important implications regarding the development of PTSD, as well as situations involving co-witness discussion and eyewitness testimony.

Keywords: post-traumatic stress disorder, false memories, dissociation, depression, eyewitness accounts

An exploration of nonverbal behaviors collocated with applicant defensive impression management tactics

WU, C. Y. (Tung-Hai University), HUANG, K. (Tung-Hai University), SHE, P. Y. (Tung-Hai University)

Verbal self-presentation tactics comprise the central part of impression management (IM), separated as assertive IM and defensive IM. When it comes to non-verbal behaviors collocated with verbal IM, only positive behaviors have been defined, such as eye contact and smile. However, those are not suitable for defensive IM tactics. This current study is to clarify the content of non-verbal behaviors specific to defensive IM tactics. The method involved: (1) An interview: we ask those interviewees who have had employment interview experiences, to understand what kind of emotion expression is suitable for different kind of defensive IM tactics, for example, regretful – apology; and (2) Observation: we request those interviewees who have applied for a job vacancy as actors. We provide them with the (verbal) scripts of each kind of defensive IM tactics, and ask the actors to perform them with non-verbal behaviors. The presentation would be recorded as video tapes, then the researchers serve as coders to code non-verbal behaviors. Non-verbal behaviors were categorized as four types in past research: (1) tone, (2) head / face, (3) hand, and (4) body. This categorization is the base for coding, and those behaviors coded from the video tapes can be classified. Finally, the complete non-behavioral content lists come out. In past research, the common measure of assertive IM tactics is “frequency” and that of defensive IM tactics is “to use or not to use”; both are measures of “quantity of IM.” According to the present study, the suitability of non-verbal behaviors can be viewed as “quality of IM.” This work intends to contribute to the literature by bringing up the collocation of verbal and non-verbal IM.

Keywords: impression management, non-verbal behaviours, defensiveness, assertiveness, eye contact

An exploration of the relationship between spirituality and resilience in the context of general well-being

DATTA, P. (Delhi University), TOMAR, P. (Delhi University), SAHAI, N. (Delhi University), MISRA, G. (Delhi University)

With the aim to ascertain what accounts for good adaptation under difficult circumstances, this exploratory study examines the correlation between spirituality and resilience in the context of general well-being. Thirty participants (15 males and 15 females) in the age range of 21 to 28 years were administered The Cognitive Behavioural Spirituality Scale (Niederman, 1999), The Resilience Scale (Wagnild & Young, H., 1993) and the General Well-Being Schedule (Dupuy, 1977). These were followed by an extensive semi-structured interview. The data obtained was analyzed using both qualitative and quantitative measures. The quantitative analysis revealed a significant correlation between
resilience and general well-being, between spirituality and resilience in females, and between spirituality and general well-being in males. The qualitative analysis of the narratives revealed a complex matrix of influences that helped shape the individual’s subjective understanding of spirituality, diverse descriptions of how individuals understood and observed spirituality, and varied coping strategies used in times of adversity. Based on the findings, a model is proposed of the relationship between spirituality, resilience and general well-being, where spirituality is one of the coping mechanisms used to augment resilience and general well-being. The results have applications in positive psychology and health psychology.

**An exploration of workplace bullying trauma symptom patterns**

FIELD, E. (Evelyn M. Field Pty Ltd), FERRIS, P. (Calgary Psychology Group Inc/Janus Associates)

The aim of this paper is to demonstrate that those experiencing workplace bullying (WB) develop psychological trauma that with the exception of Criterion A, meets the diagnostic criteria for Post Traumatic Stress Disorder (PTSD) as defined by DSM-IV. We also examine whether a particular pattern of symptoms within PTSD defines workplace bullying trauma (WBT), as treating therapists agree that victims are not only seriously injured but their symptoms present differently to other victims. Although some mental health professionals believe that that a diagnosis of PTSD is appropriate for victims of WB, many disregard the victim’s experience. They do not believe that WB bullying meets the DSM-IV Criterion A definition of experiencing or witnessing a physically life threatening event. Thus they do not recognize it as an appropriate diagnosis in medico-legal systems. As a result, these systems lag behind the practice of treating WB and result in inappropriate diagnoses, treatment, and loss of coverage through workplace insurance programs for targets. We derived participants (approximately 30 from each country) from cases presenting for treatment within the authors’ practices (Australia and Canada) and a snowball sample of participants recruited from bullying websites and word of mouth. Participants were interviewed via three methods (face to face, telephone, or Skype) to determine the presence and severity of WB. Subsequently, we mailed or administered the measures which included the screening measures from Australian Guidelines for the Treatment of Adults with Acute Stress Disorder and Posttraumatic Stress Disorder (2007), the DSM IV, additional questions probing the relevance and salience of PTSD symptoms, and the Brief Symptoms Inventory (Derogatis, 1993). We hypothesize that participants will report levels of distress on the BSI above norms on the majority of scales. We also hypothesize that scores on the obsessive compulsive, paranoia, and psychoticism scales will be particularly elevated as well as common physical symptoms. We hypothesize that those with elevated distress will meet the criterion for PTSD. There is sufficient evidence to warrant further research into WBT to assist treating practitioner, validate victims, and assist employers and insurance companies to provide effective support.

**An exploratory study of demographic and service determinants of mediation outcomes in Australian family dispute resolution (FDR) practice**

O’MARA, A. (Relationships Australia Queensland)

This study explored Family Dispute Resolution Practice within the Family Relationship Centre context in Australia by mining archival data. The study investigated the degree to which it is possible to evaluate outcomes of successful mediation by exploring associations among variables such as age, gender, incomes level, occupation, service context, the presence of domestic or family violence, and outcomes in relation to agreements or certifications. The impact of post-separation conflict on children has received much attention of late and as such has been the catalyst for change within the Judiciary/Government (McIntosh, 2004). Family Dispute Resolution (mediation) is now a
compulsory first step for separated families as an alternative to court. The establishment of 65 Family Relationship Centres (15 having commenced operation in July 2006, and 25 more being introduced in each of the two subsequent years) has seen a dramatic change in the way parents resolve conflict post separation in Australia. This does however raise questions of how much we actually know about Family Dispute Resolution, the clients who are utilising this service, and the effectiveness of the Family Dispute Resolution process in providing a successful outcome for the client. The exploratory study used SPSS to analyse archival data from 500 clients who used the Family Dispute Resolution Program and for whom cases are currently closed. Planned analysis methods include frequencies, distributions, correlation regression and analysis of variance and potential analysis of nested groups. The data for this project has recently been retrieved from the data warehouse and is currently being cleaned and prepared for exploration and analysis. Results will help inform future prospective studies and evaluation of interventions. The study will provide useful data on the Family Dispute Resolution process and assist in determining what demographic and service experiences might contribute to successful mediation outcomes. The findings are expected to have implications for theorising, research and practice. Specifically, the implications lie in the design of future research projects which can examine the determinants of healthy co-parenting relationships and whether Family Dispute Resolution is a successful intervention for improving the co-parenting relationship.

Keywords: family dispute resolution, co-parenting, mediation, separated families

An integrative approach to job satisfaction and its impact over subjective well-being in European workers

SIMON, C. (IE University), CARDENAS, W. (IE University)

Work-derived well-being has long been researched from different perspectives, both in terms of its theoretical approach (e.g. situationally-based versus trait-based) and its methodological design (inter versus intra-individuals, single-item measures versus multiple scales etc). However, few studies have conceived subjective well-being associated with work as a higher-order, multidimensional construct that requires the integration of both personal and situational factors in a systemic way. Along these lines, the objective of the present study is to test a unifying model of the relationship among different categories of factors having an impact over well-being at work. The model proposes that a combination of dispositional factors or psychological resources (optimism, self-esteem, autonomy, interest in learning, accomplishment, purpose and resilience), and situational conditions (opportunities for learning, chances to show competence, time use options, social recognition and support and belonging) influence the individual’s experience of work as defined in five dimensions (offering security, autonomy, participation, and being interesting and stressful). The impact of these factors is measured over different dimensions of satisfaction at work (getting paid appropriately, general satisfaction with job, perception of work-life balance). The study utilizes a subset of the European Social Survey database (EU15 countries, N = 16546), and focuses on the Personal and Social Well-Being Complementary Module (Huppert et al, 2005) and other work-related items were included in the survey. Descriptive analyses and regressions have been run in order to establish initial relations among variables and carry out cross-country comparisons based on national socioeconomic parameters (such as the Employment Protection Legislation Index). The model is currently being tested using structural equation modeling using AMOS software. The degree to which job is experienced as interesting (which is shown to be a function of four variables: opportunities for learning, accomplishment, purpose and recognition) was the main predictor of job satisfaction. Other variables such as the personal-working time balance, the recognition achieved and the estimation of security associated with the job entered the regression equation with a moderate weight. Such general measures of job satisfaction are moderately related to the one-item most used measure of subjective well-being (Life Satisfaction Scale; Diener, 1985). No significant differences were
Abstracts of the 27th International Congress of Applied Psychology

found for gender or age groups. The analysis of cross-national differences is in progress. Though statistical analyses are currently underway, expected results will allow us to model the construct of subjective work-related well-being integrating the combination of psychological resources and situational factors into a consistent ‘work experience’ or personal estimation of work characteristics that will have an impact over different measures of work satisfaction (material, time-quality, general). Cross-national differences will also allow us to draw conclusions about the different types of work experiences in Europe and its influence on work-related satisfaction and subjective well-being.

Keywords: job satisfaction, work-life balance, subjective well-being, psychological resources, experience

An integrative approach to sexual abuse

DROBOT, L. ("Eftimie Murgu" University Resita)

Each client that comes to therapy is unique and so are their problems, thus it is impossible to conceive a standard intervention approach. Still, intervention strategies can be formulated. The case presented is a 13 year old client, sexually abused, who was treated with the help of an integrative approach and had great importance for me as a therapist. In my opinion each client solves a part of the therapist’s problems too; the therapeutic relation is not the only one co-created, why shouldn’t healing also be co-created? The model to serve as guide has its theoretical and its practical sources in integrative psychotherapy (Evans & Gilbert, 2005), psychosynthesis (Assagioli, 1976), brief therapy (De Shazer, 1985), Ericksonian techniques (Erickson & Rossi, 1979) and the counseling intervention model (Culley & Bond, 2004). Thus, the following domains of objectives become obvious: the co-creation of a therapeutic relation, dysfunctional behaviors (intervention mechanisms, broken contact with the self and the world, identifying sub personalities, emotions, roles etc.), development of a mutual I-Thou relationship (unidentifying of personalities, abractions etcetera) and reintegration, the client’s professional integration (therapy for knowing our aptitudes and professional competencies in order to make the right decisions). The case was solved, but it also represented the therapist’s healing. The therapist’s reflexive analysis has underlined the parallel “healing” process. The paper insists on the therapeutic approach addressed to clients and the therapist’s reflexive analysis will represent the subject of this paper.

Keywords: sexual abuse, case study, therapist’s healing, therapeutic relationship, co-creation in therapy

An investigation of the relationship between big five personality factors and procrastination

DAVOODI, I. (Shahid Chamran University of Ahvaz), GHAHREMANI, S. (Shahid Chamran University of Ahvaz)

This study investigated relationships of the Big Five Personality Factors of neuroticism, extraversion, openness, agreeableness, and conscientiousness, with procrastination. A sample of 207 undergraduate students (79 male and 128 female), from Shahid Chamran University of Ahvaz, completed a Persian form of Tukman’s Procrastination Scale (Tukman, 1991) and the NEO_FFI Inventory (MacCray and Costa, 1992). The results revealed that the neuroticism has a positive correlation with procrastination. The personality factors of extraversion, agreeableness and conscientiousness negatively correlated with procrastination, while there was not a significant relationship between openness and procrastination. In addition, the results of regression analysis with a stepwise method indicated that conscientiousness was the only variable that entered into the model. This factor accounted for 58% of the variance in procrastination. The results showed conscientiousness is the most powerful predictor for procrastination among the Big Five Factors. These findings suggest the presence of overlap between procrastination and conscientiousness constructs, as operationalised in Tukman’s Procrastination Scale and the NEO_FFI Inventory.
An opportunistic qualitative study of the psychosocial benefits of blogging

BAKER, J. (Swinburne University of Technology), MOORE, S. (Swinburne University of Technology)

Bloggers provided unsolicited commentary on published research by the authors on the psychosocial outcomes of blogging following extensive press coverage of these publications. The authors aimed to a) examine the validity of the original findings utilizing this feedback, and b) further explore the nature of blogging. Blog search engines were utilized to identify blog entries relating to the published research. These entries were then copied in their entirety to word files, including comments by other bloggers. NVivo 7 was utilized to analyze level of agreement with the original research for each blogger (where present) ranging from Hostile to Advocating. Following this, individual blog entries were re-examined line by line for psychosocial references and were coded by theme for further analysis of the benefits of blogging. In analyzing agreement with the original research, the majority of bloggers (80%) either advocated or accepted the results, while only 9% were opposed or strongly opposed to them. In examining for additional psychosocial benefits a number of themes and subthemes were identified. The main themes included social benefits, affective relief, learning, communication, self-knowledge, real-world activities and self promotion. The present research lends some validity to the original findings that blogging may lead to perceived improvements in social support including increased trust in others (reliable alliance), social integration, and satisfaction with friendships both online and offline. Following analysis of the commentary it appears that blogging may have additional utility in terms of personal development and growth, improved interpersonal skills, affective relief, and social capital. While motivations and benefits appear to vary widely by individual, the majority of comments described blogging as personally rewarding and beneficial.

Animal model of PTSD: Behavioral changes following underwater trauma, situational reminders and diazepam treatment

MAKVAND HOSSEINI, S. (Semnan University), BIGDELI, I. (Semnan University), YOSSEFI, M. H. (Semnan University), SEDDEGHI, F. (Semnan University)

Ethical and practical limitations in research on human subjects have opened a window to animal research regarding post traumatic stress disorder (PTSD). PTSD modeling is critical in understanding the causes and potential treatments of the disorder. The main purpose of this experimental research was to create an animal model of PTSD based on the main features of the disorder: trauma exposure, situational reminders of trauma, behavioral anxiety and remedy in response to anxiolytic medications. A number of inbred female Sprague-Dawley rats (n = 6) at the age of two months, weighing approximately 180 grams, were obtained and evaluated in the elevated plus-maze test in three stages: 1- in the baseline state (before trauma exposure) 2 - after a single exposure to underwater trauma in the Morris water maze (water temperature 25.1 °C, to a depth of 30 centimeters) plus daily (over five days) encountering of situational reminders (observing the Morris water maze and the net basket for pushing rats under water) and 3- after daily exposure to situational reminders and diazepam (0/5 milligrams per kilogram) administration afterward. Measures of open arm ratio time and ratio entry were extracted from five days of five minute video recordings for every stag and analyzed using general linear modelling: repeated measures. Results showed significant increases in anxiety-like behavior relative to the baseline (decreased open arm ratio time and ratio entry) after exposure to underwater stress and reminders (F:119.231; α = 0.008; Mean difference = 60.587, α = 0.02) as well as returning to the baseline level of activity after exposure to reminders plus diazepam administration (F:393.923; α = 0.003; Mean difference = 56.670, α = 0.008). A single
underwater stress together with daily exposure to situational reminders successfully induced PTSD sequels in rats and anxiolytic drug administration decreased the behavioral symptoms.

Keywords: post-traumatic stress disorder, trauma, situational reminders, diazepam treatment

Anticipations of the development of job satisfaction as predictors of work-relevant types of behaviour

JIMENEZ, P. (University of Graz), ILIC, P. (University of Graz), HINTERREITER, R. (University of Graz)

The prediction of behavior using knowledge of job satisfaction is one of the aims of measuring this study. However, the aspect of time and dynamic changes of the organizational environment are seldom integrated in the field of job satisfaction. In a system oriented model the variable job satisfaction is seen as an outcome and as a cause variable in a feedback control system. The behavior is assumed to be influenced not only by the level of job satisfaction but also by the anticipation of the development of the organization and the future job satisfaction. The aim of this study is to test the model of job satisfaction and the anticipations of development of job satisfaction in relation to different types of active and passive behavior. The sample consists of 243 employees of an educational institution. Measurements were the Profile Analysis of Job Satisfaction, the scale of Anticipation of the Development of Job Satisfaction, scales for various work-relevant types of active and passive behavior (for example, intention to quit, service quality behavior or knowledge sharing etc.). Analyses support the postulated relationship between job satisfaction and development-estimations. Two different models for a moderating or a mediating effect were tested. The mediating model of anticipation of the development of job satisfaction shows good fits (GFI=.89, AGFI=.85, CFI=.93, RMSEA=.05). Earlier research of the relationship between different forms of job satisfaction and work-related behavior already showed that in comparison to resigned job satisfaction a constructive form of job dissatisfaction was related to more active behavior in the work context. The results emphasize that job satisfaction together with the anticipations of development in the organization are good predictors of different work-relevant behaviors.

Keywords: job satisfaction, work-relevant behavior, organisational change, organizational environment

Anxiety-linked attentional biases in older and younger adults

CABRERA, I. (University of Western Australia and Autonomous University of Madrid), MACLEOD, C. (University of Western Australia), BUCKS, R. (University of Western Australia), BURGESS, M. (University of Western Australia)

Previous research has demonstrated that individuals with high levels of anxiety vulnerability show a tendency to selectively attend to negative information. This attentional bias may play a causal role in the development and maintenance of anxiety symptoms (Mathews & MacLeod, 2005). In this area, some questions remain unanswered: 1) whether the attentional bias reflects facilitated engagement with threat or impairment disengagement from threat; 2) whether the anxiety-linked attentional bias is specific to negative information or favors emotional information general; and 3) whether the attentional characteristics of anxiety vulnerability change with age. The present study aimed to address these questions. The sample was composed of 16 high trait anxious (HTA) and 16 low trait anxious (LTA) young adults (age mean = 18.8, SD = 1.8) and 16 HTA and 16 LTA older adult (age mean = 69.2, SD = 7.6). Attentional disengagement from and engagement with emotional stimuli were independently measured using a novel task. Participants were required to make a lexical decision about two-letter strings (word or non-word) that appeared in different loci on each trial, one after the other. The dependent variable was the latency to make the second lexical decision, which would be influenced by the time taken to move attention from the initial string. On disengagement trials the initial letter string was a negative, positive or neutral word, and the second string was a non-word. On engagement trials the initial letter string was a non-word and the second was a negative, positive or neutral word. A mixed-design analysis
of variance (ANOVA) was carried out separately on disengage and engage bias index scores, with two between-subjects factors (trait anxiety: high/low; and age: young/older), and one within-subjects factors (negative/positive bias). Only for engage bias scores was a significant interaction between anxiety-group and valence obtained ($F(1, 60) = 4.75, p = .033$). Further analysis indicated that HTA participants were disproportionately slow to engage attention with the positive words. This result suggests that high trait anxious individual show reduced attentional engagement with positive information. No age differences were found. Possible explanations for, and implications of this finding are discussed.

Keywords: attentional bias, attentional engagement, anxiety vulnerability

Appearance-related feedback in intimate relationships: The role of verification and enhancement processes

BROWN, J. (La Trobe University), STUKAS, A. (La Trobe University), EVANS, L. (La Trobe University)

This research aimed to investigate the way that females respond to different types of feedback about their physical appearance that they imagined receiving from their intimate partner. The social psychological theories of self-verification and self-enhancement provided a framework for examining these feedback responses in the specific context of physical appearance in intimate relationships. Self-Verification theory proposes that people would be more satisfied in their relationship when their partner sees them as they see themselves, whereas Self-Enhancement theory proposes that people would be more satisfied when their partner sees them more positively than they see themselves. Participants were females who had been with their current intimate partner for at least one year. After completing self-report measures of their self-esteem, body image, and relationship satisfaction, participants received one of three feedback vignettes that described appearance-related feedback from their intimate partner that was either (a) consistent with their appearance self-view (verifying), (b) more positive, or (c) less positive than their appearance self-view. Participants then completed self-report measures assessing their cognitive reactions (feeling understood), affective reactions (feeling happy) and perceptions of their partner and the relationship in response to the feedback. Results showed that females with negative views of their own appearance responded with more positive affect to enhancing appearance-related feedback whereas they reported a more positive cognitive reaction to verifying appearance-related feedback. In addition, their perceptions of their partner and the relationship were similarly positive following both enhancing and verifying appearance-related feedback. This study was the first to use a more experimental methodology to examine responses to appearance-related feedback in the context of intimate relationships and to examine the impact of appearance-related feedback from an intimate partner on perceptions of the relationship. As such, this study contributes to the existing research in the area of body image and intimate relationships.

Keywords: relationship satisfaction, body image, gender, intimate relationships

Applicability of a five-kind personality inventory for college students’ personality measurement: A comparison study with the 16PF

WANG, A. (Beijing Normal University), XU, Y. (Beijing Normal University)

The aim of this research was to study the applicability of a five-kind of personality inventory for measuring college students’ personality. In the study, we adopted two measuring tools: a five-kind of personality inventory (Chongcheng Xue & QiuliYang, 1988) which was put forward according to theory of famous medical book “Neijing” in ancient China. Participants were 237 college students (aged 19 to 23 years, 70 male and 167 female). We made a comparison between the five-kind of personality inventory and 16PF for measuring college students’ personality. The results indicate that (1) The mean score for male students is significantly higher than for female students in Taiyong (strength) and Yinyangpinghe (equilibrium) dimensions of the five-kind of personality inventory ($p < 0.05$, $p <$
0.05). Their scores for perfectionism and creativity dimensions in the 16PF are also significantly higher than those for females ($p < 0.01, p < 0.05$); but their scores for warmth, privateness and tension dimension in the 16PF are significantly lower than for females ($p < 0.01, p < 0.05, p < 0.01$). (2) There is no difference between the five personality kind between south students and north ones. However, for 16PF, the perfectionism score of north students is significantly higher than for south ones ($p < 0.01$). (3) Besides reasoning, abstractedness, privateness, openness to change and creativity dimensions of the 16PF, all dimensions of the five-kind of personality inventory correlated with other dimensions of 16PF on corresponding content. The five-kind of personality inventory is available for measurement of college student’s personality.

Application of a process model of health motivation in physical activities

XU, X. (Sichuan Normal University)

Previous studies have shown that health motivation can enhance physical activities. Although researchers have used the term health motivation for a long time, there is no widely accepted definition or theoretical model of health motivation. In my recent studies, I defined health motivation and suggested a process model of health motivation. The present study aimed to investigate whether this model can capture individuals’ health motivation in physical activities and whether this model can predict people’s physical activities. One of the significant aspects of this study is that it can enrich the theoretical research in health motivation. I believed that health motivation produces inner force which energizes and orients individuals’ health related behaviors. Based upon this definition, I proposed a process model of health motivation. This model indicates that health motivation guides individuals’ health-related behaviors in the following consequential four-step process: to develop health motivation tendency, to form health intention, to initiate health related action, and to persist in those actions to achieve goals developed at the first stage. Upon this model, the Health Motivation Scale in Physical Activities (HMS-PA) was developed, with 12 items in total. The present study examined the construct validity and predictive validity of the scores obtained using the HMS-PA among 251 undergraduate participants in a southern university of the United States of America. The higher order confirmatory factor analysis suggested that the model fitted the data well. The predictor power of health motivation, health self-efficacy, health value, and Body Mass Index were examined using multiple regression analysis. The finding indicated that health motivation was the most powerful predictor of physical activities. Interestingly, health self-efficacy was not shown to be a statistically significant predictor of physical activities. In conclusion, the proposed theoretical model of health motivation and the scale were effective in capturing individuals’ health motivation. Health motivation significantly contributed to physical activities. This model and the scale can be applied to related theoretical and empirical studies.

Keywords: health motivation, physical activity, health related behaviours, health intention, health self-efficacy

Application of the individual zone of optimal functioning (IZOF) model for a team

MINOUCHI, Y. (Hokusei-Gakuen University)

The Individual zone of optimal functioning (IZOF) theory by Hanin (1997) is that there are individual differences in the appropriate emotional state for individual sport performance. In other word, there is an individual variation in effective emotions and in the optimal level of emotions for performance. In the research on a current IZOF model, individual athletes’ emotional states have been examined. However, it was thought that the idea of appropriate psychological state is different depending on individuals was able to be applied also to sports teams. Therefore, the aim of this study was to examine whether the appropriate emotional states for the team is determined. Another aim of the present study was to verify
whether controlling the emotional states contributes to improving and stabilising team performance. Subjects were from a female rhythmic gymnastics team of a high school (five female players). The investigation period was five months from April, 2009 to September, 2009. The procedure involved, firstly, identifying the best performance and the worst performance in the team. Next, the emotions (key words) that related to the team performance had been extracted by discussions with the team. After that, the emotional states and the performance of each official competition were evaluated. It was surveyed three times. After the competition had ended, team state before and during the competition was evaluated. The emotions and the terms that strongly influenced the team performance were searched out by comparing the best performance and the worst performance in competitions. As a result, "Confident", "Worried", "Enjoy", and "Motivated" were chosen. It was clarified that "Confident" related to the expression of their face, "Worry" related to the switching of feelings, "Enjoy" related to the enchanting the spectators, and "Motivated" related to uniting for a team. We tried the control of the emotions in the competitions because the antecedents of the emotions were identified. As a result, the performance was stable to compare before. It was suggested that controlling of antecedent behaviors leads to integration of the team and to enhancement of team performance. It is thought that it will be necessary to examine the effective methods for appropriately controlling strength of the key emotions, and to use it in other competitions in the future.

Keywords: optimal functioning, emotional states, sport, competition

Application of Versatile Leadership Model and Leadership Versatility Index® in a different cultural context

JAROSOVA, E. (University of Economics), PAVLICA, K. (Škoda Auto University)

The brief oral presentation is focused on the application of Versatile Leadership model and Leadership Versatility Index® (LVI) developed by R.B. Kaplan and R.B. Kaiser in the United States (US) in a different cultural context - in the automobile company Škoda Auto, a.s. (a part of Volkswagen Group, the largest car manufacturer in Europe) located in the Czech Republic. The aim of the LVI Škoda Auto Project was to verify the LVI and its value for Czech managers from international company. The Leadership Versatility Index® is a 360-degree feedback survey which collects the data from direct reports, peers and superiors as well as from the target manager himself or herself. It contains 67 items and it is completed by open-ended questions. The LVI is based on a model of versatile leadership. Its structure has four independent subscales for each dimension of two major pairs of opposites: enabling and forcing leadership and operational and strategic leadership. The LVI was used on a sample of the Czech managers (N = 14) twice – in 2008 and in 2009, followed by feedback and coaching sessions. In the meantime the managers completed their personal development plans. The comparison of the data collected on the Škoda Auto sample with the data in Kaplan DeVries Incorporated normative database (with ratings for 1 123 senior managers) identified no significant differences on the level of overall versatility assessment. Most of the managers from the Škoda Auto sample inclined towards leadership lopsidedness on a level of forceful-enabling dimension – in correspondence with the same trend in the sample of US managers assessed by the LVI. The analysis of the personal development plans enabled us to record how the LVI results helped Czech managers to identify their own excesses and deficits in the execution of managerial role. The LVI is a useful and well-accepted assessment tool also in a Czech cultural context. The Škoda Auto Project confirmed that the LVI - based on a model of versatile leadership – it helps managers to understand their multiple, even contradictory roles and to deal with their paradoxical demands.

Applied use of emotional intelligence data at the Anglican Church Grammar School

The brief oral presentation is focused on the application of Versatile Leadership model and Leadership Versatility Index® (LVI) developed by R.B. Kaplan and R.B. Kaiser in the United States.
WELLHAM, D., SIMMONS, N. (Anglican Church Grammar School), STOUGH, C. (Swinburne University), HANSEN, K. (Swinburne University)

The aim of this presentation is to describe the ways in which emotional intelligence research is used to support students and families at an independent School for dayboys and boarders. The School has 1700 students from Reception to Year 12. Emotional intelligence (EI) research in education is in its infancy. Churchie is a research partner with Swinburne University with the aim of developing knowledge of self and others within our student population via longitudinal research and collaboration. This presentation will outline the methods used by the School to elicit EI data and to track students with respect to planning for successful academic and social-emotional outcomes. All students in Years 7 to 12 in 2009 will have had their Emotional Intelligence measured using Swinburne University Emotional Intelligence Test (SUIET). The SUIET has four core areas of focus: (1) Emotional Recognition and Expression; (2) Understanding Others’ Emotions; (3) Emotions Direct Cognition; (4) Emotional Management and Control. It is known that the population mean score for each of the four emotional intelligences is 50. Emotional Management and Control is a key factor in academic performance and Churchie’s Year 12, 2009 mean score was 80; Understanding Others’ Emotions is also regarded as a significant factor and Churchie’s mean is 55; Emotional Recognition and Expression have not been shown to be a significant factor in academic performance and Churchie’s mean was 50; and Emotions Direct Cognition may affect thinking and performance in certain academic areas with creative arts and maths thinking affected differently by this EI trait – Churchie’s EI mean was 51. Strategies for improved academic outcomes through an EI specific language and framework in the curriculum and overt EI strategies to be further developed throughout the curriculum will be outlined.

Keywords: emotional intelligence, education, academic performance

Appraising the future: The development and validation of the Future-Oriented Appraisal (FOA) measure

DRUMMOND, S. (Griffith University), BROUGH, P. (Griffith University)

This study develops and validates a measure of future-oriented cognitive appraisal in response to current discussions concerning future-oriented coping behaviours. Both proactive and preventative coping represent future-focused efforts to manage potentially stressful future events. The differential is in how the (potential) stressor is appraised. Proactive appraisal focuses on identifying the benefits and opportunities that can arise from the upcoming event, whereas preventative appraisal identifies methods to reduce the potential negative consequences. The development of a measure incorporating both types of appraisal enables stress and coping theoretical models to be assessed within a future-oriented paradigm. A 30-item measure was initially developed based on the proactive-preventative-oriented discussions within the literature. The 30-item measure was administered twice to a total of 316 university students over a six month period. Using principal components analysis, four factors (19 items) emerged from the initial administration, accounting for 67 per cent of the variance. For the purposes of this research, the four factors were combined to produce two higher order factors representing proactive and preventative appraisal. These two higher order factors demonstrated acceptable internal consistency (.82 proactive appraisal, .87 preventative appraisal) and strong test-retest reliability (.83 and .82 proactive appraisal, .88 and .91 preventative appraisal). The measure was related to personality characteristics (e.g., neuroticism, conscientiousness, and optimism) and psychological health outcomes (e.g., psychological strain) thereby demonstrating criterion validity. Initial results indicated that the measure provides a good assessment of future-oriented cognitions and therefore marks an exciting advancement in the testing of stress-strain processes within a future-oriented paradigm. The adoption of proactive or preventative appraisal for an anticipated potentially stressful event has significant implications concerning the subsequent activities undertaken to cope in response to that event.
Are the eyes the window into what drives the own-race bias?

HILLIAR, K. (University of New South Wales), KEMP, R. (University of New South Wales)

The own-race bias refers to the tendency for people to recognise faces from their own racial group (same-race faces) better than faces from a different racial group (different-race faces). This bias has important implications for a broad range of areas, from promoting cross-cultural interactions, to having confidence in the eyewitness identifications of different-race suspects. The aim of this experiment was to investigate whether this bias is due to any differences in how participants look at same-race and different-race faces, either at study or at test. Participants were presented with ten same-race and ten different-race faces that were presented either individually, or in pairs (same-race/same-race, different-race/different-race, and same-race/different-race pairs). Participants’ viewing of each face/pair of faces was self-paced. After a two-minute filler task, participants were presented with these 20 ‘old’ faces, along with 20 ‘new’ faces, and had to decide whether each face was old or new. Eye movements and fixations were recorded throughout the experiment. Although participants showed a small own-race bias in their recognition accuracy for the faces, this difference in performance was, unexpectedly, not associated with any differences between same-race and different-race faces in terms of the length of time spent looking at these faces, the areas of the faces observed the most (i.e. internal versus external features), and the speed that old/new decisions were made. Amount of contact with different-race faces was also found to be unrelated to different-race recognition accuracy. Participants looked longer at faces that were presented individually compared to those presented as part of a pair, but viewing times and strategies did not differ across the three different types of face pairs. These results suggest that the own-race bias is not due to any differences in the strategies people use when encoding (at study) or reviewing (at test) same-race and different-race faces. Thus, despite using the same strategies, participants still show an advantage for same-race faces. A better understanding of the mechanisms that do (and do not) underlie the own-race bias will allow development of more effective interventions for reducing this bias, and thus minimising its negative social and legal consequences.

Are the Identity Foreclosures different from the Identity Achievers in terms of career decision process?

CHO, A. (Seoul National University), KIM, K. H. (Seoul National University), KIM, Y. H. (Seoul National University), LI, H. (Seoul National University), YI, J. (Seoul National University)

According to Brisibin and Savickas (1994), the measures of career indecision do not discriminate between achievers, who are committed to self-chosen goals, and the foreclosed who are committed to goals chosen by significant others without exploring alternatives. However, the measures used in this research are limited. This study investigated whether it is possible to distinguish foreclosures from achievers using measures related to career decision and career maturity. In Study 1, four hundred and thirty-three college students (233 males and 200 females) completed the revised version of Extended Objective Measure of Ego Identity Status (EOM-EIS2), the Career Decision Difficulties Questionnaire (CDDQ), and the Career Preparation Behavior Inventory. In Study 2, four hundred and twenty-two college students (205 males and 217 females) responded to the revised version of Extended Objective Measure of Ego Identity Status (EOM-EIS2) and Career Attitude Maturity Inventory (CAMI). The identity foreclosure students experienced more difficulties in career decision making than the identity achievers. Especially, identity foreclosed students experienced more dysfunctional beliefs, lack of motivation and/or indecisiveness. However, they showed the same high level of career preparation behavior as the identity achievers. With regard to career maturity, the foreclosed students had lower scores than the achiever. On the subscales of
decisiveness and preparation, the achievers and foreclosures did not differ. However, in goal-orientation and independence scales, the foreclosures scored significantly lower than the achievers. In contrast to the results of Brisbin and Savickas (1994), this study showed differences between identity foreclosures and achievers suggesting a possibility of separation.

Assessing the training and staff development needs of power sector employees

RANA, N. (Gautam Buddha University), KRISHNA, S. (Uttarakhand Power Corporation Limited), PRAKASH, V. (University of Petroleum & Energy Studies)

The recent past has seen the Power Sector change substantially in its institutional arrangements for its regulation as well as the structure of the industry in itself. Major changes are being introduced in the Power Sector through private participation, reforms, restructuring apart from technological and perceptual changes that are also taking place simultaneously. This churning process has deeper implications on manpower engaged in this sector. This paper seeks to document the nature of HRD at organizational level in India. Following a brief sketch of the Indian context, we draw on the National Training Policy. The purpose of this study was to: (1) Determine training needs for an Indian State Power Corporation; (2) Determine the course content; (3) Identify training providers, delivery methods and likely training. A case study was done at Uttarakhand Power Corporation Limited, using questionnaire and personal interviews for training needs identification, job and skills analysis. The results discuss the following points: Training currently available; Problems with current training provisions; Recommended training providers and experts to be approached for any new provision; Opinions regarding training format for new provision: advantages and disadvantages of each format; Feature of the training: case studies, levels, modules and assessment; Training support material recommendations; Constraints when providing training. Every employee has a right to receive need based training at regular intervals to enable him/her to develop his/her potential to the maximum and contribute his/her best to the organization. The ultimate goal of each training course is customer satisfaction through reduction in cost of delivered power and supply of reliable and quality power at adequate and improving levels of efficiency and accountability.

Assessment and management of anxiety and depression in married, unmarried and separated adults

AKINSOLA, E. (University of Lagos), BASHIRU, R. (University of Lagos)

The aim of this study was to evaluate the anxiety and depression levels in a sample of married, unmarried and separated adults and to determine whether cognitive therapy is effective in reducing the levels of anxiety and depression in participants who reported very high levels of these emotions. A cross-sectional design was used by administering adapted versions of anxiety and depressive symptoms checklist scales to 300 married, unmarried and separated adults. Those reporting high levels of anxiety and depression would then participate in a short intervention program using Ellis’s and Beck’s cognitive therapy techniques. Emerging results from the first part of the study tend to indicate that unmarried adults are reporting higher levels of anxiety and depression than married and separated adults. It is also expected that cognitive therapy would significantly reduce anxiety and depression in the participants allocated to the intervention program. Emerging results from the first part of the study tend to reflect the impact of the pressure arising from cultural expectations which consider it culturally abnormal not to be married after age 30, or to be married but separated, and that the impact is greater for unmarried adults. Reduction in anxiety and depression levels after intervention would reflect the efficacy of cognitive therapy.

Keywords: marriage, depression, anxiety, cognitive therapy
Assessment and management of equal opportunity and diversity in the U.S. military

The U.S. Department of Defense (DoDD 1020.02) defines equal opportunity (EO) as “The right of all military personnel to participate in and benefit from programs and activities for which they are qualified. These programs and activities shall be free from social, personal, or institutional barriers that prevent people from rising to the highest level of responsibility possible.” EO ensures all members receive the same opportunities to compete for rewards through superior performance. The U.S. military recognizes the need to accurately assess and manage EO, since members’ perceptions that fair treatment is accorded to all garners improved loyalty to the organization, generating greater trust and commitment, thereby maximizing readiness, that is, the ability of the organization to complete its mission. The Defense Equal Opportunity Management Institute (DEOMI) Equal Opportunity Climate Survey (DEOCS) assesses EO climate and traits reflecting organizational effectiveness (OE), that is, organizational trust and organizational commitment. Data from the 500K+ completed surveys completed annually characterize the relationship between EO and OE. Diversity management (DM) is the process whereby all workforce members’ individual talents, skills, and interests are accurately identified and leveraged to maximize readiness. Successful DM requires employing explicit policies and procedures that include assessment, mentoring, education and training, and optimal job assignment. Diversity management demonstrates to an organization’s members that they are appreciated for their unique contributions, and provides them with an elevated sense of participation and belonging, which further enhances their sense of commitment to the organization. DEOMI recently developed the DEOMI Diversity Management Climate Survey (DDMCS) to target command DM practices, enabling us to extend our research beyond the simple EO–OE relationship. Moreover, by linking the DEOCS and DDMCS, DEOMI can now directly determine the differential influence DM exerts on measures of OE. These data will be used to characterize various groups’ (e.g., women, minorities, junior enlisted, etc.) perceptions of DM practices; ultimately these results will be used by DEOMI’s Research Directorate to advise DoD policy.

Assessment of readability and audience rating of the large electronic paper signage in a Japanese subway station

KOYAMA, S. (Chiba University), HISHINUMA, T. (Chiba University), NAKAMURA, H. (Chiba University), KOSAI, R. (Chiba University), SASO, F. (Chiba University), HIBINO, H. (Chiba University)

Electronic paper signage is thought to be useful for advertisements and emergency signs in the public space because it is light and energy-saving, and it can alternate content quickly and easily. It can also continue to display content even after the power supply is interrupted. In Sendai, Japan, large sized electronic papers (1539 mm width X 964 height) are used for digital signage in the subway stations. We evaluated the readability of the text in the electronic paper signage in a subway station, and compared the audience rating for the electronic paper signage and existing advertising signs. First, we conducted a survey on the readability and satisfaction of the content with 201 subway users. We displayed text in three sizes (92, 60, and 44 mm, i.e., 1.32, 0.86, and 0.63 degrees visual angle from four metres away, respectively) and asked them to evaluate the font size, easiness to read, display speed, and satisfaction with the content on a five-point scale. Each display contained approximately 130 characters and it changed every 15 seconds. We also observed the behavior of the subway users waiting for the train in front of the electronic paper signage and existing advertising sign. The results from the survey suggested that in an indoor public space with the 500 lx illuminance, a large-sized electronic paper display will be comfortably read with the size of 0.56+ deg in

1071 | Brief Oral Presentations
visual angle and the reading speed of eight characters per second. The subway users were quite satisfied with the content, and news and weather forecasting were especially popular. In direct observation, we found that subway users viewed the electronic paper signage significantly longer and more frequently than existing advertising signs (p < .05). The audience rating was especially high when the content was switched. These results will allow us to optimise the font size and display speed for the text in the electronic paper signage. They showed that changing content catches the eye of viewers and holds their attention longer. Inserting non-advertising content may also be helpful to hold the viewer’s interest in the advertising content.

**Keywords:** readability, audience rating, electronic signage, Japanese, subway

**Attention to graphic cigarette warning labels in smokers, ex-smokers and non-smokers**

HOLLIER, T. (Southern Cross University), PROVOST, S. (Southern Cross University)

Do smokers notice anti-tobacco warning labels more, or are they so familiar with the labels that they have lost their impact? New graphic warning labels form part of a “fear appeal” strategy to reduce smoking behaviour. Smokers, ex-smokers and non-smokers were tested in an Attentional Allocation Task, to identify the speed of orientation and disengagement towards warning labels. All groups showed an orientation effect to the graphic, but smokers and ex-smokers also showed evidence for facilitated disengagement of attention. These results suggest that smokers and ex-smokers are avoiding the warning labels, reducing their effectiveness in smoking prevention.

**Keywords:** Tobacco-warning labels, Attentional allocation task, Smoking, Orientation effect

**Attentional bias to emotional facial expressions in dating violence survivors: A behavioral and eye-movement study**

LEE, J. (Chung-Ang University), LEE, J. H. (Chung-Ang University)

Dating violence (DV), including physical, psychological, and sexual violence, in dating relationships has negative consequences, such as depression, anxiety, and Post Traumatic Stress Disorder (PTSD). Research on attentional bias has demonstrated that individuals with PTSD are associated with trauma-related hyper-vigilance. However, previous studies using Stroop tasks and dot-probe tasks have not provided the exact nature of attentional processing. We adopted an eye-tracking methodology to investigate attentional bias in DV survivors. The aim of this study is 1) to examine the time course of attentional bias for emotional facial expressions in DV survivors using a dot-probe task and eye-tracking, and 2) to assess the emotionality hypothesis using angry, fearful, and happy facial expression stimuli. Thirty female participants will be recruited using the Conflict Tactic Scale (CTS2) and an interview. The DV group (N = 15) will have had dating violence experiences and the non-dating violence (NDV) group (N = 15) will be the control group. Sixty-four faces (angry, fearful, happy, neutral faces, 16 each; 50% male) will be selected and each emotional face will be paired with a neutral face. Each trial will begin with a fixation cross (1000 milliseconds), followed by a pair of faces presented side by side (500 to 2000 milliseconds). Participants will be instructed to press one of two keys as quickly as possible to indicate the location of the probe. Participants’ eye-movements will be recorded during the dot-probe task using an eye-tracker. This study is currently in progress. We predict that the DV group will initially fixate more on the negative stimuli (angry and fearful), compared to the NDV group. The DV group’s gaze will also be sustained for longer intervals towards the negative facial expressions compared to the NDV group. Based on reaction time results, we expect the DV group will show hyper-vigilance towards the negative stimuli, as well as a difficulty in
disengagement from the negative facial expressions. The findings of this study will support the evidence that individuals with DV survivors are associated with vigilance-rumination patterns more than vigilance-avoidance patterns, and may also help in clarifying the attentional processing mechanisms of DV survivors.

Keywords: dating violence, post-traumatic stress disorder, vigilance-avoidance patterns, attentional processing, trauma

Attitudes to the insanity defense: An Australian sample

JOHNSON, M. (Margaret Johnson Psychological Consultancy Services), TYSON, G. (Charles Sturt University)

This study examined attitudes to the concept of insanity as it is applied in the Australian legal system and whether these attitudes could be seen as ‘prototypes’ or ‘implicit theories of the concept of insanity. Participants were drawn from three subgroups: members of the general public, psychologists and members of the legal profession. They were asked to complete three questionnaires: the Conceptions Checklist, the Legal Authoritarian Questionnaire and the Insanity Defense Attitudes Scale. They were also asked to read a case vignette and render a verdict on the case. Prototypes of attitudes were able to be identified in the data obtained from the conception checklist. These prototypes could then reliably predict how a person would make judgements regarding the culpability of a defendant with a mental illness. They also factored into how a person viewed the legal use of the Insanity Defense and how the law treats those who are mentally ill. Opportunities for further research into how jurors make decisions were identified.

Keywords: insanity defense attitudes, juror decision-making, Conceptions Checklist, Legal Authoritarian Questionnaire, Australian legal system

Attitudes towards deception and lying

ARMAS-VARGAS, E. (Universidad de La Laguna), GARCÍA-MEDINA, P. (Universidad de La Laguna)

Deceptive style of communication assumes a strategy of persuasion which aims to influence the beliefs, attitudes and behaviours of others. In this work we offer the results of an Attitudes to Deception and Lying questionnaire (Ac-EM) that has so far demonstrated empirical validity and value of content in isolating the proposed constructs. We studied the relationship that such attitudes have with 20 factors for personality (using ATRAMIC) and four factors for self-esteem (using CAE). The sample comprised 306 adults, 193 men and 113 women, with an average age of 37. In the sample, 157 participants were single, 101 married and 48 divorced. We offer the results of the factor analysis for each factor, internal consistency (Cronbach Alpha) and the correlation between measures for the different factors of the Ac-EM, CAE and ATRAMIC questionnaires. For the results from the Ac-EM questionnaire, two attitudinal factors, Acceptance of deception and lying (18%; $\alpha = .71$) and Rejection of deception and lying (16%; $\alpha = .72$), explained 34% of variance. From the correlational analysis of the measures of the different factors, we noted that the attitude of Acceptance of deception and lying correlated positively and significantly with the factors for failure to make adjustments when lying ($r = .28; p \leq .001$), not being honest or confessing that one had lied ($r = .36; p \leq .001$), self-deception ($r = .40; p \leq .001$), fear of rejection and criticism ($r = .38; p \leq .001$), extreme caution ($r = .33; p \leq .001$), insecurity ($r = .26; p \leq .001$), distrust ($r = .40; p \leq .001$), hypercontrol ($r = .27; p \leq .001$) and lack of sensitivity to others ($r = .33; p \leq .001$). This attitude correlated negatively with the variables for empathy ($r = -.28; p \leq .001$), assertiveness ($r = -.23; p \leq .001$), self-control when lying ($r = -.15; p \leq .01$), being coherent ($r = -.28; p \leq .001$) and being consistent ($r = -.35; p \leq .001$). From the self-esteem questionnaire, the attitude of acceptance correlated positively with the feeling of uselessness ($r = .22; p \leq .001$) and the feeling of inferiority ($r = .15; p \leq .01$), and negatively with valuation of others ($r = -.21; p \leq .001$). The attitude of rejection correlated positively and significantly with guilt, self-criticism, empathy, social desirability, selective privacy, being transparent, control, being coherent and being
consistent. The data that we found in this work significantly support the convergent validity for the combination of the variables in the attitudes and personality questionnaire (ATRAMIC), Attitudes to Deception and Lying questionnaire (Ac-EM) and the self-esteem questionnaire (CAE).

Australian adult male help seeking for body image concerns

LEWIS, V. (University of Canberra)

The body image of Australian males has received increased attention in recent years particularly following the findings by Mission Australia reporting that body image was the number one concern for boys/men aged 12 to 25 years (2008). Concerns about the body outweighed concerns with career/job, relationships, and family. Despite this concern over their body image men are reluctant to come forward and seek help for their body concerns. This paper addresses this issue and discusses a survey conducted with Australian males over 18 years of age as to their help seeking behaviour. In particular what would assist them in coming forward and seeking help. The 40 university men surveyed reported that knowing that what they said was confidential as well as reassurance that they would get something out of help seeking was important to them. The majority stated that they would be more likely to seeking help from a personal trainer or gym instructor than a doctor and mental health specialist including a psychologist. They felt there was some stigma around help seeking from a mental health professional but not to a fitness instructor. These findings have implications for the way professionals market the service as well as society’s role in destigmatising concerns in men and their subsequent help seeking.

Keywords: male body concerns, help-seeking, stigma, body image

Australian Army as a “Learning Organisation”: Measuring organisational learning characteristics and organisational trust within a military institution

The Australian Army intends to become a “learning organisation”. This study aims to benchmark the practices known to be indicative of a learning organisation within and across a military institution, at an individual, group and organisational level. This environment differs substantially from most previously studied. The profile will allow the Army to determine and potentially improve its performance on learning organisation characteristics. The Army Learning Organisation Questionnaire (ALOQ) was adapted from existing learning organisation questionnaires (Marsick & Watkins, 2003; Goh & Richards, 2005) and consists of 11 subscales including; innovation, teamwork, knowledge systems and leadership. It also includes measures of organisational trust (Cummings & Bromiley, 1996) and attitudes towards change (Dunham et al, 1989, in Haque, 2008). The ALOQ items were piloted with Army personnel before the questionnaire was administered. In November 2009, 326 Army personnel from across all ranks completed the questionnaire at one Army location. The Army units’ mean scores, on learning organisation subscales, were comparable to normative data supplied by Marsick & Watkins (2003) and Goh & Richards (2005). Further analysis found that rank had a significant effect on these subscales: innovation, strategic leadership, holistic perspective, and organisational trust. Higher ranks tend to perceive higher learning organisation characteristics. The ALOQ organisational learning subscales were also found to be strongly correlated (r = 0.7 and above). These initial results suggest that practices within these Australian Army units, in terms of learning organisation characteristics, are similar to other (mainly private) companies or organisations. However, individual-level factors (such as rank) are likely to impact on learning organisation...
characteristics at the group and organisational level. In early 2010, the ALOQ will be administered to Army personnel around Australia, allowing further exploration of the enablers and inhibitors of organisational learning within a military institution.

Barriers and bridges to intercultural communication on a large university campus: Political and developmental influences on the meaning and impact of communication on personal and institutional levels

FUNDERBURK, J.R. (deep1914), CHOI, C. C. (University of Florida Counseling and Wellness Center), FUKUYAMA, M. A. (University of Florida Counseling and Wellness Center)

This paper presents findings of a research study conducted at a large University in the Southeastern United States on the Quality of Intercultural Communication among faculty, staff and students. Five focus groups were conducted which included students, faculty and staff exploring participants beliefs about and perceptions of the quality of intercultural communication at the University. Qualitative analysis revealed Core Ideas in the Domains of Barriers, Bridges and Strategies to enhance intercultural communication on both individual and institutional levels. Consistent with Developmental, Multicultural and Feminist theory, developmental stage of personal and cultural identity development at the individual level as well as multicultural sensitivity in combination with the influence of interpersonal and institutional power dynamics emerged as significant factors impacting effectiveness of intercultural communication. These factors will be explored and suggested strategies for facilitating intercultural communication on intrapersonal, interpersonal, and institutional levels, will be provided.

Keywords: intercultural communication, multicultural sensitivity, cultural identity

Basic assumptions about man and organizations: An empirical examination of the construct and its validation among Indian managers

SRIVASTAVA, B. N. (Indian Institute of Management, Calcutta)

The purpose of the paper is to present two studies dealing with basic assumptions of Man, Work, and Organizations by analyzing their factor structure and demographic characteristics and comparing its validation with other measures. Two studies are presented. In Study One, 177 managers from Indian firms responded to a questionnaire of 54 items on a five-point scale dealing with nine dimensions of optimistic/pessimistic basic assumptions about Man, Work, and Organizations. Study Two presents an analysis of data from 98 owner managers who responded to the 54 item questionnaire on a five-point scale and other measures of self-efficacy and strategic orientation. Exploratory factor analysis performed on Study One data considering nine dimensions - (a) Adaptability versus Non-adaptability, (b) Role-Making versus Role-Taking, (c) System Responsibility versus System Vulnerability, (d) Resourcefulness versus Resourcelessness, (e) Internal versus External Locus of Control, (f) Employee Optimism versus Employee Pessimism, (g) Collaborating versus Competing, (h) Activism versus Passivism, and (i) Evolutionary versus Interventionist change - of optimistic/pessimistic assumptions of Man, Work, and Organizations. A four factor solution explained 71.5% of variance. These factors were labeled as (1) Agenticity, (2) Catholocity, (3) Holisticity, (4) Organicity. Differences in demographic factors like age, gender, rank, industry type, and ownership were also analyzed. Study Two analyzed correlations in the total scores on basic assumptions of managers in relation to their scores on self-efficacy measures and strategic orientation measures of owner-managers. The data showed high correlations between the basic assumptions scale and self-efficacy, and basic assumptions and the strategic orientation scale suggesting strong validity of the measure. The optimistic/pessimistic basic assumptions of managers are a strong determinant of managerial effectiveness and may be considered as a variable differentiating

Beginning is the common factor: A new direction for psychotherapy research

GRIMWADE, J. (Australian Catholic University)

Psychotherapy research has been dominated by model and method wars, the search for common factors, and more recently by the issue regarding effectiveness versus efficacy. Most of this research has aimed to remove the processes of recruitment and induction from research programs as confounding factors. It is asserted that the only truly common factor is the beginning, and before any conclusion can be drawn about the relative merits of models and methods and efficacy there needs to be detailed study of the processes of beginning. A study of beginning at child and adolescent mental health services is reported. The study used qualitative data from service users retrospectively and prospectively, and interviews with professionals, especially designated Intake Workers. Sixteen parents, seven Intake Workers, and fourteen other professionals (clinicians and agency leaders) were interviewed. In the prospective study six parents were interviewed four times. A total of 55 interviews occurred. The study revealed a range of issues about beginning and its importance for service users. The range of tasks involved in telephone referral were listed and mapped chronologically. It was demonstrated that the initial telephone contact shaped the internal structure of an agency and the means of interaction with external professionals. Finally, a careful analysis of the drop out literature showed a pattern among referring families associated with the decision to pursue contact with the an agency. As a qualitative pilot study of beginnings in therapy, many issues worthy of further research were revealed. It is clear that all therapy begins. But, why haven’t therapy beginnings been systematically researched? Three reasons are provided: therapy is constructed as the action of therapists, outcome is considered the key criterion of the value of therapy, and differences in models must count for something. Most therapy research is conducted by, or on behalf of, therapists. A new research direction is required. Examining beginnings will change the way therapy is construed.

Behavioural patterns of mother-child interactions: Influence on deaf children’s language development

SALCEDO, J. (Universidad de Guadalajara), QUINTANA, C. (University of Guadalajara)

Mother-child interactions were analysed with the main purpose of understanding the basic behavioural patterns of hearing mothers and deaf children and their effect on language development. Dyads were divided as follows: 1) Hearing Mother-Hearing Child; 2) Hearing Mother-Deaf Child; and, 3) Deaf Mother-Deaf Child. Each dyad was asked to perform three different tasks (30 minutes each task): a) playing a free game by using an artificial fishing game; b) arming a puzzle with different colours, placing and naming each token correctly, and, c) creating a full story about a simple drawing representing four people. Dyads were filmed while playing at the laboratory and recordings were analyzed using the observational multidimensional system of Ribes & Quintana (2002) in order to obtain behavioural patterns. Results show that Dyad Two had more problems performing the tasks as asked and this dyad showed the highest numbers of behavioural patterns non-related with the tasks in comparison with the other dyads. Hearing mothers with deaf-children should: a) use more visual and manual procedures of behavioural patterns in order to contribute to enhance language development on their children and b) increase the opportunities of significant exchange with the child to promote the use of linguistic symbols in problem solving.

Keywords: child psychology, developmental language psychology, deafness, mother-child dyads, language development
**Being a woman and being a manager:**
**Gender management at work**

PALERMO, J. (Deakin University), KYPUROS, P. (Deakin University)

Whilst many reforms have taken place in the work setting to enable an increase in participation of women in the workforce, there has been little to no impact on their participation in the upper echelons of organisations, in managerial and decision making roles. The aim of this study was to explore female managers’ psychological responses to the barriers they currently face in male dominated work environments. In particular this study explored the process of women’s identity creation in light of their symbolic outsider status in organisational life. Semi-structured interviews were conducted with fourteen female managers aged between 39 to 50 years of age (M = 42.7 years) from six Australian corporate organisations. They each held executive level positions within typically male dominated organisations. All participants were recruited from Victoria and New South Wales. Transcripts were analysed using an illustrative approach. Results indicated that most organisations in this study had explicit and visible policies to increase the number of women at all levels. Some had been recipients of EOWA Women’s Employer of Choice awards. However, what emerged through this research was the salience of gendered institutionalised practices which are inherently biased against women and femininities. Women described the gendered aspects of their organisational cultures that required them to adapt their leadership behavioral repertoires to those that better fit a perceived image of female prototypical leadership. This study illustrated the centrality of gender as a “managed status” in the workplace (a process of changing self to achieve acceptance, and strategically combat resistance to them as women). All the women coped by deliberately renegotiated their gender identity to conform to organisational expectations of femininity. Individual coping strategies may have only a limited value in the long term Women’s adaptation strategies ultimately reinforce the masculine value system resulting in short term, individual success, and long term failure for long awaited cultural change in organisations. While “gender management” is important, this does not prompt organisational change in relation to attitudes towards female managers. Therefore a better understanding of the organisational culture features that sustain gender bias is a critical step for progressing the position of women.

**Best lessons for well-being from psychologists: Implications for public and professional practice**

THOMPSON, A. (Charles Sturt University), BOXALL, D. (Charles Sturt University), PATRICK, K. (Charles Sturt University), HODGINS, G. (Charles Sturt University)

The decades old view that Psychology has much to “give away” is still apt in terms of the discipline’s expanding knowledge base and practical relevance. This qualitative investigation explored the key precepts that psychologists viewed as most beneficial for promoting personal well-being. Individual interviews were conducted with a sample of 30 Australian psychologists (18 female, 12 male) representing diversity in terms of age, background, experience, employment and disciplinary interests. The semi-structured interviews were used to explore ideas about psychological well-being that were dominant in the way participants thought about and practiced psychology. Thematic analyses further refined and articulated these lessons and related themes. The identified lessons were tagged using the phraseology of participants (e.g., accept oneself and have empathy for others, seek to reduce distress rather than find a cure, relationships will not take care of themselves, move in the direction of your core values, focus on good things in life). In this oral presentation, the propositions that participants viewed as most helpful for personal growth are introduced and common themes considered. Although concern about the prescriptive nature of “best lessons” was raised by some participants, it was clear that guiding principles of human well-being served as fundamental heuristics. The qualitative methodology revealed how these psychological
“best lessons” were a personalised distillation of experience, training, and professional activity. The lessons have implications for public education and for promoting well-being. The results are also important for what they imply about professional practice. Although formal evidence-based interventions underpin the dominant health framework, the findings suggest ways that psychological expertise is personalised, aggregated and transmitted.

Body image experiences of Australian women

RODWELL, P. (Dr Edward Koch Foundation), CALTABIAN, N. (James Cook University)

How do middle aged and older women perceive their bodies in an era when youthful looks are important? In this study a self-report questionnaire was used to explore the thoughts, feelings, behaviours, memories and experiences that the participants associated with their bodies. The questionnaire yielded qualitative data from 68 participants, Australian women aged 40 to 92 years. The themes that emerged were explored and related to holistic models of wellness including the Model of Women’s Body Image Resilience of Choate (2005). Most frequently occurring themes across all age groups were: satisfaction with body and quality of life; coming to terms with major life stressors that affected body image; body dissatisfaction; considering the inner self as more important; thoughts and beliefs influencing lives; positive ageing experiences. Spirituality was also an important theme for all age groups, mentioned 52.9% of the time by the seventy years and over age group. These themes and less often reported themes such as family of origin support and self worth are reminiscent of the life tasks of the holistic model of wellness of Myers, Sweeney and Witmer (2000) and of protective factors in Choate’s resilience model. Many themes align with Ryff’s (1991) theory that “…with age, individuals achieve a closer fit between an ideal and their actual self-perceptions” (p. 286).

Keywords: body image, females, ageing, resilience, well-being

Boosting school girls into science – too late for an effective aid?

NEUMANN, P. (University Ulm), BUHL, H. (University Jena), VOLK, A.

A national day of action to promote scientific and technical careers for women is held every year since 2001 in Germany. On this so called “girls’ day” female students between the ages of 10 and 15 get the opportunity to spend one day within a company. In general this day should increase the pool of applications for this kind of job as well as to encourage women for scientific professions. But does this activity works? The efficacy was evaluated based on theories about formation of occupation choice as well as the theory of planned behavior. Forty-five schools within a defined area were asked to hand over study material consisting information about the aim of the study, concerns about privacy protection as well as information for parents and the web address to their female students. Participants as well as non-participants aged 10 to 15 were asked about their attitudes about science as well as scientific careers within two weeks before and two weeks after the “Girls day” in April 2007. Demographic data as well as parental background, academic self image as well as gender roles were surveyed. The questionnaires were presented using an internet based tool. One hundred and eighty two girls answered at least the first part of the survey before the Girls day took place. Dropout rate from the first to the second measurement point is nearly 50%. Based on the indicated motivation to take part or not, three groups were compared regarding sex roles, attitude about women and science as well as interest in sciences and career aspiration. Intrinsic motivated girls showed a less stereotyped gender role image, a more positive attitude regarding women and science as well as interest in sciences and career aspiration. Intrinsic motivated girls showed a less stereotyped gender role image, a more positive attitude regarding women and science as well as interest in sciences and career aspiration. Intrinsic motivated girls showed a less stereotyped gender role image, a more positive attitude regarding women and science as well as interest in sciences and career aspiration. Intrinsic motivated girls showed a less stereotyped gender role image, a more positive attitude regarding women and science as well as interest in sciences and career aspiration. Intrinsic motivated girls showed a less stereotyped gender role image, a more positive attitude regarding women and science as well as interest in sciences and career aspiration.
role and self concept and occupational preferences develop at the same time at a very early stage of child development. For that reason these days of action are quite helpful for these girls, who do not show that gender typical attitude and behavior. To change stereotypes and attitudes toward science and to foster girls into scientific professions this intervention seems not that effective. The limited number of participants should be taken into account in interpreting the results.

Broken promises in organizations: Does severity matter?

SUN, W. (Peking University), WANG, L. (Peking University), SUN, W. (Peking University), DANG, J. (Peking University)

Examples of broken promises in daily life abound, but relatively little research directly investigates these behaviors. The present research aimed at examining the classification of broken promises and the potential interactions of four severity components (probability of detection, probability of forgiveness, penalty severity, morality severity) in predicting these behaviors, especially broken promises in organizations. In Study One (n = 103), we first defined “broken promise” and used an open questionnaire to gather examples of broken promises that are common in daily life. In Study Two, we used exploratory and confirmatory factor analysis to investigate the categorization of these behaviors (n = 520). Finally, based on Elangovan & Shapiro’s (1998) trust betrayal model in organizations, we examined the relationships between the four severity components with the frequency of broken promise (Study Three, n = 126). We obtained 40 items of common broken promises through open questionnaires and the results of exploratory and confirmatory factor analysis showed that these behaviors could be classified into nine relationships (accounting for 69.39% of the total variance), including broken promises to service organizations, work units and banking organizations. We then found that: (1) the probability of detection interacted with penalty severity to predict the frequency of broken promises to service organizations; and (2) the probability of forgiveness interacted with morality severity to predict the frequency of broken promises to work units. Overall, this study contributes to a better understanding of broken promises in organizations. These results also highlight the interactive effects of four severity components on broken promises, especially the broken promises to service organizations and work units. Our findings may have important implications for employers and employees, suggesting that we can reduce broken promises by controlling these four severity components.

Keywords: broken promises, trust betrayal model, penalty severity, organizational promises

Bullying and peer victimisation in adolescent girls with attention-deficit hyperactivity disorder

SCIBERRAS, E. (University of Melbourne / Murdoch Children’s Research Institute), OHAN, J. (University of Queensland), ANDERSON, V. (University of Melbourne/Murdoch Children’s Research Institute)

Although there is an abundance of research documenting social impairment in boys with Attention Deficit Hyperactivity Disorder (ADHD), much less is known about the social experiences of adolescent girls with ADHD. This aimed to investigate in a sample of adolescent girls with and without ADHD (1) overt (i.e. physical, such as hitting or kicking) and relational (i.e. social manipulation, such as social exclusion) bullying and peer victimisation; and (2) the contribution of Social Information Processing (SIP) theories (specifically hostile attribution bias and response selection) in explaining bullying and peer victimisation in adolescent females with ADHD. Adolescent girls with ADHD (Mean age = 15.1; SD = 2.0) were recruited from the Royal Children’s Hospital, Melbourne, Australia and the community (n = 22). Control participants (mean age = 15.1; SD = 2.0) were recruited from the community (n = 22). Adolescent girls and their primary caregiver completed measures assessing social impairment, overt and relational peer victimisation and bullying behaviour, and SIP. Despite no group differences in socio-economic status, family composition, parental mental health, and full scale IQ, girls with ADHD
had more self- and parent-reported social problems than girls without ADHD. There was no evidence that girls with ADHD engaged in more overt and relational bullying than controls, however, they were more likely to be both overtly and relationally victimised by their peers (by both parent- and self-report). Comorbid oppositional defiant disorder (ODD) and conduct disorder (CD) appeared to exacerbate social problems for girls with ADHD, and in many instances accounted for differences between girls with ADHD and controls. There was no evidence that girls with ADHD are at particular risk of SIP deficits compared with controls. This study provides additional evidence that girls with ADHD experience significant social impairment in comparison to their peers. Of greatest concern, they are more likely to be overtly and relationally victimised by their peers. Comorbid ODD and CD symptoms should be targeted in treatment, as these comorbidities account for most of the social difficulties experienced by girls with ADHD.

Burnout among French operators: A contextual approach in testing the job-demand-control-support model

TRUCHOT, D. (Université de France-Comté), PONZ, Y. (University of Franche-Comte)

The job-demand-control-support (DCS) model (Karasek & Theorell, 1990) is a leading theoretical model in occupational health psychology because it provides a clear conceptual framework and a standardized measurement tool, the Job Content Questionnaire (Karasek, 1985). However, most studies on representative samples of employees that measured perceived job stress with the Job Content Questionnaire have failed to confirm the predictions of the model. In line with recent critics arguing for context specificity in occupational stress research and with the notion to develop more specific measures for specific occupational groups, the aim of the present study was to examine how the DCS model applied in a well-defined occupational group assessed with a specific occupational stress measure. Assembly-line operators \((N = 146)\) working in the same agricultural machine plant participated in the study. The context-specific occupational stress measure was developed based on semi-structured interviews with 20 participants who identified the specific sources of job demands, control, and support experienced by the operators. All participants then completed the scale established, along with a measure of burnout (MBI-GS) and of demographic characteristics. Factorial analyses revealed 3 latent factors: job demands, organizational climate (i.e., control + supervisor support), and support from colleagues. Hierarchical regression analyses indicated that job demands, control and support predicted significant proportions of burnout, in particular emotional exhaustion and cynicism. We also observed a moderator effect of social support and a three way interaction. These results support the value of augmenting the components of the Demand Control Support model with stressors that are situation-specific.

Keywords: occupational stress, burnout, job demands, job content questionnaire, job demands-control-support model

Burnout and compassion fatigue among emergency staff: The influence of demands, control, support and emotional labor

TRUCHOT, D. (Université de France-Comté), GRILLO, F. (Université de Franche-Comte)

According to the Job-Demand-Control-Support (JDCS) model, the most adverse job-related strain reactions are to be expected in work environments characterized by high demands, low control, and low support. There is now evidence that these factors cause strain, and that their effect is cumulative. However, dealing with injured or distressed people requires that emergency staff to regulate their expression of emotion what has been called “emotional labor”. However, the expression of appropriate emotions, or the suppression of felt emotions, may be at odds with actual experienced emotions. Surface acting refers to the display of emotion regarded as appropriate but not actually felt. Deep acting refers to strategies aimed at actually feeling an emotion considered
Burnout in a Scandinavian police force in times of economic turmoil: A study of its precursors and possible gender differences

SANTOS, A. (IWHO, University of Nottingham Malaysia Campus), JONSDOTTI, V. (University of Nottingham, Malaysia Campus)

The police occupation has been identified as a high risk occupation, particularly vulnerable to burnout (e.g. Goodman, 1990). Studies generally show conflicting results on gender differences in relation to burnout and stress, with some authors suggesting that women are less likely to be exposed to operational stressors (Brown and Fielding, 1993; Brown et al., 1999), but that women report higher levels of burnout (Schaufeli and Enzmann, 1998). Later studies however have failed to replicate these results (Burke, Richardsen, & Martinussen, 2006; Kop et al., 1999). Studies on bullying in the police also yield conflicting results. In Hoel and Coopers’ analysis (2000), women were on average bullied more often than men but differences proved non-significant, contradicting other scholars that have found significant gender differences (e.g. Brown & Fielding, 1993; Burke & Mikkelsen, 2005; Kop et al., 1999). This study focused on examining the effects of police stress and client bullying on burnout and organisational commitment, and the possible gender differences on these variables. It was hypothesised that police stress and client bullying would predict higher burnout scores (Hypothesis 1a) and lower organisational commitment (Hypothesis 1b). It was further predicted that females would measure higher on burnout than males (Hypothesis 2a) and display lower organisational commitment (Hypothesis 2b). A questionnaire was sent out to employees of a Scandinavian police force (N = 667). A total of 346 questionnaires were returned (response rate 52%). Stress was measured by the Operational Police Stress Questionnaire (PSQ-Op) and Organisational Police Stress Questionnaire (PSQ-Org). An adapted version of the Negative Acts Questionnaire (NAQ-R) was used to measure perceived exposure to bullying and victimisation on behalf of clients at work. Burnout was measured using the Copenhagen Burnout Inventory (CBI), while commitment was measured using the Organisational Commitment Questionnaire (OCQ). All measures were translated from English to the Scandinavian language using back-translation. Data was analysed using multiple hierarchical regression. Hypothesis 1a and 1b were partly supported, where police stress predicted burnout and organisational commitment. Research results did not lend support to Hypothesis 2a and 2b. A review of practical implications for the Icelandic police is provided.

Keywords: burnout, stress, bullying, gender differences, organisational commitment
articles of clothing (e.g. a white jacket) and each type of adjective had three words (e.g. clean). Participants were asked to respond to an item or adjective on the computer screen as quickly as possible, according to the rule which paired a type of clothing with a type of adjective, the other clothing type with the other adjective type. For each participant, we conducted two sets of IAT, and in the interval, participants were shown slides of a murder. In the slides, the offender put on Type A items, and the ambulance worker put on Type B. The results showed that the average response time, when type A items are paired with negative adjectives and type B items with positive adjectives, became faster significantly after showing the slides ($p = .02$). This indicated that the slides changed the implicit evaluation of Type A items negatively (while they changed that of Type B items positively). Our experiment confirms the hypothesis that the label “offender” gives the negative influence on items related to the offender implicitly. In the criminal court, jurors are asked to evaluate evidence reasonably, or in an evenhanded fashion. However, our study suggests that evidence may be evaluated with negative bias if they are presented as “related to the offender”. Moreover, it may be impossible to be unbiased, because it is due to unawareness.

Keywords: offender labelling, implicit association test, criminal court, offenders, jurors

**Can victim-police interactions be therapeutic for victims of violent crime?**

ELLIOTT, I. (Monash University), THOMAS, S. (Monash University), OGLOFF, J. (Monash University)

The aim of this research was to investigate the impact of victim-police interactions on psychological well-being of victims of violent crime. Twenty-eight participants were recruited by advertising the study at community health centres and police stations in Melbourne. In depth, face-to-face interviews were conducted with the participants who were victims of sexual assault, physical violence, threats to kill, child abuse, domestic violence, and relatives of homicide victims. Both quantitative and qualitative measures of participants’ perceptions of procedural justice (fair treatment by police) and the impact of the interaction on participants’ well-being were administered. Perceptions of procedural justice in victim-police interactions were a strong predictor of participants’ well-being as a result of the interaction with police. As a result of the interaction with police, victims who reported a long-standing crime (sexual assault, child abuse) were able to get closure and their depression associated with the crime was reduced. In conclusion, the way police relate to victims of crime has a powerful impact on victims’ psychological well-being. Reporting a violent crime to the police is essential for a long-term recovery from the negative psychological consequences of the crime.

Keywords: victims of crime, procedural justice, victim-police interactions, recovery, victims’ well-being

**Caregiver causal attributions in youth early psychosis**

CLARKE, K. (Monash University), COUCHMAN, G. (Monash University)

Research has examined relatives’ beliefs about the causes of psychosis and has found that caregiver causal attributions about the etiology of psychosis have a significant impact on behavioural and emotional outcomes for both patient and family. The aim in the current study was to investigate caregiver causal attributions about illness onset in youth early psychosis and the factors that influence these attributions. Caregivers and patients were recruited from a youth early psychosis service located at a rural and urban setting near Melbourne, Australia. Fifty one caregiver/patient dyads participated in the study. Caregivers were administered the Causal Models Questionnaire for Schizophrenia. Caregiver demographics and patient levels of substance use were also collected. Caregivers endorsed a range of causes across causal attribution categories. Caregivers most frequently endorsed environmental causes, followed by psychological causes, interpersonal causes and biological causes. Caregivers predominantly endorsed the individual causal attributions of hereditary/genetics and illicit drug use. There was evidence that caregiver and
patient factors were related to the types of causal attributions made about the onset of psychosis. This study has provided insights into caregiver attribution processes, where caregivers are developing causal attributions that are biopsychosocial in nature and are generally consistent with current etiological theories in youth mental health services. Of concern is the increasing perception by caregivers that substance use is a cause of psychosis. Implications for psycho-education and caregiver intervention approaches in early psychosis services will be discussed.

Keywords: psychosis, caregiver causal attributions, caregiver interventions, caregiver psychoeducation, causal models questionnaire for schizophrenia

Changes to the Pathway One training option for psychologists: A proactive response in Queensland Health

DEMPSEY, S. (Queensland Health), MORRELL, S. (Queensland Health)

The education of psychologists is currently undergoing radical change particularly with regard to the Pathway 1 option which provides a competency based supervised practice program for probationary psychologists. Specifically, the previously employed “4 plus 2” model is proposed to be replaced with a “5 plus 1” model requiring prospective psychologists to complete 5 years of university training followed by one year of supervised practice to attain general registration. The aim of this presentation is to describe an innovative project undertaken by Queensland Health to support registration board standards and radically improve the delivery and outcomes of this pathway to registration. Under the current 4 plus 2 arrangements, Queensland Health has recently appointed a project officer to design, implement and review the state wide training and assessment of Pathway 1 psychologists. In addition to this, 16 Clinical Educators have been appointed throughout the state and will be available to implement the recommendations of the project officer and oversee the education and professional development of Pathway 1 psychologists. A qualitative approach employing thematic analysis (Braun & Clarke, 2006) will be used to describe this process. Key elements which will be addressed in this presentation include the development of a curriculum framework, resource materials, supervisor and supervisee manuals, and an annual program of workshops delivered through the Allied Health Clinical Education and Training Unit (AHCETU). The introduction of a detailed curriculum framework with an accompanying set of assessment procedures will provide a significant step towards standardisation of a competency based supervised practice program in Queensland Health. Supervisors of probationary registrants employing the Pathway 1 route to registration will benefit from the development of a standardised curriculum and set of assessment procedures. In addition to this a set of recommendations will be provided for the ongoing education of Pathway 1 psychologists.

Keywords: psychology education, psychology registration standards, pathway one psychologists, standardised psychology training, four plus two training pathway

Characteristics associated with days of attendance and treatment compliance among clients in substance abuse treatment

KELLEY, M. (Old Dominion University), COOKE, C. (Virginia Consortium in Clinical Psychology), NEFF, J. (Old Dominion University), DOANE, A. (Old Dominion University)

The purpose of this study was to examine individual characteristics associated with days in treatment and treatment compliance among clients who entered a community-based treatment program for substance abuse. We expected that being female, presence of children in the home, and lack of a serious mental illness, would predict more days of treatment attendance and greater likelihood of treatment compliance. We examined primary substance of abuse as a predictor of days of attendance and treatment compliance; however, no specific hypothesis was made regarding drug of abuse and the outcome variables. Information was retrieved from medical records of male and female clients (N = 230) who took part in a community-based treatment program for substance abuse in a large city in the southeastern United States of America during a
32-month period. Primary substance of abuse at treatment admission was coded: 0) alcohol, 1) cocaine/crack, or 2) other drug. Treatment compliance was coded as 1) complete or partial treatment success, or 2) non-compliance/program discharge. Treatment compliance was determined by the treatment staff. The multiple regression with days of treatment as the dependent variable was significant, $F(4, 225) = 2.73, p < .03$. However, the only significant predictor of days of treatment attendance was gender; being female predicted longer treatment attendance ($\beta = -.21, sri = .04$). Results of the overall logistic regression with treatment compliance as the dependent variable was not significant, $\chi^2(5) = 8.84, p = .116$. Although the combination of predictors did not account for a significant portion of variance in treatment compliance scores, being female was associated with greater likelihood of treatment compliance. Wald statistic, $\chi^2(1) = 5.17, p < .05$, Odds Ratio = .32, Confidence Interval = .12 to .86. Results support previous studies that demonstrate that women may be more responsive to outpatient treatment for substance abuse (e.g. Sanchez-Craig, Leigh, Spivak, & Lei, 1989).

**Keywords:** treatment compliance, substance abuse, gender differences, community based substance abuse treatment program, mental illness

### Characteristics of item wording effect in psychological tests and reasons it is produced

**WANG, S.** (Chinese Academy of Sciences), **ZHANG, J.** (Chinese Academy Sciences), **HANNUM, E.** (University of Pennsylvania), **MA, L.** (Chinese Academy Sciences)

The aim of this study was to explore the characteristics of the Item Wording Effect in psychological tests and how this kind of effect is produced. Three hundred and forty students in high school and college were tested in this study, 268 male and 72 female and 175 in high school and 165 in college. The measure of the Chinese version of Anxiety Control Questionnaire (ACQ) was used which contains 30 items, 12 items which are positively worded and 18 items negatively worded. The questionnaire is aimed at testing the feeling people have to control the anxiety. And the structure of the whole questionnaire includes one substantive factor of anxiety control and two method factors of positive wording and negative wording. The method of data collecting used four versions of ACQ which were constructed through reversing the expression of each item, meaning that items that were originally positively worded were negatively worded after reversing and the ones originally negatively worded became positively expressed. The four versions were: all-positively-worded items, all-negatively-worded items, original version and the reversal of the original version. Firstly, the results of Confirmatory Factor Analysis of the four versions of ACQ indicated that both the original version and the reversal of the original version contained factors of item wording direction. However, versions with only one direction did not contain these kinds of factors. Secondly, comparisons of the total score of the four versions showed that there were significant differences between the original version and the version of all-positive-worded items as well as the reversal version. However there is no significant difference between the original version and the all-negatively-wording-item version. Thirdly, analysis of the difference of the total score of the four versions shows that the difference was caused by the negatively worded items in the original questionnaire. In conclusion, questionnaires with positively and negatively worded items will produce item wording factors if parts of the items are scored reversely. Questionnaires with items worded in one direction will not result in such kind of wording factors. The production of the item wording effect is directly related to the reversal of item scores.

### Childhood-adolescent caretaking experience and non-suicidal self-injury

**WALKER, G.** (Deakin University), **MILDRED, H.** (Deakin University)

Non-suicidal self-injury (deliberate self-harm) including self-mutilation, is a major health risk for contemporary adolescents and young adults
Abstracts of the 27th International Congress of Applied Psychology

(Gratz & Chapman, 2007; Gratz et al., 2002; Klonsky & Olino, 2008; Skegg, 2005). The current study aimed to examine the relationship between childhood-adolescent attachment and specific caretaking experiences, and non-suicidal self-injury (Fanous, Prescott & Kendler, 2004; Gratz, 2003; Marchetto, 2006). Based upon findings from literature on non-suicidal self-injury, it was hypothesised that perceived: insecure maternal attachment; childhood abuse including neglect, physical and sexual abuse; low maternal care; and high maternal overprotection in childhood and adolescence, would all be related to frequency of non-suicidal self-injury. One hundred and seventy one volunteer undergraduate students from a Metropolitan Melbourne university completed an anonymous questionnaire which asked about their childhood caretaking experiences, attachment and adult self-harming behaviour. Of these, a surprising one hundred participants (58%) reported self-harming at least once in their lives using a variety of methods. The most prevalent methods included body-cutting and severe scratching of the skin. The current paper articulates the specific patterns and correlates that emerge from the self-harming data of these young people. Moderate significant relationships between childhood-adolescent neglect, insecure maternal attachment, sexual abuse, and frequency of non-suicidal self-injury were found. A regression analysis also demonstrated that childhood-adolescent maternal attachment and maltreatment problems, especially a neglectful and negative home environment, predicted frequency of non-suicidal self-injury (Gratz et al, 2002; Gratz & Chapman, 2007; van der Kolk & Fisler, 1994). These results support previous reports in the literature relating childhood adversity to non suicidal self-injury in other populations. It was concluded that results from the current study show that certain social-environmental adversities in childhood-adolescence are associated with a significant part of the non-suicidal self-injury picture, and may need to be an important focus of treatment for people who deliberately harm themselves.

Keywords: self-injury, deliberate self-harm, childhood-adolescent maternal attachment, childhood adversity, caretaking experiences

The aim of this study was to investigate the development of simple and complex hierarchical patterns in children with regard to the spatial analysis ability. A drawing task and a forced-choice similarity judgement task with two simple and two complex hierarchical patterns were employed in this study. In these tasks, children were exposed to each pattern for short (300 millisecond) and long (3 second) durations. One hundred and twenty one children aged between 4 and 9 years of age participated in the drawing experiment and 100 children between 4 and 10 years of age participated in the similarity judgement experiment. The drawing task showed that the correct integrated responses increased significantly with age $F(5, 115) = 8.4, p < .01$. In the similarity judgment task, the choice for global responses increased significantly with age, $F(4, 95) = 9.6, p < .01$. A slight increase in the occurrence of these responses was observed until 8 years of age, followed by a decrease between 8 and 10 years of age, as attested by the significant quadratic trend $F(1, 95) = 6.9, p = .01$. Congruently the local partial responses decreased between 4 and 8 years of age and then increased between 8 and 10 years of age, as attested by a significant quadratic trend $F(1, 95) = 14.3, p < .01$. Results in the drawing task showed that the correct integrated responses increased progressively with age. The similarity judgment task demonstrated global preference in 4 year-old children. This preference gained in strength in the later ages, but decreased at 10 years of age, particularly when children were exposed to complex stimuli. Between 8 and 10 years of age, children found more similarities between the targets and partial patterns that preserved local information than complete patterns that preserved the global shape but not the local information. These developmental trends were sensitive to contextual factors such as the duration of exposure, underlying the importance of attentional processes in the way children analyzed hierarchical patterns.

Children’s spatial analysis of simple and complex hierarchical patterns in a drawing and a similarity judgement task

Children's psychological problems in United Arab Emirates public schools: A comparison of the perspectives of various school staff

ALGHORANI, M. A. (United Arab Emirates University)

This study aimed at comparing how differently school staff members (teachers, administrators, and vocational staff; i.e., social specialists and psychological specialists) perceive the prevalence and seriousness of various children's problems. Moreover, this research shall investigate the impact of using different measurement types. A survey outlining various psychological problems (behavioral, emotional, and mental) was constructed and administered. A multitrait-multimethod approach was used to identify children's problems. The survey included three methods: firstly, school staff were asked to rank-order problems according to prevalence and seriousness respectively; secondly, school staff were asked to compare paired categories of students’ problems; thirdly, school staff were asked identify how prevalent is each of the 61 problems that were selected from various measures and scales. When participants were asked to list children's problems in order with regard to frequency and seriousness, lack of motivation and low academic achievement were at the top of the lists. Comparing frequencies and seriousness of paired problems indicated that the most frequent and serious problems are behavioral, while the least frequent and serious are physical. When participants were asked to rate how spread each of the 61 problems identified in the survey were, more than half of the problems were rated between moderately-spread and very spread. This indicates that school staff members share a perspective that school children have a variety of many problems. Behavioral problems have been rated more frequent than physical problems by all of vocation categories in this study: administrators, vocational staff (Social Specialists,) and teachers. Significantly, teachers did so more than administrators and vocational staff. Social specialists have always rated the frequencies of problems lesser than teachers and administrators. Lack of motivation and low academic achievement were the two most commonly mentioned problems in terms of frequency and seriousness. Comparing frequencies and seriousness indicated that the most frequent and serious problems are behavioral, while the least frequent and serious are physical.

Chinese employees' psychological pressure in the workplace: Proof from industrial products marketing staff, scientific researchers and software engineers

XU, J. P. (Beijing Normal University), YU, Z. L. (Beijing Normal University), QIN, Y. (Beijing Normal University), HOU, Y. (Beijing Normal University)

During about 30 years of China modernization, the economy, technology and society have been increasing or changing very fast. With the change, work and life step is faster and faster. Due to heavy workload, worry about occupation and organization development, facing uncertain surroundings and the future, psychological pressure is an increasingly common feature of modern life and does harm to people. It is an important problem often faced by employees in the workplaces, too. The employees’ psychological pressure management is a hot research topic nowadays in China. The purpose of this study was to explore the psychological pressure status, causes and coping strategic. The study used Industrial Products Marketing Staff Psychological Pressure Questionnaire constructed by authors, Pressure Management Indicator Questionnaire (PMI), and Occupational Stressor Indexes-2 (OSI-2), surveyed 256 scientific researchers in five scientific and technical institutions in Beijing, 274 industrial products marketing staff in ten industrial enterprises and company from the whole country, 217 software engineers for small and middle Information Technology businesses in Beijing. The questionnaires were distributed amongst employees at the workplace by investigators or collected data by internet. The results showed that the psychological pressure
level of the total participants in different workplaces is very high and the occupational pressure is the main part. The main stressors of the participants are workload, relationships and organization climate, recognition and career future, role conflict, personal responsibility, home-work balance and daily hassles. The Conclusions were that psychological pressures of Chinese employees are heavier and stressors were from many different directions. The methods of coping with the pressure were personal skills and organization and social support.

Keywords: modernization, coping, employee stress, social support, pressure management

Chinese governmental culture: A vital role in the resilience of local governments of heavy disaster regions after 2008 Wenchuan earthquake

YANG, Y. (Beijing Normal University), QU, Z. (Beijing Normal University), SU, Y. (Beijing Normal University)

Resilience is commonly portrayed as a positive capability that allows individuals, groups, and organizations to survive and cope with a disaster with minimum impact and damage. This paper aims to assess the influence of Chinese culture in the organizational resilience of local government after Wenchuan earthquake in Sichuan province, China. The semi-structural questionnaire method is applied in this study. The questionnaires are based on the responses of government officers from five heavy disaster regions including Beichuan, Pingwu, Mianzhu, Shifang, and Luojiang. Eighty four officers of different levels from the five counties assisted us to complete the study according to their own working experiences after the earthquake. Four findings are obtained from the research. Firstly, China is a collectivism country which central government can allocate the resources of the whole country more efficiently. Indeed, the supports and helps from other provinces contribute significantly from the descriptions of those officers. Secondly, the Chinese culture appeals to the spirits of high responsibility. All the Chinese citizens, especially government officers, pay more attention to collective benefit compared to personal benefit. Those officers may perform beyond their capabilities in some circumstances. Thirdly, the collective efficacy of the local government is very high. They believe that the difficulties can be conquered under their efforts and the support from central government. Last but not least, the operational mechanism works well. Various resources, especially the human resources, are sufficient to guarantee the progress of reconstruction. The Chinese governmental culture will ultimately influence the ability of local governments in heavy disaster regions to adapt and respond to the damages caused by the earthquake.

Chips for challenging: The moderating effects of past attainment and future prospect on the relationship between perceived insider status and offering challenging opinions

HUI, C. (University of Hong Kong), LEE, C. (Hong Kong Polytechnic University), LIU, B. (Shanghai Jiao Tong University), KO, J. Y. O. (University of Hong Kong)

Offering challenging suggestions is important to organizational health. It is, however, less likely for employees to offer challenging suggestions than to offer supporting suggestions. In the United States of America, research on groupthink has demonstrated that group members are willing to go along with a group decision even though they see problems in the group decision. In China, the cultural value of power distance and the emphasis on social harmony suggest that challenging suggestions are less socially acceptable than conformity. Thus, examining situations under which employees are willing to offer challenging suggestions have both theoretical and practical importance. We hypothesize that employees are more willing to offer challenging suggestions if they perceive that they are insiders of an organization (Perceived Insider States, SIS, Stamper and Masterson, 2002) and that they have bargaining chips such as their past attainment in the organization. The identity of an insider puts an employee in a position to contribute and offers some buffer when an employee errs (for example, when voicing challenging suggestions is not accepted). Past
Abstracts of the 27th International Congress of Applied Psychology

Brief Oral Presentations

Attainment is the additional chips for erring because when employees have attained important accomplishments in an organization, their opinions carry more weight. Future prospect, however, may inhibit an employee from challenging for the fear of disapproval. We hypothesize that employees are most likely to offer challenging suggestions when they perceived themselves to be insiders, have attained much in the organization in the past, but have low future prospects in the organization. We tested our hypothesis using a sample of 91 employees in China from different occupations and companies who attended Master’s level classes in a university. Forty-two percent were female. They averaged ten years in their career and five years on their jobs. Their mean age was 32 years. We found a significant three-way interaction between PIS, past attainment and future prospect using hierarchical multiple regression. Results supported our hypothesis. To increase the likelihood that employees would offer challenging suggestions, organizations may consider strengthening the relationship with their employees and considering how to protect the future prospect of employees who voice challenging suggestions.

Claiming rights or claiming justice: A social psychological analysis of disputes emergence

FIEULAINE, N. (University of Lyon), NIKOS, K. (University of Lyon), VALÉRIE, H. (University of Lyon)

The process by which experiences of injustice are perceived, become grievances, and then are transformed into claims and/or disputes is in many respects a social-psychological process. Hence, aims of this field study were 1) to investigate how citizens facing injurious experiences succeed or fail to form a sense of “entitlement” to some kind of redress and assert claims in legal institutions; 2) to explore social-psychological factors that are important in the development of disputing behaviors, but also in the access to rights, law, and justice. A field study was conducted in free legal aid centres («Law and Justice Houses» and «Law shops») in an urban area in France. Methodological procedure combined observations of consultations with legal consultants, semi-directed interviews with the public (N = 46), and a questionnaire completed by users of legal aid (N = 132). Social representations of the justice system, motives for claiming, and conflict trajectories were assessed. Content and lexicometric analyses for qualitative data, and correlational, factorial and configural analyses for quantitative ones were realized. Emergence and transformation of disputes appeared as conditioned by three main social-psychological factors: social representations, social interactions, and temporality. Shared lay knowledge about justice, interactions with surrounding people or lawyers, and time orientation together participate in the configuration of “naming”, “blaming”, and “claiming” stages of disputes transformation. Perceived accessibility of legal contexts and trust in legal institutions act as potential barriers in the claiming process. Results highlighted social-psychological anchoring of individuals’ commitment to the legal-claiming process, and the dynamic process by which conflicts are transformed – or not – into disputes. It provides new insights for tackling inequalities in access to justice, especially for poor or marginalized populations. Implications for policies and future researches will be discussed.

Keywords: injustice perception, grievance, disputes, justice

Classical and modern prejudice towards intellectual disability: Attitudes of undergraduate students at Isfahan University

REZAEI DEHNAVI, S. (University of Isfahan), BAGHER KAJBAF, M. (University of Isfahan)

The purpose of this study was to investigate the prevalence of two forms of prejudice towards people with intellectual disability (classical and modern) in undergraduate students at Isfahan University. Through cluster sampling, 189 students were selected. The participants filled out a scale of classical and modern prejudice towards intellectual disability, developed by
Nazar Akrami. The data were then analyzed through a one sample t-test, paired t-test and ANOVA test. The results indicated that there were two forms of prejudice in undergraduate students. Students expressed more modern prejudice in contrast with classical prejudice, and having more knowledge about mental disability was related to decreasing classical prejudice. Two forms of prejudice existed in male and female students that studies in different academic disciplines not related to education and psychology of mental disability.

Keywords: prejudice towards people with intellectual disability, classical prejudice, modern prejudice, mental disorders, prejudice amongst students

Client satisfaction and readiness to change in court-mandated substance abuse treatment

DUGGAN, K. (University of Tasmania)

Court-mandated substance abuse treatment has become a viable alternative to incarceration for substance abusing offenders, despite the paucity of research investigating individual’s treatment processes. The aim of this study was to investigate whether readiness to change substance abusing behaviour was associated with satisfaction with court-mandated substance abuse treatment. A further aim was to investigate the influence that client age and time spent in court-mandated treatment had on satisfaction with treatment and readiness to change substance abusing behaviour. The Treatment Perceptions Questionnaire (TPQ) and the Readiness to Change Questionnaire (RTCQ) were completed by 35 clients (\(M_{\text{age}} = 28.47, SD = 6.02, 25\) males) undertaking court-mandated substance abuse treatment. The TPQ measured client satisfaction with the treatment program staff and treatment program structure. The RTCQ assessed client readiness to change substance abusing behaviours, and categorised them as being in either the Precontemplation, Contemplation or Action stage of change based on responses to 12 attitudinal statements pertaining to behaviour change. Results indicated that participants in the Contemplation and Action stages of change reported greater satisfaction with treatment staff and structure than clients in the Precontemplation stage. Additionally, clients aged 26 years and older were more ready to change substance abusing behaviours and more satisfied with treatment program structure than clients under 26 years of age. Furthermore, clients who had been in treatment for longer than 90 days were more ready to change substance abusing behaviour and more satisfied with the treatment program staff and structure than participants who had been in treatment for less than 90 days. Readiness to change is an indicator of likelihood of change, therefore any means to facilitate client’s increased readiness to change should be considered. For example, a brief motivational interviewing intervention employed at the commencement of treatment might influence clients to remain in treatment longer. Younger adults might benefit from a ‘transitional’ court-mandated treatment program that specifically addresses the unique needs of the young adult population, thus improving their readiness to change, satisfaction with treatment, and ultimately their treatment outcomes. A thorough exploration of mandated treatment issues is included in the body of the paper.

Keywords: rehabilitation, substance abuse, Treatment Perceptions Questionnaire, readiness to change, court-mandated treatment program

Clinically maladjusted and adjusted couples: A preliminary study

DINCA, M. (University Titu Maiorcescu), ILIESCU, D. (SNSPA, University at Bucharest)

Marital adjustment was originally defined (Spanier & Cole, 1976) as a multidimensional phenomenon which the Dyadic Adjustment Scale (DAS) was reported to measure adequately (Spanier, 1976). The separate dimensions of marital adjustment were reported to be the following: (a) consensus on matters of importance to marital functioning, (b) dyadic satisfaction, (c) dyadic cohesion, and (d) affectional expression. The purpose of this study is to explore if and how the behavior pattern of the woman or of the man is the one influencing dyadic adjustment of marital relationships. Ninety couples (50% males and 50% females) aged 32 to 59 years completed the Dyadic Adjustment Scale (Spanier, 1989). We selected
four groups based on the scores of the two partners, and considered T scores under 30 as indicators of severe maladjustment. There were significant differences between the four groups (t Student). The groups were the following: 1. Non-distressed couples group (n = 71); 2. distressed couples group (n = 8); 3. mixed couples group: man with clinical profile, normal pattern in woman (n = 7); 4. mixed couples group: woman with clinical profile, normal pattern in man (n = 4). First, as expected, we found different patterns of behavior for non-distressed and distressed couples. Second, if only the woman has a clinical behavior pattern (low scores on affectional expression, satisfaction and consensus) the man obtained low scores on consensus. If the man has a clinical behavior pattern (low scores on affectional expression and satisfaction), the women obtained low score on satisfaction. The results reveal different patterns of marital interaction, correlating with the behavior of the partners and their gender. These findings are important for clinicians active in family counseling and psychotherapy, as they reveal important information about the influence of the behavior of the partners on couple relationships.

Keywords: marital adjustment, dyadic satisfaction, dyadic cohesion, affectional expression, dyadic adjustment scale

Clinician-guided versus technician-guided internet treatment for depression

SPENCE, J. (Crufad (Clinical Research Unit for Anxiety and Depression), St Vincent’s Hospital, Sydney), TITOV, N. (University of New South Wales), ANDREWS, G. (University of New South Wales), DAVIES, M. (St Vincent’s Hospital, Sydney), MCINTYRE, K. (St Vincent’s Hospital, Sydney), ROBINSON, E. (St Vincent’s Hospital, Sydney), SOLLEY, K. (St Vincent’s Hospital, Sydney)

Recent studies indicate that Internet-based Cognitive Behavioural Treatment (ICBT), when guided by a clinician, is as efficacious as face-to-face Cognitive Behavioural Treatment. Emerging evidence indicates that non-clinicians (technicians) can also efficaciously administer ICBT. The question is, would reminders from a technician be as effective as guidance from a clinician? One hundred and forty people with major depressive disorder were randomly allocated to receive clinician-assisted ICBT for depression, or technician-assisted ICBT (with weekly telephone calls from a technician) or to a waitlist control condition. Participants in the clinician-assisted version received access to a six-lesson program plus regular emails and telephone calls from a clinician, automatic reminder emails, and access to an online discussion forum. Participants in the technician-assisted version received access to the program, automatic reminder emails, and regular email and telephone reminders from a technician. It was expected that the clinician-assisted groups would have higher completion rates and better clinical outcomes than the technician-assisted group. The main outcome measures were the Beck Depression Inventory (BDI-II) and the Patient Health Questionnaire-9 Item (PHQ-9). Completion rates were high, and both treatment groups reduced scores on the BDI-II (p < 0.001) and PHQ-9 (p < 0.001) compared to the delayed treatment group, but did not differ from each other. Within group effect sizes on the BDI-II were 1.27 and 1.20 for the clinician and technician-assisted groups, respectively, and on the PHQ-9 were 1.32 and 1.60, respectively. Approximately 60 minutes of clinician or technician time was required per participant during the eight-week treatment program. Both clinician and technician-assisted treatment resulted in large effect sizes and clinically significant improvements comparable to those associated with face-to-face treatment, while a delayed treatment control group did not improve. These results provide support for large scale trials to determine the clinical effectiveness and acceptability of technician-assisted ICBT programs for depression. This form of treatment has potential to increase the capacity of existing mental health services.

Keywords: internet-based interventions, cognitive behavioural therapy, treatment, depression

Cognitive functioning following liver transplantation for alcohol-related liver disease: A prospective study

CONNOR, J. (Alcohol and Drug Assessment Unit, Princess Alexandra Hospital, Brisbane / The University of Queensland), PEGUM, N. (Princess Alexandra Hospital, Brisbane), FEENEY, G. (Princess Alexandra Hospital, Brisbane)
Alexandra Hospital, Brisbane), YOUNG, R. (Princess Alexandra Hospital, Brisbane)

This study aims to identify the pre- and post-operative neuropsychological and psychosocial functioning of patients who require liver transplantation as a result of alcohol-related liver disease. A comprehensive neuropsychological (WAIS-III, WMS-III, Trails [A&B], Rey-Osterrieth Complex Figure) and psychosocial assessment (Beck Depression Inventory, Psychological Adjustment to Illness Scale) was conducted with 92 patients requiring liver transplantation. Follow-up assessment was conducted with 42 patients, 12 months post successful transplantation. Patients performed significantly below the normative sample on tests of non-verbal cognitive functioning and immediate and delayed memory tasks pre-transplantation. Difficulties with executive functioning, depressive symptomatology and vocational functioning were also identified. With the application of repeated measures MANOVA and Reliability Change Indices, significant improvements were observed from pre- to post-transplantation in non-verbal cognitive functioning, memory, and executive functioning domains, along with significant reductions in depressive symptomatology and vocational difficulty. Additional knowledge of the cognitive and psychosocial sequelae associated with alcohol-related liver disease may assist in the management of patients leading up to transplantation surgery. The cognitive and psychosocial gains and residual difficulties observed post liver transplantation present new and important data to assist planning for optimal recovery and post-operative care.

Keywords: liver transplantation, alcohol-related liver disease, cognitive functioning

Collectivist versus individualist culture: Differences in perceptions of health and wellbeing and support factors at work

WONG, A. (Deakin University), VON TREUER, K. (Deakin University), FULLARTON, C. (Deakin University)

This study aimed to examine differences between individualist and collectivist cultures in perceptions of health and wellbeing and support factors at work. Specifically, the relationship between support factors (peer level, supervisor level and organisational level) and employee health and wellbeing were investigated. Participants included 106 employees recruited utilising a snowballing technique. The majority of participants were under 30 years of age, employed full time with male and female participants equally represented. Health and wellbeing was measured using the short form 8-item Health Survey (SF-8) and Personal Wellbeing Index (PWI) respectively. Perceived organisational support (POS) was measured utilising the POS measure, while supervisor support, job involvement and peer support were measured using subscales from the Work Environment Scale. As predicted, organisational support factors did not predict health or wellbeing in individualist cultures. In contrast, in collectivist cultures, the organisational support factors were found to predict mental health. Also, in collectivist cultures the organisational support factors accounted a significant amount of variance in personal wellbeing. Supervisor support on its own contributed 19.3 per cent of unique variance in personal wellbeing. Furthermore, the organisational support factors (POS, Supervisor Support, co-worker cohesion) together accounted for a significant amount of variance in mental health. Additionally, organisational factors also contributed a significant amount of variance in personal wellbeing. The findings of the current study suggest that the relationship between organisational support factors and health and wellbeing is influenced by cultural differences.

Clinical psychology and action research: How the development of a men’s health calendar can help to change young men’s attitudes towards their health in the United Kingdom

RICHARDS, M. (Manchester Metropolitan University)

One of the major issues in health today is the reluctance of men to acknowledge health problems and to find solutions to resolve them. In addition, young men in the United Kingdom (UK) are more likely than any other group to commit suicide, break the law, be unemployed, have no qualifications and have low self-esteem. In collaboration with a young men’s project in Manchester, UK, in one of the poorest places in the UK, a young men’s group was developed to create a men’s health calendar. The aims of this project were to identify the most pertinent areas of male health, which the young men identified themselves. A semi-structured programme of activities was devised considering male health issues and young men were invited aged 18 to 25 to participate in the programme. The young men identified and actively participated during sessions around issues related to alcohol, drugs, sex, relationships, exercise, help accessing services, talking more, diet, taking less risks, positive hobbies and self image. A positive informal learning environment was created for the young men to reflect on their own ‘health issues’. They developed skills in debate, discussion, photography and simple cooking techniques. Semi-structured interviews and questionnaires were used to explore the health issues they identified and how they might look to change if change was necessary. It was found that there are serious gaps in their knowledge on the importance of health. However, through simple discussion and debate during the activities, it was collectively highlighted what the problems were, and solutions were identified to change attitudes. It can be concluded that community psychology and action research are important and useful approaches in highlighting health issues in young men and seeking solutions to
change their attitudes successfully and potentially for the long term.

Keywords: male health, young men's group, semi-structured programme of activities, health attitudes, community psychology

Comparative assessment and remediation of adaptive behaviour skills of some children aged 3-10 years

AKINSOLA, E. (University of Lagos), GOMA, R. (University of Lagos)

The aim of this study was to assess the developmental level of adaptive behavior skills of some children aged 3-10 years, and determine if training can improve the school adaptive behavior skills of those found to be deficient in this area. A cross-sectional method of administering an adapted version of Harrison and Oakland’s (2008) adaptive behavior assessment system (ABAS-II), home and school editions, was used. It was administered to 250 children from intact homes, 25 from an orphanage and 25 from a special school for children with special needs, within the age range of 3 to 10 years. An intervention program was mounted for those found to be deficient in the school adaptive behavior skills using the method of “at least prompt adaptive skills”. This second phase at the time of submitting this abstract was not yet concluded. The results obtained in the first phase of the study indicated that children from intact homes possessed better overall adaptive behavior skills than children from the orphanage and the special school. It is expected that the school related adaptive behavior skills of children that are now being given training would significantly improve after the training. The results of the first part of the study reflected the importance of parental involvement in the development of competent adaptive behavior skills of children and the need for caretakers of children, other than parents, to be more involved in the development and training of adaptive behavior skills of children under their care.

Keywords: assessment, remediation, adaptive behaviour skills, children, developmental level

Comparative optimism between offenders and legalist drivers: Impact of rehabilitation training courses

In France, despite recent improvements during the last seven years, 4443 people were killed in a car accident in 2008. Many measures were adopted by the French government to decrease the accidents: raise of police control to detect the presence of alcohol, decreased speed limit etc. Since 1992, the government has introduced driver’s licence penalty points: each driver has 12 points and each offence takes away some points. If the driver loses all his points, he has to take the driving test again. One way to recover four points is to go to driver-rehabilitation training courses. These courses stress the risks of driving. (eg. braking distance...) There were two goals of this study. Our first goal was to determine whether traffic regulation offenders have a weaker risk perception than legalist (persons who have not lost any points) ones. Offenders would consider themselves better drivers with better control in driving situations than other drivers. This consideration would cause driving offence behaviors. The second goal consisted in verifying the effects of driver-rehabilitation training courses on risk perception. We made the assumption that the training courses would reduce risk perception and comparative optimism (perception of low risk relative to peers, Radcliffe and Klein, 2002). Three groups (n = 20 in each group) were constituted: legalist drivers, offenders before a training course and offenders after a training course. All participants had to fill in a questionnaire measuring comparative optimism in six driving situations (three involved high control from the driver whereas three others involved weaker control). Results revealed 1/ an interaction effect type of driver x control situations; offenders are more optimistic in the probability of having an accident than legalist ones, but only in the high control condition; 2/ the course seems to reduce the optimistic bias of offenders; results seem not to differ from those obtained with legalist ones. Discussion will

Comparison of cognitive and quality of life outcomes in Parkinson’s Disease with and without mild cognitive impairment after bilateral subthalamic deep brain stimulation

TRÖSTER, A. (University of North Carolina at Chapel Hill), FIELDS, J. (Mayo Clinic, Rochester)

Little literature exists about neuropsychological effects of deep brain stimulation (DBS) in Parkinson’s disease (PD) with dementia, but patients with dementia are typically not candidates for DBS. Subthalamic (STN) DBS in patients without dementia is generally considered safe from a cognitive standpoint and is associated with quality of life (QOL) gains, but a minority of patients experience cognitive declines. Whether pre-existing mild cognitive impairment (MCI) affects DBS outcome is unknown and is addressed in this preliminary study. Twenty-four patients who underwent simultaneous bilateral subthalamic DBS surgery participated in the study. Patients were assessed about a month before and four months after surgery. MCI was defined independently of outcome measures in each of five domains on the basis of scores 1.5 SDs or more below age-appropriate means (without functional impairment): attention (Digit Span Backward or Spatial Span Backward), language (Boston Naming Test), executive function (Stroop Interference Condition), visuospatial (Visual Organization Test), and memory (Logical Memory delayed). Quality of life was assessed with the Parkinson’s Disease Questionnaire (PDQ). Seven patients had pre-operative MCI (six single domain; one multiple domain; all but one non-amnestic). The groups with and without MCI were comparable on key demographic (age, education, handedness, gender) and disease variables (age at onset, disease duration, medication). Motor outcomes assessed with the Unified Parkinson’s Disease Rating Scale (UPDRS) were favorable and comparable in the two groups, as were stimulation parameters. QOL also improved significantly and comparably in the two groups. Cognitive (overall level of cognitive function, attention, executive, verbal fluency, facial discrimination, verbal memory) outcome in the two groups was comparable. However, the MCI group showed greater decline in visual memory. Prevalence of MCI in this surgical sample was comparable to that reported in tertiary care and community samples. This study confirmed positive motor and quality of life outcomes in PD after STN DBS and found that the outcomes are comparable in patients with and without pre-surgical mild cognitive impairment. As a group, patients with MCI before surgery may be at risk of greater visual memory declines after surgery than those without MCI. These declines may not have dramatic functional implications however, as self-rated satisfaction with cognition after surgery was comparable in the two groups. Future studies with larger samples, and defining MCI in a variety of different ways, are needed to confirm the present findings.

Complementary and alternative medicine use and distress among Australian women with cancer: A prospective longitudinal investigation

BEATTY, L. (Flinders University), ADAMS, J. (University of Queensland), SIBBRITT, D. (University of Newcastle), WADE, T. (Flinders University)

While several cross-sectional studies have examined the medical, demographic and psychological correlates of Complementary and Alternative Medicine (CAM) use among women with cancer, few prospective longitudinal investigations have been reported. The purpose of the present study is to prospectively examine (i) whether pre-cancer distress is predictive of CAM use at cancer diagnosis, (ii) whether CAM use predicts distress after cancer, and (iii) whether CAM mediates the relationship between pre- and post cancer-related distress. Four waves of data from the Australian Longitudinal Study of Women’s Health were analysed. The participants were women who did not have cancer at Survey One, but who
reported developing cancer at subsequent surveys. Women from all age cohorts ('Younger': aged 18 to 23, 'Mid': aged 40 to 45; and 'Older': aged 70 to 75) were included. The measures included CAM usage ('How many times have you consulted an alternative health practitioner in the past 12 months?'); cancer status ('Have you been diagnosed in past 3 years with cancer?'); and distress (Medical Outcomes Study Short-Form 36, SF-36; Centre for Epidemiologic Studies - Depression scale, CES-D; and the Goldberg Anxiety and Depression Scale). Longitudinal analysis of the relationship between CAM use and distress was conducted according to a time-lag model using Linear Mixed Modelling, which models repeated measures, controls for missing data, and establishes causality. The changes in prevalence over time for CAM usage and distress within each age cohort and by cancer type will be discussed. Findings from the prospective predictive and meditational analyses of the (i) combined samples and (ii) separate age cohorts will then be presented. It is anticipated that the findings of this study will provide longitudinal confirmation of the correlations previously observed between distress, CAM and cancer. That is, this study will provide insight as to whether utilising CAM is an effective intervention for managing the distress arising from cancer diagnosis, and whether particular age groups obtain greater benefit.

Keywords: complementary and alternative medicine, cancer-related distress, women's health, global anxiety and depression scale, cancer diagnosis

Completeness of capability revelation and signaling effect: Lessons learned from intellectual property lawsuits

LI, K. (Global Entrepreneurship Research Centre, Zhejiang University), WANG, Z. M. (Zhejiang University)

This study investigates the signaling effect of intellectual property lawsuits as a mechanism of capability revelation. Partly because of the inherent international trade conflict, intellectual property lawsuits are particularly common nowadays. However, the results of the lawsuits are quite interesting, as there are several cases in which the weaker companies from developing countries were sentenced to win. As a result, they will usually experience a favorable consequence in the market of the host country. In this paper I argue that the lawsuits are important for these emerging multinational firms to reveal their capabilities, as a signaling mechanism to convince the customers in the host country. This study employed a two factors’ between-subjects design. The two factors are lawsuit responsiveness (proactively-reluctantly) and the competitiveness of the opponent (strong-weak). As such this yields four cells, and for each cell I assigned 15 subjects. Thus in total there were 60 foreign students who took part in this study. The subjects are postgraduate students in Hangzhou, China and Reading, United Kingdom. The subjects are asked to review the materials presented in an in-basket manner, and then evaluate the capability of the firms from developing countries, and indicate willingness to buy products or services from these firms. The results show that the main effects of the two factors are both significant. Lawsuit response proactiveness and competitiveness of the opponent positively influence capability evaluation and purchasing willingness. In addition, the interaction between the two factors is also significant. With a high level of proactiveness of response, no matter how strong or weak opponents are, the evaluation will be high. While with reluctance of response, the stronger opponents will yield higher capability evaluation and purchasing willingness. The results suggest that the completeness of capability revelation is positively linked with the purchasing willingness, and I argue that signaling effect is the underlying mechanism behind the phenomenon. In conclusion, the customers in the foreign host markets need the comprehensive revelation of companies’ capability to build confidence over the products they are buying. Finally, the practical implications are also discussed.

Keywords: intellectual property lawsuits, international trade conflict, competitiveness, product buying, purchasing willingness

Computer-mediated group discussion to achieve consensus

RAMDHANI, N. (Gadjah Mada University), AFIATI, N. (Gadjah Mada University)
The study aims to identify the influence of discussion mediums towards aggressiveness and communication satisfaction when discussing different issues. An experiment is conducted to compare three discussion mediums, namely: face to face (FtF), computers mediated communication with real name (CMR), and computer with closed identity (CMA). The discussed matters include social dilemmas and a criminal puzzle. Ninety students from Gadjah Mada University participated in the experiment. They had their discussions in small groups consisting of five participants. To ensure accuracy in data collection, three groups also discuss the same matters with the same medium. Aggressiveness is more evident in the criminal puzzle and the CMA group. The FtF medium became the most satisfying means of communication. Highest domination was reported in discussing social dilemma as well as the CMA medium. The participants in the CMA and CMR groups felt they had better discussions compared to the FtF participants. On the other hand, the FtF participants also felt they had better discussions compared to the CMA or CMR groups. FtF is the best medium to be used in communication. Users believe that the medium they choose is the best.

**Keywords:** discussion mediums, aggressiveness, communication satisfaction, social dilemmas, criminal puzzle

**Confirmatory factor analysis of the Chinese version of Motivation and Engagement Scale-University/College (MES-UC)**

LX. X. (The University of Hong Kong)

During the past twenty years, the concept of students’ engagement has received increasing attention in educational psychology. Martin (2005) proposed a use-inspired and integrative motivation and engagement model which has been validated in many domains. But the cross-cultural use has not been explored given that it is an important concern for its generalization. In this study, Martin’s Motivation and Engagement Scale-University/College (MES-UC), was adapted and administered to 832 Chinese university students. The cross-cultural validity of the scale was examined based on content analysis, reliability analyses, Confirmatory Factor Analysis (including two-order CFA and Multiple CFA), and Multiple-Indicator-Multiple-Cause modeling. The results show acceptable reliability of MES-UC in Chinese a university student sample; the construct of MES-UC in the Chinese university student sample is consistent with the one in Martin’s study (2005); girls broadly reflect more adaptive levels of motivation and engagement than boys; higher grade-level students reflect less adaptive motivation and engagement than their lower grade-level counterparts; adaptive dimensions of motivation is positively correlated with between-network constructs (academic satisfaction and adjustment); while impeding and maladaptive dimensions is negatively correlated with them. The cross-cultural adaption version of MES-UC will be applied in further research that will examine the process of engagement in learning among Chinese university students.

**Conflict-handling styles**

CERNI, T. (University of Western Sydney / The Scots College, Sydney)

The purpose of this paper is to examine the relationship between information-processing systems and conflict-handling styles. According to the cognitive-experiential self theory (CEST; Pacini & Epstein, 1999), all behaviour is guided by two information-processing systems: a rational and an experiential system. Although Rahim (1983) and his colleagues conducted extensive research on the five styles of handling interpersonal conflict, no research has examined the connection between the CEST information-processing systems and the five conflict-handling styles. An on-line survey was used by a large sample of undergraduate students (N = 426) to examine the relationship between CEST information-processing systems and conflict-handling styles. The survey consisted of a short demographic questionnaire, the Rational-Experiential Inventory-Long Form (REI-L), the Constructive Thinking Inventory (CTI) and Rahim Organizational Conflict Inventory (ROCI-II). Only students who held jobs were invited to complete
the on-line study. The rational system, experiential system and constructive thinking had significant positive relationships with both the integrating and compromising conflict-handling styles. Additionally, the rational system had a positive relationship with the dominating conflict-handling style. The experiential system and constructive thinking had a positive relationship with the obliging conflict-handling style. The rational system and constructive thinking had a negative relationship with the avoiding conflict-handling style. This study is unique in that it was able to show a positive relationship between the CEST information-processing systems and conflict-handling styles with the existing literature supporting the connection between transformational leadership and conflict-handling styles. This provided a good rationale for considering how the CEST information-processing system, conflict-handling styles and transformational leadership could fit together.

Keywords: information processing, conflict-handling styles, cognitive-experiential self theory, transformational leadership, constructive thinking

Constrained innovation: How designers innovate within the boundaries of safety

CHEYNE, A. (Loughborough University Business School), WIMALASIRI, V. (University of Plymouth), COHEN, L. (Loughborough University), HISLOP, D. (Loughborough University), BEESLEY, N. (Loughborough University), DANIELS, K. (Loughborough University)

Effective design can reduce or eliminate many problems associated with products in use; however, there remain tensions between the risks and experimentation involved in innovation and the risk aversion inherent in regulated, safety critical industries: The cognitive processes involved in innovation are very different from those involved in safety. This paper examines ways in which designers deal with the twin hurdles of innovation and safety in safety critical industries. The data presented is taken from interviews conducted with 20 participants who are stakeholders of the design process of the medical devices industry in the United Kingdom. Participants belonged to one of four distinct stakeholder groups: Designers (11); design academics (two); production managers (one); and regulators (six). Information was obtained through semi-structured interviews. Template analysis generated two distinct themes explaining how the groups of stakeholders construct the relationship between safety and innovation and how this influences design and innovation in medical device design. Whilst one of the themes was orientated towards creativity; the second was orientated towards facilitating the implementation of those ideas; illustrating that the stage of the process and safety instruction had significant impacts on the social construction of innovation in safety environments. The findings showed that one way to ensure safety in design within such environments is to prioritise safety education and communication over other factors. To the extent that these findings are generalisable to other innovation intensive and safety critical industries, they are relevant to those that make policy in safety critical areas. Communicating safety relevant information to designers needs to take into account how designers construe risk, so that communication can be framed in ways designers will both understand and find credible. The present findings indicate risk communications need to take into account at least two views on reconciling the tensions between innovation and safety. Implications of safety culture in this environment will also be discussed.

Construction of a parental support scale

MAO, C. H. (National Chiao Tung University)

This research aims to establish a Parental Support Scale under the hypothesized context of relational approach to career theory. Two studies are included. Study One used exploratory factor analysis to construct a Parental Support Scale, and obtain the factor constructs. Participants consisted of 215 college students in Taiwan. Based on the theoretical framework, the author classified five factors containing 33 questions. These five factors were emotional support, esteem support, information support, tangible assistance and social integration. Study Two was utilized confirmatory factor analysis to verify the factor constructs of the Parental Support Scale in Study One. Participants consisted of 435 college students in Taiwan. After the exploratory factor analysis, four factors were extracted: “Emotional Support factor”, “Recognition and Respect factor”, “Information Provision factor”, and “Tangible Assistance factor”. And these four extracted factor constructs were consistent with the theoretical
model. Only the Social Integration construct from the original framework was not included. Besides, “Recognition and Respect factor” differed slightly from the original Esteem Support. After the confirmatory factor analysis procedure, the original model which contained second-order latent variables was below the acceptance threshold. Therefore, this model required further modifications. After changing into first-order constructs, and three questions being removed, we got an optimal model in which the chi-square value was lowered to 277.63, the Root Mean Square Error Approximation (RMSEA) reduced to 0.074, the Goodness of Fit Index (GFI) increased to 0.92, and the Standardized Root Mean Square Residual (SRMR) value decreased to 0.05. Furthermore, the factor loading of observable variables all met the level of significance, demonstrating the observable variables were enough to reflect their constructed latent variables. The standardized parameter values were all significant, indicating the latent variables and the observable variables were significantly correlated. The construct reliability of all four latent variables was higher than 0.6, signifying all latent variables had sufficient construct reliability. Based on the reliability analysis in Study One, and the standardized parameter values and evaluation of internal model fit in Study Two, the results showed that observable variables had good reliability and was sufficient to reflect their constructed latent variables. The modified model exhibited high degree of model fit.

Consumer psychology: Moving from reactive to proactive consumer research

PARDO, N. (California Southern University)

The transition from Communism to Capitalism in a few of the FSS (Former Soviet States) has meant a shift in the way consumers view themselves, as well as the way their opinions are measured by the consumer researchers. This presentation will discuss the way consumer research has changed in recent years from a reactive to a proactive approach. Data initially collected by the advertising firms in some of the FSS could be described as reactive; however, more recent approaches have shifted to a more proactive approach. Instead of how do you like what we have made/what we offer (proving in a post hoc approach that what we have done is good), there are opinion surveys now designed to ask the consumers what products they would like to see, and how they could be improved. Data collected in five countries will be compared on proactive and reactive approaches across several product categories. Consumer data collected using a traditional product approach tends to be more reactive, whereas consumer data collected using more recent methods using a marketing approach (where consumer opinions are used to generate products and improve current products/services) tend to be more proactive in their approach. This shift can be linked to the shift from Communism to post-Communism in the ways consumers perceive their rights and vote with their feet in a more capitalist approach. The shift of consumer opinions is matched by the shift in the field of consumer research, as researchers (primarily psychologists working in the advertising and marketing fields) move from more economic approaches to more modern approaches to researching consumer opinions and attitudes.

Contribution of the French Society of Sport Psychology to the identification and accreditation of sport consultants

DEBOIS, N. (INSEP)

The paper presents how the French Society of Sport Psychology (SFPS) initiated a procedure of accreditation for consultants in sport psychology to promote an ethical intervention in elite sport. The concerned consultants are either certificated in sport sciences with a specialization in sport psychology, or certificated in psychology (with the title of psychologist) with a specialization in sport sciences. The committee for evaluation consists of 8 members (4 from the managing council of the SFPS and 4 other members of the SFPS). The evaluation rests both on certification, professional experience and
Abstracts of the 27th International Congress of Applied Psychology

Brief Oral Presentations

Ethical observance. The athletes and coaches encounter more and more difficulties with increasing entitled people who offer them services in mental preparation without any specific education in sport psychology nor ethical limits. To prevent this kind of unwarranted practice and better inform the French sporting area, the French Society of Sport Psychology has undertaken to draw up an informative list of warranted sport consultants and sport psychologists. Today, the procedure is always in progress and more and more consultants submit for an accreditation. This experience sets up an example of the importance of scientific associations to contribute to an ethical practice of sport psychology in elite sport.

Conversion of mild cognitive impairment into dementia: Predictive role of cognitive deficits in executive functioning

TIMPANO SPORTIELLO, M. (University of Pisa), CAMMISULI, D. (University of Pisa)

From a historical perspective, clinical research on neuropsychological features of dementia in subjects suffering from mild cognitive impairment (MCI) has focused mainly on declarative memory role. This approach has led to overestimating memory decline rather than the broader cognitive deterioration that afflicts the majority of individuals with MCI. Recently, literature has emphasized the combination of memory disorder and dysexecutive dysfunction (particularly characterized by deficits in selective attention, response inhibition, planning and mental flexibility) as risk factors for the onset of dementia. Within this way of looking, it will probably be the new configuration field for further investigation. The present study takes aim at analyzing neuropsychological profile of MCI subtype (Amnestic MCI Multiple Domain) with cognitive deficits in executive functioning to evaluate if they represent the highest risk of incipient dementia. One hundred subjects with a neuropsychological diagnosis of MCI formed the sample. They were assessed by a wide neuropsychological battery which included the investigation of Memory System, Attention System, Visual Agnosia, Constructive Apraxia and Language. Executive Functioning was tested by the Stroop Color Word Interference Test and the Attentive Matrices to evaluate selective attention, the Verbal Fluency Test to evaluate mental flexibility, the Frontal Assessment Battery (Subtest 5: Go-No-Go) to evaluate inhibitory control, the Brixton Test to evaluate rule learning and set shifting, and the Tower of London to evaluate planning abilities. According to Petersen's classification of MCI (amnestic versus not-amnestic, single versus multiple domain), MCI Type II represents the majority sub-category of the whole sample. Within frontal domains impairment, inhibitory control, planning and sequencing tasks with rule changing, are more frequently deteriorated. Our research confirms that the starting symptomatology consists of executive functioning decay in a considerable average of MCI subjects, even if declarative memory deficits are the most frequently impaired. The premature executive impairment represents a decisive risk factor for the conversion of mild cognitive impairment into dementia. Moreover certain areas of executive functioning are more fragile than others. These conclusions suggest that future research should pay attention to dysexecutive dysfunction as the main cofactor along with memory decline in mild cognitive impairment and dementia.

Coping in difficult situations by youth endangered with social exclusion

WILCZYNSKA, A. (University of Silesia), BARGIEL-MATUSIEWICZ, K. (University of Warsaw)

The objective of this research was to determine the relation between psychological personality constructs and how youth endangered with social exclusion function in difficult situations. The research involved 122 subjects – adolescents from middle and secondary school students, representing various family and social experiences. The subjects were examined with reference to their level/degree of social exclusion risk, ways of coping in difficult
situations, locus of control (LOC), pragmatism, and the need of social approval. The subjects were divided into four groups representing various levels of social exclusion risk as well as various, characteristic of each group, methods of coping in socially difficult situations. The tool applied in order to compare the average results of the above variables in individual groups endangered with social exclusion was the single-factor analysis of variance (ANOVA). Statistically essential differences were found with the scales of Coping ($F(118, 3) = 9.66; p < 0.001$) and LOC ($F(118, 3) = 7.02; p < 0.001$). The analysis of correlations between the variables revealed a strong relationship between preferred preventive behaviours in difficult situations and LOC: $r^2 = 0.75 (p < 0.001)$. In addition, during the research, it was possible to observe statistically essential correlation factors between: the group endangered with social exclusion and the variables of Coping $r^2 = 0.44 (p < 0.001)$; LOC $r^2 = 0.38 (p < 0.001)$ and Need of Social Approval $r^2 = 0.18 (p = 0.048)$, as well as between the Need of Social Approval and preferred preventive behaviours $r^2 = 0.56 (p < 0.001)$ and Locus of Control $r^2 = 0.54 (p < 0.001)$. The statistical analysis revealed that subjects of the group representing the highest risk of social exclusion are characterised by external LOC and escapist methods of coping in difficult situations. A very low or very high result on the self-monitoring scale reveals unadaptiveness of social behaviours, rigidity or excessive adaptation to social environment in isolation from one’s own needs. The subjects from the group representing the highest risk of social exclusion probably ignore social signals enabling social inclusion. The discussion will be concerned with the ways of identification of such processes in endangered environments and the methods of therapeutic work.

Keywords: personality constructs, youth social exclusion, social approval need, locus of control, self-monitoring

Coping styles and family support as predictors of well-being in high school students

LUDLOW, T. (Griffith University), HOOD, M. (Griffith University), SEE, L. (Griffith University), DALE, R. (Griffith University)

This study examined family support as a mediator of the relations between coping styles (active and support seeking) and wellbeing in high school students. Participants were high school students ($N = 156$) aged 12 to 16 years ($M = 13.44$ years, $SD = .85$). Forty five percent of the sample was female. The measures used in the study included the WHO Well-Being Scale – 5 (Heun et al., 1999), the Child and Adolescent Social Support Scale (Malecki, et al., 1999) and the Children’s Coping Strategies Checklist (Ayers et al., 1996). Participants completed the measures in one testing session at school. Regression analyses, using the procedures outlined by Baron and Kenny (1996), investigated whether family support mediated the link between coping strategies (active and supportive) and wellbeing. Significant, positive linear associations were found between coping (active and support seeking) and wellbeing, between coping (active and support seeking) and family support, and between family support and wellbeing ($r = .43, p < .01$). Using mediation analyses, results show that when family support was entered into the regression equation with active coping, family support was the only significant contributor to the relationship with wellbeing ($z = 2.25, p = .02$). Similarly, when family support was entered into the relationship with support seeking coping, only family support remained a significant contributor to the relationship with wellbeing ($z = 3.28, p = .00$). This study examined the extent that coping styles (active and support seeking) and family support account for wellbeing in high school students. Mediation analyses found the effect of either active coping strategies or support seeking coping strategies on wellbeing occurred as a result of the relations between each of the different coping strategies and family support. The results of this study highlight the importance of supportive family relationships to coping styles and as predictors of wellbeing in high school students.

Keywords: support-seeking, well-being, support, child and adolescent social support, children’s coping skills

Coping styles, affective responses and examination performance of university undergraduates
BRIGGS, E. (University of Southern Queensland),
TERRY, P. (University of Southern Queensland)

Previous research has shown that emotional intelligence has an indirect beneficial influence on exam performance among university students by reducing psychological distress and negative mood states. The present study sought to extend this line of investigation by assessing whether the coping styles of students also influenced the impact of affective responses on examination performance. A sample of 329 undergraduate students from an Australian university completed the Coping Orientation to Problems Experienced (Brief COPE) to establish coping styles. They then completed the Brunel Mood Scale (BRUMS) and the Depression, Anxiety and Stress Scale (DASS-21) on three occasions during a university semester to monitor affective responses. Examination performance at the end of semester was recorded. Affective responses showed that participants found university study to be stressful. They reported high levels of psychological distress throughout the semester, with mean values for all subscales above the ninetieth percentile. Similarly, mood responses were above the norm for negative mood dimensions. Exploratory factor analysis identified four coping factors, termed approach, avoidance, reframing and problem disengagement. Regression analysis showed that high scores for avoidance and problem disengagement predicted psychological distress and negative mood states over the three testing occasions. Psychological distress mediated relationships between coping styles and negative mood states at mid-semester and pre-examination. Coping styles and mood responses predicted examination performance, whereas psychological distress did not. Use of problem disengagement as a coping strategy was associated with poor exam performance, whereas higher mid-semester and pre-exam tension, higher pre-exam vigour, and higher mid-semester fatigue were all associated with good exam performance. Results showed that coping styles of university students predicted psychological distress, mood responses and exam performance during the course of a semester of study, and highlighted the negative effects of avoidance and problem disengagement coping. This raises the possibility of implementing programs for undergraduate students to encourage their use of adaptive rather than maladaptive coping strategies.

Coping with chronic life threatening illness: The Filipino adolescent’s experience

RAMOS, H. (IWHO, University of Nottingham Malaysia Campus)

This study looks into the process of coping for the Filipino adolescent with chronic life threatening illness. A chronic illness is defined as a “a condition that lasts for a substantial period of time or that has symptoms that are debilitating for a long period of time” (Perrin, 1985, p. 2). It often involves the presence of multiple physical and psychological symptoms that are highly pervasive and emotionally stressful (Squirres, et. Al 2002). The life of an adolescent is generally made more difficult by the need to balance the developmental demands of adolescence and the challenges brought about by the diagnosis of chronic life threatening illness. Using a multiple case study design, the study documented the experiences, hardships, and coping of 10 chronically ill adolescents aged 14-19 years with an illness duration that ranged from 4 months to 19 years as reflected on their own narratives based on in-depth interviews. Results indicated that chronic illness changed the world of the adolescent and made living a challenge. The reactions of the adolescents to their condition varied greatly from disbelief to active acceptance, to denial and resignation. The study highlights some uniquely Filipino ways of coping with chronic illness such as the use of insights, reflections and the instrumental role of families in helping these adolescents to find unique ways to cope with their health conditions and live enriched lives with, and not despite of, their illness.

Keywords: coping strategies, chronic illness, adolescence, Filipino, case study
Core concepts of Self: Therapeutic value and the development of an inventory for their measurement

BRABIN, P. (Monash University)

Some 30 years ago the self-esteem movement advocated the promotion of high self-esteem to replace the suffering of low self-esteem. This ‘movement’ has influenced policy and procedures in educational and parenting programs world-wide. Sadly, this has not led to the desired outcomes for ‘happiness’ in our current society. Instead, the rates of depression and suicide have increased several-fold.

Inspection of typical ‘self-esteem’ inventories indicates they usually measure an externally validated self-construct, expressing high levels of subjective control yet lacking the notion of an internally validated self-identity. While the construct of ‘self’ has been part of psychological theory since Freud and Kohut, empirical science has largely ignored a construct not readily observable. Karen Horney, however, did suggest a framework for analysis; self idealisation and its mirror image self hatred juxtaposed with their qualitatively different self realisation. Her work influenced Albert Ellis in his theory and application of Rational Emotive Behaviour Therapy. Although focussing on self-acceptance as a core component of the theory, Ellis failed explicitly to differentiate the core irrational self, Horney’s duo of self-idealisation and self-hatred, from the core rational self defined by self-realisation. Despite recognising the dynamic differentiation between these – living to prove oneself versus living to enjoy oneself – Ellis did not clearly articulate the risk of remaining subjectively bound within the self. This paper proposes a model which articulates and expands an objective concept of self, the internally validated OK self (who I am) and the value-laden duo, the Not-OK self (what I am) with its defensive reaction the Not-Not-OK self (what I should be) which emerges from attempts to prove that one is not Not-OK. This model describes numerous processes related to living an emotionally healthy life and clearly locates many common sources of distress, including personality disorder, providing a readily assimilated framework for case formulation in therapy. The development and preliminary data for a ‘self-valuing’ inventory designed to measure loadings on the subjective and objective constructs of the self is also presented, as a means of providing empirical data for this core therapeutic model.

Keywords: self-concept, self-esteem, self-valuing, inventories

Corporate performance and work stress of contact centers in Manila, Philippines

REYES, G. (University of Santo Tomas)

The booming contact center industry in the Philippines is characterized by intense, global competition with the goal of optimizing corporate performance. Contact center agents in this industry experience varying work stress levels caused by inherent and unique dynamics of the job. This investigation aimed to determine the relationship between Philippine contact centers’ corporate performance and their agents’ work stress levels. Descriptive-correlation method was used to measure the levels and analyze the relationship between the variables of this study. Specifically, corporate performance is evaluated using the profitability ratio analysis of financial statements of four selected contact center corporations in Manila, Philippines. Work stress of 257 rank-and-file contact center agents from the four selected contact centers were measured using the Job Stress Survey (JSS), a standardized psychological instrument developed by Spielberger and Vagg (1999). Four out of the five ratios (i.e. Return on Asset and Equity, Asset Turnover, and Net Profit Margin) indicate high profitability, as compared to global industry standards. Although there is no significant difference among corporate performance of the selected contact centers, Company D stands out as it is the only company that surpassed industry standards on all five profitability ratios. Company A is also notably profitable with the highest average of 0.80 in the five profitability ratios among other companies. Contact center agents are moderately stressed as indicated by the average JSS t-score of 59 while company-specific t-scores range from average to high work stress. Company A has the healthiest level and a moderate level of work stress while Company D has the highest and most unhealthy level. Pearson Correlation
results at 0.05 level of significance show that corporate performance is significantly and negatively correlated with work stress. Specifically, high corporate performance of contact centers is related to low and moderately stressed agents. The contact center agents who have healthy work stress levels tend to belong to highly profitable organizations while those with high and unhealthy work stress are associated with organizations which are not as profitable. The coefficient of determination also shows that work stress accounts for 5% to 26% of the variability in corporate performance, and vice versa. Therefore, sustained success of Philippine contact centers involves various salient business factors including healthy contact center agents who are motivated by moderate work stress. Moreover, improving the quality of work life of contact center agents may directly translate into better corporate performance.

Correlation research of urban residents’ lifestyle and physical fitness

MINGQIU, F. (Chongqing University of Posts and Telecommunications)

The aim was to research the correlation of Urban Residents’ Lifestyle and Physical Fitness. Two hundred urban residents were selected randomly who were twenty to fifty nine years old in Chongqing. A lifestyle questionnaire was used and 190 valid questionnaires were returned. The results were: 1) All the subjects’ average scores of physical fitness were more than 25, which is in the excellent level. For all subjects, the physical fitness scores of 40 to 49 and 50 to 59 years old were slightly lower, but the scores were between 22 and 23, which is in the good level. 2) The lifestyle scores of females were higher than those of the males. The group of 40 to 49 years olds had the highest scores, followed by the group of 50 to 59, 20 to 29 and 30 to 39 year olds; 3) There was a distinct correlation between physical fitness and lifestyle. Reaction time, which is one of the indicators of physical constitution, had a significant relationship with the use of drugs, alcohol and tobacco, life satisfaction, health habits and sexual life. Lung capacity, one of the indicators of body’s functional capacity, was significantly related to the use of drugs, tobacco and alcohol and health concept. In conclusion, 1) There was a distinct correlation between the action tropism of lifestyle and physical fitness; 2) There was distinct correlation between the height, weight of urban residents and work and sleeping; 3) There were distinct correlations among the lung capacity of urban residents, the use of substances, tobacco and alcohol health values; 4) There were distinct correlations among the reaction time, the use of substances, tobacco and alcohol, health habits, sexual life and life satisfaction; 5) This research pointed out the theoretic model to promote the adults’ physical fitness for the first time.

Keywords: urban residents’ lifestyle, life satisfaction, health habits, substance abuse, adults’ physical fitness

Cover story: Body image messages on the cover of popular Australian weekly magazines

BONGIORNO, L. (Deakin University), KING, R. (Deakin University)

Recent ethological theories of social anxiety have emphasized that social anxiety is related to perceptions of social rank. While a submissive type of social anxiety (cf. DSM-IV-TR) has been extensively studied, recent cluster analytic studies have identified a variation associated with dominant/aggressive, impulsive and disinhibited behaviours. Viewed through the lens of Personality Psychology, this type shares similarities with narcissistic personality. Therefore, the current study sought to explore the role of narcissism in social anxiety. In response to notices on social anxiety websites, 349 people completed a questionnaire. The questionnaire measured social anxiety (Social Interaction Anxiety Scale), narcissism (Narcissistic Personality Inventory), covert narcissism (Hypersensitive narcissism scale), narcissistic pathology (Narcissistic Personality Disorder scale), anger (Dimensions of Anger Reactions), Shame (Experience of Shame Scale) and Depression (Depression, Anxiety, Stress Scale). The sample was heterogeneous with 150 participants in North America, 141 in Europe, 40
in Australia/New Zealand, 10 in Asia, and seven in other regions. Ages ranged from 18 to 74. Cluster analysis of the data revealed the presence of five distinct social anxiety clusters. Subsequent multivariate analysis indicated that the groups significantly differed on social anxiety, narcissism and anger. On the basis of group differences in these variables, the groups were labelled: narcissistic social anxiety group (NSA), covert narcissistic social anxiety group (CNSA), angry covert narcissistic social anxiety group (AnCNSA), general social anxiety group (GSA) and low social anxiety group (LSA). In terms of social anxiety, the covert narcissistic groups were more impaired than the other groups. Additionally, all three social anxiety groups with narcissistic characteristics evinced higher scores on measures of depression and shame than the non-narcissistic social anxiety groups. The current results are consistent with Paul Gilbert’s ethological model of social anxiety. Viewed from this perspective, the narcissistic social anxiety groups can be characterised as individuals who have a perception of low social rank (high social anxiety) coupled with a desire for power, control and grandiosity (high narcissism) but feel unable to “challenge” those perceived to be dominant for fear of the interpersonal consequences of such a challenge. More broadly, the current results suggest that social anxiety is a broad and heterogeneous phenomenon, and that re-analysis of social anxiety using alternative theoretical paradigms (such as ethology) yields meaningful distinct variations of the disorder.

### Crisis and consumer behaviour: A pilot study in Spain

PRADO GASCO, V. J. (Universidad de Valencia), QUINTANILLA-PARDO, I. (University of Valencia)

The aim of the study was to describe the economic perception of Spain by Spanish people and to analyse the links between “crisis perception” and “consumer behaviour” and its influence in “hedonic balance”. The study sample comprised 50 households and participants completed the Satisfaction with Life Scale (Diener, Emmons, Larsen, & Griffin, 1984) and a four factor ad-hoc scale (“Economic Perception”, “Consumption”, “Purchasing Styles” and “Lifestyle”). The data was analysed using SPSS 16.0 and a range of statistical analyses were conducted including descriptive statistics, correlations, and non-parametric techniques. Most of the respondents state that the country is facing a crisis; however, they think that the economic situation has not changed by the crisis. On the other hand, respondents believe that their economic situation is slightly lower than in the currently overall country, although this perception is the opposite when considering the pre-crisis period. Moreover, respondents consider that changes in the overall evolution of consumption have not been significant except for leisure activities. Also, according to respondents, there have been no changes in most purchasing styles except for “prices and shops comparison”, “quality-price focus”, “purchase of second brands or generic” and “information increase before the shopping/buy”. In all these cases there has been an increase in those activities. Respondents affirm that the only changes that have occurred regarding to lifestyles are: a decrease in “going out” or “going out for a meal” and an increase in “home meals” and “extend the useful life of objects”. Regarding “hedonic balance” and “economic perceptions” it is not possible to conclude that exist a significant relations between them with our sample. Some variables may be modulating the effect of the crisis. Currently work is focused on expanding the sample with other different households and on controlling those variables.

**Keywords:** crisis perception, consumer behaviour, hedonic balance

### Cross-cultural adaptation of the U.S.A. students in China

YAN, W. (East China Normal University)

More and more international students are coming from the U.S.A. to China. There were 223,499 foreigners studying in China by the end of 2008, with students from the U.S.A. ranked second. The objectives of the current research were to understand students’ adaptation to situations and strategy in China, and explore the main factors influencing their psychological and
sociocultural adaptation, as well as how their adaptation influences their studying performance in China. International students from the U.S.A. who had studied in Shanghai (east China) or Chengdu (south-west China) for three months or more completed questionnaires (N = 65). The core variables were sociocultural adaptation, psychological adaptation and acculturation strategy. The antecedent variables were multicultural personality, cross-cultural communication self-efficacy and Chinese language competency, and the outcome variable was studying performance. The results showed that for acculturation strategy 58.5% of the sample adopted separation, 13.8% marginalization, 12.3% integration, and 7.7% assimilation. For adaptation, sociocultural (M = 3.94, SD = 0.55, 1-5 rating) and psychological adaptation (M = 3.69, SD = 0.56, 1-5 rating) was good, and for antecedent variables, two sub-dimensions of multicultural personality, openness and emotional stability and cross-cultural communication self-efficacy, were significantly positively correlated with both adaptation variables. For outcomes, two adaptation variables were significantly positively correlated with performance. Flexibility, emotional stability, cultural empathy, self-efficacy and Chinese language competency were the main factors influencing two adaptation variables, and these two variables influenced performance. The general trends of the current research were consistent with previous research about international students in other countries, but there were some differences. Although more than half of the students adopted separation strategy, most of them adapted well in China. Their choices of strategies were due to living and studying together with their conations in most situations. Social initiative, one sub-dimension of multicultural personality, did not show significant positive correlation with adaptation. The reason for this is not clear; however one possibility is that students perceived that Chinese culture did not emphasize social initiative. Future research may include more samples from other regions of China and qualitative research such as interviews can be used to gain specific information about students’ adaptation. Personal change can be included as one of the outcome variables.

Keywords: Cross-cultural adaptation, Multicultural personality, Sociocultural adaptation, Psychological adaptation, International students

Cross-cultural study on peer experience and loneliness of Chinese and American children

ZONGKUI, Z. (Hua Zhong Normal University), XIAOJUN, S. (Hua Zhong Normal University), YEH, H. (Memphis University), COHEN, B. (Memphis University)

Multiple mediating effects between peer experience and loneliness were investigated in this research among Chinese children. The influence of peer interaction on loneliness in the comprehensive ecological background (China & America) was also taken into consideration. Sociometric nomination and questionnaire method were applied in this study. Participants were 430 Chinese children and 165 American children in elementary school from grade four to six. The children completed Peer Nomination, Friendship Quality Questionnaire, Class Play, and Who am I?, in June 2005. Cross-cultural design was employed in the study. The data were mostly analyzed by t-test, SEM and MANOVA. The results of the study are as follows: (1) A significant correlation was found between peer experience and loneliness; (2) Chinese children get higher scores on friendship quality, while American children get higher scores on self-perceived social competence and loneliness; (3) Social behavior had an impact on loneliness through four different types of mediating path: (a) social behavior → social preference → self-perceived social competence → loneliness, (b) social behavior → friendship quality → self-perceived social competence → loneliness, (c) social behavior → friendship quality → loneliness, and (d) social behavior → self-perceived social competence → loneliness. There was only an indirect relationship between loneliness and social preference, and there were direct and indirect relations between loneliness and friendship quality. Self-perceived social competence was the most powerful predictor of loneliness. (4) The predictive power of friendship quality to self-perceived social competence; and self-perceived social competence to loneliness in China are greater than in American. The conclusions drawn from this study are as
follows: (1) Chinese children get higher scores on friendship quality while American children get higher scores on self-perceived social competence and loneliness; (2) there was no significant cultural difference on the functioning pattern between peer experience and loneliness; and (3) the predictive power of friendship quality to self-perceived social competence; and self-perceived social competence to loneliness in China are greater than those in America.

Cross-cultural validity of integrity testing: A tale of three banks

FINE, S. (Midot)

Integrity is universally considered to be a key requirement for a variety of jobs, and integrity tests have increasingly found their places in employee selection processes around the world as a result. Integrity tests are especially prevalent among financial institutions, where preventing Counterproductive Work Behaviors (CWB) is paramount. Despite consistent research describing the effectiveness of integrity tests for predicting CWB, very little data is available from non-American samples, and even fewer from cross-cultural comparisons. The present study, therefore, aims to provide contributing evidence towards a better understanding of the cross-cultural validity of integrity testing in general and the financial sector in particular. This study was based on data collected from 1,632 job applicants from three large financial institutions located on three continents: South America (29%), Asia (31%), and Eastern Europe (40%). All applicants were administered a commercially available integrity test as well as a CWB admissions survey as part of their selection processes. Significant test score differences were found across the groups, as expected considering the large cultural differences between them. However, no evidence of adverse impact for age or gender was found for any sample, which is critical for adhering to legal and international best practice standards. The operational validity for predicting CWB was significant overall ($r = -.30$), and was remarkably consistent across all three samples ($- .32 \leq r \leq - .30$). In addition, based on a derivation of the Brogden-Cronbach-Gleser utility model, the total monetary savings for these companies in using the integrity test for selection was estimated at more than $391,000 by preventing counterproductive behaviors. This study provides compelling evidence towards the effective use of integrity tests cross-culturally for personnel selection. The results support the validity generalization literature by showing successful transportability of validity across different settings, and attest to the relevance of integrity as a key job requirement cross culturally. Finally, the results of this study are believed to be of particular importance to the numerous organizations and practitioners using integrity tests internationally today.

Keywords: integrity, counterproductive work behaviour, cross-cultural personnel selection, predicting work behaviors, employee selection processes

Cultural activities and math literacy among Saoras in India: Learning as dialectic between self, meaning systems and boundary concepts in MLE Plus schools

PANDA, M.

Numerous artifacts, cultural concepts and practices mediate mathematics learning, both in the community and in school. At home, mathematical concepts, ideas and numbers are embedded in children’s everyday activities like play, shopping, making brew, cultivating, house making etc. Saora child, like any other child anywhere in the world, learns many mathematical concepts and ideas by engaging in these artifacts. In school, she finds the language (and, therefore, the cultural concepts) and the artifacts (such as textbooks, note books, games, measurement, writing using a specific convention) in mathematics and science class neither familiar nor comprehensible. In order to make learning meaningful, culturally relevant and worth engaging in, we intervened in four multilingual education (MLE) schools in Saora areas using the principles of CHAT (the third generation Cultural Historical Activity Theory as espoused by Engestrom and Cole, 1997). We call
this program MLE Plus since, along with using children’s language(s) in the classroom, we tried to create numerous contact points between Saora children and school mathematics discourse by allowing many boundary concepts to operate between Saora artifacts and cultural practices and school mathematical concepts/discourse through specially designed pedagogic practices. This paper discusses how the classroom discourse took the shape of many interlinked spirals and learning in these classrooms was more a byproduct of the dialectical relationship between Saora artifacts (like Saora number system, Saora folk games, make belief plays etc.), meaning systems, school mathematics concepts and the agencies of Saora children and teachers. We clearly chose a little more messy, chaotic but multi-voiced multimodal non-linear spiral discourse over a clean, clearly laid down linear discourse.

Keywords: mathematics, Saora, Cultural Historical Activity Theory, classroom discourse

Cultural influence on personal epistemology: Variations of epistemic beliefs of Thai university students

FUJIWARA, T. (Mahidol University International College)

The purpose of this study was to explore the cultural influence on personal epistemology through comparison of groups of students sharing the same culture except one aspect: type of secondary education. This study investigated the nature and dimensional structure of the beliefs about knowledge and knowledge acquisition held by Thai university students. It further examined whether their epistemic beliefs were significantly different among the groups of Thai students educated in different secondary educational systems. The participants of this study (N = 405) were recruited from undergraduate students studying in a Thai university. They were all Thai native speakers and of Thai nationality. The students completed a 39-item questionnaire, developed for this study from two versions of Schommer’s (1998) Epistemology Questionnaire. The participants were asked to indicate how they agreed or disagreed with the statements about domain-general epistemic beliefs given in the items in the measurement instrument. A five-factor structure was identified for the epistemic beliefs through a principal component analysis of the participants’ responses to the 39 items in the questionnaire. MANOVA identified a significant difference among the groups of students educated in different systems of secondary education in terms of two of the five identified factors. In addition, a significant difference was also identified between the two groups of students differing in their previous English language learning experience in terms of one of the five factors. Meanwhile, no significant difference was identified in terms of their epistemic beliefs between the groups of participants differing in the demographic variables, i.e. age, gender, and declared subject major. The results suggest that students might have different epistemic beliefs if they were educated previously in a different educational system, even if they all share the same cultural backgrounds, including the native language. Thus, it is likely that education could make an impact on personal epistemology, at least on the one that was measured in this study.

Keywords: personal epistemology, beliefs, epistemology questionnaire, epistemic beliefs, cultural influences

Customer orientation and type of organization: Impact on levels of achievement and control orientation of an organizational climate

VERGHESE, M. (MATS University), SINGH, P. (Pandit Ravishankar Shukla University), VERMA, O. P. (Pt. Ravishankar Shukla University)

The aim of this research was to analyze the differential effect of high/low customer orientation on the achievement and control orientation of organisational climate, and to see how the type of organization (public and private) effects the achievement and control orientation of organisational climate. About 500 employees of Public and Private Sector Banks of Chhattisgarh region, India, were requested to respond on a given scale for measuring their perception on prevailing levels of Customer Orientation in their banks along within its Organisational Climate. To measure Organization Climate, a comprehensive tool prepared and
developed by Udai Pareek (1997) was used called Motivational Analysis of Organisational-Climate (MAO-C). MAO-C was designed to study organisational climate, with special regards to motivation. To measure perceived customer orientation, a scale has was developed by the investigator. To test the significance of differences, the F-ratio was calculated. The results showed that the high customer oriented employees perceived their organization to be more ($M = 69.55$) achievement oriented compared to low customer oriented employees ($M = 64.05$). F-ratio was found to be significant ($F = 15.95$, $p = 0.01$), indicating a significant difference between the two groups with respect to their perception organizational climate. The obtained results showed that the high customer oriented employees perceived their organization as less control oriented ($M = 45.33$) compared to low customer orientation employees ($M = 53.33$). The F-value was found to be significant ($F = 23.29$, $p = 0.01$) indicating a significant difference in the two groups with respect to their perception of control dimension of organisational climate. The mean score of employees working in Private Sector Banks was found to be more on achievement dimension ($M = 73.81$) compared to the mean score of employees working in the Public Sector Banks ($M = 61.20$). It indicates that employees of private sector banks perceived the climate of their banks as more achievement oriented than employees of public sector banks. The F-ratio ($F = 73.48$, $p = 0.01$) was found to be significant. Findings in this regard indicate that the mean control score of private sector employees ($M = 42.20$) was less compared to private sector employees ($M = 55.04$). The F-value ($F = 36.04$, $p = 0.01$) was also found to be significant indicating thereby a significant difference between the two groups. In other words employees of public sector perceived their organization as more control oriented compared to private sector bank employees. The main finding of this research work is that the high customer orientated employees perceived their organization as more achievement oriented whilst low customer oriented employees perceived their organization as more control oriented. Similarly, private sector bank employees perceived their organizational climate as achievement oriented while public sector bank employees perceive their organizational climate as control oriented. High customer orientation leads to low control oriented climate.

Keywords: customer orientation, organisational climate, achievement orientation, control orientation, private sector bank employees

Cyberspace, interactive media and video games: The impact on psychological development and well being

CAMPOS, W. (Helplines Australia)

The aim of this research was to discuss how interactive technologies impact on a person’s relationships and emotional and social well-being. The new frontier of cyberspace, interactive media and video games, are increasingly mimicking real life experiences, which calls for a revision on how they are developed and legislated. The method will involve gathering qualitative evidence utilising video, media and case studies on the following: (1) Game developers, designing interactive environments to induce emotional responses and reactions; (2) Interactivity of cyberspace allows many services (including counselling) to take place in this environment, with little legislative framework to assist consumers; (3) Addictive behaviours relating to interactive devices, such as texting, social networking, interactive video games and multiplayer environments, (4) Educational and developmental issues that require stringent policies, regulations and legislations to guide and inform parents, protect children as well as providing health and safety guidance for consumers. Research on this area is emerging with a number of social and psychological studies show both positive and negative views on the uses of technology media. Presently however the body of research is inconclusive regarding the impact of interactive media has on children’s and adolescent’s development. There are emerging trends to indicate that utilising this media excessively can induce addictive behaviours impacting on persons’ social and emotional well being. There are also trends to indicate that a person’s social and economic well being is enhanced by utilising this technology. However the broader social context of how appropriately the interactive media to “fits in”
with people’s everyday lives is often overlooked as the technology presently being developed is increasingly being developed to engage and encroach on people’s lives. Technology has a number of uses that can enrich people’s well being which can most commonly be seen in the area of disability and rural and remote services. There are also increasing educational uses that can be immensely beneficial for parents, educators and service providers. However with a large proportion of this technology being utilized for entertainment and being increasingly developed to get people’s attention and evoke emotions there are a number of issues that psychologists should be addressing, including: (1) Developmentally appropriate content; (2) How the uses of technology impact on day to day life, and people’s perception of relationships and social and moral norms; (3) How does the technological environments impact on people’s ability to express themselves, be creative and freedom of speech, considering the diversity of people’s cultures, nationalities and communities; (4) People’s ability to trust and be emotionally engaged to the content; (5) How to assist societies, communities, people and individuals to contextualize (make sense) between real life and technological environments; (6) How does (or should) interactive media impact on the most profound human emotions, such as love, anger, trust, honesty. Social dynamics can impact on people at a personal level, for example, work-family time, privacy, confidentiality and cyberbullying. Some of the social and financial costs of using technology include the “technological inflation”, keeping up with the Jones’ and the have or have not mentality.

Keywords: interactive technologies, addictive behaviours, emotional well-being, social well-being, cyberbullying

David gNATenborough’s Island: A new computerised CBT game for children

O’REILLY, G. (University College Dublin), COYLE, D. (Trinity College Dublin), MCGLADE, N. (University College Dublin), DOHERTY, G. (Trinity College Dublin)

This oral presentation will describe David gNATenborough’s Island, a new six-session Cognitive Behavioural Therapy (CBT) programme for children delivered through a computer game. It is played by children in clinical sessions with their therapist. It delivers a CBT programme for the treatment of young people who experience anxiety and mood disorders. Core principals of a CBT intervention are taught to a young person by a computer character called David gNATenborough who presents the cognitive model for internalizing problems where Negative Automatic Thoughts are introduced as gNATs. In playing the game over six sessions the young person is taught thought monitoring (gNAT trapping), thought restructuring (gNAT swatting), and core belief appraisal and restructuring (following gNATs back to their hive). The PC game format and characterisation of CBT techniques makes the programme appealing and easily accessible for children. Preliminary results on the effectiveness of the programme with anxiety, mood and somatisation difficulties will be presented. David gNATennborough’s Island effectively combines interesting characters in a PC game world with direct intervention from a clinical psychologist to teach young people with internalizing difficulties how to benefit from CBT.

Keywords: cognitive behavioural therapy, anxiety, mood disorders, young people, internalizing difficulties

Dealing with diversity and dissent in cross-cultural virtual teams: Convergent qualitative and quantitative analysis

SEYR, S. (ETH Zurich), VOLLMER, A. (ETH Zurich)

Collaboration in a globalised environment implies specific requirements and possibilities. Increasing numbers of allocated teams are challenged with new communication forms and organisational and cultural differences. Because of the structural complexity and difficulty to reach this target group, they are seldom addressed in research studies. In order to fill this gap, two highly virtual operating teams from a Swiss engineering company, with collaboration partners in Croatia and India, have been studied for over 12 months. To identify when diversity emerges and how it is dealt with in allocated collaboration, we used a multi-method approach. In the first step, expert interviews
with 17 project leaders and key project team members took place. Summative analysis identified foci for further research: management of dissent against the background of cultural differences, mutual learning for process and organisational improvement, and communication climate and tools in use. In the following phase we conducted guideline-based interviews with 16 experienced team members from the three respective locations. Confirmatory analysis displays the assumed differences in culture, communication, and conflict management, and provides opportunities for mutual learning. Similarity is found regarding the preference of face-to-face communication whenever possible and getting to know the other members personally to overcome cultural differences. In the final step, 15 allocated team members of ongoing virtual projects completed a total of 30 event-based questionnaires each time a communication event took place within a defined period. Correlation analysis identifies specific situations where differences and dissent emerge. The perception of the communication climate and conflicts relates to the character of the communication event, such as intention, structure and complexity of content. The results are currently brought together and practical suggestions for structuring collaboration in virtual projects are made. Strengths and limitations of our approach will be discussed as well as implications for further research. The results may affect conflict management in cross-cultural cooperation.

**Keywords:** collaboration, virtual operating teams, cross-cultural issues, communication

### Decision-making and egalitarianism in Chinese young children

Human social interaction is strongly shaped by other-regarding preferences. These preferences are important for a unique aspect of human sociality – large scale cooperation with genetic strangers – but little is known about their developmental roots. Ernst Fehr’s research published in *Nature* (2008) showed that young children’s other-regarding preferences indicated that human egalitarianism and parochialism have deep developmental roots and the simultaneous emergence of altruistic sharing and parochialism during childhood. Ernst Fehr believed the results were perfectly interpreted by the evolutionary theories. However, we highly doubted the universality of the conclusions and explanations so we replicated the experiments using the same designs and methods to investigate the egalitarianism and decision-making in Chinese young children. We recruited 243 young children (aged 4-8 years) from a kindergarten and a primary school in China for our experiments so as to learn about the development about Chinese children’s concepts of fair, generous and other-regarding preference. We also analyzed the reasons for the differences of cognitive egalitarianism. Each child played the pro-social game, the envy game and the sharing game against anonymous partners. The partners came either from the in-group or from an out-group. Results show that the concepts of sharing fairly and altruism have emerged to some degree between the ages of 4 and 8. In addition, Chinese young children’s other-regarding preferences assume fairness that develops strongly between the ages of 4 and 8. Moreover, fairness is strongly shaped by parochialism, a preference for favouring the members of one’s own social group. The results above are identical to Fehr’s; however, Chinese children show significant differences to western children in some aspects. In a contrary direction, parochial egalitarianism emerges more frequently in Chinese boys than Chinese girls. Fehr’s conclusion and explanation about differences in gender in the view of the evolutionary theories cannot apply to the results above at all. These results indicate human egalitarianism and parochialism do have deep developmental roots, but the universality of the evolutionary theories concerning egalitarianism’s development in young children must be scrutinized in the context of multi-cultures with discretion.

**Keywords:** other-regarding preferences, young people, cultural diversity

### Deepening the in-depth interview: A case study of the athlete-to-coach transition
using conversations and projective data gathering techniques

KAVANAGH, T. (Victoria University), ANDERSON, M. (Victoria University)

The aims of the current study were: (1) to construct an in-depth picture of one individual’s transition from athlete to coach in an attempt to learn more about relocation within sport after athletic retirement; and (2) to determine if the Athlete Apperception Technique (AAT; Gibbs, 2006) could elicit material that complemented, illuminated, and added to the information gathered from the in-depth interview, and help provide a more complete picture of the lived experience. This research used a qualitative approach to explore the transition experience of a retired tennis player who became a coach. The participant’s story was collected using an in-depth semi-structured interview and is presented as a case study. The AAT, which is a projective technique designed specifically for athletes, was also administered. This tool is designed to tap into athletes’ personality features, relationships, anxieties, motivations, perfectionism, and so forth at the conscious and subconscious levels. It involves presenting athletes with ten ambiguous images relating to different sport situations. Athletes are asked to create stories based on the images, and their responses are analysed using sport psychology and psychodynamic formulations and interpretations. The data collected from the AAT were used to complement and add to the participant’s in-depth interview. The information collected from the interview shed light on the athlete-to-coach transition, and highlighted the messiness and complexity of the lived experience. The participant’s responses to the AAT images complemented, clarified, and added to the in-depth interview, and allowed a greater, and clearer, understanding of the athlete-to-coach journey. The AAT is an exciting tool and might be a useful technique that sport researchers and practitioners could use to access processes that are not easily studied using common data collection methods.

Keywords: athletes, coaching, sport, athlete apperception technique, qualitative

Deliberate self-harm, childhood trauma and dissociation in a homeless sample

MORRIS, C. (Deakin University), MILDRED, H. (Deakin University)

Childhood trauma (CT) is assumed to play a role in the development of both dissociation and deliberate self-harm (DSH), although conjecture exists regarding the impact of different types of trauma. The purpose of this study was to investigate the extent and association of DSH, CT, dissociation and substance abuse in a homeless population, as well as to examine the relationship between DSH, types of CT and dissociation in more detail. Eighty homeless participants who presented to a housing service completed a questionnaire comprising housing and demographic questions, as well as a variety of standardized measures investigating childhood trauma, dissociation and deliberate self-harm. Due to extreme skew in some variables, data were analysed using non-parametric testing and logistic regression. Results identified high rates of pathology across the range of measures used, when compared with community sample scores. Positive associations were found between, DSH, dissociation, drug abuse, emotional abuse, physical abuse, emotional neglect and physical neglect. No such associations were found between DSH and sexual abuse, alcohol use, or length of homelessness. When comparing individuals who did, with those who did not report DSH, similarly there were significant differences identified between groups for all variables except sexual abuse, alcohol abuse or length of homelessness. Dissociation and physical abuse emerged as strong predictors of DSH in this sample, particularly when comparing those who reported no DSH with and those who are, or have been, frequent self-harmers. In conclusion, results serve as a reminder that homeless people are a very vulnerable group along a range of physical and psychological dimensions. Service providers working with the homeless may need to be more proactive both in identifying, and assisting interested individuals to link with psychological support as well as accommodation services where such histories and behaviours are present.
Dentistry and design: An interprofessional online learning program in oral health promotion

HOWE, E. (University of Sydney), SCHNABEL, M. (Chinese University of Hong Kong), LOPEZ, A. (University of Sydney)

Dental caries is the most prominent chronic disease affecting oral and systemic health. It is preventable but nevertheless presents as a global pandemic affecting all age groups, despite measures for its prevention being known and available for decades. Key factors in the failure of oral health promotion campaigns have been poor understanding of the relevance of oral health literacy and the tendency to define literacy without reference to semiotics or other visual design components. The interprofessional dentistry/design project aims to teach students the skills required for successful promotion of community oral health in published media. Dentistry and design students collaborated to devise solutions to the problem: how can the message “Tooth decay can be stopped, reversed and prevented” be communicated effectively to various target community audiences (parents, children, adolescents, ethnic groups, etc). The groups were required to design promotional products (brochures, booklets, games, PowerPoints) for use by health educators. In 2009, the project was expanded as a virtual interprofessional collaboration, Hong Kong architecture students acting as design consultants to Australian dentistry students. Promotional designs were presented in virtual seminars and evaluated in terms of health evidence (community dentistry) communication (behavioural sciences) and design competence (architecture) by both experts and students. Results of student focus group evaluation were analyzed using N-Vivo. Sixty-six promotion programs, of quality suitable for publication as determined by the two teaching faculties, were developed and used during Australia’s Oral Health Awareness Week. Students reported confidence in learning design skills and understanding audience demographics and text literacy. Although they found self-directed learning motivated effort, they requested allocated communication time with international consultants and assistance with occasional problems of group dynamics. The interprofessional online learning project is an authentic action-based learning program which successfully enables dental students to understand and use graphic media effectively in oral health promotion.

Depressive symptoms in university: A cross-sectional study with Portuguese Students

SANTOS, M. L. (University of Aveiro), PEREIRA, A. (University of Aveiro), VEIGA, F. (University of Lisbon), KHAWAJA, N. (Queensland University of Technology)

Depression is one of the most common and devastating mental health problems among higher education students. The aim of the present study was to assess depression levels and to investigate the association of socio-demographic variables with depressive symptoms in Portuguese university students. A total of 666 subjects completed the Portuguese version of University Student Depression Inventory (USDI; Khawaja & Bryden, 2006) and answered a group of questions regarding socio-demographic data. Statistical analysis consisted mainly of mean comparisons between groups and correlations. The results showed that 11% of students suffered from mild levels of depression and 4% of moderate or severe levels. When demographic factors were considered, females presented more depressive symptoms than men. No differences were found between those who left home and those still at home or between first year and following year students. A negative association between the perception of academic achievement and depressive symptoms was found. These findings may help define vulnerable groups and therefore guide the development of prevention and mental health promotion initiatives in campuses.
In the field of nursing for the elderly empathy is one key issue for optimal service quality. However, too much of it constitutes an intense emotional burden for helpers. Helping relationships are characterized by high emotional demands, which play an important role in developing burnout (Maslach, 1978, 1982). Detachment might be an important factor in dealing with these emotional stressors. Yet too much emotional distance has negative consequences for performing effectively in the job. A sense of Detached Concern (Lief & Fox, 1963) is required, which means a professional balanced attitude at work with clients characterized by emotional distance on the one hand and genuine concern on the other hand. Up to date rarely any empirical support for the relationship between Detached Concern and burnout as well as workers` well-being is available, in spite of the theoretical fact that Detached Concern is described as a meaningful coping strategy (Le Blanc et al., 2007; Maslach, 1978, 1993; Maslach, Schaufeli & Leiter, 2001; Schaufeli & Enzmann, 1998). Based on theoretical considerations and results of 16 qualitative interviews, a scale was designed to measure Detached Concern because established instruments do not exist. Three hundred and ninety-one employees in elderly care were surveyed using self-reported questionnaires. The psychometric quality of the generated scale was examined. Exploratory and confirmatory factor analyses were conducted for the factor structure. Path diagrams and one-way ANOVAs were applied to investigate the relationship of Detached Concern and burnout. First results show very good reliability and construct validity of the generated scale. Exploratory analyses indicated two factors. Confirmatory analyses supported the two-factor-structure. Based on different levels of Detachment and Concern four types of Detached Concern were derived. Successful Detached Concern was associated with significantly lower levels of exhaustion and depersonalization, significantly higher levels of personal accomplishment and significantly better health-indicators. Presented first results indicate the significance of Detached Concern in the context of burnout. More research into the concept of Detached Concern could be worthwhile and have practical value for preventing people in human service professions from falling victim to chronic emotional burden.

Keywords: Burnout, Emotional burden, Elderly empathy, Helpers, Detached concern

Developing argument evaluation skills with the Reason!Able software in senior psychology students

CÁZARES, A. (Universidad Pedagógica Nacional)

The aim of the study was to develop in psychology undergraduate students abilities related to argument evaluation, one of the most valuable critical thinking skills (CTS) in sciences such as Psychology. Participants were 50 senior psychology students from two research seminars related to special education in educational psychology. Participants completed Argument Evaluation Test (Version CT7; Stanovich, K. E., & West, R. F., 1997). This test contains 23 statements about informal arguments that students must to answer using a four-point Likert scale. It also contains the Evaluation of Counter-Arguments Questionnaire, which measures the ability to evaluate counter-arguments. Participants also used the stand-alone Windows-based program, Reason!Able. In this program, students are guided through the complex processes involved in representing and evaluating reasoning on any topic. The program covers two abilities: critical evaluation and argument production (Gelder, 2001). The current study was based on an explicative study founded in an experimental design. Participants were allocated to one of two groups (25 per group). The experimental group was trained to use the Reason!Able software and used the program while they worked on their thesis projects within a special education seminar. They were asked to argument and critically evaluate different topics covered in the special education needs subject as well as the research problems and objectives related to their dissertations. The control group did not use the software. Both groups completed the Argument Evaluation Test at the beginning and the end of the semester. Cronbach’s alpha coefficients were obtained for both scales in the instrument,
Arguments (.75) and Counter-Arguments (.79). An independent samples t-test showed no significant statistical differences between means ($p \leq .134$) for both groups, experimental and control, in the pre-test. An independent samples t-test for shows significant differences between means ($p \leq .001$) for both groups, experimental and control, in the post-test. Working with Reason!Able software for one semester helped to develop arguments evaluation skills in senior students while they were using the program to evaluate their own dissertation arguments.

Keywords: argument evaluation, critical thinking, reasoning

Development and application of a class-related academic emotions questionnaire for college students

MA, H. (Tianjin Normal University), LU, Y. (Tianjin Normal University)

The aim of this research was to develop a Class-related Academic Emotions Questionnaire (CAEQ) for college students, and to research the class-related academic emotions’ characteristics of college students. The method combined theory with job analysis to develop a questionnaire, and the questionnaire was used with 585 college students (319 males and 266 females). A self-report instrument measuring college students’ enjoyment, pride, hope, relief, anger, anxiety, shame, hopelessness and boredom was developed. The Cronbach α coefficients and test-retest stability coefficients of the sub-tests ranged from 0.61 to 0.82 and 0.50 to 0.79. Confirmatory factor analysis showed that the questionnaire had good construct validity ($RMSEA = 0.068; NNFI = 0.92; CFI = 0.93$). Correlations of sub-tests as well as with the Positive / Negative Affect Scale were moderately correlated. Through surveying 585 college students, this study explored the characteristics of class-related academic emotions of college students. The results showed that the means of seven sub-tests (except for anxiety and anger) were greater than the theoretical mid-value and the top four were positive emotions. In addition, significant effects of gender, grade and major in college students were found. Boys experienced more anxiety and boredom and less relief than girls. Students in Grade One experienced more positive emotion than other grades; students in Grade Two experienced more negative emotion than other grades. Arts students had more positive emotion and less negative emotion than the specialties of Science, Engineering and Technology students. The CAEQ developed in the present study attained acceptable psychometric properties. College students experience diverse emotions in their academic career. Positive emotions were the major class-related academic emotion in Chinese college students.

Keywords: positive emotion, negative emotion, class-related academic emotions, positive/negative affect scale, gender

Development and validation of the Child Behaviour Assessment Instrument (CBAI)

SAMARAKKODY, D. (Monash University Accident Research Centre), FERNANDO, D. (University of Colombo), PERERA, H. (University of Colombo), MCCLURE, R. (Monash University Accident Research Centre), DE SILVA, H. (Department of Health)

Behavioural abnormalities of children have grown to epidemic proportions and create a larger social and economic burden to society. Young children with behavioural problems are at a greater risk of developing psychiatric disorders in later life. These disorders have a good prognosis if treated at the onset and therefore should be identified early and referred for appropriate care. The aim of this study was to develop and validate a screening instrument to identify behavioural abnormalities of children aged 4 to 6 years in the community. Following systematic review of literature, 54 variables were identified. Three round Delphi technique was used to reach consensus in a panel of experts. Experts included paediatricians, child psychiatrists, child psychologists, community physicians, policy makers and service providers for children with behaviour abnormalities. The criterion validity and construct validity of the developed instrument was assessed in a community sample of 332 children aged 4 to 6 years. The reliability of the instrument was assessed by test-retest method and internal consistency analysis. Child Behaviour
Assessment Instrument (CBAI) containing 15 items was developed following the Delphi technique. The scoring method for CBAI based on the frequency of the problem behaviour, resulted in an area under the Receiving Operating Characteristic curve of 0.94 (95% Confidence Interval is 0.92-0.96). At cutoff of greater than or equal to 16, the sensitivity of CBAI is 88.52% and specificity is 81.54%. The mean score of children with behavioural abnormalities (21.37) was significantly higher than that of children with normal behaviour (7.040). The Cronbach’s alpha exceeded Nunnally’s criterion of 0.7 for items related to inattention, aggression and impaired social interaction. The Child Behaviour Assessment Instrument is a valid and reliable screening instrument to identify behavioural abnormalities of children aged 4 to 6 years in the community.

Keywords: community screening, behavioural abnormalities, child prognosis, child psychology, child assessment

Development of a formal examination of clinical psychology knowledge and skills

HELMES, E. (James Cook University), PACHANA, N. (University of Queensland), O’DONOVAN, A. (Griffith University), MURRAY, G. (Swinburne University), SOFRANOFF, K. (University of Queensland), BAILLIE, A. (Macquarie University), KYRIOS, M. (Swinburne University)

Clinical training in psychology is in transition in Australia. The current system of a four-year undergraduate degree with two years of supervised practice permitting practice is transitioning towards one in which two years of formal training together with supervised practice and research will become standard. As part of the process of moving towards national registration of professional psychologists, a formal examination has been proposed for those graduates without at least a Master’s level qualification to join the Australian Psychological Society’s College of Clinical Psychologists, so that their experience can be recognised. Here we describe the format and developmental stages of this examination. The College of Clinical Psychologists of the Australian Psychological Society tendered for the development of a competency-based examination as part of the process of alternative entry to the College. A consortium from five universities is in the process of developing this examination to comprise three components. A written examination will evaluate knowledge of the field; a second stage will assess complex case formulation, treatment planning, and higher-level analytic skills related to case management in its cultural and ethical context; a third in-vivo examination assesses applicants through a series of examination “stations” to evaluate the broad range of skills required for competent practice as a clinical psychologist, including assessment, formulation, treatment, process and ethical practice domains. The overall framework is based upon competencies in the domains of Theories and Knowledge, Assessment, Interventions, Research and Evaluation, Professional Practice and Non-psychological Components. A pool of multiple-choice items was derived from several sources, including existing item pools from commercial sources and teaching programs of the consortium. Case vignettes for the second and third stages were again derived from several sources, including existing teaching material and cases from the consortium’s teaching clinics. A complex examination process has been developed in response to the request for a measure to evaluate critical clinical competencies of individuals’ educational backgrounds that are not equivalent to conventional clinical training. Procedures planned to evaluate the validity of the examination include formal content analysis, together with criterion validity studies using graduates and senior students of existing training programs.

Keywords: clinical training, competency-based examination, psychology qualifications in Australia, entrance examination for Clinical College membership, competency domains of psychologists

Development of a Male Masking Behaviour Scale (MMBS)

GARGIULO, R. A. (Deakin University), WALKER, A. (Deakin University)

An existing body of literature (Brownhill, 2003; Cochran & Rabinowitz, 2000; Rutz, 1999) argues that gender differences exist in the way depressive symptoms are expressed, managed
and controlled. Conventional assessments of depression do not seem to target behavioral issues specific to men and as a result the extent to which these measures can specify gender differences in depressive symptoms is questionable. A review of the literature identified only one gender sensitive measure, but this measure was developed with a European sample, and has not been tested in an Australian context. The aim of the present study was to develop and validate a male masking behaviour scale that could indicate depressive symptoms in men. The development of the Male Masking Behaviour Scale (MMBS) was conducted in two phases. In Phase One, 101 items were generated based on seven categories identified in the literature. These items were assessed by a small group of Psychology experts (N = 36) to establish content and face validity. In phase two, the items were further refined and validated against other measures of depression such as the Depression, Anxiety and Stress Scale (DASS) and the Mini Mood and Anxiety Symptom Questionnaire (Mini MASQ) with 143 participants from the general population. A four factor structure obtained by a factor analysis of the data and the overall MMBS were found to have good reliability Alphas. Convergent validity of the MMBS was established with significant correlations between the MMBS, the DASS and the MiniMASQ. The results of this study did not support the seven broad categories initially identified in the literature (Brownhill, 2003; Cochran & Rabinowitz, 2000; Rutz, 1999). In examining the four factor structure of the MMBS it is evident that the seven categories have been collapsed into four factors measuring male masking behaviours. This study constitutes a first step, suggesting evidence of the construct validity of the MMBS. Further studies could validate the MMBS using a clinical sample and other cultural groups.

Keywords: depression, male masking behaviour, anxiety, assessment of depression

Development of gender personality in Japanese adults

KATSURADA, E. (Kwansei Gakuin University), SUGIHARA, Y. (Los Angeles County Department of Mental Health)

The aim of the present study is to investigate the development of gender personality in Japan. Participants include 768 Japanese adults (339 males and 427 females). The participants were divided into three age groups: young adults (20 to 25 years old; 77 males and 114 female university students), adults (25 to 46 years old: 198 mothers with young children), and older adults (57 to 81 years old: 262 males and 115 females). The participants were asked to fill out the Japanese Gender Role Index consisting of ten masculine and ten feminine items with ten non-gender items. There is no significant gender difference between young males and young females, whereas significant differences were found in both masculinity, \( t(df = 357) = 4.60, p < .001 \), and femininity, \( t(df = 351) = 5.25, p < .001 \), between older males and older females. Examinations of generational differences showed that male older adults scored significantly higher than young adults in both masculinity, \( t(df = 329) = 12.57, p < .001 \), and femininity, \( t(df = 324) = 14.36, p < .001 \), whereas female young adults scored significantly lower than adults and older adults in both masculinity, \( F(2, 414) = 35.78, p < .001 \), and femininity, \( F(2, 413) = 81.58, p < .001 \). The results of the present study are consistent with Block’s model (1973) which postulates the association between personal maturity and the integration of masculine and feminine personality traits.

Keywords: Japanese, masculinity, gender personality, personal maturity, generational differences

Development of the test of Chinese employees’ competency in private and foreign enterprise

XU, J. P. (Beijing Normal University), YANG, M. (Beijing Normal University), WU, L. (Beijing Normal University), TAN, X. Y. (Beijing Normal University)

The purpose of this study is to develop a test of general employees’ competency in private and foreign enterprise based on the competency model on technical, financial, marketing, administrative, service and managerial employees in private and foreign enterprise. The test of general employees’ competency in private and foreign enterprise was developed based on the competency model, which was...
conducted using document analysis. One thousand and sixty employees of private and foreign enterprise from different part of the country were assessed by the test. The test was composed of 105 items and 21 sub-scales, which were respectively named as communication skills, achievement oriented, learning capacity, client oriented, self-confidence, conscientiousness, initiative, professional dedication, ability to analyze and judge, ability to reason and abstract, integrity, innovation, relation establishing, influence power, insight into interpersonal relationship, organizing and coordinating ability, team work spirit, encouraging capacity, executive ability, planning capacity and so on. Reliability analyses, confirmatory factor analyses and correlation analyses showed the reliability and validity of the scale achieved the psychometric criterion. The difference of the test scores between excellent performance group and common performance group was significant. The reliability and validity of the test are strongly supported. The test could be effective to identify excellent employees and could be an effective tool for staff selection, training and performance appraisal.

Keywords: staff selection, employee competency, group performance, staff training, performance appraisal

Diagnostic accuracy of the Child Behavior Checklist for externalizing and internalizing disorders in Asian children and adolescents

SEAH, S. L. (Nanyang Technological University), ANG, R. (Nanyang Technological University), FUNG, D. S. S. (Institute of Mental Health), OOI, Y. P. (Institute of Mental Health)

Recent research advocates an integration of categorical and dimensional approaches, and a multi-informant approach, to the diagnosis of childhood mental disorders. In view of this, the present study sought to examine the diagnostic accuracy of Achenbach’s parent-rated Child Behavior Checklist (CBCL) for clinician-diagnosed externalizing and internalizing psychopathology, as well as for specific childhood mental disorders, namely Attention-Deficit/Hyperactivity Disorder (ADHD), Oppositional Defiant Disorder/Conduct Disorder (ODD/CD), anxiety disorders and depression. Upon receiving ethics approval, cross-sectional data was obtained from case files of 1,000 Singaporean children and adolescents who received treatment at a mental health institution in Singapore. These children range from 4 to 18 years of age. Using data gathered from completed CBCL forms, two broad-band scales (Externalizing and Internalizing) and three narrow-band syndrome scales (Attention Problems, Delinquent Behavior, and Anxious/Depressed) were selected for analysis. On a broad-band level, CBCL Externalizing and Internalizing scales were shown to differentially predict clinician-diagnosed externalizing and internalizing disorders respectively. On a narrow-band level, CBCL Attention Problems, Delinquent Behavior, and Anxious/Depressed scales differentially predicted ADHD, ODD/CD, anxiety disorders and depression respectively. In demonstrating the diagnostic accuracy of the CBCL, study findings illustrate that parent-rated CBCL scales possess the ability to discriminate among various clinician-diagnosed disorders. This supports a multi-informant approach to clinical diagnosis, which involves not only clinicians, but also parents and others who interact frequently with the child and are able to provide important perspectives on the child’s behavioral and emotional problems. Additionally, results suggest that a dimensional approach to clinical diagnosis complements a categorical approach as the former provides valuable insight into the severity of a child’s problems. Diagnostic accuracy of the CBCL on both broad-band and narrow-band levels also support the reliability and robustness of the CBCL as a rating scale in its totality.

Keywords: diagnosis of childhood mental disorders, externalizing and internalizing psychopathology, attention deficit hyperactivity disorder, dimensional approach to clinical diagnosis, Achenbach’s parent-rated Child Behavior Checklist

Dialectic behaviour therapy (DBT) with torture and trauma clients at The New South Wales Service for the Treatment and Rehabilitation of Torture and Trauma Survivors (STARTTS): A case study
This case study elaborates on Dialectical Behaviour Therapy (DBT) that was implemented in a treatment of a female client from Sierra Leone who had been experiencing symptoms of Post Traumatic Stress Disorder (PTSD) and dealing with suicidal thoughts. Treatment was conducted at the New South Wales, Service for the Treatment and Rehabilitation of Torture and Trauma Survivors (STARTTS). The assessment included Harvard (PTSD 2.20) and Hopkins (Anxiety 3.80, Depression 2.53) Checklists and PTSD (3.00) questionnaire. As the client was highly symptomatic, DBT was utilized in order to reduce the symptoms and improve her mental health condition. DBT has a number of distinctive defining characteristics. As its name suggests, its overriding characteristic is an emphasis on "dialectics" - that is, the reconciliation of opposites in a continual process of synthesis. The most fundamental dialectic is the necessity of accepting the client just as she is within a context of trying to teach her to change. The assessment included Harvard (PTSD 2.20 reduced to 0.80) and Hopkins (Anxiety 3.80 reduced to 0.50, Depression 2.53 reduced to 0.40) Checklists and PTSD (3.00 reduced to 0.20) questionnaire. DBT has been utilised in a form of cognitive-behavioural therapy, in order to help the client to learn problem-solving techniques for dealing with stressful experiences in her life. It appeared important for the client to improve social skills and control anger and depression. As the client experienced multiple psychological, physical and sexual traumas and losses in her country of origin, her Autonomic Nervous System (ANS) reacted excessively to stressful stimuli and it took her a long time to achieve homeostasis. DBT helped the client address multiple traumas and suicidal thoughts by utilising the following DBT aspects: a) Mindfulness, b) Emotional Regulation, c) Distress Tolerance, and d) Interpersonal Relationships.

Keywords: torture survivors, dialectical behaviour therapy, multiple trauma, trauma

Dialysis patients' self-esteem and social anxiety

The great progress that has been made in the application of dialysis lets patients with end-stage renal disease live in satisfactory somatic states for many years. Patients' well-being becomes a raised question more and more often. The main aim of the presented study was to compare self-esteem and social functioning of dialysis patients to people from general population. The study was a randomized controlled trial using a convenience sample of 102 fully informed and consenting patients with end-stage renal disease and 102 people from general population. The instruments comprised of the Self-Esteem Inventory and Social Contact Inventory. The results show that there are differences between dialysis patients and the general population in the case of Physical Self-esteem and Acting/Task Self-esteem. Dialysis patients’ Physical Self-esteem ($M = 10.26$) is lower than healthy peoples’ Physical Self-esteem ($M = 13$); $t(101) = -5.56$, $p < .001$. Dialysis patients’ Acting/Task Self-esteem ($M = 19.87$) is lower than healthy peoples’ Acting/Task Self-esteem ($M = 21.55$); $t(101) = -2.89$, $p = .004$. There are not any differences in case of Social Self-esteem ($t(101) = .30$, $p = .77$) and Emotional Self-esteem ($t(101) = .38$, $p = .71$). There is not any difference in the case of Social Anxiety ($t(101) = -1.27$, $p = .21$). On the basis of the presented study it is possible to claim that there are some differences between dialysis patients and general population as far as self-esteem is concerned. There is no difference in case of social anxiety. This research shows that dialysis patients need some psychological support, but generally their social adjustment level is quite good.

Keywords: well-being, self-esteem, social functioning, dialysis patients, somatic state

Differences between Chinese and New Zealand Students: The impact of the statistical method

SHULRUF, B. (University of Auckland), ZENG, M. (Hong Kong University), WATKINS, D. (Hong Kong University), HONG, F. (Nanjing University)
The aim of this research was to compare the impact of statistical techniques on measurements of Collectivism and Individualism. Attributes of Collectivism and Individualism (using the Auckland Individualism and Collectivism Scale) were compared across undergraduate students from Mainland China ($n = 172$) and New Zealand ($n = 210$). Two statistical techniques (T-Test and k-mean cluster analysis) were used to compare the samples and establish the differences in the results. The mean scores on both Collectivism and Individualism of the Chinese sample were lower than those of the European New Zealanders (3.35 versus 3.94 and 3.47 versus 4.33 accordingly, $p < .001$). This result does not indicate which population is more collectivist or individualist than the other. The k-mean cluster analysis found that among the Chinese sample, 41% identified as collectivist and 24% were individualist whereas among the New Zealanders, 37% were individualist and 22% were collectivist ($p < .0001$). It is noteworthy that among the Chinese 30% had high scores and 5% had low scores on both collectivism and individualism whereas among the New Zealanders this trend was reversed (4% and 37% respectively). In conclusion, cluster analysis may provide important information which cannot be yielded from t-tests when psychological attributes (in this case within cultural contexts) are compared across different populations, particularly when the measures are constructed by more than one factor/domain. Cluster analysis may provide some mitigation for biases relating to culture and/or language differences, for example, the tendency to use the low or the high end of the scale.

**Keywords:** collectivism, individualism, psychological attributes, cultural context, cluster analysis

**Differences between values and behaviors among diverse undergraduate students**

MURRAY, K. (San Diego State University), KلونOFF, E. (SDSU/UCSD Cancer Disparities Partnership), GARCINI, L. (SDSU/UCSD Cancer Disparities Partnership), BARNACK-TAVLARIS, J. (SDSU/UCSD Cancer Disparities Partnership)

Studies have highlighted differences in the reports of values and behaviours across cultures, with studies of acculturation frequently exploring how those values and behaviours change over time when people enter a new cultural context. As values and behaviours change, particularly across generations, dissonance may arise as there are discrepancies between self-reported values and behaviours. The current study examines how differences between ratings of values and behaviours contribute to psychological distress in a sample of diverse young adults. The current study surveyed undergraduate university students (840 females, 328 males) with a mean age of 18.9 ($SD = 2.3$) and included 714 Whites, 196 Asian-Americans, 172 Latinos, and 84 African-Americans. Participants completed Matsumoto’s Individualism-Collectivism Interpersonal Assessment Inventory (ICIAI) and the 58-item Hopkins Symptom Checklist (HSCL) along with demographic information and reports of discrimination in the past year on the General Ethnic Discrimination (GED) scale. Difference scores were calculated to assess discrepancies in individual ratings of their values and behaviours with family members on the 19 items on the ICIAI and four subscales (social harmony, social identification, self-control, and social sharing of recognition). There were significant group differences for all subscales on the ICIAI, except for the behavioural self-control subscale; with Asian-American students consistently reporting higher scores (greater collectivism) for each of the subscales. Regression analyses controlling for age ($b = -.863$, $p<.05$), gender ($b = -5.760$, $p<.01$), and reports of discrimination in the past year ($b = .633$, $p<.001$), found that differences between self-reported values and behaviours on the ICIAI significantly predicted ($b = .446$, $p<.001$) total scores of symptomatology on the HSCL-58. The current findings replicate prior research which has found cross-cultural differences in reports of values and behaviours. Moreover, it underscores the importance of dissonance among young adults, during an important time of identity development and has implications for future research on intergenerational conflict and the processes of acculturation. Discussion of the limitations of the research and recommendations for further inquiry is provided.

**Keywords:** values, psychological distress, acculturation, young people
Differences in Japanese mothers' touch by nurturing scene: Focusing on playing, crying, feeding and putting infants to sleep

ASO, N. (Japan Women's University), IWATATE, S. (Japan Women’s University)

The purpose of this study was to examine whether maternal touch of four-month-old infants by Japanese mothers differs depending on four nurturing scenes: playing, crying, feeding, and putting infants to sleep. We carried out a questionnaire survey using the Japanese Touch Rating Scale with 901 mothers of four-month-old infants. Based on the findings of three preliminary research studies, we established 19 categories of touch (touching, stroking, rubbing, holding up infant's hands or feet, waving infant's hands or feet, patting, poking, tickling, picking infant up, changing infant's position, quietly swaying, shaking, holding infant's hands or feet affectionately, massaging, pinching, kissing, holding, hugging, and supporting infant's body) and four nurturing scenes (playing, crying, feeding, and putting infants to sleep). Participants were asked to evaluate on a five-point scale the frequency of the 19 categories of touch in the four nurturing scenes and the mean scores for each were calculated. The data were analyzed using a 4×19 Kruskal-Wallis test. The main effect of nurturing scene was found to be significant. The factor of nurturing scene was then evaluated with the Mann-Whitney U test for multiple comparisons. The major results were as follows: in the playing scene, mothers used significantly more frequent maternal touch categories of touching, stroking, rubbing, holding up infant's hands or feet, waving infant's hands or feet, patting, poking, tickling, shaking, holding infant's hands and feet affectionately, massaging, pinching, kissing, holding, hugging, and supporting infant's body than in the three other nurturing scenes. In the playing scenes, mothers used various kind of touch in order to draw the infant's smile to please infant. Thus, maternal touch of young infants shows different characteristics for each of the four nurturing scenes, suggesting that maternal touch can be functionally used depending on the nurturing scene.

Keywords: maternal touch, nurturing scenes, Japanese Touch Rating Scale, mother-infant interaction

Different video game playing habits related to attentional function

SUZUKI, D. (Tohoku University), IWASAKI, S. (Tohoku University)

Previous studies suggest that playing video games improves attentional functions (Green et al., 2006). However, it may be considered that different video game play habits such as frequency, playing time and types of games would lead to differential development of attentional functions in their players. In this study, we examined whether attentional functions differ depending on different types of video games engaged at different ages with questionnaires including the one that purported to measure attentional functions. Questionnaire data were collected from a total of 300 participants (191 men, 109 women). All participants were undergraduate and graduate students, aged 18 to 25. Questionnaires were composed of two domains. One domain asked about video game play habits, such as frequency, hours of playing, preferred types of games and game career. The other domain measured individual characteristics related to attention related functions with Attentional Function Scales, Attentional Effort Scale (measuring ability to exert active attentional control over attentional concentration and sustained attention), Cognitive Failure Questionnaire (CFQ; Broadbent et al., 1982, measuring ability related to traffic accident tendency), Barratt Impulsiveness Scale Version 11 (BIS-11; Patton et al., 1995), Thought Occurrence Questionnaire (TOQ; Sarason et al., 1986) and Boredom Proneness Scale (BP; Farmer et al., 1986). First, based on frequency of playing video games within the past six months, we divided participants into three groups: high frequency video game player group (HVGP), low frequency video game player group (LVGP) and no video game player group (NVGP). It was found that HVGP were more hyperactive (being impulsive and prone to boredom) and poor in active control (such as low abilities of attentional switching and attentional efforts) than LVGP and NVGP. Furthermore, it was found that the
differences of the age when participants got most involved in their video games were associated with attentional abilities in HVGP. Participants who got most involved in them in middle adolescence (high school) were higher in impulsiveness and weaker in attentional efforts, but participants who got most involved in childhood (elementary school) were lower in impulsiveness and stronger in attentional efforts. We conclude that playing different types of video games during development is related to attentional functions. Participants who currently played video games intensively were more hyperactive and poor in active control. Furthermore, particularly those participants (HVGP) who became involved in video games in middle adolescent were higher in impulsiveness and weaker in attentional efforts. In contrast, participants who played them during childhood were lower in impulsiveness and stronger in attentional efforts. Although it is not possible to explain these results in terms of direct cause and effect between these factors, they suggest that video game play habits affect people’s attentional functions differently depending on the age of most active involvement.

Keywords: video game playing, Attentional Function Scale, Attentional Effort Scale, Cognitive Failure Questionnaire, impulsivity

Differential effects of practice on the dissimilar cognitive attribute processes used for truthful and deceptive responses: An event-related brain potential study

LIU, H. (Chinese people’s public security university)

The aim of this research was to provide some suggestions for how to choose and organize stimuli efficiently during the deception detection. Event-related potentials (ERP) and Behavior were recorded while participants made truthful and deceptive responses about the Chinese sentence which forms subert-six words and the photographs. The 700 Chinese sentences were labeled equably as three sorts: (1) self identity (birthday, homeplace, the twelve Earthly Branches, stature, shoes size etc; and self related information: self parents name, placenames etc, which parallel to 1 and never heard of before; (3) proverbial knowledge: a name of mark, well-known placenames etcetera. Two hundred and ten photographs were labeled equably into three sorts as Chinese sentences. The two pressing the reactor’ keystroke methods, (1) changelessness: mouse leftward keystroke is “yes”; rightward is “no”, (2) appointment: in conformity to the screen in the underside left “yes” or right “yes” and right “no” or left “no”. One hundred participants took part in the series experiment. ERP was recorded in the series experiment using the Neuroscan 4.3 system with 64 scalp electrodes in standard 10 to 20 placement. The deceptive response, compared to the honest response, was longer in reaction time and lower in the correction rate, the ERP amplitude evoked was smaller while the ERP amplitude evoked by strange-ID information was smaller than that of self-ID information in the interval of 550 to 800 milliseconds. The difference in terms of ERP amplitude on the left brain was greater than that on the right brain. In conclusion, 1. The left brain may be more involved in the process of deceptive response. So choosing the ERP data from the left brain for analysis will be better able to identify the deceptive response. 2. The executive control process existed in the deceptive response may consume more psychological resources, which makes the psychological resources used in the information processing decrease. These mentioned above may be the reason why the ERP data between the deceptive and honest response is different. 3. Chinese sentences can be used as effective stimuli material in the deception detection with ERPs.

Keywords: event-related potential, deception detection, Chinese sentences

Difficulties in facial emotion recognition in post-traumatic stress disorder

LEE, Y. (Chung-Ang University), LEE, J. H. (Chung-Ang University)

Individuals with Post-Traumatic Stress Disorder (PTSD) tend to attribute more negativity towards threatening (negative) stimuli. The purpose of this study is to examine processing of facial emotions in a sample of PTSD patients. By using a Morphed Facial Emotion Identification Task,
we aim to investigate emotional sensitivity of sexual abuse victims on their accuracy. Individuals with PTSD have been associated with atypical processing of emotion. According to Litz’s advanced network model, Trauma cues prime fear-related information processing, which in turn temporarily inhibit the ability to experience emotions of incompatible valence (e.g. positive affect). However, research has provided little evidence indicating how sexual abuse victims’ processing of emotion might vary with the valence. Participants will include a diverse sample of PTSD patients (PTSD group, \( n = 15 \)) and those with no history of abuse (Control group, \( n = 15 \)). Prior to the task, the participants will rate the affective and arousal valence of the facial emotion expression stimuli. Participants’ reaction times and labeling of emotions (Happy, Neutral, Fearful) will be measured using a Morphed Facial Emotion Identification Task by identifying facial expressions morphed from neutral to maximum intensity. They will then complete various self-rating scales designed to assess impulsiveness, post-traumatic stress symptoms, depression, and anxiety. This study is currently in progress. It is expected that, the PTSD group will display faster reaction times than the control group when labeling emotional facial expression and will correctly identify facial affect at an earlier stage, and this result will be most pronounced for fearful faces. In contrast, the PTSD group will show slower reaction times and correctly categorize facial emotion at a later stage for happy faces. These results will demonstrate that participants with PTSD are more sensitive for fearful faces, but less responsive for happy faces than controls in identifying emotional expressions. This is an empirical study to investigate the mechanism of processing facial emotions in a sample of PTSD individuals. The predicted results may provide valuable information in understanding the impact of PTSD on social-cognitive processing and assist in the development of possible treatment solutions for PTSD patients.

CROME, E. (Macquarie University)

Social phobia, characterised by a fear of negative evaluation or embarrassment, is a prevalent disorder in community and clinical samples. It is has an early onset and chronic course and is associated with negative psychosocial outcomes and co-morbid disorder. Current categorical conceptualisations of social phobia lack empirical support. The aim of the current study is to explore the latent structure of social phobia to determine whether “social phobia” reflects a discrete and qualitatively different condition, or alternately, whether all people experience a degree of social phobia. Data from two large scale community surveys in Australia (National Survey of Mental Health and Wellbeing (NSMHWB), 1997) and the United States (National Comorbidity Survey – Replication: NCS-R) were used. In both samples, a subsample of respondents screening into the Composite International Diagnostic Interview social phobia section were selected for analyses. Three mathematically distinct taxometric procedures (MAXEIG, MAMBAC and LMode) were used, along with various consistency tests. Indicators for analyses were constructed using current DSM-IV social phobia diagnostic criteria and personality factors (e.g., neuroticism) reported to be related to social phobia. A majority of analyses in both samples supported dimensional structure of social phobia. A MAXEIG analysis in the NSMHWB sample identified a small peak which identified a potential small-base rate taxon; however, this was not observed in the NCS-R sample. These results are consistent with a growing body of evidence supporting dimensionality of social phobia. Support for dimensional structure of social phobia has important implications for assessment, diagnosis, measurement and treatment. Dimensionality supports using assessment measures focusing on the degree of social phobia symptoms experienced and levels of meaningful change following treatment. Dimensionality also supports using statistical methods such as factor analysis and item response theory models. Applying dimensional models for psychopathology has important implications for public policy and early intervention.

Dimension or category? A taxometric analysis of social phobia
Disadvantage and prosocial behavior: The effects of the Wenchuan earthquake

The evolution of prosocial behavior is one of the most compelling puzzles facing scientists. An earlier study showed that being at a territorial disadvantage promoted children's prosocial behavior. The May 12, 2008 Chinese earthquake of 8.0 magnitude on the Richter scale placed residents in devastated areas in a disadvantaged position. We conducted three sequential surveys to test our hypothesis that residential devastation would evoke more prosocial behavior. A total of 8,023 residents in three non-devastated areas (the Tangshan area in Hebei Province, Fujian Province and Beijing City) and two devastated areas (Sichuan Province and Gansu Province) participated in the post-earthquake surveys. All participants were recruited by going door to door and asking people to take a survey, and all were given a small present (such as a bar of soap, a towel, or a packet of washing powder) in return for their participation. As expected, the results revealed that the degree of prosocial behavior increased with an increasing level of residential devastation, but decreased with the passage of time. However, we also found evidence that a catastrophic disaster leaves a long-lasting effect on prosocial behavior. The results supported our hypothesis that prosocial behavior could be induced by individuals being at a disadvantage. These findings should improve the conceptual understanding of the origin of prosocial behavior.

Discrimination against older workers: The role of implicit attitudes

MALINEN, S. (University of Canterbury), JOHNSTON, L. (University of Canterbury)

Negative attitudes and discriminatory practices towards older workers are well documented. However, the role that implicit attitudes may play in such discrimination has not previously been explored. The objective of the present research was to investigate implicit ageism in an employment context. Implicit and explicit attitudes towards older relative to younger workers were measured, and a mental imagery exercise was used to investigate the malleability of bias. The relationship between attitudes and behaviour toward a younger and an older worker was investigated in an employment interview exercise. Negative implicit bias against older relative to younger workers was found. There was some evidence for the effectiveness of mental imagery in alleviating such bias. The explicit attitudes were relatively positive and influenced by the mental imagery. The results also showed some evidence of youth bias in the interview situation. The present research showed that negative implicit attitudes exist towards older workers. The implications for both older workers and employers are highlighted in the context of the ageing workforce.

Diversity in Community Mass Syndrome (CMS): Evidence based analysis

SINGH, A. P. (Government Maharani Laxmi Bai Girls Postgraduation College)

Mass psychogenic illness is characterized by symptoms, occurring among a group of persons with shared beliefs regarding those symptoms, that suggest organic illness but have no identifiable environmental cause and little clinical or laboratory evidence of disease (Am Fam, 2000). Community Mass Syndrome (CMS) is being interpreted as normal behavior where hundreds to millions of people of more or less the same community with the same beliefs are motivated towards a certain type of behavior acceptable in the society with one, or more than
one, common goals (Singh, 2005). The Community Mass Syndrome (CMS) was first reported in the fifteenth century as “Tarantism” in the context of normal behavior in Germany, and in the rest of Europe it was known as St. Vitus’s dance. The behavior was similar to the ancient orgiastic rites where people worshipped the Greek God Dionysus. These rites had been banned with the advancement of other religions, but they were deeply embedded in the culture and were apparently kept alive in secret gatherings. With time, the meaning of dance changed so that the participants were no longer sinners and dance became a source of “cure”. The CMS became the undefinable method of catharsis, relaxation, in some cases cure, and a means of mental hygiene. The aim of the present evidence-based study is to explore, analyze and classify CMS including its symptoms, types, geographical expansion and diversity. The method adopted for this study is evidence based analysis focusing on symptoms, history, etiology, types and outcome. The historical evidence is collected from the twelfth century to twentieth century. The present analysis examines the origin, history, geographical area, age, gender, duration and behavioral differences in the diversity of CMS. The results indicate that diversity in CMS occurs, and with time some symptoms have been added or eliminated and thus diversifying its form, from psychogenic illness to religious form to political form to commercial form etc. The CMS is classified in religious, political, commercial and undifferentiated types. The feast of fools was a very popular medieval celebration for Roman Catholics. World Youth Day has a young history of twenty years in Europe. Since twelfth century in Hajj hundreds of thousands of Muslim pilgrims participate in Mecca, Saudi Arabia. The carnival tradition still flourishes in Belgium, Italy, France, and West Germany. In the Western Hemisphere, the principal carnivals are those of a commercial nature in Rio de Janeiro and the Mardi Gras in New Orleans. The Sydney Gay and Lesbian Mardi Gras (SGLMG) is a unique Australian festival. It is a party of the rarest and most uninhibited kind and it is the single largest night-time parade of its kind in the world. The fall of the Berlin Wall, the non-cooperation movement in India, and the Bloody Sunday of the Russia Romanian Revolution are evidence based examples of political CMS. All exhibit behavior in mass which was otherwise abandoned in community or society. This evidence based study concludes that there is diversity in CMS and further meta-analyses and research are required for psychosocial, cultural, political, commercial and religious mega events.

Keywords: community mass syndrome, community behaviour, mass psychogenic illness, dance, historical evidence of mass gatherings

Do foils safeguard against false identification decisions? Comparing choosing and accuracy rates in simultaneous lineups and showups

SAGANA, A. (Maastricht University), SAUERLAND, M. (Maastricht University)

There has been much discussion about which lineup procedure (simultaneous vs. sequential vs. showups) is most suited to finding the guilty while at the same time protecting the innocent. The arguments made mostly rely on the relative-absolute judgement model (Wells et al., 1984). In the present study, 384 participants watched a videotaped staged theft of a wallet. Thirty minutes later they were asked to make an identification from a target present (TP) or target absent (TA) lineup. Four identifications were made in total, one of the suspect, one of the victim and one for each of two bystanders. For half of the participants, the lineups presented were showups, for half simultaneous, six-person-lineups. For each participant, two identifications were presented as TA and two as TP. It has been argued that a showup creates unreasonably high risk that an innocent suspect will be chosen. For this reason, a suspect is always to be presented in the context of a number of foils, that is, fillers who are known to be innocent. According to Gonzales et al. (1993), eyewitnesses express greater caution because of the presence of foils in the lineup. However, recent findings (Steblay et al., 2003) indicate that there are lower choosing rates in showups compared to simultaneous and sequential lineups, which is consistent with the idea that the similarity structure of a lineup created by the addition of foils might affect criterion placement. Consistent with this idea, our preliminary results show that the choosing rates in showups are much lower for both TA (16% vs
62%) and TP (33% vs. 70%) lineups. The results will be discussed with regard to lineup administration and the need for filler persons.

Keywords: lineup procedure, showups, sequential lineups, simultaneous lineups

Does cognitive fitness training work?

WELLS, Y. (La Trobe University), SHATIL, E. (CogniFit)

One determinant of healthy ageing is cognitive capacity. Several programs have recently been designed to promote cognitive fitness. The aim of the current study was to conduct an independent appraisal of one of these programs to determine whether it is beneficial and, if so, for which subgroups of participants. Participants’ performance on a range of tasks was measured in a 45-minute baseline assessment prior to an individualized program of exercises being set. Participation then required 20 minutes of training three times per week. Measures of performance were then taken at three further points. Slightly more women than men participated in the program. Participants’ average age was 64 years. Two-thirds were highly educated. The majority had no health problems and used a computer daily. Over 1800 participants commenced the program, but by Time Three, only 423 remained. Significant overall group differences in performance on the tasks were observed. Women performed better than men on several tasks, and good health, tertiary education, computer experience, and being younger rather than older all promoted high performance. Performance on all measures improved significantly over the course of the training. The greatest improvements were noted for Visuomotor coordination and Short-term memory. Women improved more than men on both of these tasks. However, Reaction time improved most for people with serious health problems and those with low levels of education. Multivariate analysis of attrition showed that persisting with the program varied by age, health, and education, and both with performance at Baseline and with improvements over time. Overall, the program resulted in significant improvements with training in all domains, especially for participants with low levels of initial performance. However, whether the cognitive gains shown in training generalize to everyday performance is not known. Success in the initial stages of the program led to improved retention, highlighting the importance of a sense of achievement for persisting with training.

Keywords: cognitive fitness, healthy ageing, visuo-motor coordination

Does emotional intelligence influence employees’ job outcomes? Some evidence from the Indian information technology industry

PRADHAN, R. K. (Indian Institute of Technology), MAITRA, D. (Amity University, Noida)

The present study examines the influence of emotional intelligence on employees’ job outcomes (job performance and job satisfaction) in the Indian Information Technology (IT) industry. The study also investigates the relationships among emotional intelligence, stress and coping of IT professionals. The study was conducted on a sample of 126 young executives randomly selected form a group of IT companies located in the Kolkata metro city of India. The findings of the study revealed that emotional intelligence positively correlates with job outcome variables and executives coping. Regression analysis was used to observe the effects of Emotional intelligence on job outcome variables. Based on the results, detailed theoretical and practical implications of the findings are discussed.

Keywords: emotional intelligence, stress, job satisfaction, job performance, executive coping

Does human resource management (HRM) really matter in tourism organizations? Strength of HRM systems from a managerial perspective

CORREIA, A. (Instituto Politécnico de Setúbal / ESCE), BENTES, L. (University of Aveiro), CHAVES, F. (Lisbon University Institute), GOMES, J. (Lisbon University Institute)
Abstracts of the 27th International Congress of Applied Psychology

Strategic Human Resource Management (HRM) directs attention to the ways in which the HRM system is critical to organisational effectiveness. Several authors have urged scholars and managers to devote time and efforts to understand the associations between HRM and organizational performance (Becker and Gerhart, 1996). Bowen and Ostroff (2004) responded to this plea, and introduced the concept of strong HR systems. In such systems, messages regarding what is appropriate behaviour are communicated to employees in an unambiguous and consensual way. Hence, HR systems must possess a set of unique features, which relate to the process by which a consistent message about HR content is sent to employees. HR strength affects the way people interpret their surrounding environment, that is, the situation strength. Stronger HR systems lead to stronger situations, and weaker HR systems lead to weaker situations. Based on seven semi-structured interviews to HR managers in hotels, we explored the attributes which make a HRM System strong or weak. Data was compared with the theoretical propositions of Bowen and Ostroff, and results offer some insights regarding each of the attributes put forward by authors. We observed that none of the constructs seem to be part of the agendas of the HR function. The attributes which were less supported were: understandability, validity and justice. Implications are drawn in respect to the way HR communicates with employees.

Does job, organization, procedure or interviewer really matter? Testing the mediating mechanisms of multiple fit perceptions on applicant attraction within a field interview context

YANG, I. W. (National Chiao Tung University ), YANG, I. W. (National Chiao Tung University), CHEN, C. C. (National Taipei University of Technology), HSU, Y. Y. (National Taipei University of Technology)

To realize how applicant reaction mechanisms affect organizational attractiveness and applicant job choice, the present study tests the effects of four important factors (i.e., job relevant attributes, organizational attributes, applicant perceived fairness, and interviewer behavior) and the mediating roles of multiple applicant fit perceptions in a field interview setting. Data were collected from 289 applicants participating in job interviews. The participants were invited to complete questionnaires after their interviews. In order to prevent the concerns of social desirability effects, the true purpose of the research was undisclosed and all participants were told that the results would be used only for research purpose and unrelated to the final results of the job interview. The results of structural equation modeling showed that organizational attributes were positively related to organizational attractiveness. Applicant-job fit fully mediated the relationship between job attributes and organizational attractiveness. Applicant-organization fit mediated the effects of perceived procedural justice and interviewer ingratiation behavior on attractiveness. Moreover, the results also indicated a positive relationship between applicant received job offers and attraction. Building on previous research findings on organizational attractiveness, the present study simultaneously tested the mediating roles of applicant-job, applicant-organization, and applicant-interviewer fit within a field interview setting. With regard to the current results, organizations may consider to utilize their recruitment efforts and applicant perceived attractiveness through enhancing positive images, providing job related information and assigning well-trained interviewer in the recruitment process to strengthen different important applicant fit perceptions.

Does task type affect the efficacy of performance goals: A comparison of discovery and instruction-based skill acquisition

HOWE, A. (University of Sydney)

A growing body of research from the cognitive domain has suggested that performance goals impair the acquisition of cognitive skill due to
their inhibitive effect on systematic task exploration. This research however has typically employed complex control tasks where skill acquisition is dependent on discovery-based learning. The present research sought to determine whether performance goals resulted in poorer skill acquisitions under instruction-based skill acquisition. Eighty two undergraduate psychology students were instructed to perform the Kanfer-Ackerman Air Traffic Control task under one of four conditions in a 2x2 design. Participants were either given performance or exploration goals coupled with specific or non-specific feedback. Results suggested that performance goals and specific feedback were more beneficial for both task acquisition and transfer performance under learning from instruction conditions, contrary to the predictions of a number of cognitive theories of skill acquisition. It appears that performance goals can be effective in facilitating skill acquisition under instruction-based learning.

Does the importance and the achievement of entrepreneurial success criteria vary across cultures and genders?

DEJ, D. (Dresden University of Technology), CZERNEK, M. (University of Silesia), PARUZEL, M. (University of Silesia), STEPHAN, U. (Katholieke Universiteit Leuven)

Entrepreneurial success is considered to include multiple criteria of a financial, non-financial, social and psychological nature. Previous studies reported women attach higher importance to socio-emotional aspects of success such as workplace relations and community impact. At the same time, women were found to be less successful in terms of objective success criteria including growth and financial performance. The present study introduces culture as an essential variable to extend our understanding of gender differences in entrepreneurial success. We hypothesized that gender differences in importance and achievement of success criteria will be more pronounced in a culture of low gender equality. Self-developed scales measuring importance and achievement of success criteria were distributed to 184 German (women n = 46) and 70 Polish entrepreneurs (women n = 31). Underlying structure of importance and achievement was established using structural equation modelling, while cultural and gender differences were analysed using parametric statistical tests. Confirmatory factor analyses revealed a five-factor solution for both importance and achievement ratings. Importance consisted of personal fulfilment, workplace relations, community impact, personal rewards and company performance, while achievement included financial outcomes, personal balance, dynamism/growth, workplace relationships and community impact. Polish entrepreneurs scored significantly higher on the importance of personal rewards (p < .001) and evaluated themselves to be less successful compared with their German counterparts. More precisely they reported lower achievement on workplace relations (p < .001), dynamism/growth (p = .03) and community impact (p = .05). In line with our hypothesis that gender differences will be more pronounced in a culture of low gender equality, German females attached significantly higher importance to community impact (p = .04) compared with males. Additionally they scored higher on this success criterion (p = .02) and workplace relations (p = .04), however lower on the total success achievement. Interestingly, Polish female entrepreneurs attached lower importance to workplace relations comparing males (p = .01), however it was the only one gender difference we found. This study contributes to research on gender diversity in entrepreneurship by demonstrating that gender differences are not the same across cultures, therefore cultural background should be taken into account when exploring gender differences and similarities.

Keywords: entrepreneurial success, socio-emotional aspects of success, achievement, gender differences, workplace relationships

Does the pattern for autobiographical memory and arousal vary among breast cancer patients with and without PTSD?
MAKKAR, S. (University of Delhi), KHOSLA, M. (University of Delhi)

This study examined how breast cancer patients diagnosed with and without post traumatic stress disorder (PTSD) varied in memory patterns and arousal. A mixed method study was chosen to address the research objective. Thirty breast cancer (Stage I-III) patients were chosen for the study who completed the screening tool Detailed Assessment of Posttraumatic Stress (DAPS; Briere, 2001) and Autobiographical Memory Test (AMT; Williams and Broadbent, 1986). Their arousal level was assessed before and after the retrieval of memories in response to cue words. Among the thirty patients, five demonstrated PTSD symptoms and the other 25 did not fulfill the PTSD criteria. PTSD group recalled more over-general memories on the AMT while the non-PTSD group recalled more specific memories. In addition, PTSD as compared to non-PTSD women displayed higher levels of arousal. The narratives of the life experiences as revealed in the word cueing test surfaced prominent themes across the responses. Themes that emerged were beliefs, health, work, society and social relationships. This study suggests that a life threatening illness like breast cancer can precipitate PTSD symptoms and result in changes in cognitive and physiological domains. Thus, research is needed to examine the effects of PTSD symptoms on immune responses, cancer outcome, and adherence to medical regimens.

Keywords: post-traumatic stress disorder, cancer patients, memory patterns, arousal, autobiographical memory

Domestic violence response training for health professionals

WHITE, K. (Lifeline Australia)

Domestic/Family Violence affects one in three women between the ages of 15 to 44 in Australia in their lifetime and many children witness the abuse. However, many health professionals receive little or no training on how to respond to families experiencing abuse. Since July 2007, approximately 800 health professionals have been trained in DiVeRT (Domestic Violence Response Training). It is a project funded by FaHCSIA and DoHA for Practice Nurses and Aboriginal Health workers in rural and remote areas. The aim is to increase awareness and train workers to identify, respond appropriately and refer clients to specialised Domestic/Family Violence services. This training has been in the form of either two day workshops or an online version and has been delivered against a recognised Unit of Competency. Topics include effects on children, links to mental health, risk assessment and safety planning. Of the 800 health professionals who have been trained, most were nurses or Aboriginal Health workers but also included were other health workers such as psychologists and counsellors. The effectiveness of the training has been evaluated after the workshops and the online version and again at the end of 2 year period. The evaluations show the need for the training, increased awareness and confidence amongst workers and that the training has been used to assist clients once back in the workplace. All health professionals are in an ideal position to identify and respond to clients experiencing abuse. With appropriate training they can identify and refer families on to specific services.

Keywords: domestic violence, domestic violence response training, health care providers, family abuse

Driving better with distraction: Auditory attention can decrease visual inattentional blindness

BEANLAND, V. (The Australian National University), PAMMER, K. (The Australian National University), COLTON, D. (The Australian National University)

The relationship between auditory and visual attention has both theoretical importance and practical relevance to domains such as driving. Evidence suggests that talking on a cell phone impairs visual attention (Scholl, Noles, Pasheva, & Sussman, 2003; Strayer, Drews, & Johnston, 2003). Some research suggests that attending to auditory stimuli produces failures of visual awareness (Pizzigallo & Bressan, 2008), while other research suggests listening to music can improve visual attention (Olivers & Nieuwenhuis, 2005). We used a moderate-load sustained inattentional blindness (IB) task,
combined with a low-load auditory listening task. Participants tracked shapes that moved around the display and occasionally "bounced" off its edges. During critical inattention trials an unexpected object (UO) crossed the display. There were 104 participants (70 female) in three conditions: no-audio participants (n = 33) heard either silence or low background sounds; instrumental participants (n = 35) listened to instrumental music through headphones; and language participants (n = 36) listened to either short stories or pop music with lyrics. Sixty-four percent of no-audio participants experienced IB (i.e., failed to notice UO). IB was significantly lower in the language condition (44% IB) compared to no-audio, $\chi^2(1, N = 36) = 5.71$, $p = .023$. IB was also reduced in the instrumental condition (54% IB) but the difference was not significant, $\chi^2(1, N = 35) = 1.31$, $p = .292$. Within the language condition, there was no difference in IB comparing short stories (45% IB) with pop music (44% IB), $\chi^2(1, N = 36) = 0.01$, $p = .604$.

Repeated-measures ANOVA indicated no significant differences in primary task accuracy across trials comparing experimental conditions, $F(2,97) = 1.44$, $p = .243$, and noticers versus nonnoticers of the UO, $F(1,97) = 0.85$, $p = .358$. We found that IB decreases when listening to auditory stimuli, specifically language-based audio. Our results support the idea that IB can result from overinvestment in the primary task (Olivers & Niewenhuis, 2006). Focusing attention on a single task prompts observers to block all potential distractions, whereas distributed attention allows the opportunity to notice unexpected objects that are unrelated to the primary task.

Keywords: attention and driving, auditory attention, visual attention, inattentional blindness, unexpected objects

Dual decision making styles can enhance self efficacy

NYGREN, T. (Ohio State University), PAULSEN, A. (Ohio State University)

Popular applied decision making models have categorized individuals as either “rational” or “emotional”, and more recently as either “maximizers” or “satisficers.” Although these dichotomies have some anecdotal appeal, they are unsatisfactory because they lack a clear theoretical mechanism for relating important latent individual differences’ variables affecting decision making processes, and because they imply that individuals tend to be of one type or another. There is no empirical evidence for these simple dichotomies and we suggest a different distinction between propensities toward a more intuitive decision style or a more analytical style that need not be mutually exclusive. Mutually exclusive dichotomies seem contrary to what we witness in both everyday decision making and expert decision making. Experts such as airplane pilots, emergency room physicians, stockbrokers, and firefighters who must make both deliberate analytical decisions and quick intuitive decisions seem to have mechanisms that allow them to move from one mode to another as the situation warrants. We describe exploratory and confirmatory factor analyses indicating that analytical and intuitive styles are robustly identified and validated and reflect independent psychological latent variables. Correlations with other widely used individual differences measures are presented and suggest strong concurrent and discriminant validity. We provide empirical evidence that these two styles are not opposite extremes on a single continuum, where strong endorsement of one style precludes endorsement of the other. In particular, we present results that suggest an interesting relationship between endorsements of decision styles and self-efficacy. Individuals who report a propensity for either an analytical or intuitive decision style are much more likely to experience greater self-efficacy. Further, those individuals who endorse both styles report even higher self-efficacy. We argue that this evidence suggests that in applied decision environments the most self-efficacious decision makers may be those who show flexibility in their decision style – that is, those who are willing to endorse both approaches, depending on the demands of the situation. We argue that to enhance decision self efficacy it does not matter whether you have a dominant decision style, as long as you endorse both and feel comfortable using either.

Keywords: decision-making, analytical and intuitive decision making, self-efficacy, expert decision making, latent psychological variables

Early intervention with children who witness domestic violence

WORTHY, S. (Metropolitan State College of Denver)

The data for presentation was collected as part of a three year, U.S. federal demonstration grant conducted by a group of agencies in Colorado to assist children in rural areas who witness domestic violence. The data to be presented are the results of the pre-treatment and post-treatment measures designed to understand the impact of proactive treatment on children who are observers of family violence within their home. As part of the grant, 108 children participated in the study due to their parent being treated for mental health issues related to domestic violence. The children were assessed using the age-appropriate form of the Trauma Symptom Checklist (TSC). All participants were administered the assessment tool prior to treatment. The children were then treated with a combination of individual and group therapy. The TSC was again administered at termination or after six months of treatment, whichever came first. There are eight sub-scales as part of the TCS. Those sub-scales include anxiety, depression, anger/aggression, posttraumatic stress introversion, posttraumatic stress avoidance, posttraumatic stress arousal, dissociation, and sexual concerns. Out of the eight sub-scales, five areas demonstrated significant improvement on the post-treatment measure. In addition, the TCS provides a Posttraumatic Stress Total (PTS Total) score. In this case the PTS Total score also yielded a significant positive change. Children who witness domestic violence experience symptoms of trauma. These symptoms are not typically significant enough for them to be referred for treatment by parents, teachers, or school counselors. However, these symptoms can be identified by using appropriate assessment strategies. More importantly, early mental health intervention can reduce these trauma symptoms. This early symptom reduction may ameliorate more significant symptom expression and more serious problem behaviors in the future.

Keywords: domestic violence, trauma, early intervention

Economic circumstances as a motivator for fraud amongst non-gamblers, gamblers and problem gamblers

ENGLAND, M.

The aim of the current study was to examine whether a severe change in economic circumstances triggers fraud. The recent economic crisis provides a critical circumstance against which changes in indicators for fraud amongst non-gamblers, gamblers and problem gamblers are measured. The implications for the changes provide evidence regarding the motivation to commit fraud. A more thorough understanding of the motivation to commit fraud can provide a basis to take more effective preventative action.

Keywords: fraud, gambling, economic, problem-gambler, fraud-prevention

Educational diagnosis by graphical testlet response model

OHMORI, T. (Tama University), SHIGEMASU, K. (Teikyo University)

This study shows a new adaptive testing method for diagnosing students’ misconceptions or errors (which are called bugs) with the Bayesian network model. Item Response Theory (IRT) model is often used for usual adaptive testing, but when those tests are made up of testlets which are groups of test items, standard IRT models are often not appropriate due to the assumption of local dependence between items or testlets. Some testlet-based IRT models have recently been developed under such conditions (Wainer et al., 2000), but there are not so many. In this study, avoiding the local independence problem, a Bayesian network model is introduced to represent the structures within testlet and also relations between each testlet directly and intuitively. Incorporating bug model to the adaptive testing, not fully mastered students can realize their abilities. The simulation study shows the validity of this method, and also real data (arithmetic) is applied to this method. This study can be applied to all educational testing, especially arithmetic. If a new web based testing (WBT)
system would be constructed, it will provide advice to misunderstanding students for correcting their errors.

**EEG biofeedback in the treatment of complex PTSD comorbid with substance abuse**

ASKOVIC, M. (New South Wales Service for the Treatment and Rehabilitation of Torture and Trauma Survivors)

This presentation aims to provide an overview of the innovative clinical work of the New South Wales Service for the Treatment and Rehabilitation of Torture and Trauma Survivors (STARTTS) using electroencephalographic (EEG) biofeedback as an adjunct to psychotherapy when working with complex post-traumatic stress disorder (PTSD) comorbid with substance abuse. A detailed case study will be used to show how EEG biofeedback is conducted with torture and trauma survivors and integrated with psychotherapy. A two-step approach will be described. The first step begins with Sensory Motor Rhythm (SMR) training for regulation of the client's physiological arousal and reduction in fear response. The second step entails work on addiction via deep state Alpha/Theta training combined with the constructive visualization of the desired outcomes. A series of psychological and physiological pre and post treatment measures including Harvard Trauma Questionnaire, Hopkins Symptom Checklist, Test of Variables of Attention and Quantitative Electroencephalogram will be presented. Long term positive changes in the client's psychological and physiological state will be discussed. Based upon our extensive practice of EEG biofeedback, this paper will explain how this intervention, when integrated with psychotherapy, offers an effective approach to successful treatment of traumatized clients with complex presentations.

**Effect of 30 practices in improving attention in children with ADHD**

GHOLAMI, M. (Islamic Azad University), AZHDEHFAR, L. (Ruzbeh Clinic), GOLKARIAN, P. (Islamic Azad University Tehran)

The most common problem in children with Attention Deficit Hyperactivity Disorder (ADHD) is the attention deficit. The main goal of this study is improving the ability to concentrate in children with ADHD by training and practicing 30 special activities for developing attention within five months. Among children coming to Ruzbeh Clinic with ADHD, ten were chosen and the mean age of this group was 8 years and 3 months. They were divided randomly into two groups of five, and the children in one group just received pharmacotherapy (control group) and the other five children received pharmacotherapy and 30 practical exercises during five months (experimental group). After treatment, individuals in both groups were tested by the Test of Everyday Attention (TEA) which estimates permanent attention, transforming attention and selective visual attention, through three ways (auditory method, visual method and pencil and paper method). The cut off mark is five and the experimental group's mean was 3.90 in pretest and the control group's mean mark was 3.82 and the post test was totally different. In the control group it was 5.30 and in the experimental group the mark reached at the point of 7.1. The 30 practical exercises play an efficient role in improving attention in children with ADHD.

**Keywords:** attention deficit hyperactivity disorder, test of everyday attention, attention, concentration

**Effect of 70 practices in decreasing learning disorders in children with ADHD**

GHOLAMI, M. (Islamic Azad University), AZHDEHFAR, L. (Islamic Azad University Tehran), GOLKARIAN, O. (Ruzbeh Clinic)

As we know children with ADHD are more vulnerable to have learning disorders. The question is do the 70 sensory-motor activities have effective role in decreasing learning...
disorders? Among children coming to Ruzbeh Clinic with ADHD, 16 first grade students were chosen. They were divided randomly into two groups of 8 with the children in one group only receiving pharmacotherapy (control group) and the other 8 children receiving pharmacotherapy and 70 sensory-motor exercises during six months (experimental group). Before and after treatment the Grade Point Average (GPA) of individuals in both groups was compared. In the pretest, the GPA of the control group was 13.30 of 20, and the experimental group’s GPA was 13.25 of 20. Post test was totally different. In the control group it was 16.50 of 20, and in experimental group the GPA reached at the point of 19.30 of 20. The 70 sensory-motor exercises have an efficient role in eliminating learning disorders in children with ADHD.

Keywords: attention deficit hyperactivity disorder, learning disorders, attention, sensory-motor activities

Effect of age on fairness perceptions: A comparative study on Indian Banks

PURANG-SINHA, P. (Indian Institute of Technology Bombay), SHRIVASTAVA, A. (Indian Institute of Technology, Bombay)

This study aimed at examining the effect of age on the perception of fairness of different performance appraisal systems in Indian banks. Liberalization of economic policies has brought significant changes in the structure and operations of Indian banks. Past researchers have compared Public and Private Sector Banks and found differences in structures, use of technology, economic efficiency, Human Resources (HR) systems, etc. Employees of diverse age-groups differ in terms of their needs, values, and expectations and organizations face the challenge to address these ‘differences’. This study explores the effect of age on the perception of fairness of performance appraisals. A survey research was conducted in two banks with a total sample of 340 bank employees from a leading Public Sector (N = 230) and a Private Sector Bank (N = 110) in India. Convenience sampling was used to collect the sample. Performance Appraisal Fairness Scale with eight dimensions was adapted from Thurston (2001). Regression analysis was used. The results indicated a positive linear relationship between age and perception of fairness in the Public Sector Bank (older employees found their performance appraisals fairer) and a negative relationship for the Private Sector Bank (younger employees perceived more fairness with their appraisal practice). This study shows the needs of younger employees not being met in Public Sector Bank and older employees in Private Sector Bank. Both banks need to develop HR practices and policies that address employee differences.

Keywords: age differences, employee differences, performance appraisal, perceived fairness, employee appraisal

Effect of spatial attention on dynamic expression processing

ZHANG, L. (Chinese Academy of Sciences), ROEDER, B. (University of Hamburg), ZHANG, K. (Chinese Academy of Sciences)

Affective expression is one of the most salient events for human survival and successful social interactions. Many studies have revealed spatial modulation on affective expressions. In fact, emotions are usually perceived by combining facial and vocal expressions in everyday life. More important, dynamic and static facial expressions are processed differently. However, few studies are concerned with dynamic expressions. Our study used dynamic real-life facial expressions and vocal prosody and explored the spatial modulation on the processing of multisensory affective expressions. Sixteen volunteers (five male; M = 24.7 + 4.2 years) participated in this research. The stimuli included videos with an actor uttering a bisyllabic word in angry, happy or neutral emotion. Mean duration of the stimuli was 700 milliseconds (SE = 26 milliseconds). Participants were seated in front of a computer screen. In every block, participants were asked to pay attention to one side (left/right) only and detected a 200 millisecond interruption in the facial expression. There were sixteen blocks in the experiment (a total of 132 stimuli in one block, and 24 of them with the interruption). The behavioral responses and electroencephalographic results (EEG) were recorded. From the behavioral results, the
average reaction time to the targets was 1324.3 + 12.8 milliseconds. Participants’ accuracy of detection was 93.45 (SE = 0.016). There was no significant difference among emotions. From the EEG results, spatial attention effect was found short after stimulus onset (100 to 120 milliseconds). The mean amplitudes were marginally significant at ipsilateral parietal-occipital sites (Difference = -.433, p = .073) and midline parietal sites (Difference = -0.689, p = 0.058). From 240 to 280 milliseconds, attended ERPs were more negative at contralateral parietal-occipital sites (Difference = -.707, p < .05). There was a sustained difference at late component (380 to 580 milliseconds, main effect of attention F = 5.041, p < .05; 660 to 900 milliseconds, main effect of attention F = 7.889, p < .05). However, no significant and steady emotion effect was found. Facial-specific component N170 was found in all conditions. The expressions perception was modulated by spatial attention. However, expressions as the salient stimuli were processed fast even in the unattended location and irrelevant to the task, no matter which kind of emotion valences. N170 was not modulated by spatial attention and facial emotion valence.

Keywords: affective expression, facial expression, facial emotion valence, spatial attention

**Effectiveness of a life skills intervention on psychosocial parameters among Tibetan school adolescents**

BISWAS, U. (The Maharaja Shivaji Rao University of Baroda)

The present study examined the effectiveness of life skills interventions in reducing stress and anxiety, strengthening coping styles, self-confidence and emotional intelligence among Tibetan refugee adolescents studying in SOS Tibetan Children’s Village in the Indian state of Himachal Pradesh. A pre-post controlled trial design was used. An initial sample of 600 Tibetan refugee students aged 12 to 19 years participated in the study. They were administered a questionnaire measuring the level of stress, anxiety, coping styles, self-confidence and emotional intelligence. Using a median split the sample was divided into two equal sized groups. Participants scoring below the median score were randomly assigned to two equal sized groups (experimental group and control group). The experimental group was assigned to a standardized training module consisting of ten life skills for four months on average. The participants were assessed on life skills and if it was required, they were retrained until they achieved the pre-set standard. After a gap of two weeks of attaining the set standards they were administered the same questionnaire. The Pre and Post intervention data were analyzed using ANCOVA and paired t-tests to measure the effectiveness of life skill intervention on the psychosocial factors. In the pretest, experimental and control group differed significantly only on trait anxiety. However, after the life skills interventions, paired t-test revealed that there was a significant difference between experimental and control group on perception of stress, anxiety (state and trait), use of coping strategies, self-confidence and emotional intelligence. Life skills interventions which have been previously found effective in combating HIV, AIDS, smoking, teenage pregnancy also contributes greatly to manage stress and anxiety and enhance coping skills, self-confidence and emotional intelligence among adolescents.

Keywords: life skills, stress, anxiety, coping, self-confidence

**Effects of an educational television program on reduction of prejudice towards schizophrenia**

ITO, T. (Wako University), KODAIRA, T. (Seirei Christopher University)

The present paper reports on the development of television-based education to reduce the Prejudice Towards Schizophrenia (PTS) of nursing students. The television (TV) program was derived from a thirty-minute educational program which featured a newly married couple with schizophrenia. The effects of the TV
program were measured by the Attitude toward Mental Disorder Scale in a pre and post-test. Scores on the Social Distance Scale ($M = -.30$, $F (1, 276) = 97.014, p < .001$) and the Bad Image Scale ($M = -.83$, $F (1, 276) = 820.164, p < .001$) were smaller after program viewing with larger effect size for the Bad Image Scale ($ES = 1.84$) than the Social Distance Scale ($ES = .55$). The percentage of attitude change in the desired direction was 98% for the Bad Image Scale, and 69% for the Social Distance Scale. Attitude change was observed in most of the participants. Results of the present study indicated that even a short, 30-minute TV program can be effective in reducing PTS.

**Keywords:** stigma, schizophrenia, prejudice, nursing, image

**Effects of electronic media use on children's quality of life: Website survey for mothers**

HASEGAWA, M. (Yokohama-City University), SAKAMOTO, A.

This study addresses the question “what are the factors that enhance children’s Quality of Life (QOL)?” Children in the modern era are exposed to electronic media such as TV and video games for many hours. Does contact with electronic media enhance or lessen children’s QOL? In this research, we conducted a two-wave panel study targeting mothers who have elementary school children in order to investigate whether media contact affects children’s QOL. We also examined the differences in media influences by socio-economic status. Research subjects were 2531 mothers who have elementary school children. Participants were recruited from the registrants of an internet research company. The participants completed two identical website surveys two months apart. The first survey was conducted in March 2009, and the second survey in May 2009. We measured the length of time a child was exposed to TV, video games, mobile phone and computers as media contact (weekdays and holidays), the type of involvement of the parent and child during media contact (e.g. “There is a limit on television watching time”, “My child watches television alone”), the parent’s feeling towards media (e.g., “It is possible to be impressed”), the household’s annual income, and QOL (KINDL(R) Parents’ version). Results indicated that the group with high annual income also had high QOL scores. Mothers in the higher income group tended to control the child’s media use, and mother and child were involved in the media together. We conducted a pass analysis on annual income, QOL score and media contact condition, and found that annual income influenced the type of media contact, and type of media contact influenced children’s QOL. It was indicated that QOL related to; types of involvement of the parent and child during media contact, the parent’s feeling towards media, and the household’s annual income. The results of this study also showed that annual income influenced the type of media contact, and the type of media contact influenced children’s QOL.

**Keywords:** electronic media, children, quality of life, mothers, parental involvement

**Effects of self-evaluation of computer proficiency on computer self-efficacy in general information education**

KAGEMURA, Y. (Koshien University), HARADA, A. (Koshien Junior College)

The present study explored the relationship of computer proficiency used by general information education and computer self-efficacy, testing the instability of computer self-efficacy and computer anxiety in general information education. We conducted a survey on “self-evaluation of computer proficiency”, “computer self-efficacy” and “computer anxiety” which was administered three times (April, June, July) to 212 university students. The scores of “self-evaluation of computer proficiency” were categorized into three groups (Low group, Middle group, High group). The result indicated that the interaction between three times and groups of computer proficiency was significant in both “computer self-efficacy” and “computer anxiety”. High group in July was higher than in June, and low group in July was lower than in June. Furthermore, it was indicated that students lost their confidence and increased anxiety when they learned the unknown course contents.
Effects of snowfall on seat belt use

SIMSEKOGLU, Ö. (Izmir University of Economics), LAJUNEN, T. (Middle East Technical University)

The present study aimed to investigate the effects of adverse weather conditions (snowfall) on seat belt use and child restraint use among Turkish car occupants. A total of 611 front seat occupants (drivers and front seat passengers) were observed for their seat belt use, age and sex. Also, 137 child passengers were observed for their seat belt use, age and seating location. In order to study the effects of weather on seat belt use, observations were conducted in two different times with two different weather conditions (sunny dry weather versus cold weather with snow on the road). Chi-squared analysis revealed that a significantly higher proportion of the observed drivers, front seat passengers and child passengers were using a seat belt in bad weather than in good weather condition. Increase in seat belt use in adverse weather conditions compared to normal weather conditions suggests that effects of adverse weather conditions are compensated by using a seat belt. However, the increase in seat belt use in adverse weather conditions was still far from sufficient for car occupant safety.

Keywords: seat belt use, driver safety, weather condition effects on driving, car occupant safety

Efficacious social control in neighbourhoods prevents antisocial behaviour: Mediation of socialization and unstructured activities

YOSHIZAWA, H. (Gifu Shotoku Gakuen University), YOSHIDA, T. (Nagoya University), HARADA, C. (Nagoya University; Japanese Society for the Promotion of Science), PARK, H. J. (Aichi Bunkyo Women’s College), NAKAJIMA, M. (Mie University), OZAKI, M. (Kanazawa University)

On the subject of preventing antisocial behaviour by efficacious social control in neighbourhoods, collective efficacy (Sampson et al., 1997) has been explained using two theoretically distinctive mechanisms: (1) the successful socialization of children at the community level, which develops their aversion to antisocial behaviours, and (2) the imposition of restrictions on unstructured activities that increase the probability of children engaging in antisocial behaviours. We hypothesized that the lack of collective efficacy within communities could be mediated by certain types of social information-processing and degrees of self-regulation. A lack of collective efficacy would increase children’s exposure to violence within the community, which could eventually lead them to engage in similar acts (i.e. unstructured
routine activities). A total of 503 undergraduates were instructed to recall their early-to-middle adolescence periods (from elementary school to junior high school) when answering the questionnaires. The perceived level of collective efficacy and the frequency of exposure to violence in the communities they belonged to were assessed using self-report items. Positive and negative aspects of social information-processing were assessed by social rule appropriateness, normative beliefs about aggression and cognitive distortion scales. The level of self-regulation was assessed by using the social self-regulation scale. Routine activities were assessed through memories of unstructured socializing activities during high school years. Antisocial tendencies were assessed based on the estimation of the seriousness of the delinquent behaviours of the respondents, along with their experiences in the past. The results of structural equation modeling revealed that the effect of collective efficacy on antisocial tendency was perfectly mediated by social information-processing and self-regulation (i.e. socialization indices); further, the frequency of exposure to violence was found to be partially mediated by routine activities. These findings provide evidence that high informal control (i.e. collective efficacy) fosters community level socialization and eventually decreases the likelihood of antisocial behaviour. On the other hand, the lack of informal control within the community (i.e. social control dysfunction) increases the crime rate of the area as well as the likelihood of children engaging in unstructured and antisocial behaviours. Future research in this area should include longitudinal investigations and community level analyses.

Keywords: antisocial behaviour, social control, collective efficacy, social information-processing, self-regulation

Efficacy of neurofeedback as a treatment for executive dysfunction: Establishing best practice from clinical evidence

ANIFTOS, M. (Inclusive Education Services (R)), MCKENNA, M. (University of Southern Queensland)

The primary aim of the present study was to investigate the clinical utility and ecological validity of neurofeedback (NFB) in an Australian sample, effectively contributing to the recognition of NFB as an evidence-based practice. It was anticipated that this study would demonstrate improvements in the core symptoms of executive dysfunction (poor behavioural and metacognitive self-regulation) following NFB intervention. The present study also aimed to investigate the minimum number of neurofeedback training sessions required to demonstrate significant improvements as indicated by client reports and quantitative measures. The secondary aim of the study was to establish the viability of using clinical data for longitudinal studies to investigate the retention of NFB treatment effects. Participants were patients seen at a private clinician’s practice in Toowoomba, Australia. The participant pool consisted of both males and females aged between 6 and 12 years. They were referred to the clinic by their general practitioner or primary caregiver(s) and received treatment on a fee for service basis. The participants were assessed to be demonstrating symptoms of executive dysfunction, predominantly associated with developmental disorders of childhood such as ADHD, PDD, or Anxiety. Some of the participants were on an existing treatment plan of psychostimulant medication while others were seeking psychological intervention as a non-invasive method of treatment. At the time of consultation, the clinician obtained informed consent in writing for data to be de-identified and collated in the event of a future study. All participants engaged in at least one session of neurofeedback training within the past two years. The study is currently in progress.

Keywords: neurofeedback, behavioural self-regulation, meta-cognition, executive dysfunction, developmental disorders

Effort counts and achievement goal matters: Patterns of credit and blame in pursuit of achievement in a Chinese society

FWU, B. (National Taiwan University)

Previous research indicates that more credit is given to academic success whereas less blame is assigned to failure. This study argues that patterns of credit and blame may vary with levels of effort and types of achievement goals.
Abstracts of the 27th International Congress of Applied Psychology

1137

Brief Oral Presentations

Academic goals, like maths achievement, are burdened with high social value, whereas non-academic goals, like art, are endowed with high personal value in Chinese tradition. Scenario questionnaires were administered to 720 high school students in a Taipei metropolitan area in Northern Taiwan. Statistical analysis of MANOVA was applied to analyse the data. The results show that: (1) the moral value of effort-making in pursuit of achievement goals; (2) in case of success, there were larger differences in credit assignment between ‘diligent’ and ‘idle’ students in the maths than in the art domain; and (3) in the failure situation, there were larger discrepancies in blame infliction between ‘diligent’ and ‘idle’ students in the maths than in the art domain. The findings shed light on how students learn in the Chinese cultural tradition, and add a new perspective to the existing literature of credit and blame in the educational setting.

Emotion regulation in children with acute lymphocytic leukemia: A qualitative study of patients and survivors in Indonesia

MANSOER, W. (University of Indonesia), FITRI, S. (University of Indonesia), ATMODIWIRYO, E. (University of Indonesia)

The aim of this qualitative study is to examine emotion and emotion regulation among children with Acute Lymphocytic Leukemia. Data were collected by interviews with four patients (9-13 years) and their parents, and also with two survivors (21-24 years) who had the same illness during their childhood. Results showed that both inpatients and survivors, during initial diagnosis and chemotherapy preparation, experienced negative emotions such as feeling sad, scared, angry, and embarrassed. They reported that they felt bored when they went through chemotherapy period. To regulate their emotion when they were diagnosed with leukemia, the children used response-focused actions (i.e., crying, angry, hiding their feelings), while antecedent-focused action was provided by others (situation selection and situation modification). After undergoing chemotherapy for 1-3 months, the children were able to use antecedent-focused responses by themselves (attention deployment and cognitive change), and their response-focused actions decreased. Children with supports from others could sort adaptive response alternatives that could be used in various kinds of situation to regulate their emotion.

Keywords: emotion regulation, antecedent-focused, response-focused, leukemia, children

Emotional evaluation and cognitive activity: Examining the condition and internal mechanism

FANG, P. (Capital Normal University), MA, Y. (Capital Normal University), XU, H. (Capital Normal University)

This study intends to explore the internal mechanism that reveals how elicited emotional evaluation influences subsequent cognitive activities, and to help make proper emotional evaluation in daily life, as well as to provide empirical evidence to improve quality of cognitive activities. Four hundred and sixty-five secondary school students are chosen as subjects in two experiments. One experiment explores whether the activated certainty impacts on assured judgment. The other intends to find which emotional factor impacts the choice of cognitive processing style without an activation process. It has been found that, when asked to make assured judgment about their evaluation accuracy, the subjects with different evocative emotions have significantly different judgments. Without activated evaluation, emotion valence is automatically activated. The elicited evaluation influences the subsequent judgments and people take this activated evaluation as information that affects subsequent cognitive activities.

Keywords: elicited emotional evaluation, cognitive processing style, evaluation, evocative emotions

Emotional experiences, empathy and the influencing factors

The aim of this qualitative study is to examine emotion and emotion regulation among children with Acute Lymphocytic Leukemia. Data were collected by interviews with four patients (9-13 years) and their parents, and also with two survivors (21-24 years) who had the same illness during their childhood. Results showed that both inpatients and survivors, during initial diagnosis and chemotherapy preparation, experienced negative emotions such as feeling sad, scared, angry, and embarrassed. Emotional experiences, empathy and the influencing factors
FANG, P. (Capital Normal University), LI, Z. (Capital Normal University), JIANG, Y. (Beijing Sport University)

This study explores the relationship between emotional experiences and empathy, as well as the role of emotion regulation and environmental factors. The results of the study will provide evidence and empirical support for intervention and treatment in this field. Experiments and questionnaires were used to investigate approximately 500 individuals in three studies. This research has found that people with a higher level of emotional experiences have more sympathy and less personal distress. Emotion regulation and emotional experiences have interaction effects with empathy. Environmental factors (including behavioral validity and cultural comparability) and emotional experiences have joint effects with empathy. The results suggest that emotional experiences affect empathy. Emotion regulation and environmental factors regulate the relationship between emotional experiences and empathy.

Keywords: emotion experiences, empathy, emotion regulation, personal distress, cultural comparability

Emotional intelligence and its relation to human abnormal behaviour: Comparison between addicted and nonaddicted people

HOMAYOUNI, A. (Islamic Azad University)

Emotional intelligence (E/I) consists of appraisal of emotion in the self and others, regulation of emotion in the self and others and utilization of emotion in solving problems. Subsumed under these branches are functions such as verbal and non-verbal appraisal and expression of emotion and using emotions to motivate as part of the utilisation of emotions (Salovey & Mayer’s, 1990). Emotional intelligence components are important in psychological functions such as problem-solving, happiness, stress-tolerance, self-actualization and interpersonal relationship. So the research aimed to investigate role of Emotional intelligence in tendency to addiction.

In the sampling process a total of 73 addicted people and 73 non-addicted people were randomly selected. All participants were requested to complete Schutte's Self-Report E/I Test (SSREIT) (33 items). The test measures ability of E/I in three fields: Appraisal of emotion, regulation of emotion and utilization of emotion. In order to analyze the data, an independent T test was used to compare means of two groups. Findings indicated significant differences between two groups in components of emotional intelligent. Non-addicted people...
had more scores in appraisal of emotion, utilization of emotion and general score of emotional intelligence. However, there was no significant difference in regulation of emotion in two groups. Considering the results, it is recommended to apply the plans for enhancing emotional intelligent components in order to increasing abilities and competencies in confronting with crisis and bad events and reducing risk of abnormal behaviors, especially addiction.

Keywords: emotional intelligence, addiction, emotion expression

**Emotional social sharing, emotion recovery and influencing factors**

Jiang, Y. (Beijing Sport University), Ma, Y. (Capital Normal University), Hong, J. (Capital Normal University)

This study attempts to examine the relationship between emotional social sharing (ESS) and emotion recovery, and explore the influencing factors on the relationship. The study helps better understand skills of emotional social sharing, make proper use of sharing in daily life, and provides empirical evidence for psychotherapy. This research uses the laboratory experimental method to investigate 58 volunteers, involving college undergraduates and graduates. The study shows ESS has a significant effect on negative emotion recovery. Irrelevant sharing is more helpful for short-time recovery from negative emotions than ESS, which has no effect on positive emotion recovery. For respiration rate, the valence of emotion and type of sharing have an interaction effect on emotion recovery at different stages. Irrelevant social sharing decreases the respiration rate for positive emotions, and increases negative emotions. This study shows the relationships between different types of social sharing and emotion recovery are different, and that the relationship is affected by the valences of emotion. Respiration rate is a sensitive index for the change of emotion valence.

Keywords: emotional social sharing, emotion recovery, emotional valence, sharing, respiration rate

**Empirical investigation of family environment among aggressive individuals: Therapeutic implications**

Kaur, H. (Punjabi University), Singh, P. (Punjabi University Patiala), Kaur, B. (Punjabi University Patiala)

The study was aimed at exploring various elements of family environment that might predispose the development of aggressive behaviour in individuals. With the knowledge of these factors, aggressive behaviour can be prevented by incorporating a specific family counseling program to reduce or minimize the presence of such an environment at home. Three hundred individuals in the age range of 14 to 22 years were selected randomly from various schools and colleges of Patiala district of Punjab, India and were given the family environment scale (Moos, 1989) and Aggression Questionnaire (Buss & Perry, 1992) to assess present elements of their family environment and aggression levels. Correlation coefficients were calculated to assess the relationship between aggression and elements of family environment. Aggression was found be significantly correlated with conflict \( r = 0.16, p < 0.05 \), expressiveness \( r = -0.17, p < 0.05 \), independence \( r = -0.16, p < 0.05 \) and organization \( r = -0.20, p < 0.05 \) sub-dimensions of the Family Environment Scale. More specifically, conflicts in families are found to be related with anger \( r = 0.16, p < 0.05 \) and physical aggression \( r = 0.17, p < 0.05 \) sub-dimensions of the Aggression Questionnaire but not with hostility and verbal aggression. A highly significant correlation has been found between the physical aggression and independence \( r = -0.26, p < 0.01 \) sub-dimensions of the family environment. From the findings it can be concluded that conflicts in family are found to be associated with aggressive behaviour of the individuals, the more conflict in the family the higher the tendency of its members to behave aggressively. On the other hand, family environment which promotes expressiveness, independence and organization may minimize the probability of developing aggressive behaviour in its members as these elements are found to be negatively correlated with aggression. The above mentioned findings suggest that by developing a family counselling model which would emphasize mainly on
developing conflict resolution strategies and inculcating expressiveness, independence and organization in family setup, development of aggressive behaviour can be prevented. Parents can be informed about the relationships so that they can modify their parenting style to avoid the occurrence of maladaptive behaviors like aggression.

Keywords: family environment, aggression, India, conflict, counselling

Employee engagement: A validated model

HICKS, R. (Bond University), O’REILLY, G. (Bond University)

The aim of the research was to confirm an engagement model that demonstrates the predictive relationships between engagement; its drivers (antecedents), and outcomes (consequences) in a multinational travel organization. Positive relationships were anticipated between variables. Model confirmation was conducted in two parts: the measurement model (engagement and its drivers), and the structural model (engagement, its drivers and outcomes). Part one of the study used confirmatory factor analysis to validate a 52 item engagement scale comprising of eight engagement drivers (senior leadership, team leadership, work demands, work support, employee empowerment, continuation, customer focus, and financial rewards), and an engagement variable. Part two used structural equation modeling to validate the structural model which detailed the causal relationships between engagement drivers (a latent variable with eight confirmed indicators), engagement, and engagement outcomes (a latent variable with five initial indicators; retention, productivity, customer satisfaction, employee commitment, and profit). The measurement model was confirmed with all eight drivers showing positive loadings onto the latent engagement driver variable (path values ranged between .52 and .82). However, the proposed structural model failed to converge. Anticipated error in the outcome variables lead to post hoc modifications. Convergence was achieved after grouping engagement outcome variables into personal and organizational outcomes. The anticipated positive causal relationship between the combined eight engagement drivers and engagement was confirmed (standardized coefficient = 0.93). However, the anticipated positive causal relationship between engagement and its outcomes was only partially supported. Engagement had a positive effect on personal outcomes (employee commitment), but a negative effect on organizational outcomes (productivity and profit). In both instances the effect was non-significant. Predictive relationships confirmed in this study indicated that effective management of engagement drivers can significantly improve engagement levels within an organization. Positive effects at the individual level such as increased commitment may also be anticipated. However, contrary to previous research, engagement may not always have a positive impact on organizational outcomes such as productivity and profit.

Keywords: engagement, structural equation modeling, organisational outcomes, engagement, positive relationships

Encounters with theory and personal process: Students’ experiences of studying Process Experiential Emotion-Focused Therapy (PEEFT).

CHONG, M.

To date research on Process-Experiential Emotion-Focused Therapy (PEEFT) has focused on therapy outcomes. An investigation of the published literature on post-graduate therapist training revealed that few authors had previously examined training from the student perspective. Training in PEEFT involves readings, demonstrations, experiential learning via skill development and live practice. The aim of this study was to examine students’ experiences of PEEFT training, using qualitative methods and principles drawn from experiential learning. A post-graduate class in Counselling Psychology and Professional Counselling received intensive PEEFT training as part of their course requirements. Six volunteers were asked during and after their training to provide, via email, short written reflections of their experience. Data were analysed using an approach consistent with Grounded Theory. Participants
reported both positive and negative experiences in their training. They noted how client experiences in demonstrations helped them to feel comfortable and to learn the method; how exercises helped them open up their awareness; how experiencing a technique as a client helped when in a counsellor role; and how positive lecturer feedback helped when practicing the method. Participants also noted potential difficulty using PEEFT and rigidity in how the method was applied. They were concerned about the lecturers’ perceived expectations and assumptions; they also expressed a need for freedom to critically appraise the theory and to learn at their own pace. In addition, the participants described discomfort linked to their own preparation, to the length of the sessions, and to a need for more interpersonal and conceptual safety. Analysis indicated that the participants wanted more demonstrations and practice, and wanted the theory to be delivered more expeditiously in order to facilitate this. They asked for more attention to be given to group processes, preparation and debriefing, and for more support from their lecturers. The participants especially valued the opportunities to experience PEEFT for themselves, and drew parallels between their learning experience and a therapy experience. The analysis undertaken in this study provided a means to explore students’ personal experiences of training in PEEFT.

Energymark: A behavioral intervention program designed to reduce household greenhouse gas emissions

GARDNER, J. (CSIRO), DOWD, A. (CSIRO), ASHWORT, P. (CSIRO)

Finding ways to promote positive action in response to climate change is arguably the greatest ever challenge to the field of applied psychology. Emission reduction targets set by governments typically do not specify how emissions will be reduced, but it is likely that regulation and other market-based mechanisms alone will be insufficient. Encouraging individual action through behavior change interventions will be an important component of the effective mitigation of climate change. We designed an intervention program, Energymark, which incorporates a number of mechanisms known to encourage behavior change, including social support, group discussion, goal setting, feedback, and provision of information from a trusted source. Currently there are more than 1500 people involved in the program, which involves meetings of existing social networks to discuss information that is provided to them about sources of energy and emissions. Groups meet eight times over a period of several months. In these meetings they provide data on their emissions profile, identify topics for further information, set goals to reduce emissions, and discuss problems meeting their goals. Initial results of the program show substantial impacts. Positive shifts were found on measures of environmental beliefs, knowledge of climate change mitigation, attitudes toward climate change topics and intentions to reduce emissions. More importantly, there were substantial behavioural impacts, with participants engaging in further information searches and discussions with others outside the intervention group, and average reductions in household carbon footprints of more than 30 per cent. The Energymark program represents a cost-effective intervention based on known principles of applied psychology, which has demonstrated a substantial impact on household greenhouse gas emissions. Further research is planned to examine the relative contribution of each of the intervention components to the overall outcomes, and to track long-term outcomes.

Enhancing physical activity in the school context: Experiences of the collaborative planning method

PASI, H. (University of Jyväskylä), LINTUNEN, T. (University of Jyväskylä), SUOMI, K. (University of Jyväskylä)

As physical activity among youth decreases at the age of 13 when they move from elementary to secondary school, it is important to find new possibilities for physical activity for them. This may be possible in a school context, if the recesses and the school yard facilities are
utilized effectively. In this study, the goal is to enhance the physical activity of secondary school students in the school context by using the collaborative planning method. In this method, students’ autonomy is supported by allowing them to participate in the planning process on equal terms with other members of the school community and researchers. The aim of the study is to describe the planning process and to find out what activities students would be interested to engage in during the recesses and how they would improve the school environment. For collaborative planning, we used Optima, an internet based electronic platform designed for online collaborative learning and planning. Optima usernames and passwords were delivered to the students during the lessons, and possibilities to use Optima were offered during the school days. The students of one secondary school (n = 300) participated in the planning process. The data consists of the discussions in Optima, which were analyzed using quantitative content analysis. In addition, the main researcher wrote field notes to describe the planning process. The students were most eager to write comments about the activities during the recesses and about the schoolyard area. For example, a slide, wooden stairs, and additional balls were suggested. In the beginning, the students were not autonomous enough to participate actively, and therefore the help of the teachers and the student union were essential in the planning process. We faced the following challenges while using this method. Firstly, to participate, students need to feel that it is safe to use Optima. Secondly, they need to feel that their opinions are listened to. Thirdly, students perceive working in Optima as a school task which has to be done during the school days. These factors need to be considered when using this collaborative planning method in the future.

Enhancing the meta-cognition of college students through their learning styles

CASTRO, N. (University of Santo Tomas)

The goal of this study is to identify the learning styles of college students and to investigate how they enhance meta-cognition. This research also sought to identify gender differences between Intelligence Quotient (IQ), academic performance, meta-cognition and learning styles. This study focuses on the meta-cognition theory of John Flavell. It refers to higher order thinking which involves active awareness and control over the cognitive processes engaged in learning. In line with this research, it investigates the meta-cognition and learning styles of college students with the following: IQ, gender, and academic performance. The participants were randomly selected college students of the University of Santo Tomas (UST), Manila, Philippines. They were given the following tests: Barsch Learning Style Inventory, Meta-cognitive Survey, Mental Ability Test and Test of Academic Performance. This is a correlational study that generates quantitative and qualitative sets of data that were gathered from UST college students, and investigated the associations between the variables. Aside from the goal of the researcher to provide an output for the recognition of an individual with his or her potentials, this research helps educators to formulate a teaching methodology that is suited to the level of understanding of college students. It also provides data that will help the educators in designing an instructional material that is conducive to maintaining the learning atmosphere. This research widens educators’ and students’ beliefs of how IQ, academic performance, gender differences, and learning styles influence the meta-cognition of human beings by providing high quality formative feedback.

Keywords: learning strategies, academic performance, intelligence quotient, meta-cognition, teaching

Entrepreneurship from emerging economy to developed economy: Entrepreneurial absorptive capability of Chinese firms

JIANG, H. (Shanghai Jiao Tong University), BIAN, D. (EM Lyon Business School)

Ventures from emerging economies to developed economies may face two crucial
challenges. One is to adapt the capabilities obtained in the fast-paced emerging economies to the slow-paced developed economies. The other is to maintain the transformed and/or newly acquired capabilities’ operation at full capacity to rapidly achieve leadership in developed economies. This paper aims to complement the theoretical framework developed by Yamakawa, Peng, and Deeds (2008) so as to map out a landscape of newly emerged international entrepreneurship studies. Using cases studies, we argue the importance of developing the entrepreneurial absorptive capabilities in developed economies to overcome the above difficulties. We would like to testify the construct of entrepreneurial absorptive capability of Chinese venture transnational entrepreneurship from emerging market to development market, which will highlight the future direction of transnational entrepreneurship. A series of propositions are accordingly proposed. Our theoretical model of entrepreneurial absorptive capability may map out a whole landscape of the newly emerged international entrepreneurship studies.

Keywords: emerging economies, entrepreneurship, absorption, international entrepreneurship, economic ventures

Environmental threats: New empirical findings on the role of personal involvement in the lay thinking about collective risk. The case of earthquakes in Romania and France

ERNST-VINTILA, A. (Universite de la Mediterranee Aix-Marseille II)

This empirical study focused on seismic risk and showed how social practices and personal involvement determine and explain the social representations of environmental threats in the lay thinking. Its originality consists in 1) distinguishing risk from hazard from a psychosocial perspective, and 2) completing an analysis of lay thinking about environmental threats at the collective level of explanation, a complement to the to the intra- and inter-individual levels often adopted in environmental psychology. Previous studies showed that practices are a determinant factor in shaping social representations and have suggested that personal involvement is a major explanatory variable of lay thinking. Personal involvement (Flament & Rouquette, 2003) corresponds to an individual’s relationship to a social object, such as threat, and is a combination of three dimensions: threat valuation, personal exposure to threat, and perceived capacity to act towards it. The study was run in France and Romania (low vs. high seismic risk countries) to compare the social representations of seismic risk among participants (N = 486) who had different levels of seismic experience/practice and of personal involvement. The study was conducted within the structural approach to the Theory of Social Representations (TSR), which enables formal comparisons among representations with the aid of its specific methodologies (here, we used the standard procedure of the Basic Cognitive Schemes model, Rouquette and Guimelli, 1992). A change in personal involvement in risk should trigger a change in some of the aspects of its social representation. Which aspects are affected? Results showed that in all groups, the social representation of seismic risk displayed salient normative aspects and low functional orientation. This structure explains the social representation’s low efficiency in prescribing collective conducts (e.g., low engagement in collective prevention, educational campaigns, antiseismic retrofitting, etc.). However, participants who had seismic experience/practice expressed a more functional social representation, which was more practically oriented and stronger in guiding collective conducts. When, in addition to seismic experience/practice, participants also felt involved, their social representations were even more practically oriented. However, the effects of personal involvement on the structure of the social representation were only observed if participants had seismic experience/practice. In contrast, when participants felt involved but had no seismic experience/practice, personal involvement had no effect on their social representation of seismic risk. These empirical findings have practical consequences for the campaign strategies aiming at seismic risk prevention: 1) when individuals with seismic experience/practice increase their personal involvement, their social representation should exert a stronger guidance on collective risk-related conduct (they should be more likely to engage in collective risk prevention); and 2) in
contrast, the strategy consisting in increasing individuals’ involvement (fear) without having provided them with sufficient antiseismic training, is ineffective.

Keywords: environmental threats, lay thinking, seismic risk, social practices, personal involvement

Environmental threats: New empirical findings on the role of personal involvement in the lay thinking about collective risk. The case of water quality in the South of France

ERNST-VINTILA, A. (Université de la Méditerranée Aix-Marseille II)

This empirical study focused on the lay thinking about water quality and showed how social practices and personal involvement impacted the social representations of environmental threats (water pollution). Its originality lies in completing an analysis of lay thinking about environmental threats at the collective level of explanation, a complement to the to the intra- and interindividual levels often adopted in environmental psychology. Previous studies showed that practices are a determinant factor in shaping social representations, and suggested that personal involvement is a major explanatory variable of lay thinking. Personal involvement (Flament & Rouquette, 2003) corresponds to an individual’s relationship to a social object, such as risk to water quality, and is a combination of three dimensions: risk valuation, exposure to risk, and perceived capacity to act towards it. A change in personal involvement should trigger a change in some of the aspects of the social representation of water quality. Which aspects are affected? The study compared the social representations of water quality among participants (N = 96) who had different levels of water quality practice: professionals who worked in the industrial area of the Berre Pond in Provence (southern France), and lay residents of that area. Participants’ personal involvement was measured as a selection variable on a six-point Likert scale. The study was conducted within the structural approach to the theory of social representations (TSR), which enables formal comparisons among representations with the aid of its specific methodologies (cf. infra). The structure of the social representations of water quality was analysed through a standard procedure developed within the structural approach of the TSR: prototypicality analysis (Vergès, 1992, 2002). Results showed that, in both groups, social representations of water quality displayed salient normative aspects but only low functional orientation. This structure explains the social representation’s low efficiency in prescribing collective preservation conducts. However, in the professionals group, the social representation of participants who reported ”high personal concern” with water quality was more structured than that of participants who felt ”just as concerned as anyone else”. In contrast, for lay persons, being concerned, or not, with water quality did not contribute to structuring the social representation. Thus, personal involvement structured the social representation and increased its prescriptive efficiency, but only in the professionals group (i.e., only provided that participants had established practices related to water pollution). These empirical findings have practical consequences for the campaigns of water quality reservation. Firstly, when individuals with established preservation practice increase their personal involvement, their social representation should exert a stronger guidance on their conducts (preservation of water quality, “best practices”, etc); and secondly, in contrast, the strategy consisting in increasing individuals’ involvement (concern) without having provided them with sufficient preservation training, is ineffective.

Keywords: environmental threats, lay thinking, water pollution, social representations

Evaluation of cognitive behaviour therapy group intervention for perinatal mood disorders

FOSTER, G. (Belmont Private Hospital), WILLIAMS, M. (Belmont Private Hospital), OOSEN, J. (Belmont Private Hospital)

Postnatal depression is the most prevalent mood disorder associated with childbirth and affects up to 15% of childbearing women. The aim of this study was to examine the effectiveness of a Cognitive Behaviour Therapy (CBT) group program on women diagnosed with a perinatal mood disorder. The program had traditional CBT
components as well as specific topics and themes pertinent to perinatal mood disorders designed to target negative cognitions and challenge distorted motherhood-specific beliefs. A convenience sample of women admitted to a private mental health hospital was used. The sample consisted of 87 participants (completed data sets) throughout 2007, 2008 and 2009. Groups were conducted every six weeks with an average of ten women per group. The program consisted of psychosocial topics for one and a half days per week and one session per week with a nurse therapist. Participants completed three self-report questionnaires pre and post the five week treatment program. Three aspects of patient functioning were measured: depression (Edinburgh Postnatal Depression Scale, EPDS), anxiety (State-Trait Anxiety Inventory, STAI) and the impact of postnatal depression on their primary relationship (Abbreviated Dyadic Adjustment Scale, ADAS). An analysis of the data for 2007, 2008 and 2009 revealed that the program made statistically significant differences across two of the measures. Specifically, the women’s depression and anxiety levels were significantly reduced after completing the program. No significant improvement was found in the women’s level of adjustment in their primary relationship. The results support the effectiveness of the CBT program in treating depression and anxiety in women with perinatal mood disorders. A Cognitive Behaviour Therapy program which includes topics relevant to perinatal mood disorders and in particular distorted motherhood-specific beliefs has the potential to assist women suffering from antenatal and postnatal depression. In addition, presenting the program in a group format can assist a greater number of women when resources are limited. Possible explanations for non-significant results will be discussed.

Keywords: postnatal depression, cognitive behavioural therapy, perinatal mood disorder, motherhood-specific beliefs, state-trait anxiety inventory

Evaluation of competence development in professional coach training

DREXLER, A. (University of Innsbruck), STIPPLER, M. (University of Innsbruck), PAUZA, E. (University of Kassel), MOELLER, H. (University of Kassel)

This study focuses on specific characteristics and soft skills of counsellors. It uses an evaluative approach to measure their development over the course of training. The study focus lies in identifying personality changes and social skills related to training. The study does not primarily concentrate on the increase of specific knowledge. Up to now, training evaluations have mostly been based on participants’ self reports following events. To catch a variety of developmental aspects, the applied instruments in the presented evaluation model cover a wide range of methods and represent a framework for evaluating further education and training in a more complex way. In this study we use a multifaceted form of examination and we refer to different theoretical concepts, for example, knowledge and problem solving, personality and emotion theories. All the Instruments intend to collect objective data instead of subjective self-assessments by the participants. Results show that there are changes of personality traits and tendencies of improved recognition of affects – in addition to receiving the intended coach-qualification. Finally, we believe that our generic, yet multifaceted, model to evaluate coach-training produces valid findings. It highlights the improved qualifications as well as the human development of the participants during the course. It therefore enables assessment of the quality of such training using a broader approach than usual.

Evaluation of programs designed to improve literacy development in at-risk children: The case for longitudinal assessment

STANISLAW, H. (California State University, Stanislaus), MCCREARY, J. (California State University), HENK, J. (California State University, Stanislaus), ESTERLY, J. (California State University, Stanislaus)

We examined literacy skill development in at-risk children, and determined how this varied with native language and with participation in “school readiness” programs designed to foster academic readiness in children aged 0-5 years.
Of particular interest was how conclusions regarding program effectiveness derived from examination of single grade levels compared with those derived from studying developmental trajectories. A longitudinal design was used to assess literacy skills of 168 native English speakers and 229 English language learners in Kindergarten, Grade 1, and Grade 3. All literacy assessments were conducted in English. Cluster analysis was used to group children according to the similarity of their school readiness program history. Separate developmental trajectories were mapped out for each of these groups. English language learners lagged behind native English speakers in their literacy skills at Kindergarten. Children with different school readiness program histories differed little in their literacy skill levels at Kindergarten. However, the groups had markedly different developmental trajectories: sizable group differences emerged in Grade 1 and were maintained through Grade 3. Furthermore, some clusters of school readiness programs had steeper developmental trajectories for English language learners than for native English speakers, helping to reduce the literacy gap for English language learners as the children matured. Programs designed to foster academic readiness can accelerate literacy development in children aged 0-5 years, and can help English learners overcome the challenges they face relative to native English speakers. Longitudinal assessments are particularly valuable in documenting the impacts of these programs.

### Evaluation of the effectiveness of cognitive behavioral therapy in improving college students’ self-esteem and self-efficacy

GHANBARI HASHEM ABADI, B. (University Ferdowsi of Mashhad), KAZEMEINI, T. (Ferdowsi University of Mashhad)

The present study examined the effectiveness of cognitive behavioral therapy (CBT) in improving college students’ self-esteem and self-efficacy. This research was based on a pre-test/post-test control group. Twenty four college students, referred to a psychological clinic at Ferdowsi University of Mashhad, produced low scores in Coopersmith Self-esteem Inventory screening determining attendance in group CBT, were randomly assigned to the experimental and control groups (eight females and four males in each). The experimental group received eight weekly 90 minute sessions of cognitive behavioral therapy while the control group received no specific intervention. The measurement scales used were the Self-Esteem Scale (Coopersmith, 1972) and the Self-efficacy Inventory (Shere et. al. 1982). After controlling for baseline scores, the experimental group participants demonstrated significantly higher levels of self-esteem and self-efficacy compared to the control group. These results suggest that group CBT can enhance self-esteem and self-efficacy in college students.

### Evaluation study on the effect of the “Temporary Stop To See” campaign: Recent findings

NAGATSUKA, Y. (Niigata University)

Drivers in our country have “biased” Accident Cause Concept (ACC) in that they regard “speeding” and “drunk driving” as most frequent causes of accidents regardless of the fact that the common causes of accidents are “perceptual failures”. The writer considered that, to change drivers’ dangerous behaviour into desirable (safety) behaviour, we must change their ACC because human behaviour is determined by someone’s cognition (concept) of a situation where they live as Koffka (1935) advocated. To make drivers notice the factual cause of accidents, the “temporary stop to see” (TSTS) campaign developed in 1988 by the writer was conducted at lecture meetings in two transportation companies. Drivers of the companies served as subjects. Changes of ACC were surveyed by a questionnaire listing fifteen road violations before and after the campaign. The writer first informed drivers only of “the facts of occurrence of accidents” and then made them ponder the “causes of accidents, in other words, the kind of worst violations to be removed from the road”. After the pondering,
Drivers noticed that looking carefully and observing precisely were the effective measures and realized the importance of perception. Drivers were asked by the writer how to achieve this. They pondered again and replied, “By making a temporary stop, we can look and attend surroundings precisely”. The biased ACC was modified into an unbiased (factual) one by the TSTS campaign. Drivers were motivated to practice a temporary stop at the intersections without a signal to avoid perceptual failures. Reduction of accidents was attained in the two companies following a desirable change of ACC and behaviours. It was hypothesized that it was important for drivers to form a factual ACC to motivate them to perform a temporary stop which was considered an essential prerequisite to a successful perception of surroundings. Based on the campaign activities, a factual ACC was formed, and desirable driving behaviour developed. As a result, accidents have been reduced in the two companies.

Evidence based management – an effective approach for public agencies?

STUMM, S. (University of Mainz, Department of Psychology), DORMANN, C. (University of Mainz), MOHR, N. (University of Mainz)

Evidence Based Management (EBM) means using the best facts available to make critical decisions. A lack of EBM is proposed to negatively affect organizational productivity. However, this hypothesis relies on poor evidence itself. Moreover there is no widely accepted model of EBM in the literature. Consequently we propose a theoretical framework of EBM and investigate its job-related outcomes. We assume that EBM appears in terms of EBM bases, to be conceived as foundation issues for EBM and EBM practices, which implies making decisions on the basis of the latest research. Specifically, we examined whether organizations with common use of EBM are more successful than those with rare application of EBM in respect to established job-related variables (job satisfaction, commitment, well-being and work engagement). The sample comprises of managers and employees of public organizations. Our hypotheses were tested by means of a multi-source (questionnaire and archival data) multilevel (managers and employees) design. We used a questionnaire to measure EBM practices and EBM bases on the one hand and common job-related variables on the other hand. Data was analyzed using hierarchical linear models (HLM). To analyze postulated main effects, structural equation modeling was applied. Data analysis provides evidence that EBM emerges in terms of foundation issues for EBM and EBM practices. Organizational EBM-aspects show positive relations between job-related as well as organizational outcomes. Our findings show that EBM leads to positive outcomes in terms of employees’ attitudes and organizational outcomes. Increasing EBM bases of organizations on the one hand and increasing applications of organizational EBM practices on the other hand result in positive job-related outcomes. These findings underline our suggestion that EBM presents best management practice. Future research should aim at identifying critical organizational and personal determinants that promote EBM.

Examining the relationship between admission to a sub-acute mental health service and hospital admissions

PETRENO, J. (Eastern Health), MILDRED, H. (Deakin University/Eastern Health), GEDGE, R. (Deakin University/Eastern Health)

In many Western countries, there has been an increasing shift away from reliance on acute inpatient forms of mental health treatment to community mental health services. However, there have been some concerns that there is a significant gap between community and acute mental health services along the continuum of care. In Victoria a model of short sub-acute residential care has been piloted in an attempt to avoid hospital admissions or reduce their length. These facilities, named Prevention and Recovery Care (PARC), are also designed to be an early discharge option for people leaving acute
inpatient units. The aim of the current study was to evaluate the effectiveness of a PARC in reducing acute inpatient days, crisis team contact and improving the mental health of people who use the PARC. Data from 182 clients who had used a PARC between January 1st 2006 and June 30th 2008 were extracted from the mental health database. Client inpatient days, crisis team contact and mental health functioning were measured for the 12 months before a client’s admission to PARC and for the 12 months post admission. Independent t-tests were used to analyse the data. Results demonstrated that client mental health significantly improved across the time of their admission to PARC (a maximum of four weeks). Inpatient days and crisis team contact were both significantly lower in the 12 months post PARC compared to the 12 months prior to PARC. Whilst this study is preliminary in nature, employing correlational data and lacking a control group, the robust effects in a relatively large sample are very encouraging. The findings offer considerable early support for the PARC model of mental health care as an effective treatment option in acute episodes of the low prevalence disorders.

Keywords: community, mental health, residential care, acute inpatients

Experts in their own lives: Engaging with children in family and domestic violence service provision

CAREY, L. (Women’s Council for Domestic and Family Violence Services, Western Australia)

The aim of this research was to obtain insight to children and young people’s experiences of separation and Refuge Services in order to inform future services. Metropolitan Refuges in Perth were approached to gain a sample for the consults. Consent was gained through the Refuge as well as guardians, and the children were explained the process in child friendly and age appropriate language. The consults were undertaken by two female staff members, and were unstructured group consults. This method was chosen so as to not guide the responses, and to combat issues of power arising between children and adults. Seven Refuges participated in the consultation process, resulting in 32 children being consulted, aged three to 14 years old, including 19 girls and 13 boys. Each child experiences leaving home and Refuge life differently. Children and young people experiencing family and domestic violence were eager to share their experiences. Responses fell into broad categories including; leaving home, arriving at the Refuge, living at the Refuge, staff and services and leaving the Refuge. Overall children and young people consulted were happy to be in Refuge as it provided a safe space for them. However there were many challenges to living in a Refuge, such as sharing small spaces and living closely with other families. It is vital to consult with children when setting out service principles for them. It acknowledges their voice and authority in their own lives, and works to empower them, particularly in the case of family and domestic violence. Children have the right to be heard.

Keywords: young people, refuge services, domestic violence, children’s empowerment

Exploring relationships between job loss and obsolescence: Directions for future research

KAUFMAN, H. (Polytechnic Institute of New York University)

The purpose of this paper is to address how job loss among professionals may be related to the obsolescence of their knowledge and skills. While both job loss and obsolescence have been subject to research over many years, little is known about the relationship between them. This study reviewed, analyzed and integrated previous data in order to identify potentially fruitful directions for future research. Data collected primarily from technical professionals who experienced job loss included survey instruments measuring a variety of constructs, including professional obsolescence. Other measures related to the possible effects of job loss were also utilized. These included the Job Preference Inventory by Williams (1965) as an index of flexibility or rigidity with respect to occupational role and the self-assurance scale from Ghiselli’s (1971) Self-Description Inventory to measure self-esteem. The length of time out of work was found to be positively related to professional obsolescence ($r = .49, p < .001$) as
well as to occupational rigidity ($r = .43, p < .001$). However, only among those with high self-esteem was obsolescence positively related to occupational rigidity ($r = .48, p < .01$). Long-term unemployed professionals experience higher levels of obsolescence as well as occupational rigidity, but there is a clear question of causality. Does the length of time professionals remain jobless result in greater obsolescence as well as occupational rigidity? Alternatively, are professionals who are up to date and more flexible in the type of job they are willing to accept, re-employed faster? It is likely that both occur, but a clearer answer to the question of causality requires longitudinal research. Obsolescence was related to occupational rigidity only among high self-esteem professionals. The role of self-esteem as a moderator in the relationship can be compared to Korman’s (1966) results on occupational choice. The findings with self-esteem highlight the need for future research to address the complex role of personal characteristics in job loss.

**Keywords:** obsolescence, job loss, job preference inventory, self-esteem, occupational rigidity

**Exploring the Chinese-Filipino social identity: A social representational framework**

YU, A. (University of the Philippines-Diliman)

The research explores self-perceptions and social identity representations of the Chinese in the Philippines using the social representations framework. In particular, it seeks to understand how Chinese culture and personal and group migration history are translated into the ethnic minority’s self-construal and social identity. Additionally, it investigates the influence of various communication processes (education, linguistic ability, social interactions and adherence to customs and traditions) as well as individual (age and gender) and environmental attributes (migration status and parents’ cultural background) in self and social identity development. It will likewise explore Chinese in the Philippines’ subgroup’s social representations. A combination of qualitative and quantitative methods will be utilized: in-depth interview of ethnic Chinese respondents will be done in Study 1 to elicit social representations of the social identity as well as sub-group classifications; survey questionnaires will be fielded in Study 2 with the aim of understanding the variances in the social representations of the subgroups, as well as the attitudinal link between self- and social identity. Chinese-Filipino social identity representations, self-referent labels, customs and traditions, historical events/people salient in Philippine, China and Chinese migration to the Philippines’ histories, sub-groups identified within the migrant group. Subgroups are differentiated by their place of origin in China and length of stay in the Philippines. Phase 2 results are to follow. Communication processes targeted in the study are seen to influence self- and social construal. Age at migration and migration status are likewise factors that affect self-construal and social identity.

**Keywords:** self-perceptions, social identity, migration, self-construal

**Exploring the efficacy of an integrated child and family service model: Child development and behaviour outcomes**

GIBSON, F. (Institute of Early Childhood Macquarie University), GRACE, R. (Macquarie University), MCMAUGH, A. (Macquarie University), CALDIS, E. (Macquarie University), BOWEN, J. (Macquarie University)

While integrated service models are widely viewed as optimal for intervention in socially disadvantaged communities (Ofsted UK, 2009), their efficacy has not been investigated in an Australian context. This study reports child outcomes in a newly developed integrated service. Participants were mothers ($N = 18$) and their 27 preschool age children referred to an integrated service in Sydney, Australia. Child development using the Battelle Developmental Inventory and an early literacy task was assessed at time of recruitment on 18 children (in their mother’s care) and again nine months later ($n = 16$). Mothers also completed an overall rating of behaviour (MOR) concerning their preschool age children (whether they were in maternal care or not); ratings ranged from ‘much easier than average’ to ‘much more difficult’. At Time 1, 15
of 18 children (83%) were in the pass range on the Battelle and one child each scored in the ‘borderline’, ‘clear’ or ‘serious’ indication for referral categories. The most risk apparent subdomain was Communication (n = 9 in ‘borderline’ or ‘refer’ categories) followed by Cognitive (n = 7), Personal Social (n = 4), Adaptive and Motor (n = 3 per domain). Early literacy scores revealed that most children (n = 16) were within age level expectations or above. A total of five (16%) of 27 of children were rated as “more difficult than average” (MOR) at Time 1. Analysis of follow-up data at Time 2, nine months after service entry found no significant change in children’s developmental categories, nor in early literacy scores. There was however, a significant change in regard to mothers rating of child behaviour (MOR), indicating a perceived improvement in child behaviour from Time 1 to 2 (p = .015). These results indicate the difficulties in capturing developmental change in young children involved in multifaceted integrated service initiatives using more formal measures of development. However, maternal perceptions of child behaviour were more sensitive to change over a relatively short time period. Longer term follow-up of children engaged in such services is desirable, as well as the use of measures sensitive to change across key areas of development.

Keywords: child behaviour, social disadvantage, child development, maternal perceptions, literacy

Exploring the link between self-concept, adjustment and sport performance

KHANNA, D. (Panjab University), LOHAN, U. (Kurukshetra University), MALIK, R. (Government School Haryana), Dahiya, R. (Government College for Girls)

The present paper aims to explore the link between self-concept, adjustment and sports performance. The study also focuses on assessing the self-concept and adjustment levels of Indian female wrestlers that will impact on their sports performance and identify the implications of these for the drive to enhance sports performance as wrestling is very popular as one of the oldest sports of India, so numerous research studies have been done on it over the years. Although many aspects of wrestling related to physical powers have been investigated by the researchers yet few of the studies undertaken to date have specifically concerned female wrestling and implication for performance enhancement. To achieve the same, 112 Indian female wrestlers were selected for surveys. These subjects included those wrestlers who won medals at states and national levels and also those who have not won medals. The Self-concept questionnaire conducted by Raj Kumar Saraswat (1984) was used to measure the physical social, temperamental, educational, moral and intellectual aspects of self-concept. Adjustment inventory by Sinha and Singh (1980) was used to measure all the dimensions of adjustments i.e. home, health, social, emotional, educational and total adjustments of the subjects. Results show that there is significant difference in the level of self-concept and adjustment between national medalist and national non-medalist Indian female wrestlers. A significant difference has also been recorded between state medalist and state non-medalist female wrestlers as far as adjustment is concerned, whereas no significant difference has been found in their level of self-concept. National and state medalist female wrestlers have been found to be significantly different from each other both in their level on self-concept and adjustment. From the results of the present study it has become clear that on the psychological predispositions selected for the study, they have positive relationships with each other as well as with achievement. So, it has become necessary that female wrestlers must be conditioned not only physically but psychologically as well. So, the coach or the psychologist attached with the team must take care of level of self-concept and level of adjustment. He must also be acquainted with the technique of managing the hyperactivity of all these psychological variables. Thus, it becomes important that a coach while giving coaching must also counsel the player for their psychological preparations.

Keywords: female wrestlers, sport, sport psychology, adjustment, self-concept

Exploring the nature of obsessive compulsive checking
While people with Obsessive Compulsive Disorder (OCD) may present with a range of obsessions and compulsions, for many, excessive, ritualised, time consuming checking behaviours and related obsessions are dominant expressions of the condition (e.g. Fullana et al., 2009; Samuels et al., 2006). Sub-typing by predominant symptom presentation has been suggested to be important since qualitative differences between OCD subtypes mean that when conducting research into the origin, nature and treatment of OCD, findings may not be generalisable across the different subtypes (McKay et al., 2004). In this study we investigated the nature of Obsessive-Compulsive Checking (OC-Ch) by examining the type and frequency of obsessions and compulsions experienced in a large sample of people diagnosed with this subtype. As part of a comprehensive pre-treatment assessment the Yale-Brown Obsessive Compulsive Scale and checklist (Goodman et al., 1989) were administered to 50 people with OC-Ch subtype. Additionally, exploration into the nature of these phenomena was made by examining the prevalence of features such as pathological doubting, indecisiveness, avoidance behaviours, insight and pervasive slowness. The results of this phenomenological exploration are described and presented. Overall, participants met criteria for severe OCD that was causing a moderate to severe level of interference in most areas of their lives. All participants reported experiencing checking compulsions and aggressive obsessions, with high levels of endorsement for all checking compulsions and fears and obsessions about harm to self or others. Other features prominent in this group were avoidance, obsessional slowness, doubting and indecision. It is argued that enhancing our knowledge of the nature of specific OCD subtypes, such as OC-Ch may assist in determining disorder related pathogenesis, maintaining factors, prognosis and treatment. Identifying the underlying variables that mediate the concerns experienced by people with OC-Ch subtype could enable the development of treatment strategies to address these most frequently reported concerns and features.

Keywords: obsessive compulsive disorder, checking compulsions, aggressive obsessions, pathological doubting, avoidance

Exploring the relationship between ideal affect and emotion regulation

YEUNG, D. (City University of Hong Kong), LOK, D. (City University of Hong Kong)

According to the Affect Valuation Theory (Tsai, Knutson, & Fung, 2006), Chinese people differ from North Americans in the types of emotions they ideally want to experience (known as ideal affect). Compared with Americans, Chinese value more low-arousal-positive affect (LAP) such as calmness but fewer high-arousal-positive affects (HAP) such as excitement. The present study explored the relationship between ideal affect and emotion regulation among Chinese youngsters in order to test whether the type of ideal affect serves a motivational purpose to guide our way to regulate emotions. The sample consisted of 800 high school and university students residing in Hong Kong. They first completed a set of questionnaires on ideal affect and general emotion regulation strategies, followed by rating emotional feelings and expression in response to six hypothetical scenarios. Preliminary results (N = 464) demonstrated that individuals who value high-arousal-positive emotions (HAP) were less likely to use suppression whereas individuals who value low-arousal-positive emotions (LAP) tended to use more cognitive reappraisal. In response to the six hypothetical scenarios, individuals with higher level of HAP expressed their emotional feelings to a greater extent, and were less likely to avoid subjective emotional feelings than did those with LAP. Findings of this study reveal that the type of emotions that we want to feel may partly affect the types of strategies that we use to regulate emotions. It provides important implications to educators in order to understand mechanisms of emotion regulation among young people.

Keywords: emotion regulation, affect valuation, low-arousal-positive affect, high-arousal-positive affect, regulation strategies
Exploring the social and cultural factors of suicide in Sikkim

VERMA, S. (Sikkim University)

The objective of this study was to explore the role of social and cultural factors as mediators in suicide as a phenomena occurring in the North Eastern region of India. A psycho-autopsy approach was adopted in which narrative as a tool of data collection was undertaken. The sample (N = 35) for this study comprised of close family members of suicide victims. For analyzing the data, Structural Model Analysis was adopted. Data reveals that changes in structures level (changing value system, individual need and desire, unemployment, low education, changing family dynamics etcetera) leads to psychological process (stigmatization, guilt, depression isolation, alienation) triggering suicide. Thus, the paper entails detail understanding of the function of these variables in a specific cultural context.

Keywords: cultural context, suicide, psycho-autopsy approach, structural model analysis

Exploring the wellbeing of students studying at an Australian university

ANDREWS, A. (The University of New South Wales), CHONG, J. (The University of New South Wales), HEALY, M. (The University of New South Wales), ANDREWS, A. (The University of New South Wales)

Mental health problems are one of the leading contributors to the burden of disease amongst Australians, with anxiety and depression accounting for a significant proportion of this relationship. Over the last, decade with the internationalization of higher education, the wellbeing and mental health of university students has increasingly become a cause for concern for university management internationally. Student wellbeing and mental health can have considerable impact on academic performance and student and university community safety. The present study sought to examine the prevalence of mental health problems and general wellbeing amongst university students enrolled at one Australian university, and to explore how stress impacts on student mental health and wellbeing. A total of 1193 university students participated in a study exploring the impact on stress on student wellbeing, completing measures on general distress (Kessler Psychological Distress Scale), mental health (Depression, Anxiety, Stress Scales), and quality of life (WHO Quality of Life – Brief) under conditions of low versus high stress (varied by proximity to examinations). Overall, the findings revealed that with increasing stress, students exhibited increased levels of psychological distress, anxiety, stress, and depression, and quality of life was impacted. Factors such as gender, first language (English versus other), and student status (Local versus International) and financial security also impacted on psychological distress and quality of life. Understanding the factors impacting on the mental health and wellbeing of university students with diverse cultural, language and life style backgrounds are relevant for the provision of educational, psychological and health services to university students. Implications of the findings of this research for service provision to enhance student wellbeing and mental health are discussed.

Keywords: university students, well-being, mental health problems, student health, academic performance

Facial expression analysis using motion capture and generalized procrustes analysis

KOMORI, M. (Osaka Electro-Communication University), FUKUI, M. (Osaka Electro-Communication University), NAGAOKA, C. (Kyoto University), KATSUMATA, G. (Osaka Electro-Communication University), KAWAMURA, S. (Osaka University)

Human facial expressions provide various signals for social interaction. In many studies on facial expression, Facial Action Coding System (FACS) which was invented by Ekman & Friesen (1976), has been used. However, most of the studies that employed FACS focused on ‘static’ facial expressions (that is, photographed facial expressions), instead of ‘dynamic’ expressions, since conventional FACS methods render it difficult to treat dynamic facial sequences. The present study aims at solving these difficulties by
using a motion capture system and Generalized Procrustes Analysis (GPA). GPA converts coordinate data of landmark locations into multivariate normally distributed value that can be statistically analyzed. Two Japanese undergraduate students provided the facial time sequences. Prior to each recording, the positions of 19 feature points were marked by blue dots on each face to define the locations and shapes of the eyes, mouth, eye brows, etcetera. Each participant played the UNO game with two opponents for a few minutes. A facial sequence of each participant during the game was captured using two video cameras (30 frames per second; Participant 1, 9846 frames; Participant 2, 8148 frames). Stereo camera calibration and image rectification were performed based on checkerboard pattern using OpenCV. The feature points were tracked over all frames on each of the movies using a program written by the authors. The 3-Dimensional coordinates of the feature points of each frame were obtained by triangulation. Each captured face differed in location and orientation. In order to standardize them, we performed GPA on the facial feature points separately for each participant. Using the GPA, each face of each frame was represented as 53 dimensional (19 x 3 - 4) normally distributed values. In order to reduce the dimensions, principal component analysis (PCA) was performed for each participant. Results indicated that the contributions of the first two principal components (PCs) were relatively large for both participants (Participant 1: PC1, 37.0%, PC2, 8.7%; Participant 2: PC1, 23.6%, PC2, 6.1%). In order to interpret these components, ±3SD images of the first and second PCs for each participant were plotted. For both participants, the first PC was found to be related to mouth opening indicating that the first PC was linked to smiling. The second PC was related to eye blinking for Participant 1, and was related to eyebrow movements for Participant 2. These results suggest that the combination of motion capture and GPA is an effective method to analyze dynamic facial expressions in social interactions.

Factors influencing the intention to be an entrepreneur

RIYANTI, B. (Universitas Katolik Indonesia Atma Jaya), SUWARTONO, C. (Unika Atma Jaya)

The fact of an ever-growing unemployment rate in Indonesia dictates that the country should work hard to boost the number of its entrepreneurs. One way to overcome the problem of unemployment is by enhancing the spirit of entrepreneurship in young people. This research is intended to explore the direct and indirect factors affecting the intention to be an entrepreneur among students. This study will emphasize nine traits of entrepreneurship according to Sukardi (1991), personality types from Miner (1996) and self-efficacy notions (Bandura, 1977) which will be used to describe entrepreneurial behavior. Intention was assumed to take hold of emotional factors that influence behavior; intention is an indicator of how large one's effort is to try to perform intentional behavior (Ajzen, 1991). In the context of entrepreneurship, intention was identified as the important property for establishing an organization (Katz & Gartner, 1988) and as a predictor of a new reliable enterprise (Krueger, 2000). This research involves 125 students from the Faculty of eEngineering of Atma Jaya University in Jakarta. Questionnaires and accidental sampling were used. Analysis of structural equation model of Linear Structural Relation (LISREL) indicated that: (1) personality types from Miner had direct and significant impact on self-efficacy, (2) personality types from Miner had direct and significant impacts on the intention to be entrepreneur, (3) self-efficacy had a direct and significant impact on intention to be entrepreneur, (4) the nine characteristics of entrepreneurship had direct and significant impacts on intention to be entrepreneur. The result of this study is similar with experts' opinions that to be an entrepreneur, certain personality characteristics are needed and self-efficacy is important.

Keywords: intention, self-efficacy, entrepreneurship, personality types, self-efficacy
Factors related to intellectual media consumption: Behavior of undergraduate students in Bangkok

WONGPINPECH, P. (King Mongkut’s University of Technology), TANSUWANNOND, C. (Suan Dusit Rajabhat University)

The aims of this study were to examine the causes of unsuitable behavior with media consumption and to study the relationships between personal factors (media literacy, media effect awareness, inquiry and self control) and social factors (socialization from family and influence of peer groups) related to intellectual media consumption behavior. A further aim was to investigate the predictive factors of intellectual media consumption behavior of undergraduate students. Qualitative data was collected via in-depth interviews and focus groups from 30 key informants consisting of scholars, persons involved in child and adolescent development and undergraduate students. Quantitative data was collected from a sample of 481 undergraduate students via multi-stage random sampling. The data was collected by questionnaires and analyzed by Pearson Product Moment Correlation Coefficient, Stepwise Multiple Regression Analysis and One-Way ANOVA. Both personal factors and social factors were found to cause unsuitable behavior with media consumption. Students did not have media literacy, inquiry, media effect awareness and self control. They were induced to consume unsuitable media by peer groups and were unsuitably socialized by family. The educational sector did not support students’ media literacy and thinking system, and they were able to easily access unsuitable media. Media producers lacked ethics and entrepreneurs and government officers did not have social responsibility. Self control, media literacy, inquiry, media effect awareness, influence of peer groups and socialization from family had positive correlation to students’ intellectual media consumption behavior at the .01 significance level. Finally, media literacy, self control, inquiry, and influence of peer groups were the co-predictors of intellectual media consumption behavior that could predict 40% at the .001 significance level. According to the results, organizations, guardians and administers/lecturers in universities should support and promote socialization of their students so that they have media literacy, self-control and inquiring behavior from a young age.

Keywords: intellectual media consumption, undergraduate students, media, media effect, Bangkok

Family carer attitudes toward medications are related to self-reported medication adherence amongst people with mental illness

DEANE, F. (University of Wollongong), BYRNE, M. (University of Wollongong), MORTIMER, C. (University of Wollongong)

Others’ beliefs influence our own attitudes and behaviours. Parents in particular can affect their children’s behaviour by influencing their attitudes and cognitions. The aim of the present study was to explore the beliefs that family carers had toward medications and to determine whether these were related to the attitudes and medication adherence of their family member with mental illness (consumers). Forty adult carer-consumer dyads independently completed the Beliefs about Medicines Questionnaire (Horne, Weinman & Hankins, 1999), the Drug Attitudes Inventory (Hogan, Awad & Eastwood, 1983) and measures of medication adherence. Carer and consumer attitudes toward medications were strongly positively correlated. Further, carer attitudes were significantly correlated with consumers’ self reported adherence. However, consumers’ own attitudes were more strongly related to their adherence ratings. Consumers and family carers had high levels of awareness of each other’s attitudes toward medications. The moderate relationship between carer and consumer attitudes highlights the need to target psycho-educational activities to increase adherence at both carers and consumers. There is also a need to better understand whether attitude transfer between carers and consumers is a two-way process.

Keywords: medication adherence, caregivers, beliefs, family, medication
Family environment and career orientation among boarders and day scholars

MISRA, U. (Him Giri Nabh Vishwavidyalaya), JUYAL, L.

The present study was an attempt to learn about the Family Environment and Career Orientation of Boarders and Day Scholars. The sample of the present study comprised of 400 adolescents equally divided into four different grades (ninth, tenth, eleventh and twelfth) and Boarders and Day Scholars. All the subjects were selected from the Public Schools of Mussourie, Uttarakhand. Individual testing was done by using quota random sampling technique and administering the Career Development Inventory: School Form (Super and Thompson, 1981) and Family Environment Scale (Moos and Moos, 1986). All the subjects were matched on socio-economic status. A four by two factorial design was used to draw inferences. Means, standard deviations and analysis of variances were computed to interpret the raw data. The results of the study revealed that Boarders and Day Scholars differed significantly on Family Environment and Career Orientation. The main effect of school residency was found to be significant on only three dimensions of Family Environment namely, Expressiveness, Active Recreational Orientation and Moral Religious emphasis. Boarders showed higher levels of these characteristics in their families as compared to Day Scholars. On the World of Work and Career, Boarders were found to be significantly higher on Career Planning, Decision Making, World of Work and Career Development Knowledge, while Day Scholars scored better on Career Exploration and Career Development. The interaction of grade and school residency was found to be significant with respect to Career Orientation dimensions. Boarders were found to be higher on Career Orientation than Day Scholars. Boarders of the 9th and 12th grades experienced more conflict than Day Scholars of these classes. The study concluded that Boarders and Day Scholars differed on some Family Environment and Career Orientation dimensions among adolescents. All the obtained findings will be discussed in reference to the Indian context.

Keywords: career orientations, career development inventory, school residency, family environment, decision making

Feelings and effectiveness: Elementary reading teachers

YE, R. (Houston Independent School District, Research), LU, J. (Shanghai Normal University), GU, H. (Shanghai Normal University), STEVENS, C. (Independent School District Houston)

This research compares four types of fourth grade reading teachers’ feelings: for profession as a teacher, for school as a group, for enthusiasm on teaching, and for responsibility as a teacher; and analyzes relationships of these feelings with factors regarding instruction or teaching activities; and reveals how the teacher feelings affect students’ reading interests and achievement. Using an international educational database, PIRLS 2006 Teacher Questionnaire, the sample of 1,838 elementary reading teachers in eight units were gathered from China, Taipei, England, France, Germany, Hong Kong, Russia, Spain, and the United States. Descriptive methods, tables and figures, ANOVA, and Partial Correlation (removing influences of teachers’ age, teaching years and gender) were used. Elementary reading teachers’ feelings for responsibility were the highest among the four types, and their feelings for the profession as a teacher and for school as a satisfied group were also very high, but feelings for enthusiasm were low in the eight units. Reading teachers with better feelings, especially those higher scores on profession as a teacher and school as a satisfied group, had negative correlations with their time on maintaining discipline in classrooms; but they tended to teach more reading contents; had more teaching methods or forms in instruction procedures; asked students to answer questions, discuss, write, and work on projects following reading, more; gave more help in developing students’ reading skills and strategies; designed more methods to help students falling behind to catch up with whole class; and met and sent messages to parents to get parents’ assistances, more often. This study also discusses the large differences of correlations between teachers’ feelings and their use of assessment methods, computers and libraries among the participating countries and this needs further studies.
Research on teachers’ feelings is important as they are strongly related to instruction and students’ learning and development effectiveness. This cross-cultural study using PIRLS is a start trial for further research. Based on different cultures and reading teachers’ education and training levels, this study also suggests how to promote teachers’ positive feelings, and provide meaningful references for further studies in reading instruction and teacher education fields.

Keywords: teacher education, teachers’ feelings, teaching

Forensic psychological assessment of female victims of domestic violence: A differential study

ARMAS-VARGAS, E. (Universidad de La Laguna), BENCOMO-HERNÁNDEZ, I. (Instituto de Medicina Legal)

It is very important that the expert psychological evidence in cases of abuse is prepared in a rigorous and scientific way, to help expert psychologists take appropriate decisions. Among the many variables or criteria to be considered in the assessment are: depression, self-esteem, anxiety, personality, social support, adaptation, symptoms of post traumatic stress, distorted thoughts, relationships, communication within a relationship, criminal and psychopathological records, motivation to report, consumption of toxic substances, psychological and psychiatric treatments etc. In our investigation we wish to deliver other psychological variables that have been demonstrated to have valid content and discriminant properties. The sample was formed of 101 women, 37 in a control group (group of mothers from a training workshop on social skills), 29 in a clinical group (patients from clinical consultations) and 35l in a forensic population (female victims of abuse by their partners). The aims were: 1) To study whether there were differences between the groups (clinical, forensic and control) in the variables or criteria described, and 2) to identify the predictive factors by performing a discriminant analysis. The ATRAMIC questionnaire (Armas-Vargas, 2007) was used to assess 22 variables of personality. The Self-Esteem Questionnaire (CAE Questionnaire; Armas Vargas, 2004) was used to assess four factors of self-esteem including: 1) The assessment of: “Himself/Herself”; 2) that perceived or held for “Others”; 3) the Feeling of “Incompetence/Uselessness”; 4) the Feeling of Inferiority or of “Negative Comparison with Others”. Using the discriminant function, 86% of the control group and the female victims of abuse group were correctly classified. The variables with the highest discriminant power were: Self-Control when Lying, Failure to make Adjustments for Lies Told, Selective Privacy, Assertiveness, Transparency, Social Desirability, Guilt, Self-Criticism, Being Consistent, Being Coherent, Empathy and Insecurity. Using the discriminant function, 92% of the cases in the control and clinical groups were correctly classified. The variables with the highest discriminant power were: Failure to make Adjustments when Lying, Fear of Rejection or Criticism, Control, Self-Criticism, Being Consistent, and from the CAE, the variables “I-myself” and “Others”. On the basis of the groups used in this study, we found sufficient differences using the ATRAMIC and CAE instruments.

Keywords: expert psychologists, forensic assessments, female victims of abuse, assessment instruments, expert decision-making

Formal volunteering: Can working for no money still be called work in occupational psychology?

METZER, J. (University of South Australia)

Results of several studies of motivation, stress and job satisfaction of various groups of formal volunteers are examined with the aim of determining similarities of volunteering and paid work. The applicability of data from these studies to two major models, specifically, the Demand-Control-Support (DC-S) and the Job Demands-Resources (JD-R) Models in the literature on occupational psychology are critically examined. Outcome variables include mental health, stress and job satisfaction. Some longitudinal study results are reported, analysing the benefits of unpaid work for volunteers in the context of employment and unemployment in paid work. Both models are supported moderately well by data from the multiple volunteer group studies examined. There is
some evidence of benefit to volunteers in terms of mental health and wellbeing. A new construct of connectedness in volunteers emerges as a contributor to the variance in some of the outcome variables. Outcomes of volunteer work studies suggest that there is good similarity between paid and unpaid work, probably through their multiple benefits for volunteers and the paid workers. Support for the DC-S and JD-R models in volunteer studies suggest that formal volunteering should be considered to be another form of work.

Keywords: job satisfaction, job demands-resources model, volunteerism, unemployment, well-being

Formative evaluation of the Japanese version of the DVD, "Bandura’s social cognitive theory: An introduction", and its application to the development of learning and instructional guides

ITOH, H. (National Institute of Multimedia Education)

The aim of this research was to investigate the effects of verbal and visual presentations of the DVD, “Bandura’s social cognitive theory: An introduction”, on learning its content, in order to develop effective Japanese captions and learning and instructional guides. Eighteen graduate students, naive about Bandura’s theory, responded to multidimensional evaluation tests using texts and images. Formative evaluation and revision of Japanese captions and test items were repeated in three cycles. Results are discussed from a viewpoint of interactions between senders and recipients of information. Recipients chose “images combined with captions” and “images” more often than only “captions” as the main information for judging the most impressive scenes. They rated all the topics as interesting. Recipients scored highly in the correct response comprehension tests on aggressive modeling in the correct-incorrect judgment test and moral disengagement in the image-text matching test. They also had high correct responses in the multiple-choice test for major methods of developing efficacy and major processes of efficacy. However, correct response rates decreased in the image-text matching test, possibly because the recipients processed information using Japanese captions more often than information processing for getting the impressions. Error analyses revealed trends of learners’ errors. They highly evaluated the construction of captions and images. Among subitems, scores on Professor Bandura’s own narration had the highest evaluation. The test of applying acquired knowledge to their own research, practice, or life situations revealed that social cognitive theory could be helpful to the learners. The author’s interview with Professor Bandura was very helpful for understanding the background of the images and the narration, and thereby, to improving Japanese captions. Analyses of the multidimensional evaluation tests clarified the recipients’ information processing technique, whereas the interview with Professor Bandura clarified sender’s intention. Suggestions for improving Japanese captions and the development of learning and instructional guides include: highlighting key words, explaining key concepts, providing related printed materials, discussing personal experiences and applications of the theory with others.

Keywords: Japanese, learning and instructional guides, social cognitive theory, learning errors, social cognitive theory

Formulation, cognitive-behavioural therapy and restorative justice conferencing in addressing depressive symptoms

D’CRUZ, R. (University of Canberra)

The aims of this research were to appreciate the value of frequently revising case formulation, to see the link between formulation and choice of therapeutic approach, and to explore the possibility of integrating Restorative Justice Conferencing (RJC) along with Cognitive-Behavioural Therapy (CBT) to reduce depressive symptoms, of a client whose husband had repeatedly cheated on her. Case formulation is an evolving process requiring frequent revision before a treatment plan can be devised. Adopting CBT exclusively with individual clients may not be effective in all cases. By being creative, the CBT therapist can explore other therapies which, when combined with CBT, can help resolve this challenging problem. This case illustration explains how RJC was integrated...
along with CBT to help a family attain closure from the repeated infidelity of the husband, and move forward. The agreement was worked around the issue of trust. The husband agreed to look his wife and each of his daughters in the eye and tell them “it was over”, and “he would never ever betray their trust again”. Another outcome was that both agreed to undergo Couples’ Therapy, so they could work through their other differences. This was something my client’s husband was, hitherto, quite averse to accepting. His request that his daughters start to call him “dad” again was accepted. A last clause in the agreement stated that at some point during or after Couples’ Therapy, the two of them would renew their marriage vows in the presence of their children. In conclusion, careful formulation will almost always point the therapist in the direction of the most suitable therapeutic approach to be used. RJC can be very effectively used along with CBT for resolving complex clinical cases.

Keywords: restorative justice conferencing, cognitive behavioural therapy, case formulation, couples therapy, depression

Friendship motivation and role behavior expectation

NAKAYAMA, M. (Nara Women’s University), KUNINORI, Y. (Nara Women’s University)

The aim of the present study was to investigate the correlation between friendship motivation and the expectation about the role behaviors. Particularly, the developmental change of individuals was examined by comparing junior high school students and university students. The Friendship Motivation Scale (Okada, 2005) was used, which was developed in the framework of the self-determination theory. Based on the self-determination theory, four subscales were expected; external, internalized, indentified, and intrinsic reasons. The Role Behavior Expectation Scale (Shimotomai, 1991) consisted of six subscales; support, proximity, autonomy, amusement, similarity and dynamics. Both scales were scored using a 5-point Likert scale. The participants were asked to imagine a person with whom they kept company and to classify him/her as an intimate friend, friend or acquaintance. They then rated their expectation about the role behavior for an identified person. The questionnaire survey was completed by 69 junior high school students and 182 university students in Japan. Scores from each subscale of the Friendship Motivation Scale and Role Behavior Expectation Scale were averaged. The results revealed that the mean scores of intrinsic reasons on the Friendship Motivation was highest in both junior high school students and university students, with the mean scores decreasing in the order of indentified, internalized and external reasons. The mean scores of external reason were higher in university students than in junior high school students. In contrast, the mean scores of intrinsic and identified reasons were higher for junior high school students than for university students. As for the role behavior expectation, the scores were higher in junior high school students than in university students as a whole. Especially, the tendency was noticeable in proximity and amusement. The expectations for proximity, support, autonomy, and dynamics were high, and the expectation for similarity was low as a whole. Significant correlations were found between friendship motivation and the role behavior expectation.

Keywords: friendship, role behavior expectations, students, autonomy, proximity

Gender and innovation: The mediating and moderating effect of psychological capital

TONG, J. (Peking University), WANG, L. (Peking University)

Previous research showed that there were gender differences in innovation (e.g., Mostafa, 2005). This research aims to explore the possible mediating and moderating effects of Psychological Capital (PsyCap) on the relationship between gender and innovation. Study One examined a general employee sample ($N = 339$) on PsyCap and self-reported innovation behavior. Results showed that after controlling for demographic variables such as age, education level, management position and tenure, the higher PsyCap level resulted in more innovation behavior in males than in females. Meanwhile, PsyCap mediated and explained 58.43% of innovation gender differences. Study
Two examined PsyCap and supervisor-rated innovation behavior in employees from four corporations \((N = 861)\). Results demonstrated the mediating and moderating effects of PsyCap found in Study One. Overall, the findings showed the new function of PsyCap and helped to develop and cultivate innovation behavior in organizations.

**Keywords:** innovation, gender differences, psychological capital, management, employees

**Gender and temperament differences in meaning attribution**

TROFIIMOVA, I. (McMaster University), SULIS, W. (McMaster University)

The aim of this study was to investigate gender and temperament-related differences in meaning attribution. Osgood’s semantic differential applied to the most neutral and abstract concepts assessed using basic adjectives bipolar scales, could be used as a semi-projective method to study the characteristics of meaning attribution. The analysis of direct estimations of the abstract concepts was combined with a component analysis of semantic spaces (derived from factor analysis of the subjects’ estimations). The study was conducted in English for 1180 Canadians, in Russian for 167 Russians and in Chinese for 161 Chinese subjects. The direct estimations showed gender and temperament-related differences in meaning attribution. Males in all three samples attributed more negative estimations to abstract objects than females. People with stronger endurance and tempo in verbal-social activities differed dramatically from other temperament groups. At the same time there were cultural differences in semantic spaces of various gender and temperament groups. Gender and temperament differences in meaning attribution indicate a possible contribution of biological factors in resulting attitudes. The differences between “extraverts” and other temperament groups also show deficits of so-called “lexical approach” in studying personality and individual differences, which rely on factor analysis of descriptors of human behavior.

**Keywords:** meaning attribution, temperament, gender differences, lexical approach, personality

**Gender differences in mate selection: The effects of socioeconomic status and physical attractiveness**

LO, H. (Yuan Ze University), LO, W. N. (Yuan Ze University), HUONG, N. T. T. (Yuan Ze University), JHANG, J. L. (Yuan Ze University), LIN, Y. C. (Yuan Ze University), CHIOU, W. T. (Yuan Ze University)

The selection of marriage partner is one of the most important decisions in one’s life. Two criteria, socioeconomic status and physical attractiveness, are frequently discussed in literature. However, researchers have shown that the weight of these criteria differs between sexes. The aims of this study were to examine whether Asian people select their spouse according to the rules of matching theory and competition theory, and whether this selection outcome reveal similarities between Western and Asian populations and between sexes. A pilot test was used to choose four pictures and then an experiment was carried out to examine our research questions. Participants were recruited from Taiwanese college students. We found that the spouse selection of females and males conforms to Western matching theory only when considering education status. There was a difference between females’ and males’ mate selection only when earnings status was taken into account. Females tended to select a spouse who had higher earning status than themselves, whereas males tended to select a mate who had similar earnings status to themselves. Finally, we also found support for the different impact of physical attractiveness on males and females. In conclusion, both males and females tended to select spouse based on similar cultural status. In regards to economic status, males preferred a partner who was in the same status while females preferred a partner who was in higher status. Both males and females emphasized economic status over cultural status. In regards to physical attractiveness, both males and females were affected by physical attractiveness but this effect was significantly stronger on males than on females.
Gender specific self-management of technical university teachers

VYNOSLAVSKA, O. (National Technical University of Ukraine “Kyiv Polytechnic Institute”)

A contemporary teacher of a technical university must be educator, scientist and organizer simultaneously. Due to the increase of number of female teachers among them during the last few years it is important to study the reasons leading to irrational use of teacher working-time, especially when its gender specific. The aim was to show gender specific differences of teachers’ self-management and to create a program of psychological training in self-management skills for postgraduates and young teachers. Two hundred and eighty university teachers (146 male and 134 female) took part in the research. Techniques applied for the development of self-perfecting consist of four stages: (1) activity monitoring and time analysis; (2) inventory of registered "time-eaters"; (3) study of main functions of self-management; and (4) creation of individual technology of economical time usage. Grouping of primary data, alternative and comparative analysis, and graphic interpretation of data were used. Qualitative analysis identified three categories of "time-eaters": subjective (26.9%: 11.2% – male; 15.8% – female); objective outside university (63.8%: 26.3% – male; 37.5% – female), and objective inside university (22.4%: 9.1% – male; 13.3% – female). However, women have a higher level of self-management than men irrespective of pedagogical experience. After training, men decreased number of subjective time-eaters from 11.2% to 7.1%, and women decreased these from 15.8% to 9.2%. Nevertheless, the tendency of women to register a bigger number of "time-eaters" remained and they registered 31% more "time-eaters" than men. The data obtained allow us to assume that males think of rational use of time less thanks to a combination of smaller number of functions. Women who need to combine teaching, scientific work, house affairs etcetera, have time to do all these due to more effective self-organizing only. The further analysis has shown that with development of pedagogical skill (postgraduates – young teacher – experienced teacher) men have less "time-eaters" and women – bigger number. In conclusion, the research confirmed expediency of psychological training of postgraduates and young teachers in self-management skills for both females and males. However, the problem of effective time use by teachers should be solved in a complex manner, that is, on the one hand by individual inventory of time, and on the other hand, by improvement of university life as a whole.

Gendered culture at the workplace: How is it related to occupational stress?

LAU, M. (Deakin University)

Stress in the workplace is the most commonly reported claim of job-related illness. It has a significant negative impact on the employers and the employees which remains costly to both parties. Previous research showed that women tend to be over-represented in work-related stress claims. Despite an increased number of women entering the workforce, female workers still remain under-represented in management compared to their counterparts. This may stem from organisational management structures that give preference to masculine attributes such as determination, assertiveness and ‘toughness’ which are more commonly found in men than in women. The study aims to investigate occupational stress from a gendered identity perspective, where the gender-fit between the employee and the workplace is explored. It is hypothesized that incongruence between an individual’s gender attributes and the organisation’s gender attributes is associated with occupational stress. The moderating effect of negative affect on the relationship between gender-incongruence and occupational stress will also be examined. An anonymous, self-reported questionnaire was developed from the Gender Scale (Palermo, 1992), which measured the gender attributes scores (IV’s: feminine/nurturance and masculine/autonomy) for the individual and the organization that produced the incongruence scores; the Positive
and Negative Affect Scale (PANAS; Tellegen, 1984) to collect scores for (IV) negative affect; and the Occupational Stress Inventory – Revised (OSI-R; Osipow, 1998), which measured stress in terms of (DV’s:) Role Overload, Vocational Strain and Responsibility. Participants were recruited from masculine (autonomous), feminine (nurturing) and other organisations across a diverse range of industry sectors. One hundred and forty employees (69 males, 70 females), aged between 18 and 65, completed the paper-based or online questionnaire which indicated their individual and their organisations’ gender attributes. Occupational stress, coping mechanisms and personality attributes are recorded. The model as a whole explains 16.5% of stress in the form of Role Overload and 36.3% of stress in the form of Vocational Strain after block 5 variables have been included. Gender Incongruence is found to be associated with occupational stress for nurturance incongruence and not for autonomy incongruence. Results do not support that negative affect moderates on relationship between gender incongruence and occupational stress. It is hoped that the findings will encourage more research that incorporates gender identity in the areas of occupational stress. Otherwise, researchers may miss an opportunity to explore the construct of occupational stress from a gendered, systematic perspective within an organization and its culture, which in turn, could aid both employers and employees to better understanding and managing this occupational health hazard.

Keywords: workplace stress, job-related illness, gender attributes, coping strategies, organizational management

Generalised self-efficacy in relation to the life transitions of adult learners in a university setting: Towards a narrative constructivist model of self-regulation

DU PREEZ, J. (University of Southern Queensland)

This paper demonstrates a model of self-regulation based on a qualitative research project with adult learners undertaking an undergraduate degree. The narrative about the participant’s life transitions, co-constructed with the researcher, yielded data about their generalised self-efficacy and resulted in a unique self-efficacy narrative for each participant. A model of self-regulation is proposed with potential applications for coaching, counselling and psychotherapy. A narrative method was employed to construct narratives about an individual’s self-efficacy in relation to their experience of learning and life transitions. The method involved a cyclical and iterative process using qualitative interviews to collect life history data from participants. In addition, research participants completed reflective homework tasks, and this data was included in the participant’s narratives. A highly collaborative method entailed narratives being co-constructed by researcher and research participants as the participants were guided in reflecting on their experience in relation to learning and life transitions; the reflection focused on behaviour, cognitions and emotions that constitute a sense of self-efficacy. The analytic process used was narrative analysis, in which life is viewed as constructed and experienced through the telling and retelling of stories and hence the analysis is the creation of a coherent and resonant story. The method of constructing self-efficacy narratives was applied to a sample of mature aged students starting an undergraduate degree. The research outcomes confirmed a three-factor model of self-efficacy, comprising three inter-related stages: initiating action, applying effort, and persistence in overcoming difficulties. Evaluation of the research process by participants suggested that they had gained an enhanced understanding of self-efficacy from their participation in the research process, and would be able to apply this understanding to their studies and other endeavours in the future. A model of self-regulation is proposed as a means for coaches, counsellors and psychotherapists working from a narrative constructivist perspective to assist clients facing life transitions by helping them generate self-efficacious cognitions, emotions and behaviour.

Government corruption perception, political trust and “hedonic balance” in Argentina and Spain: A transcultural study

Keywords: self-efficacy, adult learners, narrative constructivist model, self-regulation, narrative analysis
The aim of the study was to analyze and compare the government corruption perception and political trust in Argentina and Spain and to study the relations between government corruption perception, political trust and “hedonic balance”. The study sample comprised 100 households (51 from Argentina and 49 from Spain) and participants completed the Satisfaction with Life Scale (Diener, Emmons, Larsen, & Griffin, 1984) and a scale created ad-hoc to study government corruption perception, and political trust. The current study had three hypotheses. Specifically, it was hypothesised that: 1) there is a strong and negative relation between government corruption perception and political trust; 2) there is a positive relation between hedonic balance and political trust and negative with government corruption perception; and 3) there are significant differences in the perception of the country between Argentines and Spanish people. Results showed that “hedonic balance” has a positive and significant relation with “political trust”. There was also a positive and significant relation between the economic perception of the country and “political trust”. On the other hand, there seems to be a negative correlation of the economic perception of the country and “government corruption perception”. Finally there was a strong, significant and negative relation between “government corruption perception” and “political trust”, as we had considered previously. If we consider the significant differences between the two countries, on balance, Spanish people have a more positive perception of the economic situation, a bigger trust in government, and a perception of less corruption in the government than Argentines. There are other demographic variables that may have an effect.

**Keywords:** government corruption perception, political trust, hedonic balance

**Group attitudes and self-identity:**
Refugee attitudes and their attitudes towards their education system

Kozlowicz, C. (University of Phoenix and Literacy Council)

The aim of this research study was to examine refugee families and how their group norms and attitudes can relate to their children’s educational performance. Several teachers and educators initially feel that the English language barrier is one of the key challenges that prevent refugees from learning. Yet, several educators are finding that it is not so much the language barrier, but the refugee families’ different attitudes towards education and especially, the refugee parents’ role in the child’s education. Many refugee parents feel that they should have no role in their child’s educational system because of their culture. The goal of this correlational study was to analyze the incongruence between the refugee values of the education system and the education system of their new culture. Furthermore, the goal is to understand how intra-group and social psychological dynamics of the refugee families will affect or hinder this attitude change. This study will also help understand how educators can address this and make changes to improve the refugees’ performance in school. Five schools in Wisconsin who have refugee placements were surveyed determining their knowledge of the refugee students’ culture and their attitudes towards school. Twenty six teachers were surveyed. Through a translator, 56 refugee families, who were in the United States (Waukesha County) for at least a year but not over a year and a half were also surveyed about their attitudes towards school. Twenty-four females and 32 males were interviewed with 25 refugee participants from ages 10-18 and 31 over 18. These refugee families were then asked a series of questions about their level of disagreement with newly arrived refugee families who they have had contact with, questions determining cultural identity and comfort level with newly arrived refugee families as it relates to education. Finally, report cards and attendance at parent-teacher conferences was also examined. This study indicated a $r = .81$ correlation that beliefs that low parent involvement of school, high discord within the refugee community as it relates to cultural assimilation and incongruence between teachers attitudes of parent involvement and refugee involvement lead to academic performance.
issues. This study indicated that there was a strong positive correlation between the refugee attitude’s stating that they feel that education is the teacher’s job, not the parents, the wider the discrepancy between the educators and families and the discord with other members of the refugee community and the refugee families’ parental involvement and academic performance. This study indicated that educators can benefit and social service placement agencies can benefit from understanding the attitudes of refugee families (that teachers are in authority and that parents should not have any involvement), how this incongruence with the teachers and affects these student’s self-self-identity and self-esteem and this affects academic performance. When refugees arrive, sponsoring organizations can learn from this research and communicate and educate incoming refugee families on the culture of the educational system.

Group counseling for domestic violence offenders

LANG, Y-C. (Da-Yeh University)

The study was conducted to evaluate group counseling for 12 domestic violence offenders in Changhwa County, Taiwan, to create a model for future group counseling for this group of offenders. These participants were mandated by the parole office to join this program. The skills of Solution-Focused Brief Therapy (SFBT) were applied, together with Art Therapy for warm-up. Three measurements were used to evaluate the participants’ behaviors in order to understand their changes, if any. An objective observation report was also used for evaluation. The results showed that these participants had certain biases toward females, especially their wives. Most of them felt that their wives should take responsibility for making them angry and violent. The study also revealed that most of them were part-time workers or even jobless, and their wives were from other countries. More details will be discussed. Although group counseling for domestic violence offenders is mandatory, the results indicate the program was not effective due to limited time and budget. A SFBT model could be considered for this special group of offenders.

Acculturative dynamics with overseas work

JOHNSON II, B. (deep1914)

Despite the tremendous influence of the Multicultural Counselling Competencies (MCCs) (Sue et al., 1998) on the field of psychology, Leung (2003) pointed out that the multicultural movement within psychology continues to lack a sufficient focus on globalization. Working and living overseas has been offered as one mechanism for internationalizing psychology and enhancing ones multicultural competence (e.g., Wedding, 2007). Specifically, this approach can assist academic educators with: (a) equipping the field to meet the needs of an increasingly diverse population, (b) exposing the field to diverse worldviews and perspectives that can inform interventions, (c) equipping psychologists to effectively address emerging social, cultural political and environmental problems around the globe that impact individuals and groups; and (d) increasing psychologists’ participation in the global research community (Kitayama & Markus, 1995; Leong & Ponterotto, 2003; Marcella, 1998, 2007). Despite these and other advantages, a number of challenges have been identified for those psychologists working internationally, including: (a) lack of cultural awareness, understanding and sensitivity on the part of the host culture (e.g., Bochner, 1999; Draguns, 2001; Leong & Santiago-Rivera, 1999), (b) difficulty navigating issues related to acculturation and ethnic identity on part of the international professional. This is a complex matter and it is imperative that more attention is devoted to addressing the experiences of professional psychologists working internationally. This paper will focus upon the personal and professional impact of a Black-American Clinical Psychologist working at a University within regional Australia. Specifically, I will examine how this experience offered an

Having a sense of efficacy: Considering adolescent and adult perceptions of self and self-in-community in relation to meeting personal and communal challenges

PRETTY, G. (University of Southern Queensland), INGLIS, R. (University of Southern Queensland)

This review paper reports on a series of five studies that have sought to understand differences and commonalities regarding the constructs of self efficacy and communal mastery in relation to personal and community problem solving. Adult studies include university students’ management of stress, rural residents’ management of land use issues and volunteering behaviour, and urban residents’ management of water resources. Adolescent studies of mental health and community engagement include general and clinical samples. Once shared variance for measures of generalised self efficacy (Schwarzer & Jerusalem, 1995) and communal mastery (Hobfoll, Schroder, Wells & Malek, 2002) was removed, the relative significance of the two constructs tended to differ in relation to predicting aspects of personal problem solving (coping and well-being) and community problem solving (volunteering and engagement). For example, while adults’ reported self efficacy was a better predictor of managing worries, communal mastery was more predictive of managing actual stressful events. Adolescents’ reports of communal mastery were a better predictor of mental health indicators and coping than their reports of self efficacy. In regard to environmental issues, self efficacy contributed more to the prediction of pro-environmental behaviour than communal efficacy. Findings are discussed in terms of advancing conceptual understanding of the two constructs and the importance of promoting the development of communal as well as self efficacy in caring for the good of the one and the good of the many.

Healing and recovery amongst survivors of torture and trauma

KAPLAN, I.

This paper will present an overview of pre-arrival, settlement experiences and recovery processes as they apply to people coming to Australia from Burma, Iraq and Afghanistan. An early intervention program and a longer-term counselling and advocacy program at the Victorian Foundation for Survivors of Torture will be described in order to highlight the process of understanding needs and how both specialist and community-based strategies, are shaped accordingly. Healing occurs on many levels and this paper will also explore the language and concepts required to understand the changes which occur and the barriers to change when promoting and assisting in the remaking of lives which have been subjected to the extremes of human rights violations. A human rights framework is essential to understanding the distinctive risk and protective factors to be considered when working with newly-arrived survivors of torture and trauma. Pre-arrival experiences characterised by extensive exposure to violence and loss and forced displacement have their roots in systematic human rights violations. The struggle over being selected for resettlement is a rarely acknowledged additional experience beyond the control of survivors. Once in Australia, a host of factors influence whether new lives do indeed begin. They range from the broadest contextual factors, such as international security concerns and ongoing zones of war and conflict, to the local context, especially the quality of service systems and the capacity of communities to respond to survivors. Many settlement experiences can inadvertently exacerbate pre-arrival experiences of systematic
persecution when they reinforce helplessness, lack of belonging, injustices and lack of respect. Recovery requires restoring a sense of control, connections, meaning, justice, and dignity as well as addressing difficulties which may manifest as psychological symptoms.

Health and psychological measures of inpatients with schizophrenia

MOORE, G. (Macquarie Hospital), MOORE, G. (Macquarie Hospital)

Individuals with a diagnosis of schizophrenia have greater health problems than the general population. Amongst this segment of the population there is little research on weight and health control from a psychological perspective. This study examined a program from a Self-Regulation perspective. A quasi-experimental and case study design was employed to test 14 inpatients in a Dual Diagnosis (mental illness and substance abuse) rehabilitation program. A health psycho-education group combined with an exercise session (or other activity choice) made up the components of the program under study. Self-report questionnaires were administered at four periods: baseline, pre-treatment, post-treatment and at one month follow-up over a five month period. Physiological measures were taken weekly. Three representative case studies are included. Self-efficacy increased and there was a non-statistical trend towards greater activity. Although other psychological measures were not significant, there was a positive trend. As self-efficacy is a prelude to greater self-regulation, it could be suggested that this program was long enough to psychologically prime the participants but not to the degree that self-regulation would be changed. A longer time frame for program efficacy is required with this population.

Health behavioral model among school aged children in private schools in Bangkok, Thailand

KITIIPICHAI, W. (Mahidol University)

The aim of this study was to develop the causal model of health behaviors among school aged children. The causal factors consisted of sex, health behavior knowledge, student’s care by parent, self esteem, perceived self efficacy, self regulation, and self care. The consequence was health behaviors which were included factors: nutrition, exercise, and leisure time. The samples were 297 school age children (Grades 4 to 6) among two private schools in Bangkok. The data were collected by seven questionnaires which had the range of internal consistency reliability coefficients from 0.70 to 0.90 and construct validity tested by confirmatory factor analysis method. The data were analyzed using structural equation modeling method (SEM) from LISREL software. The developed model were consistent with the empirical data (p = 0.63) revealed that the six causal variables accounted for 42% of the variance of students’ health behavior. The details of the causal relationship of variables were as follows: (1) The students’ health behaviors were most directly affected by students’ health care by parent (β = 0.58), followed by perceived self efficacy (β = 0.23), self care (β = 0.10), sex (β = 0.09), self regulation (β = 0.04), and self esteem (β = 0.03) respectively. (2) The students’ health care by parents directly affected perceived self efficacy (β = 0.39), self care (β = 0.18), and self regulation (β = 0.14). Students’ health care by parents was the important antecedent of students’ health behaviors and the enhancing factor of students’ attributes on the social cognitive theory. Thus, parents should be devoted to looking after their children’s nutrition, exercise, and leisure time.

Keywords: health behaviours, child health, parental care, social cognitive theory

Helping behavior and contextual variables

DINIZ, P. (Victoria University of Wellington), GOUVEIA, V. (Federal University of Paraiba), MILFONT, T. (Victoria University of Wellington)

This quasi-experimental study investigates the influence of situational variables on helping
behavior. A 2 x 2 x 2 x 2 factorial design was employed in which manipulated scenarios of helping situations were depicted to form the four factors, containing two levels each: 1) the reason why the needy person asks for help (emergency x non-emergency), 2) gender of the needy person (female x male), 3) the kind of situation (public x private), and 4) the degree of proximity between the needy person and the person who helps (close person x unknown person). Participants were asked to indicate their intention to help in each situation. A total of 408 undergraduate students from public and private Brazilian universities took part in the study. Most of them were female (60.3%), single (83.9%) and with a medium self-reported economic status (60.1%), and with ages ranging from 17 and 58 years ($M = 22$; $SD = 6.39$).

ANCOVAs were conducted to examine the effects of the situational variables on helping behavior, with social desirability entered as a covariate. Main effects for three of the four situational variables were observed: the type of the situation, the reason for asking for help, and the relationship between who helps and who asks for it ($F > 5.00$, $p < .001$ for all). There was no main effect for the gender of the needy person [$F(1,337) = 0.178$, $p = 0.643$], but significant interactions were observed between gender of the needy person and both type of situation and relationship between the needy person and the person who helps. Overall, the results indicate that participants would be more likely to help when the situation (1) is an emergency, (2) is a public situation, and (3) involves a close person. Also, the gender of the needy person does not seem to be important. These empirical findings support previous studies showing that helping behavior depends on contextual variables. The theoretical and practical implications of these findings are discussed.

Hope and curiosity: Two significant strengths on mental health - A study among Chinese college students

BAI, Y. (University of Hong Kong), HO, S.M.Y. (University of Hong Kong)

Peterson & Seligman (2004) introduced the 24 character strengths in the literature on positive psychology. Hope, curiosity, gratitude, love and vitality were proposed to be the five “key strengths” due to their strongest relationships with well-being (Shimai, Otake, Park, Peterson & Seligman, 2006). However, rare evidence revealed the comparative importance among the five key strengths on predicting well-being as well as depression. Therefore, we designed two sequential studies to answer this question. First, a cross-sectional study was conducted among 420 college students (aged 16-23 years) in China to compare the relative importance of these five key strengths on mental health. Participants completed corresponding items of the Values in Action Inventory (VIA; Peterson & Seligman, 2004) to measure their key strengths. Subjective Happiness Scale (SHS; Lyubomirsky & Lepper, 1999) and Center for Epidemiologic Studies Depression Scale (CESD; Radloff, 1977) were used to measure happiness and depression levels respectively. A second study was conducted after obtaining the results of study 1. Four hundred and twenty three student participants (aged 16-21 years) were recruited from a single college in Beijing. Their strengths of hope and curiosity were assessed by Adult Dispositional Hope Scale (ADHS; Snyder & Harris, 1991) and Curiosity Exploration Inventory (CEI; Kashdan, 2004), respectively. Their happiness and depression levels were assessed using the same inventories as in Study 1. Correlational analysis with Study 1 data indicated that all of the key strengths were positively correlated with happiness ($r=.31$-$-.59$) and negatively correlated with depression ($r=-.27$-$-.48$). In particular, multiple regression analysis showed that hope ($\beta=-.31$, $p<.01$) and curiosity ($\beta=.42$, $p<.01$) were the strongest predictors of depression and happiness, respectively. To confirm these results, we examined the relationships between hope, curiosity and happiness, as well as depression, with Study 2 data, using a structural equation modeling (SEM) method. The results will be reported at the Congress. Although the five key strengths all related to mental health, hope and curiosity showed outstanding roles in predicting depression and happiness, respectively. Understanding these two strengths more will benefit human fulfillment.

**How corporate social responsibility practices, and human resource practices, interact to influence job-seekers: An empirical study**

SMITH, V. (Macquarie University), LANGFORD, P. (Macquarie University), SEARLE, B. (Macquarie University)

Whilst corporate social responsibility (CSR) appears to have benefits for employee outcomes (e.g., Brammer, Millington & Rayton, 2007; Pettijohn, Pettijohn & Taylor, 2008), research suggests that it explains little unique variance in employee engagement beyond traditional human resource (HR) practices. One explanation for this finding is that employees view HR practices as a form of social responsibility. An experiment was designed to examine the extent to which HR and CSR practices influenced job-seeker ratings of organisation social responsibility and organisation attractiveness. Participants were asked to play the role of job seekers. They were given a description of an organisation, in terms of its attractiveness and social responsibility, and were asked to rate the organisation. This experimental approach allowed for manipulation of information about hypothetical organisations, to give a clearer indication of how such information is perceived. A 2x2 factorial design was used such that descriptions manipulated organisational performance in terms of HR practices (high/low) and corporate social responsibility practices (high/low). The descriptions were counterbalanced, resulting in eight final descriptions, which were randomly allocated among the 128 participants. A two-way ANOVA was used to analyse the hypotheses. Results suggest that whilst both high HR, and high CSR, practices significantly increase ratings of organisation attractiveness, HR practices increase organisation attractiveness to a greater extent than do CSR practices. Conversely, whilst both high HR and high CSR practices significantly increase ratings of social responsibility, CSR practices increase social responsibility ratings to a greater extent than do HR practices. No interaction was found between CSR practices and HR practices in their impact on either outcome. These results support the suggestion that job-seekers view HR practices as one of the ways in which an employer can be socially responsible. The lack of interaction between CSR and HR practices questions the suggestion that CSR may have little impact on employee outcomes beyond the impact of HR practices. Finally, these results suggest that positively engaging in both HR practices and CSR practices will have benefits for organisations in terms of increased attractiveness.

**How does emotional valence affects time perception and situational awareness**

NIKOLLA, D. (University of Gloucestershire)

The aim of the study was to examine how positive and negative emotional arousal affects the perception of time and situation awareness (SA). Several studies have suggested that different emotional states affect the perception of time differently. In the present study, a different method of time estimation was tested with the aim of circumventing some of the problems faced by more traditional time estimation methods. Three different sets of 20 emotional slides rated for valence and arousal (International Affective Picture System) were shown to three groups of participants for six seconds. Each set of slides was designed to evoke one of positive the following emotional reactions: positive high arousal (PHA), negative high arousal (NHA), or neutral low arousal (NLA). The State-Trait Anxiety Inventory (STAI) was administered in order to control for baseline levels of arousal. The emotional slides were sandwiched between two emotionally neutral slides, each having a duration of either three or nine seconds, counterbalanced across 20 trials. Analysis of variance revealed a statistically significant difference ($p < 0.05$) in the perceived duration of the slides for the three emotional groups (PHA, NHA & NLA), $F(2, 38) = 7.7, p = 0.02$. Eta squared was 0.29. Post-hoc comparisons using Tukey’s HSD indicated that the mean score for the NHA group ($M = 11.76, SD = 2.69$) was significantly different from the PHA group ($M = 8.57, SD = 1.45$). The NLA group

How does psychological empowerment influence employees’ turnover intention: The mediating effect of organizational commitment and the moderating effect of work involvement in the mediated model

YU, S. (Peking University), WANG, L. (Peking University), KONG, H. (Luxottica Group), YU, Z. (Luxottica Group), ZHANG, X. (Peking University)

Due to the influence on the organization’s performance, employee turnover and turnover intention have received considerable attention worldwide. This study examined the relationship between psychological empowerment and employee turnover intention, as well as the mediating role of organizational commitment and moderating role of work involvement in the mediated model. In one sample, 481 employees from a manufacturing company located in southeastern China rated their psychological empowerment, organizational commitment, work involvement and turnover intention. Results showed that psychological empowerment was negatively related with turnover intention through the mediated effect of organizational commitment. Work involvement moderated the mediated model, that is, psychological empowerment was positively related with organizational commitment, especially for the employees with high work involvement, and organizational commitment was negatively related with turnover intention, especially for the employees with high work involvement. Based on the above results, psychological empowerment was found to be a factor on the employees’ turnover intention. Whereas organizational commitment played a mediating role in the relationship, and work involvement played a moderating role in the mediated model. Thus, the results underscore the importance of accounting for work involvement when examining the relationships between empowerment, organizational commitment, and turnover intention.

Keywords: empowerment, employee turnover, turnover intention, organisational commitment, work involvement

How does self-consistency influence organizational variables: The moderating effect of relational interdependence

HUANG, Y. (Peking University), WANG, L. (Peking University)

Self-consistency describes individuals’ tendency to be consistent across different social roles. Previous research demonstrates that high self-consistency is associated with less depression and more subjective wellbeing. But the effect of self-consistency on organizational variables is ignored. The present study focuses on this question. Moreover, cultural psychologists find that relational interdependence moderates the relationship between self-consistency and wellbeing such that self-consistency is not important for highly interdependent individuals. Thus, we also examine the moderating effect of interdependence. Finally, we separate workplace-specific self-consistency and general consistency so as to investigate their different effects on organizational variables. Two hundred and twenty-four employees from 28 different companies participated voluntarily. They were asked to finish the questionnaire independently and seriously, and return the questionnaire the second day. The valid response rate was 91.25%. Measurements included self-consistency (i.e. 104 employees finished the workplace self-consistency measurement while 115 employees finished the general self-consistency measurement), life satisfaction, job satisfaction, organizational commitment (i.e. affective commitment, normative commitment, and continuance commitment), and relational...
Interdependence. General self-consistency was found to be positively related with individuals’ life satisfaction, but negatively associated with the continuance commitment. Workplace-self-consistency was positively related with life satisfaction, job satisfaction, and normative commitment, but negatively associated with the continuance commitment. Furthermore, interdependence moderated the relationship between general self-consistency and organizational variables. For those with low interdependence, higher general self-consistency predicted higher job satisfaction, affective commitment, and normative commitment. For those with high interdependence, higher general self-consistency predicted lower continuance commitment. Self-consistency is important in workplace. Compared with general self-consistency, workplace self-consistency better predicts individuals’ perception in organizations. Interdependence moderates the relationship between general self-consistency and organizational variables.

Keywords: self-consistency, relational interdependence, job satisfaction, organisational commitment, subjective well-being

How emotional valence colors our attention

Fu, X. (Chinese Academy of Sciences), Shen, X. (Chinese Academy of Sciences), Xuang, Y. (Chinese Academy of Sciences)

Emotional stimuli have a priority to be processed relative to neutral stimuli. However, it is still unclear whether different emotions have similar or distinct influences on attention. To answer the question mentioned above, we conducted three experiments, which used three emotion valences: positive, negative and neutral. Pictures of money, a snake, a lamp and Character X were used as stimuli in Experiment One. In Experiment Two, schematic emotional faces (angry, smiling and neutral face) were used as experimental stimuli to control the stimuli complexity. In Experiment Three, the stimuli were three line drawing pictures selected from the Chinese Version of Abbreviated PAD Emotion Scales, corresponding respectively to the emotions of anger, joy and neutral. We employed the paradigm of inhibition of return (IOR), an effect on spatial attention where people are slow to react to stimuli which appear at recently attended locations (Posner & Cohen, 1984) which used exogenous cues and included 20% catch trials. Fifty-three university students participated in the experiments. We found that participants needed more time to process negative picture (Experiments 1, 2 and 3), and the effect of IOR could happen at the Stimulus Onset Asynchrony (SOA) in as short a time as 50 milliseconds (Experiment 1). Meanwhile, the data demonstrated that IOR had happened at an SOA of 50 milliseconds only when the schematic face was angry, and the Reaction Time (RT) for angry schematic face was significantly longer than RT of the other two faces (Exp2). In all three experiments, we consistently found that there was a U-shaped relationship between RT and SOA, irrespective of the cue validity and emotion valence. These results showed that different emotional valences have distinct influences on attention and also indicated that emotions of happy or neutral could be processed more rapidly than the emotion of anger.

How fast? The effect of post event information and perceived involvement on memory for the details of motor vehicle accidents

Kemp, R. (University of New South Wales), Sriram, V. (University of New South Wales)

Eyewitnesses are often called upon to provide information to police and insurance investigations into the causes of motor vehicle accidents. One of the most critical details they may be required to recall is the speed of the vehicle(s) immediately prior to the accident. Research has shown that information presented to an eyewitness after the event (post-event information) is likely to be incorporated into their memory of the event, regardless of accuracy. In real motor vehicle accidents one powerful source of post-event information may be the sight of the accident itself. That is, the knowledge that the vehicle crashed may affect
the witness’s memory of the details of the event, including the vehicle’s speed prior to the crash. Furthermore, there is reason to predict that participants who are more actively involved in the event are less susceptible to the effect of post-event information than those who see themselves as passive observers. This study was designed to investigate these issues. Seventy-eight participants sat in a driving simulator with a confederate and watched the car drive around a track. For half the participants the drive ended with an unavoidable collision with another car. Half the participants believed that the confederate was driving the car (high involvement) while half knew the simulation was pre-recorded (low involvement). Participants were tested for their memory of the details of the event including the speed of the vehicle immediately prior to the end of the simulation. For participants who believed their partner was driving the car, seeing the car crash resulted in a significantly higher estimate of the vehicle’s speed compared to those who did not see a crash (a difference of about ten kilometers per hour). However, unexpectedly, this difference was reduced and marginally non-significant for participants who knew they were watching a pre-recorded drive. Memories for other details of the event were also assessed. Our results demonstrate that eyewitness accounts of the circumstances of a motor vehicle accident can be inaccurate and are likely to be influenced by extraneous sources of information. In particular this study presents the first clear evidence that an eyewitness’s estimate of the speed of a vehicle is likely to be inflated if they saw the vehicle crash. This finding has important practical implications for police and insurance investigations of the cause of motor vehicle accidents. Further, the demonstration that level of perceived involvement influences susceptibility to post-event information has important implications for eyewitness memory research.

Keywords: eyewitness memory, perceived involvement, post-event information

How workplace hazards and training influence learning and performance

BURKE, M. (Tulane University), SALVADOR, R. (University of New South Wales), SMITH-CROWE, K. (University of Utah), SONESH, S. (Tulane University)

Based on hypotheses derived from social and experiential learning theories, this investigation meta-analytically examined how different types of hazardous events/exposures, when considered in safety training programs that vary in terms of social interaction, relate to enhanced learning and behavioral outcomes. A central premise of this study is that one’s understanding of risk associated with different types of hazardous events/exposures is socially developed, which in turn shapes one’s motivation to learn and transfer acquired knowledge to the job. For this meta-analysis, a total of 118 primary studies that had 151 independent samples, and 172 safety training effects based on a total sample size of 28,753, were included. An important finding from this study was that hazard event/exposure severity interacted with training engagement to, on average, produce more pronounced learning and performance only when hazard event/exposure severity was high and training was highly engaging. For knowledge acquisition, the mean standardized effect size (d-statistic) difference between the lesser (mean effect = .75) and highly engaging (mean effect = 1.67) forms of training under the high hazard severity condition was .92 (p < .05). Likewise, the mean difference between the lesser and highly engaging forms of training for safety performance was .64 (with the mean effects for the lesser and highly engaging forms of training being .40 and 1.04, respectively) and statistically significant (p < .05) under the high hazard severity condition. Under the low hazard severity condition, as expected, the mean training effects for the lesser and highly engaging forms of training were comparable in magnitude (with mean differences being statistically non-significant) for both knowledge acquisition and safety performance. The psychological mechanism offered for the expected interaction effects was referred to as the “dread factor,” the realization of the dangers associated with ominous hazards and the experienced feelings that one has about the possibility of such events/exposures. This affective response was expected to promote the motivation to learn about and avoid ominous hazards. Implications of these findings for theory
testing in regard to the dread factor and for incorporating information on objective risk into safety training will be discussed.

Identification and the embedding of strategic change

HENDY, J. (Imperial College), BARLOW, J. (Imperial College, London)

Literature has illustrated how successful strategic change requires identification to fundamentally alter, with transformation occurring over three stages. Our research aims to elaborate on this process. Using Fiol’s (2002) model we investigate whether, during a period of strategic change, individuals and organisations move alike thorough a series of predictable phases. Secondly, we investigate the effectiveness of managerial strategies employed at each phase. Focusing on the role of individual managers, we examine whether managerial levels of organisational identification relate to sensemaking. Finally, we provide new insights into levels of identification required for achieving strategic change, and discuss sensemaking techniques leaders can utilise. This paper presents a study of five health and social care organisations in England as they attempt to embed a strategic change (moving services to a remote care model). The increased provision of remote care is a key policy in the UK and elsewhere. Our longitudinal, ethnographic case studies document both successful and aborted attempts by top managers to shift the provision of healthcare services. We found that language and shared behaviour enable and guide organisational identity transformation but neither is wholly sufficient to engender the level of change required. Symbolic and rhetorical strategies are most useful in the first phases of change. For newly learned understandings to then gain purchase a wide range of shared tasks and role based behaviours must be consistently employed, that allow for no backward slippage. In understanding variations in change across our five sites, we found a strong link between managerial identification at the start of the study and subsequent attempts at sensemaking, with high levels of organisational identification problematic. The relationship suggests a strong connection between organisational action and individual motivations; that powerful individuals direct organisational actions in ways that are coherent with protecting their identity. When attempting to strategically change organisational identity leaders need to employ a range of different sensemaking strategies that allow identity to be negotiated at each stage of transformation. This process may be best facilitated with the help of outside agents.

Keywords: strategic change, identity, organisational identity

Illness representations as predictors of quality of life in hemodialysis patients

DAVOODI, I. (Shahid Chamran University of Ahvaz), HONARMAND, M. (Shahid Chamran University of Ahvaz), SHIRVANIAN, E. (Shahid Chamran University of Ahvaz), SARARUDI, R. (Isfahan University)

Health-related quality of life in hemodialysis (HD) patients is a significant predictor of mortality and hospitalisation. This study examined illness representations as predictors of quality of life in HD patients. Two hundred HD patients completed the Kidney Disease Quality of Life-36TM (KDQOL-36 TM; mean age 49.15±15.42). Illness representations were assessed using the Brief Illness Perception Scale. A canonical correlation analysis was conducted using eight illness perception variables as predictors of the five of quality of life variables to evaluate the multivariate relationship between the two variable sets. The analysis yielded five functions ($R^2_c = 0/55, 0/10, 0/08, 0/028, 0/018$ respectively). The full model was statistically significant ($\lambda = 0/344, F = 5/65, p < 0/001$) and explained 65% of the variance shared between the variable sets. Given the $R^2c$ for each function, only the first two functions were considered noteworthy (55% and 10%, respectively). The dimension reduction analysis indicated the full model and functions 2 to 5 were statistically significant ($F= 5/65, p < 0/001, F = 1/74, p < 0/01$, respectively). Structure coefficients for function 1 indicated that relevant criterion variables in dependent linear combination were primarily; mental component, symptoms, effects of Kidney Disease (KD) on daily life, burdens of KD and physical
component; with consequences, personal control and treatment control, identity, concern and emotional response making independent synthetic criterion variables. Moving to function 2, structure coefficients suggest that the dependent variables of most relevance were mental component, symptoms, identity, understanding and emotional response that have most shared variance in independent linear combination. The results suggest that illness representations predict quality of life in end stage renal disease patients treated by HD, and could have important implications for treatment of these patients.

Keywords: kidney disease, hemodialysis, quality of life, chronic disease, illness representations

Imagined contact with a stigmatized outgroup: Impact on social distance and intergroup anxiety towards people with a mental illness

BROWN, P. (University of Canberra), SLY, R. (University of Canberra)

Imagining positive contact with an outgroup member has been shown to reduce prejudice towards that group. The present study assessed the effectiveness of imagined intergroup contact as a method for reducing stigma towards a highly stigmatized outgroup, namely people with a mental illness. One hundred and seven undergraduate psychology students were randomly assigned to either imagine a positive interaction with someone labeled with a mental illness (schizophrenia or depression) or to imagine contact with someone with no explicit label. Participants then completed measures of social distance, intergroup anxiety and prior contact with the outgroup. Results showed a significant positive effect for imagined intergroup contact on both desired social distance and intergroup anxiety; however this effect was not dependent on the type of mental illness label (schizophrenia or depression). Prior contact with the outgroup was shown to moderate the positive effect of imagined intergroup contact on social distance, with the effect being stronger for those who reported previous positive contact with persons with a mental illness. Contrary to previous research, intergroup anxiety did not mediate the relationship between imagined intergroup contact and social distance. This study demonstrated that imagining intergroup contact can lead to a reduction in prejudice against a highly stigmatized group, such as persons with a mental illness. Such results have implications for reducing stigma towards outgroups where opportunities for regular contact may be rare and for enhancing the positive effects of ‘real’ contact when it occurs.

Keywords: mental illness, stigma, anxiety, outgroup, imagined contact

Immigrant wives’ parental experiences in Korea

PARK, Y. (Daejeon University)

Multicultural families are highly increasing in Korea in recent years. Korean multicultural families are specific because they were mostly composed of Korean husbands and immigrant wives who came from Southeast Asia. This study examined immigrant wives’ parental experiences. Subjects were 17 immigrant wives who settled in Gyeonggido province. Data were collected by in-depth interview individually. Results indicated that (1) immigrant wives have experienced difficulties in communication, household economy, and childcare. (2) They were interested in children’s academic achievement and social-emotional development. (3) They stressed education and basic care for the parenting role. (4) They demanded teaching academic skills for their children, parent education or counseling, and information about child development from childcare centers.

Keywords: multicultural families, Korea, parental experiences

Impact of implicit attitudes toward smoking on selective exposure to prevention information

Many studies deal with the impact of prevention campaigns. Whatever the method used, most of them postulate that people take the campaign into consideration as soon as they are exposed to it. Yet, according to Festinger (1957), people expose themselves to attitude-consistent information and tend to avoid attitude-inconsistent information that could arouse dissonance. The goal of this study was to enhance such effects with tobacco campaigns. We intend to show that exposure to information dealing with tobacco effects depends on attitudes and behavior toward smoking. Forty-four smokers, 80 non-smokers and 58 quit-smokers were proposed to participate in a survey that would supposedly determine the content of a future information session dealing with the harmful effects of tobacco, alcohol, junk food, drugs etc. People were asked what kind of topic would interest them most. Then, their attitudes, behavior and dependency toward smoking were evaluated. To evaluate attitudes toward smoking, we chose to use both an explicit (Attitude Toward Smoking Scale, ATS; Etter et al., 2000), and an implicit measure (the Single Category of Implicit Association Test, SCIAT; Karpinsky and Steinman, 2006). Based on response latencies, this kind of measures allows the access to unconscious attitudes and thus avoids social desirability bias (for stigmatized objects). Derived from the Implicit Association Test (IAT; Greenwald, McGhee and Schwartz, 1998), the SCIAT allows us to measure implicit attitudes toward a single concept. Finally, smokers and quit-smokers filled in two questionnaires measuring respective stages of change in the process of smoking cessation (Prochaska and DiClemente, 1983) and nicotine dependency (Fagerström Tolerance Nicotine Dependency, FTND; Fagerström, 1991). The main results are consistent with the theory of selective exposure: the more the implicit attitude is negative, the more they are willing to have a training dealing with tobacco. Measures of dependency, explicit attitude or stage of change were not predictive of selective exposure. The discussion will focus on the consequences of selective exposure on prevention, on ways to reduce its effects and the primacy of implicit measures of attitude toward tobacco to measure the probability of smoking cessation.

**Impact of inattention provoked by sadness on older drivers’ behavior**

LEMERCIER, C. (University of Toulouse), QUAIREAU, C. (University of Rennes 2), PÊCHER, C. (University of Toulouse)

In regards to attentional defects in driving situations, inattention is probably one of the less studied. Inattention refers to an endogenous long lasting orientation of the attentional focus on thoughts to the detriment of the driving activity. The present study was interested in the impact of inattention provoked by induced sadness on older drivers’ behavior. To evaluate the hypothesis of a defect of attentional focus linked to inattention, we were interested in the impact of a negative emotional state on the three components of spatial attention measured with the Attention Network Test (ANT; Fan, et al., 2002). Fifty-nine older drivers (mean age of 65) were divided into four groups: (a) controls which were neutrally induced and then performed the ANT, (b) sadness-induced subjects which had to imagine eight dramatic described situations with sad music in background, and then performed the ANT, (c) ruminative subjects which were firstly neutrally induced and then invited to hear sad music and ruminate sad thoughts while performing the ANT, and (d) sadness-induced and ruminative subjects, which firstly received the same induction as (b) and then, the same ruminative procedure as (c). Analyses on the Brief Mood Introspection Scale (BMIS; Mayer & Gascke, 1988) showed a significant increase in sadness score following the sad induction for the (b) and (c) groups. Moreover, the sadness score also increased after the ruminative procedure for the (c) and (d) groups. Analysis about the impact of inattention on the ANT demonstrated that neither alert nor conflict components were altered whatever the experimental groups. On the contrary, the orientation effect was
eliminated for the (b) and (d) groups (respectively, $F < 1$; $F = 2.7$, NS). Inattention due to sadness and rumination only leads to the abolition of spatial attention for older drivers. This result suggests that when an older driver is inattentive, they normally prepare themselves to act (alert), they normally resolve conflict between contradictory road information (conflict), but they are “blind” to spatial information (orientation), which may have dramatic consequences on driving performances.

**Keywords:** attention and driving, attentional defects, sadness, rumination, spatial attention of older drivers

### Impact of parenting skills training on the increasing of parent-child interactions and the decreasing of parental stress on parents of adolescent drug abusers

**RAHMAWATI, H. (Malang State University)**

The research was aimed to examine the effectiveness of parenting-skills training in increasing parent-child interactions and decreasing parental stress level of parents of adolescent drug abusers. Parenting-skills training included activities for parents with the adolescent drug abuser to learn and practice about: addiction and relapse prevention, parenting dimensions (care, control and communication), and identifying and managing stress. The research was conducted experimentally using a pre and post-test group design. The measurements were based on a scale which were carried out three times on the subjects, i.e. at pre-test, post-test-1 (after training), and post-test-2 (two weeks after the measurement). A quantitative analysis was done with one-way kovarians analysis. Furthermore, a qualitative analysis was done using the in-depth interview results, the training evaluation and observations during the training. The subjects of this study were 22 women who were members of Yayasan Arofah and which were split into a control group (11 women) and an experimental group (22 women). Subjects were mothers of adolescent drug abusers. The results showed that: (1) There was a significant difference in parent-child interactions before and after parenting-skills training in the experimental group. Parent-child interactions increased after receiving parenting-skills training compared to before (post test 1 = 104,727 and post test 2 = 111,091). (2) There was a significant difference in parental stress level before and after parenting-skills training in the experimental group. Parental stress level decreased after receiving parenting-skills training (post test 1 = 80,455 and post test 2 = 75,818). (3) There was a significant difference between the experimental group and the control group in parent-child interactions after parenting-skills training. Parent-child interaction levels of the experimental group were higher than control group. ($F = 177,220$; $p < 0,010$). (4) There was a significant difference between the experimental group and control group in parental stress level after parenting-skills training. Parental stress level of the experimental group was lower than the control group ($F = 24,801$; $p < 0,010$). Parenting-Skills Training contributed to a 90.3% increase in parent-child interactions and 55.5% decrease in parental stress level.

**Keywords:** parenting skills training, parent-child interaction, parental stress, parents, adolescent drug abuse

### Impact of value incongruence on work satisfaction: A gender marginality perspective

**PALERMO, J. (Deakin University)**

Gender identity, when applied to organisational culture, is descriptive of the predominant beliefs about sex-roles, inherent within cultural values, mores and processes. Tenets of marginality and gender schema theory suggest that individuals who experience incongruence between their own gender identity and that of the organisation are more likely to experience adverse psychological effects. This study aimed to investigate the impact of marginality on work satisfaction for women and men across diverse segments of industry. It was hypothesised that gender identity incongruence would be a unique predictor of work satisfaction for both women and men. In consideration of the proposed links between incongruence and well-being, we also hypothesised that gender identity incongruence would mediate the relationship between work satisfaction and occupational stress. Participants
(N = 252) completed a survey online or in hard copy which comprised scales related to gender traits, occupational stress (OSI-R; Osipow & Spokane, 1998) and work satisfaction (based on items adapted from the Job Descriptive Index). Two gender incongruence scales were used: Nurturance incongruence (related to stereotypically positive feminine traits) and Autonomy incongruence (related to stereotypically positive masculine traits). Results of a fully specified structural equation model suggest gender identity incongruence related to Nurturance rather than Autonomy as the marginality factor that predicted work satisfaction. Nurturance incongruence was a negative predictor of psychosocial resources, which in turn predicted the variance in occupational stress and work satisfaction. The findings of this study suggest that organisations values and practices that embody nurturance, such as empathy, compassion and a focus on concern for others may discriminate organisations on levels of marginality and vocational strain. Maintaining value congruence related to nurturance may indeed result in higher work satisfaction and less occupational stress for an organisation’s employees.

Implicit gender-rationality stereotypes among successful counter-stereotypic women

Smeding, A. (University of Toulouse)

Women are underrepresented at the top of Mathematics, Science, and Engineering (MSE) education relative to men. One explanation is that women’s knowledge of self-relevant negative gender stereotypes reduces their interest in pursuing a career in counter-stereotypic (i.e. masculine) domains. However, why do some women graduate in such domains and are highly successful? Possibly, they simply do not know the negative gender stereotypes. However, stereotypes are widely known in a given culture. Therefore, these women might be successful despite their stereotypic knowledge. Besides the extensively studied gender-math stereotype, women’s perceived lack of rationality is particularly relevant in MSE educational and professional settings. However, this gender-rationality stereotype has never been assessed at an implicit level, which is problematic because explicit stereotype measures are prone to social desirability bias. We created a new Implicit Association Test (IAT; Greenwald, McGhee and Schwartz, 1998) to assess implicit associations of rationality with men rather than with women. We tested this tool among highly successful graduate female and male engineering students and its relation with explicit stereotype measures (Study One). This IAT was also tested among larger samples of engineering and literature students (Study Two). In Study One, participants were 23 graduate engineering students attending very selective engineering schools (13 males). They completed the explicit stereotype measures and the gender-rationality IAT. In Study Two, participants included 117 similar engineering students (64 males) and 89 literature students (45 males) who all took the gender-rationality IAT. Study One’s results showed a gender-rationality IAT effect among female and male engineering students, meaning that they implicitly associated rationality more with men than with women. Self-report measures did not show explicit knowledge of the gender-rationality stereotype, and no relation with IAT scores was found. Study Two replicated the gender-rationality IAT effect among engineering and literature students, with no difference between populations. Findings support the relevance of the new IAT to assess implicit stereotypes in the reasoning domain, which is particularly important given the superordinate nature and shortcomings of self-report measures. Successful counter-stereotypic women are so despite a real obstacle, signaling that efficient self-protective strategies may underlie their success.

Keywords: gender stereotypes, self-relevant negative stereotypes, gender rationality, implicit association test, self-report measures

Improving speed of processing in older and younger adults with HIV: A pilot study

Vance, D. (University of Alabama at Birmingham), Fazeli, P. L., Mckie, P. R. (University of Alabama at Birmingham)
The co-occurrence of HIV and aging may lead to decreased speed of processing (SOP) which can interfere with performing instrumental activities of daily living. This becomes especially important when considering the growing population of older adults with Human Immunodeficiency Virus (HIV). The aim of this study is to determine if SOP training can improve this cognitive ability in adults with HIV. In this on-going pre-post-experimental study, 26 older and younger adults with HIV (26 to 70 years old; mean age = 46.27 (SD = 9.14)) were assigned to either the no-contact control group (n = 9) or to a SOP training group (n = 17). SOP training consisted of ten hours of computerized, self-administered training in the laboratory using the POSIT Science software. After approximately four to six weeks after the baseline assessment, participants were administered a post-test assessment. An intent-to-treat analysis was employed. Using the Useful Field of View (UFOV®) test, those in the SOP training group improved their performance by 209.65 milliseconds (ms) on average (SD = 161.11) while the control group improved by 14.67ms on average (SD = 189.08). This training effect was significant, $F(1,25) = 7.66, p = .01$, power = .76. Although age was significantly related to UFOV® performance in adults with HIV ($r = 33, p = .02$) in that older adults performed worse on this cognitive measure, age itself was not a factor in the treatment gains observed ($r = .22, p = .40$), which suggests that SOP training in adults with HIV is effective in improving SOP regardless of age. This study shows that cognitive training can improve cognitive functioning in adults with HIV. Implications for other applied interventions and future research are posited.

Keywords: HIV, speed of processing, cognitive ability, self-administered cognitive training, adult cognitive functioning

Impulsive buying and self control failure

BALIKDJIAN, A. (Université Libre de Bruxelles), POHL, S. (Université Libre de Bruxelles), VAN DE LEEMPUT, C. (Université Libre de Bruxelles)

The impulsive purchase is a type of purchase that is more and more widespread in Western Society. Impulsive buying behaviour gives evidence of all impulsive acts (Giraud & Bonnefont, 2000). It is described as more arousing, less deliberate, and more irresistible buying behaviour compared to planned purchasing behaviour. Highly impulsive buyers are likely to be unreflective in their thinking, to be emotionally more attracted to the object, and desiring immediate gratification (Hoch & Loewenstein, 1991). Previous researches (Rook & Fisher, 1995; Balikdjian & Pohl, 2008) demonstrate that impulse buying is positively linked to dispositional factors (Impulsiveness). In other words, cognitive considerations modify the impulse buying behaviour (Puri, 1996). The aim of this research is to try to understand impulsive buying behaviour as the result of a complex interaction between self control failure due to cognitive resource depletion and impulsiveness. One-hundred and ten people took part in this study. The design varied a single factor (cognitive resources availability). The participants were randomly assigned to one of the two experimental conditions: with or without cognitive depletion task. In the condition “with cognitive depletion task”, participants were asked to respond to a culture-free intelligence test. After the time devoted to this test elapsed, participants engaged online buying. After that, participants responded to an Impulsiveness scale (Neo PRI) and impulse buying measure (Rook & Fisher, 1995). Results show a positive relation between impulsive buying and impulsivity. Furthermore, an overview of the means of impulse buying suggests that non-impulsive individuals in the depletion condition are higher than in the control condition. There are no differences between the two conditions for the impulsive individuals. According to the self control failure framework, consumers will increase impulse buying behaviour when they face cognitive resource depletion in a specific context. Nevertheless this relation is observed only for the “non impulsivity consumers”.

Keywords: impulse buying, impulsivity, cognitive resources availability, cognitive depletion, cognitive depletion tasks

Incivility: A qualitative analysis across differential power distributions
Acts of disrespect such as incivility are common in and outside the workplace, and studies have shown that victims tend to suffer negative consequences. This study aims to understand how power dynamics (formal and informal power distribution) affect the incidence of and responses to incivility. Utilizing a qualitative approach, 177 undergraduates with work experience were asked to write about an incident in which they were treated with disrespect at or outside work. They provided details about the act itself, the context in which it occurred, the consequences of the event, the impact of the experience and finally the action taken to resolve the issue. Incivility was found to be perpetrated across conventional relationships between peers and superior-subordinate associations as well as non-conventional ones, when the relationships were based on an informal distribution of power. The most prevalent acts of incivility were of the Direct Verbal form (43%) when victims were formally or informally lower in status as compared to the perpetrator. In contrast, the Behavioral form (31%) of incivility was common when the perpetrator was formally or informally of a lower status. There were very few cases when the incivility spiraled into another act of incivility (15.25%) and this was generally found in those relationships that had an informal hierarchy or where the victim was of a higher formal status. Most victims received some form of support after the incivility (69%). Emotional support was mostly provided to victims who were formally or informally at a lower status as compared to the perpetrator. On the other hand, instrumental support was given to victims who were formally and informally of higher status and to the victims who were informally in a lower status. In more than 85% of the cases where support was provided it helped the situation. The acts of incivility were brought to the perpetrators notice mostly when the victim was formally in a higher status. Following which, usually an apology was rendered in these situations. Incivil acts vary in their nature and consequences across formal and informal power distributions.

Keywords: Incivility, Power distributions, Disrespect, Victim, Perpetrators

Increasing adaptive motivation through information enhancement and goal setting

SEPEHRI SHAMLOO, Z. (Ferdowsi University of Mashhad), COX, M.W. (Bangor University)

The aim of the current study was to develop and experimentally validate factors that increase individual’s Adaptive Motivational Structure (AMS). AMS promotes successful goal attainment and emotional satisfaction in life, whereas Maladaptive Motivational Structure (MMS) hinders people from effective goal seeking. Evidence shows that decisions to drink are more likely when the individuals are unable to achieve emotional satisfaction through other goal pursuits or to overcome miseries in their lives. Through an experimental study (N = 144, 38% males), we tested the relative and combined effects of enhancement information (including, choice, knowledge and feedback) and goal setting as two motivational techniques while participants were completing a series of experimental tasks (i.e., Computerized Conceptual Cards, Anagrams). The design was a 2 x 2 (i.e., control group; goal-setting group; information group and combination group) factorial that included pre- and post-test measures, including the Task Specific Personal Concern Inventory, Task Specific Sense of Control Inventory and Task Specific Intrinsic Motivation Inventory. The results showed that the greatest increase in AMS resulted from the combined technique, and the order of the groups on the post-test was: Combination Group (enhancement information and goal-setting) > Information Group > Goal-Setting Group > No-Intervention Group. In addition, a 45-day follow-up assessment showed that the Combination Group’s task-specific AMS continued to increase after the post-experimental assessment. The implication of the motivational enhancement techniques for intervention, education, and prevention will be discussed.

Keywords: motivation, information enhancement, goal setting, adaptive motivational structure, maladaptive motivational structure
Individual and environmental predictors of psychological capital

TONG, J. (Peking University), WANG, L. (Peking University)

This research examined the impact of trait-like qualities (like Five Factor Model and Core Self Evaluations), and environmental settings (like People-Organization Fit and People-Job Fit) on Psychological Capital, in order to find out its formation mechanism in organizations. A total of 339 employees from various industries in China participated in the research. They were requested to finish the questionnaires of Psychological Capital, Five Factor Model, Core Self Evaluations, People-Organization Fit, and People-Job Fit. Results indicated that Psychological Capital is significantly influenced by individual’s personality characteristics, the environmental variables, and their interactions. When there is a good match between people and job, as well as people and organization, trait-like qualities help to form high Psychological Capital. The poor match with the environment weakened the relationship between trait-like qualities and Psychological Capital. It is suggested that when developing Psychological Capital, organizations may adjust the environment conditions to make full use of the trait-like qualities of individuals in improving Psychological Capital.

Keywords: psychological capital, trait-like qualities and environmental settings, big five model of personality, people-organization fit, core self evaluations

Influence of achievement goal orientation on goal setting and study behaviour in computer training

JAYASURIYA, R. (University of New South Wales), CAPUTI, P. (University of Wollongong)

Goal setting theorists (Locke & Latham, 2002) have shown that self-set personal goals mediate the relationship between personality (e.g., achievement) and performance. Goal orientation research distinguishes between mastery (learning) and performance orientations. Goal orientation been used as distal personality factors in comparison to self efficacy and state anxiety (proximal factors) in learning performance research (Chen et al, 2000). An integration of theories of goal setting and goal orientation has been tested (Seijts et al, 2004), but not with goal striving (Gollwitzer & Sheeran, 2006), as a useful extension to understand training behaviour. The aim of this study was to ascertain direct and indirect effects of goal orientation, self efficacy and state anxiety on goal setting processes and learning behaviour in a computer training context. Undergraduate students in an introductory Information Systems subject completed three questionnaires (before training, following mastery training and prior to an examination). The questionnaires measured goal orientation, application specific computer self efficacy (CSE), computer anxiety (CA), personal goals (PG), and the effort taken in learning and study strategies undertaken for learning a software application. Participation in this study was voluntary and 166 students completed all three phases of the study. Following tests of measurement reliability and validity, a structural model was tested using path analysis. The tested model showed good model fit (chi square 20.7; df 15; p > 0.1; NFI = 0.92; IFI = 0.96; TLI = 0.91; CFI = 0.97; RMSEA = 0.039). The overall model explained 17 per cent of study effort and study behaviour. Mastery approach was significantly related to CSE (β = 0.17; p < 0.05), PG (β = -0.21; p <0.01), and study behaviour (β = 0.27; p <0.01), but not CA (β = -0.13; p > 0.05). Performance approach was significantly related to CSE (β = 0.25; p <0.01), CA (β = -0.27; p <0.01) and effort (β = 0.20; p <0.05). Mastery Avoidance was related to CA and performance avoidance to CSE. CSE and CA had significant effects on effort for studying, but did not mediate the effects of mastery and performance goal orientation on effort and behaviour. The study provides evidence of the direct roles of mastery and performance goal orientation in goal setting and goal striving behaviour in computer training. Interventions that enhance mastery orientation result in more engaged and successful strategies for learning.

Keywords: goal orientation, goal setting, mastery approach, trait anxiety, self-efficacy
Influence of protected values and framing effect on omission bias under managerial decision situations

ZHU, Q. (Zhejiang University), HE, G. (Zhejiang University)

The aim of this research was to reveal how protected values and framing effects could impact on omission bias in managerial decision situations. This study designed three questionnaires to simulate managerial situations. Questionnaire One measured the subject’s protected values and uniformity between his/her recognition and action; Questionnaire Two contained nine scenarios, each divided into “action” and “omission” where framing effects (positive versus negative) and output certainties (risky versus secured) were introduced and where the subject was asked to make choices between “action” and “omission”. Risk preference was applied in Questionnaire Three. A survey on Master of Business Administration students showed evidence of protected values in decision-making. Managers made choices under the control of their protected values system and in accordance with different management tasks which included framing effects and output certainties. The results indicated that: 1. Protected values do exist in management and they do not substantially vary with position and ownership structures. Mismatch is noticeable between recognition and action. 2. In “action” scenarios, preference to action is significantly and positively correlated with protected values, the same as it is in “omission” scenarios. Protected values will not only prevent certain behaviors, but also initiate and execute. Action and omission are both demonstration of protected values. 3. Either in “action” or “omission” scenarios, subjects with firm protected values make decisions in favor of protected values regardless of framing effects and output certainties. In scenarios where the output was secured, framing effects would further justify the subject’s decision: to take actions preferable to the positive frame in “action” scenarios while to withhold under the negative frame in “omission” scenarios. However, the subjects with swerving protected values have preference to neither action nor omission. Their decision is subject to framing effects and output certainties. Under the positive frame, they tend to secure their benefits actively. Under the negative frame, they opt for risky outputs to minimize losses.

Keywords: protected values, framing effect, managerial decisions, omission bias, risk preference

Initial standardization of the Oxford happiness test on students of the Islamic Azad University - Roodehen Branch, Iran

SABET, M. (Islamic Azad University, Roodehen Branch), LOTFI, F. (Islamic Azad University), HAKAMI, M. (Islamic Azad University), SEIRAFI, M. (Islamic Azad University), POUR, L. S. (Iran Avandfar Company)

The present study had two goals. These were the standardization and assessment of rate of validity and reliability of a happiness assessment scale and to review the relationship between happiness and gender. The present study is a field study using exploratory research that has been done based on classic psychometric theory and this investigation is in the test construction area. From the total population of male and female students of Islamic Azad University, Roodehen branch, who were studying in academic year of 2008 to 2009, 500 students (250 boys and 250 girls) were selected by stratified random sampling. The research tool was translated from Oxford Happiness Scale Form to Farsi language. The alpha reliability coefficient calculated for total group score was 0.9, for the male group it was 0.882 and for the female group 0.916. The first factorial analysis output that was a 29 x 29 matrix showed there was a positive correlation between almost all questionnaire subjects of the present study, and more than 70% of matrix correlations were statistically significant. The “Scree” model showed that probably was a major factor that dominated all questionnaire subjects of the present study, and the greatest difference between males and females actions in the Oxford Happiness Scale was that the females’ mean of 122.32 was higher than the males’ mean by 116.68. This difference is significant. After ensuring of Oxford Happiness Scale validity and reliability for the study group, the totally norm of both the genders were tabulated, which can be used for all
psychologists and counselors in case of clinical diagnoses.

Keywords: happiness assessment scale, test development, classic psychometry theory, scale validation

Insights into mindful-based art therapy practice for anxiety: A case study

DAVIS, B. (Art & Soul Connections)

Mindfulness-based techniques can be used by art therapists to engage a deeper level of understanding in the treatment of anxiety. This presentation focuses on how mindfulness-based strategies assisted the therapeutic art process; as an impetus for the cathartic release of emotions, as a holding space for difficult feelings, and as a visual language resource for processing multidimensional layers of anxiety. A brief overview of the theoretical rationale and techniques used to assist a 30-year-old woman who presented with anxiety are introduced. In translating theory to practice, a single case study summarizing 16 weeks of therapy illustrates how multimodal therapy led to deeper insights and direct involvement in the management of anxiety. Where the process enabled the client to draw on a range of inner resources, outcomes show greater psychological flexibility around the emotional tone which had previously kept her stuck. This method illustrates how mindfulness-based techniques enhance art therapy intervention and facilitate a deeper understanding of anxiety experience.

Keywords: mindfulness, anxiety, multimodal therapy

Intergenerational knowledge transfer as a matter of organizational culture?

STIPPLER, M. (Institute for Communication in the Professional Field and Psychotherapy), MITTERHOFER, H. (University of Innsbruck), SCHNEITTE, I. (University of Innsbruck), GROPPE, S. (University of Innsbruck)

Central European countries like Austria are facing a severe demographic change due to the mandatory retirement age being raised. This leads to changes in the age-composition of the workforce and increases the importance of intergenerational knowledge transfer. To this end, knowledge management systems and databases have been developed, but practice has shown that these systems are not the best way to transfer knowledge. The project “Diversity and Knowledge Management”, funded by the Austrian National Bank, aims to analyze the possibility of using the knowledge of elder workers in age-mixed teams as the key success factor. The analysis focuses on factors that enhance intergenerational knowledge transfer, including intra-company conditions as well as psychological factors. To identify these factors interviews and discussion groups with members of all hierarchical levels have been conducted in small and medium enterprises across different sectors. The qualitative data have been analyzed using atlas.ti. The approach is based on a triangulation of Grounded Theory (Strauss & Corbing, 1996) and Qualitative Content Analysis (Mayring, 2007). The results show that the crucial factors for successful knowledge management are based in organizational culture and leadership. These results demonstrate that developing successful knowledge management in companies is a tedious venture, as it means, in certain circumstances, changing the organizational culture. However the results also show that successful knowledge management has clear advantages for companies.

Keywords: intergenerational knowledge transfer, knowledge management systems, organizational culture, organizational leadership, age-composition of the workforce

Intervention study of different person narrative on personality development

WANG, X. (NanKai University), ZHU, Y. (Nankai University)

Three studies manipulated memory perspective (first-person versus third-person) individuals used to recall autobiographical events and examined its effects on personality development. A correlational study (Study 1) using the Cattell-16PF questionnaire was done to examine college students who use different memory perspectives. Intervention studies (Studies 2 and 3) used a standardization semi-
structured life story interview to examine different perspectives and different person narrative style effects on personality development. In Study 2, participants \((n = 37)\) wrote, and in Study 3, participants \((n = 12)\) discussed in group psychotherapy. Participants in each study were divided into two groups: first-person and third-person. The results of Study One showed that there were significant differences between the participants who used third-person perspective and those who used first-person perspective in E, G, Q1. Results of Studies 2 and 3 showed that (1) participants in Study 2 have more changes in personality than those in Study 3. In two studies, Q1 were all changed, and (2) the participants who used third-person had more changes in personality than those who used first-person. In two groups, H, Q1 were all changed (1) third-person narrative has more effects on personal change than first-person narrative; (2) as means of intervention, individual writing was more effective than group psychotherapy discussion; (3) after the intervention, there were changes in H, Q1 of personality; and (4) different person narrative could be used as an intervention approach to influence personality development.

### Introducing a new leader: Building explicit and implicit trust

**KIM, M. (Ajou University), SHI, X. (Ajou University), YEONG, D. Y. (Ajou University)**

Trust toward a new leader is important since it facilitates the followers’ cooperative behavior. Previous research suggested that trust is built when followers perceive the leader’s trustworthiness (e.g. ability, integrity, and benevolence, Mayer et al., 1995). However, followers may process the leader’s trustworthiness not only in an explicit (conscious evaluations of trust) manner, but also in an implicit manner (non-conscious associations between leader and trust). Study One examined how conscious and non-conscious associative processes could influence the formation of explicit and implicit trust toward a new leader. In Study Two, we considered a common phenomenon in which followers hear rumors about a leader before meeting them and examined how positive or negative rumors would influence the formation of explicit and implicit trust. In Study One \((N = 125)\), participants completed explicit (self-report) and implicit (Implicit Association Test-based) trust measures at Pre-test. Then, they were randomly assigned to either a Reading group which read about the leader’s trustworthiness (i.e. conscious processing), or a Conditioning group which conducted a lexical decision task which subliminally exposed participants to associations of the leader with trust (i.e. a non-conscious processing), or a Control group which took a break for ten minutes. At Post-test, the same measures were completed as in Pre-test. In Study Two, an identical procedure was used as in Study One, but all participants \((N = 142)\) were presented with positive or negative rumors before Pre-test. Unexpectedly, in Study One, the Reading group showed higher explicit and implicit trust compared to controls, while the ‘Conditioning’ group showed no higher explicit and implicit trust compared to controls. In Study Two, positive rumors resulted in significantly higher explicit and implicit trust in Pre-test than negative rumors. The manipulation effect was largely replicated Study One. In conclusion, providing information of trustworthiness may be critical in forming both explicit and implicit trust, since consciously processing such information was effective in forming explicit and implicit trust while non-conscious associative processing had no effect, and, in addition, this pattern was not affected by positive or negative rumors.

**Keywords:** perceived leader’s trustworthiness, implicit evaluations of trustworthiness, implicit association test, non-conscious associative processing, effect of rumors

### Investigating Socially Desirable Responding (SDR) in volunteer selection: Stakeness, helping motivation, and double rating method

**MAN, C.Y. (Chinese University of Hong Kong)**

This paper investigates the effect of situational stakeness, helping motivation, and rating methods on Socially Desirable Responding (SDR) in volunteer selection. It hypothesises that whether volunteers fake in selection tests
Abstracts of the 27th International Congress of Applied Psychology

depends on their helping motivation. When they are self-oriented, they fake to secure their personal interests associated with a successful application. When they are other-oriented, they do not fake as they associate less personal interests with volunteering. In addition, the study investigates the effect of a Double-Rating Method (DRM) on reducing SDR among the volunteer sample. Subjects were 178 Hong Kong students recruited from a local university. The researcher manipulated the level of stakeness into high or low by inviting participants to complete an online personality test for volunteer selection or anonymously answer an online personality test for research purposes. The Balanced Inventory of Desirable Responding (Paulhus, 1984) were administered in both conditions. Participants were also randomly assigned to either a single or double rating method. Finally they were required to complete a set of online questionnaires concerning their helping motivation including the Volunteer Functional Index (Clary et al., 1998) and, the Interpersonal Reactivity Index (Davis, 1983). Results showed that SDR related positively and significantly to situational stakeness and other-oriented helping motivation. This suggests that the selection pressures volunteer applicants to overrate themselves, albeit related to their wish and inability to help others. In addition, administering a double rating method did not control SDR as suggested by previous literature. This suggests the effect of the double rating method may be hampered by computer administration. Investigating the effect of stakeness, helping motivation, and rating method on SDR, the study shows that both stakeness and other-oriented empathy is highly and positively associated with SDR. This causes people to reflect on their reasons for volunteering and their effects on clients. Together with the failure of DRM in controlling IM in the current study, this study suggests the use of personality tests in volunteer selection warrants caution.

Keywords: socially desirable responding, volunteer selection, stakeness, helping motivation, double-rating method

Dystrophy: Interviews with patients and their families

SAEKO, T. (Osaka University), SHIBATA, S. (Osaka University), IMURA, O. (Osaka University)

Muscular dystrophy (MD) is a genetic disorder that weakens the muscles that help bodily movement. Because MD is genetic, patients who have this disease are born with this problem. MD weakens muscles over time, so they gradually lose the ability to do the things most people take for granted. Although truth-telling about the diagnosis is said to be important, the realities of truth-telling are not known well in Japan. In this study, we tried to investigate actual conditions of truth-telling for patients and their family of Duchenne muscular dystrophy (DMD), the most common type of MD. We interviewed 15 DMD patients in the hospital. The Questions were: 1. Who explained about the sickness? 2. How did you feel at that time? 3. What is the ideal way of truth-telling or preferable notification? This study have approved by Ethical Review Committee of the hospital that cooperated in this research. We interviewed 13 patients in the hospital, and were refused by two patients. The range of the age was from 18 years to 46 years old. Many patients answered that the illness was explained to them when they were in middle grade of elementary school by a doctor. However, there were a few patients answered that they noticed naturally by seeing other patients when in hospital. The typical way of explain was “your muscle will become weak little by little, you will not be able to walk in the future”. Though there were few patients who had emotional disturbance after truth-telling, many patients said that they didn’t feel anything or the illness felt out of touch with reality because they could move their limbs at that time. Many families expressed discomfort at having to broach the topic of the prognosis, including limited life expectancy, and some withheld information or not disclosed the prognosis. On the other hand, the majority of patients with DMD have high information needs concerning its prognosis. We concluded that health professionals and families of the patients of DMD, should make an assessment about what the patient does not know, what they want to know and whether
they understand the actual conditions of the illness or treatment.

Keywords: muscular dystrophy, notification of a diagnosis, information needs concerning prognosis, truth-telling to patients

Is integrity universal across cultures? Conceptual and measurement challenges

KOEHLER, T. (The University of Melbourne), FINE, S. (Midot), GONZALEZ MORALES, M. G. (The University of Guelph)

Few traits are as important for employee performance as that of integrity, and measures of integrity are widely used in personnel selection around the world as a result. Previous research has suggested that when using tests in different countries cross cultural measurement equivalence should first be established (Vandenberg & Lance, 2000). However, underlying this requirement is the implicit assumption that the construct in question is in fact the same in each country. Recent research indicates that the meaning of several constructs often used in applied psychology can differ cross culturally (Köhler & Berry, 2008; Fischlmayr, Lähteenmäki, & Saarinen, 2007). The current study therefore assesses the cross cultural meaning of integrity in the context of personnel selection, and discusses the implications for measurement equivalence requirements. Data was collected using items from a typical overt integrity test measuring attitudes towards societal norms, the sanctioning of counterproductive behaviors, and personal admissions of wrongdoing. Participants were job applicants from four countries: Israel (N = 4896), Mexico (N = 6261), Ukraine (N = 4700), and Colombia (N = 2268). These samples were chosen to represent four culturally distinct country clusters. The data were analyzed using multidimensional scaling and multiple group confirmatory factor analysis techniques. While reliability analyses showed that the integrity test is consistently scored across the four countries, multidimensional scaling and factor analysis found significant differences between the four countries. This study goes beyond previous research, which has found the extent of dishonest behaviors to differ cross culturally (Doh et al., 2006), by suggesting that the very concept of integrity may take on different conceptual meanings in different countries. As a result, in order to fully understand and accurately measure the concept of integrity, cross cultural differences need to be considered carefully. Furthermore, the universal requirement for demonstrating cross cultural measurement equivalence may be inappropriate for constructs that are shown to differ in their underlying concepts, such as integrity. The implications for international integrity testing in personnel selection will be discussed.

Keywords: personnel selection, international integrity testing, integrity, cross cultural measurement equivalence, cultural meaning of integrity

Is it more than medicine? The impact of optimism and illness perceptions on quality of life after total hip replacement surgery

JESZENSZKY, C. (Technical University Dresden), BALCK, F. (The Technical University of Dresden), LIPPMAN, M. (University Hospital Carl Gustav Carus and Technical University of Dresden)

The common treatment method for coxarthrosis - the arthrrosis of the hip joint - is total hip arthroplasty (THA), a replacement surgery with good outcome rates and low risk of complications. Recovery after surgery is highly influenced by psychological factors. The main purpose of our study was to examine whether pre-operative optimism and illness perceptions determine quality of life three months after THA. The sample consisted of patients undergoing THA for the first time. The participants had to fill out questionnaires immediately before and three months after the intervention. Data about optimism (LOT-R) and illness perceptions (IPQ-R) were collected prior to the surgery while data about quality of life (EQ-5D) both pre- and postoperative. One hundred and forty patients were included in the investigation, with a mean age of 56.3 (SD = 12.6), 65% being female. Gender differences were found in the specificity of quality of life, women having lower ratings both before and after surgery. Multiple linear regressions were used to calculate the relative effect of optimism, illness perception and age on the postoperative outcome. The outcome in
women was determined by optimism and personal illness control, explaining variance of 27%, while in men illness consequences and age were the most relevant factors, explained variance being 36%. In the whole sample, optimism, illness identity and age accounted for postoperative quality of life, explaining 20% of variance. Our findings indicate that optimism and illness perceptions are important predictors of quality of life after THR surgery. Thus the results highlight a meaningful starting point for further design and evaluation of patient’s training in order to enhance recovery after surgery.

**Keywords:** optimism, illness perceptions, quality of life, surgery recovery, illness identity

**Is quitting smoking bad for your mental health? Reports of depressive symptoms among quitline callers with and without a depression history**

SEGAN, C. (University of Melbourne), WILHELM, K. (St Vincent’s Hospital, Sydney), BHAR, S. (Swinburne University of Technology), BORLAND, R. (The Cancer Council Victoria), HANNAN, A. (The Cancer Council Victoria), FERRETTER, I. (The Cancer Council Victoria)

Many clinicians and scientists believe smoking cessation increases the risk of Major Depressive Disorder (MDD), particularly among smokers with a depression history. This study tested this hypothesis within the context of a state-wide quitline callback service that offers a specialised service for depression-history smokers. Three groups of smokers were followed over six months: 1) Disclosed current depression to quitline, i.e. doctor diagnosed depression and use of anti depressant medication or depressive episode within last 6 months, n = 199; 2) Disclosed past depression, i.e. prior doctor depression diagnosis, no use of anti-depressant medication or depressive episode within last 6 months, n = 120; 3) No depression history disclosed, n = 483. Telephone interviewers contacted participants at baseline (i.e. following initial call to quitline), two months (74% response rate, no differential drop-out) and six months (70% response rate, no differential drop-out). The Patient Health Questionnaire (PHQ-9) measured depressive symptoms. Quitters were less likely to report experiencing two or more weeks of feeling depressed at both two and six months whatever their depression status (six month figures: 16% quitters versus 34% failed, 37% non attempters). Overall, there was a decrease in depressive symptoms between baseline and six months, which was attributable to successful quitters reporting less depressive symptoms and this was not related to depression status. At both follow-ups, around ten percent of participants reported a significant increase in depressive symptoms to major/severe levels. This was not statistically associated with whether people had quit or not, but was related to depression status, i.e. more likely among current depression group (18%) versus past (11%) or no depression (5%). Quitting smoking was associated with improved mood and was not reliably associated with precipitation or exacerbation of MDD. The findings allay concerns about the safety of quitting for smokers with a depression history and have resulted in quitline policy and practice changes.

**Keywords:** major depressive disorder, depression history, quitting smoking, mood, depression

**Is Rugby bad for your intellect? The effect of repetitive mild head injuries on the neurocognitive function of university rugby players**

SMITH, I. (St John of God Health Care), SHUTTLEWORTH-EDWARDS, A. (Rhodes University), RADLOFF, S. (Rhodes University)

The objective of this study was to compare university level players of Rugby Union (hereafter rugby) with non-contact sport controls in order to identify indications of neurocognitive deficit amongst rugby players in association with long-term participation in the game. A non-clinical population of top team university rugby players (n = 27) and university level non-contact sports controls (n = 18) were tested at pre-season and post-season on the ImPACT test, Trail Making Test A and B (TMT A and B), and Digit Span Backwards and Forwards. The comparative groups were evenly distributed for race and language, and broadly equivalent for age, education and IQ, although rugby players had a history of more concussions than
controls (p = .001). All neurocognitive measures were subjected to repeated measures two-by-two factorial ANOVAs, and effect sizes were calculated. Results revealed significant lowering for rugby players relative to controls at the post-season interval for attentional tasks with a speeded visuomotor component (ImPACT Visual Motor Speed; TMT A and B). There was a practice effect for controls only between the pre and post-season intervals for attentional tasks that commonly reveal improvements after a long retest interval (TMT A and B; Digits Backwards). Medium to large effect sizes were demonstrated in respect of the obtained significant results. It was concluded that clinically relevant cognitive vulnerability was implicated for university level rugby players in association with years of exposure to repetitive concussive injury.

Keywords: repetitive concussive injury, neurocognitive deficit, trail making test, digit span backwards and forwards, cognitive vulnerability

Japanese pet ownership psychological and social challenges

KIKUCHI, K. (Teikyo Heisei University), OSADA, H.

Due to a congested population, many dog owners in Tokyo have trouble when they let their dogs off the leash. Dog owners want to build a leash free area for their dogs, and volunteers and the local government started trial community Dog Runs in 2007. We conducted surveys at these events during 2008 and 2009 and evaluated the potential of community “Dog Runs” based on participants feedback. The location was in the southwest part of a Tokyo suburb at a public park, next to a river bank and walking path, with an area of 7500m², surrounded by a plastic fence. Visitors to the event agreed to participate in the survey and we handed out survey papers to each dog owner. The survey points were; demographics, living area, usual dog walking area, event information access, user evaluation, and comments. Approximately 60% of the 81 participants were female. Most of the participants were around 40 years of age, lived nearby and used the area for walking their dogs. Participants acquired information from various sources including posters, word-of-mouth, leaflets and visually. Participants felt that this event gave them an opportunity to meet other pet owners, share information, relax, have some community involvement and learn about pet ownership. They thought it was a positive activity for everyone (pet owners and non-pet owners) in the community. The event encouraged dog ownership and gave people a chance to think about the responsibilities of pet ownership. It was felt that the Dog Runs were a positive activity but not easy to set up. The area was viewed as a community meeting place and a chance to exchange ideas and the event enhanced social networking and built social capital. Due to the pet boom in Japan, local governments and their citizens are under pressure to accommodate the growing number of pet needs. The Dog Runs had many benefits but it was difficult to evaluate the overall positive effect within the community.

Job burnout, job satisfaction, and turnover intention: The moderating role of conscientiousness

DAI, H. (Peking University), WANG, L. (Peking University), KONG, H. (Luxottica Group), YU, Z. (Luxottica Group)

The aim of this research was to estimate the prevalence of burnout and the level of job satisfaction and turnover intention among production line workers, and to examine conscientiousness as a moderator of the relationship between job burnout, job satisfaction and turnover intention. Questionnaires were sent to front line workers who participated voluntarily. The sample consisted of 526 production line workers who were surveyed for their job burnout, job satisfaction, turnover intention and conscientiousness. Hierarchical regression was performed using job burnout, conscientiousness, and the product of them as explanatory variables, and job satisfaction and turnover intention as the outcome measures. The results showed that job burnout was not related to job satisfaction for those low in conscientiousness, but for individuals high in conscientiousness, those who were higher in job burnout were lower in job satisfaction. In addition, those high
in job burnout had high turnover intention, and the relationship between the two variables was stronger for those high in conscientiousness than those low in conscientiousness. This study has shown a high turnover intention and a moderate prevalence of burnout and job satisfaction among production line workers. The results also indicate that employees with high conscientiousness would be more adversely affected by job burnout than those with low conscientiousness.

Keywords: job satisfaction, burnout, turnover intention, conscientiousness, production line workers

Job insecurity and employees’ job performance, and well-being: The moderating effect of supervisor support

CHEN, J. (Peking University), WANG, H. (Peking University), LU, C. (Peking University)

Job insecurity is becoming one of the serious stressors in the workplace, especially during the current times of economic crisis. The present study aimed to examine the relationships among job insecurity and job performance, and well-being, and focused on the moderating effect of perceived supervisor support (PSS). A self-administered questionnaire survey method was used to collect data from 387 subordinate-supervisor dyads in diverse Chinese organisations, and employees’ job performance was rated by his/her supervisor. A series of hierarchical regression analyses were conducted for data analyses. The results showed that job insecurity was negatively associated with both job performance and well-being. Moreover, PSS buffered the relationship between job insecurity and job performance. Specifically, employees with higher PSS would react less negatively to job insecurity than those with lower PSS. However, PSS did not have any moderating effect on the relationship between job insecurity and well-being. The present study revealed that job insecurity had emerged as one of the serious job stressors which negatively impacted employees’ job performance and well-being in the Chinese context. Furthermore, supervisor support was found to be an important resource to employees in resisting the adverse effect of job insecurity on job performance.

Keywords: job crafting, job performance, autonomy, work variety, self-efficacy

Juror perceptions of alibi evidence in the presence of a positive, foil or non-lineup identification

MARION, S. (Ryerson University), POZZULO, J. (Carleton University), BURKE, T. (Ryerson University), DEMPSEY, J. (Carleton University)

Recent research on alibi perceptions suggest that the believability of an alibi is highly dependent on the relationship between the suspect and the corroborating witness, where an alibi corroborated by a stranger is perceived as more credible than one corroborated by a close other. However, jurors also seem to be greatly influenced by an eyewitness’ positive lineup identification (ID) of a suspect. The purpose of this study is to examine how the type of lineup identification decisions made by an eyewitness influences jurors’ perceptions of more or less credible alibi evidence. This study was a 3 (eyewitness identification: positive ID versus foil ID versus non-ID) X 3 (alibi corroborator: no corroborator versus family member versus stranger) between subjects design. One hundred and eighty psychology students read a mock trial transcript of an attempted murder case. In the transcript, an eyewitness testified to have made one of three line-up identification types: 1) a positive identification of the defendant, 2) an identification of a foil, or 3) a non-identification. The trial transcript also included testimony regarding the defendant’s alibi, which was either 1) corroborated by a family member, 2) corroborated by a stranger, or 3) not corroborated. The dependent variables included guilt ratings, verdict, and ratings of the credibility and reliability of the eyewitness, the corroborating witness (when present), and the alibi itself. Preliminary results suggest that although mock jurors perceive an alibi that is corroborated by a stranger as more credible and than an alibi corroborated by a family member or by no one at all, alibi corroborations do not significantly influence verdict nor guilt ratings. There was, however, a weak interaction between alibi corroborations and eyewitness identification on jurors’ perceptions of the reliability of the alibi corroborator’s testimony. Family corroborators are perceived as most credible when a non-identification is made by the eyewitness. No such interaction was observed on verdict and guilt ratings. These results are a further indication of the overwhelming influence that eyewitness identification has on potential jurors’ verdict decision, even in the presence of other evidence that, in the absence of eyewitness testimony, has been shown to influence verdict.

Keywords: alibi corroboration, eyewitness accounts, juror perceptions, verdict, alibi believability

Jyotir Dhyana - A pilot study in enhancement of immediate memory

K., H. V. S .S. N. (Banaras Hindu University)

The aim of this research was to study the effect of Jyotir dhyana in male college students. Dhyāna is a Sanskrit word that is derived from the verbal root dhyai which means to contemplate, to meditate, to think. It is the most common designation both for the meditative state of consciousness and the yogic techniques by which it is induced. In the Gheranda-Samhita (6.1-3), a celebrated text book of Hatha-yoga, it has been described that the dhyana is of three types viz. 1. Sthula (coarse), 2. Jyotir - (luminous) and 3. Sukshma - (subtle). Jyotir-dhyana is the contemplation of the Divine as a mass of light either in the lowest psycho-spiritual center of the body, the muladhara-cakra or in the ajna-cakra highest psycho-spiritual center. A pilot study was conducted with 40 male college students (ranging from 20 to 30 years of age) were taken from some departments of Banaras Hindu University, Varanasi. First they were screened for immediate memory on immediate memory digital span scale. Then the students were given training of jyotir dhyana on Ajna chakra and asked to practice regularly. After one month, the students were again rated on the same scale. The results indicated that students who received the training of jyotir dhyana showed the significant increase in the memory span scale. On the basis of present study it is concluded that jyotir dhyana enhances memory and the power of concentration, probably by stimulating the Ajna Charaka (that is, the highest psycho-spiritual center).
Kapwa in the workplace: A preliminary study of using cultural values for engaging Filipino workers

MATTISON, H. (University of the Philippines Diliman), MENDOZA, A. (University of the Philippines Diliman), YACAT, J. (University of the Philippines Diliman), BOLANTE, F. (University of the Philippines Diliman), CANTILLER, J. (University of the Philippines Diliman)

Migration and outsourcing has placed Filipinos in many global organizations. As such, the need for understanding their culture and leveraging this to engage the Filipino at work is becoming more important in the global environment. The purpose of the research was to examine the understanding and use of core Filipino values (malasakit, pananagutan and bayanihan) in organizations. Prior to this study, there have been few attempts to empirically validate the use of Filipino values in the workplace and how best to manage Filipino workers by acknowledging and utilizing their culture and value system. In this preliminary study, five high-performing Filipino organizations participated in ginabayang talakayan (GT) (indigenous focus group discussions) of groups of employees - one GT for staff levels and another for managerial levels. These were then supplemented by interviews of their Human Resources Directors or the person directly responsible for culture and organization development in the company. The questions for both methods centred around their understanding of each value, how these values can be seen in the workplace, and how these values are utilized by the company in terms of human resources practices and programmes. The data collected was analyzed using the KJ method. The data showed a consistent definition for each of the values, generating a better understanding of malasakit, pananagutan and bayanihan. Human Resources policies and programs tended to vary between the organizations, but seemed to produce the same engagement and commitment of the employees. The consistency of definitions for the three core Filipino values seems to indicate that the understanding of these among Filipinos is deep seated. As such, the understanding and reflection of these in programs and policies may in fact be useful in engaging and managing Filipino workers in the global environment. More studies along these lines need to be attempted to further our understanding of Filipino work culture.

Keywords: migration, global organizations, human resources, work environment, employee engagement

Ketamine as a model for semantic memory deficits in schizophrenia

NEILL, E. (Monash and Alfred Psychiatry Research Centre), ROSSELL, S. (Monash and Alfred Psychiatry Research Centre)

The glutamate/ketamine model is gathering support as a useful adjunct to the dopamine hypothesis of schizophrenia (Javitt, 2007), one reason being that ketamine is capable of eliciting the cognitive deficits associated with this illness including those seen in semantic memory (Adler et al., 1998; Morgan et al., 2005). Two recent reviews (Rossell & Stefanovic, 2007; Pomerol-Clotet, et al., 2008) have found larger than normal indirect semantic priming affects in schizophrenia suggesting an abnormality in implicit access to indirect relationships. In the current study, implicit and explicit tasks were employed to examine access to direct and indirect relationships in the semantic network. The purpose was firstly to see if the indirect priming findings from the schizophrenia literature can be replicated in a ketamine group (providing support for the ketamine model) and secondly, to determine whether such abnormalities are restricted to the indirect, implicit nature of the task or whether they are more widespread and detectable in explicit and direct tasks. Should ketamine mimic schizophrenia deficits closely, then the answer to the second question will help to determine the nature of the semantic memory deficit in schizophrenia. This was a double blind placebo controlled cross over design. On one occasion, participants received ketamine, on the other, saline. On each occasion, participants completed a battery of semantic memory tasks along with measures of psychosis and dissociation. The results showed statistically significant indirect priming under the influence of ketamine but no...
significant indirect priming in the same individuals in the placebo condition. In addition, ketamine only disrupted semantic access significantly on indirect tasks. Priming effects under ketamine matched those seen in schizophrenia offering support for the ketamine model. Further, semantic memory deficits were found to be associated with indirect relationships regardless of the implicit/explicit nature of the task.

Keywords: cognitive neuropsychology, glutamate ketamine model of schizophrenia, cognitive deficits, semantic memory, psychosis

Knowing your team members: Its effects on incivility and trust in work teams

SUN, S. (National University of Singapore), LIM, S. (National University of Singapore)

The current study focuses on the functional role of knowing team members in reducing incivility and increasing trust in a team context. The study intends to extend the current literature by (1) Examining incivility and trust in a work team context, (2) Exploring the role of knowing team members’ expertise in reducing the occurrence of incivility and increasing trust, and (3) Examining the impact of incivility on collective trust. We adopt a longitudinal panel design. Subjects are recruited from the student subject pool of a business school in Singapore. As part of their coursework requirements, each student has to complete a term project in teams of six to eight students. Data was collected via online surveys which were administered at three time points. Knowledge of expertise location was measured at Time One (beginning of the term), incivility was measured at Time Two (middle of the term), and trust was measured at Time Three (end of the term). We employed lagged path analysis to examine our hypotheses. All the path coefficients are significant and in the direction as predicted. Knowledge of expertise location is negatively related to incivility (b = -.10, p = .02), and positively related to both cognition-based collective trust (b = .32, p < .01) and affect-based collective trust (b = .44, p < .01). In turn, incivility is negatively related to both cognition-based collective trust (b = -.13, p < .01) and affect-based collective trust (b = -.08, p = .04). Expertise, as a critical resource for a team project, must be effectively coordinated. To achieve this, team members need to have an understanding of the strengths of each team member. In the current research, we propose that team expertise knowledge is effective because it can increase trust and reduce incivility among team members. Thus our study has important managerial implications for team management.

Keywords: expertise, team management, collective trust, incivility, expertise

Knowledge, perceptions and use of sport psychology: A survey of Australian Football League (AFL) players

TEMBY, P. (University of South Australia)

Research has found that elite athletes generally have positive attitudes towards sport psychology, including a belief that mental skills are important for training and competition success. While sport psychologists are utilised by Australian Football League (AFL) clubs, little is known about AFL players’ knowledge, perceptions and use of sport psychology. The aim of the study was to address this gap in the literature by surveying elite-level AFL players in these areas. One-hundred and sixty-one elite-level AFL players took part in the study. Participants completed a 94-item questionnaire covering their knowledge of sport psychology, attitudes towards sport psychology (using the Sport Psychology Attitudes-Revised scale), frequency of use of six techniques (self-talk, imagery, goal setting, relaxation, activation, attention control), and perceived effectiveness of these techniques. Participants responded to items on Likert-type rating scales or with qualitative comments. The survey found the majority of players reported having limited knowledge of sport psychology. Positive attitudes towards sport psychology were found, including: confidence in sport psychology consultation, an interest in learning more about sport psychology, and taking part in mental skills training. Players reported using a range of techniques, albeit infrequently and mainly for competition. Self-talk, imagery, and goal setting were used most frequently, and all six techniques were rated as being at least
somewhat effective. This is the first known study to comprehensively examine AFL players’ knowledge, perceptions and use of sport psychology. The findings suggest AFL players have positive perceptions of sport psychology, which is encouraging for the profession. Players’ knowledge and use of sport psychology were consistent with levels reported in previous studies with elite athletes. There is a need for practitioners to educate AFL players about the benefits of using mental skills on a more frequent basis. It is hoped the survey findings will encourage further research in this area, and provide practitioners with information that can be used to help AFL players to achieve their potential on and off the field.

Keywords: attitudes, self-talk imagery, goal setting, sports’ players potential, mental skills and elite sport

Learning climate and its effects on work outcomes

HAUER, E. (Umea University), WESTERBAG, K.

In the present study the learning climate in elderly care in an average sized Swedish municipality, before and after an intervention, is investigated. The intervention was part of the programme “Steps for skill” and the basic idea was to build new infrastructures for learning and development in elderly care. In regards to the results of “Steps for skill”, taking into account different organizational levels but considering home help services and residential homes as one context, the specific research questions were: Are there differences between the two types of elderly care as well as between managers and employees’ in their experience of the learning climate? How do the learning climate and its variables effects work outcomes? What is the outcome of the intervention? Prior to, and one year after, the development intervention surveys were distributed to 29 workplaces and answered by 270 care assistants and 29 managers working in working in elderly care. The sample consisted mainly of females (91%), the average age was 43 years, and 13% had a university degree. Preliminary results show that there is a difference between the two types of elderly care. When it comes to learning climate the groups working in home help services have a lower estimation than the groups working in residential homes, and a higher level of perceived stress. Regarding the outcome of the intervention, the learning climate only at the home help services became significantly better. To work in home help services seems to have a negative influence on the learning climate, which is not surprising considering the lack of opportunities to discuss everyday work activities and specific problems when they occur. The home help services have specific working conditions that are not in line with the suggested key factors in workplace learning; but that improved after the intervention. Choosing one context over another may influence both research results an implications.

Keywords: elderly care, work learning climate, home help services, residential homes, perceived stress

Leaving two impressions: How do explicit and implicit attitudes form towards a new brand?

JANG, D. (Ajou University), KIM, D. Y. (Ajou University), OH, S. (Ajou University)

The advertising paradigm is a means by which people form attitudes about a new brand. To investigate the formation of explicit and implicit cognitions when consumers turn toward a new brand, participants were exposed to marketing material of an unfamiliar brand in an unfamiliar product category, in an experimental setting. In Study One, marketing material about a fictional brand of wine was introduced to participants in increasingly elaborate conditions (low, medium and high groups plus a non-exposure control group), to explore the effect of elaboration on explicit and implicit attitudes. Study Two was a replication of Study One, but using a real brand and a website as a source of information. Study Three was similar to Study Two, except that a competing brand was introduced. In Study Four, students were exposed to a supraliminal priming procedure, designed to artificially create associations between the brand and positive valences. All studies used a mixed (between and within-pre/post) experimental design, and identical explicit (thermometer and semantic differential scales) and implicit (Implicit Association Test-based) measures. Study One
showed that exposure to marketing material resulted in a cognitive preference towards the fictional brand in the low, medium and high exposure groups. Favorable affective evaluations were seen only in the medium and high exposure groups. Positive implicit preference toward the brand was not observed. Results of Study Two showed the same pattern. In Study Three, the introduction of an additional, unfamiliar competing brand resulted in favorable cognitive preferences, but no affective or implicit preference toward either product. Study Four showed that creating an artificial association toward a product formed cognitive, affective and implicit preferences toward the primed brand. In conclusion, being exposed to marketing material about a new brand can create positive cognitive attitudes, but positive affective attitudes may require greater elaboration or presentation in isolation. Furthermore, a single exposure does not lead to positive implicit attitudes. In contrast, repeated associations between a brand and positive experiences could be effective in enhancing explicit attitudes through the perception of validation of marketing materials, whereas for implicit attitudes, they could be effective through the strengthening of associations between a brand and positive concepts.

Keywords: explicit and implicit cognitions, attitudes, marketing, affective evaluations, repeated associations

Leftward or rightward: Does matching horizontal stimulus movement with habitual reading direction improve evaluations?

LI, E. (The University of Sydney), BRILEY, D. (The University of Sydney)

People frequently encounter alphanumeric stimuli that move across the field of vision horizontally. This research examines whether the direction of motion - leftward or rightward - affects processing and evaluations of such stimuli. In particular, it is predicted that when the direction of motion coincides rather than conflicting with the viewer’s habitual reading direction (e.g., left-to-right for English speakers), evaluations of the alphanumeric stimulus should be more positive - an effect that is driven by processing fluency. The sample consisted of 153 students from an English-speaking university who were randomly assigned to two conditions that varied the direction in which a fictitious brand name moved across the computer screen (left-to-right and right-to-left). After watching the moving brand name, participants were asked to report their attitudes toward it, the difficulty with which they were able to process it (processing disfluency—direct measure of fluency), the strength with which they were engaged in the evaluation (strength of engagement—indirect measure of fluency), and the extent with which they felt right (feeling right—indirect measure of fluency). Consistent with our predictions, the brand name moving left-to-right was liked more than the same brand name moving right-to-left ($t=1.99$, $p<.05$). Mediation analysis (Baron & Kenny 1986) showed that “feeling right” experience drove participants’ liking toward left-to-right vs. right-to-left moving brand name ($Sobel z=2.42$, $p<.05$). In addition, neither processing disfluency nor strength of engagement was correlated with motion direction ($r=-.05$, $p>.10$; $r=.11$, $p>.10$ respectively). In sum, our results support that viewers like an alphanumeric stimulus more when the direction of its motion matches rather than mismatches their habitual reading direction, and feeling right experience underlies this effect. Indirect instead of direct measure of fluency being qualified as the mediator may suggest processing fluency drives this effect in a nonconscious manner.

Keywords: field of vision, motion direction, reading, alphanumeric stimulus, reading direction

Levels of dual-goal expectancy determine strategies of effort allocation

MAN, C.Y. (Chinese University of Hong Kong)

As multitasking becomes an everyday-life phenomenon, learning the dynamic processes by which multiple goals are pursued is essential. This is especially true because performance inevitably suffers from competing goals that exceed individual resources. Hence, this study aims at investigating how multiple-goal pursuit may be possible by exploring how effort is allocated to competing goals. Specifically, it
expands Schmidt and Dolis’ (2009) theoretical model of dual-goal expectancy to include goal importance. Different levels of dual-goal expectancy enact different regulation strategies, resulting in different effects of perceived progress and goal importance on effort allocation, which correspond to control theory and expectancy theory respectively. This study tests all predictions in a laboratory setting using unobtrusive measures of effort allocation across multiple goals in multiple performance episodes. Sixty university students were required to perform two secretarial tasks on which they were free to allocate time. They were randomly assigned into one of six conditions: two levels of cumulative goal difficulty (high and low); and three types of incentive structure (reward for the first, the second, and both tasks). Participants performed five, six-minute trials, in between which they completed self-report measures including Goal Progress, Goal Expectancies, and Goal Importance. In addition, Effort Allocation and Performance were the two main dependent variables. Effort is operationalised as the amount of time spent on tasks. Performance refers to the degree of task accomplishment. Statistical procedures were employed to test the mechanisms involved in how dual-goal expectancy affects effort allocation and performance. In support of the research hypotheses, preliminary results reveal that cumulative goal difficulty partly determines dual-goal expectancy, whereas incentive structure determines goal importance. The effects of relative progress and incentives on effort allocation seemingly vary when the level of dual goal expectancy differs. This implies different effort regulation strategies are enacted. In addition, effort allocation predicts performance in a positive direction. Using an unobtrusive measure of effort allocation in a laboratory setting, the study investigates effort allocation involved in competing-goal pursuit. It conceptualises the role of dual-goal expectancy as enacting different self-regulation strategies. Theoretically, this conceptualisation helps shed light on reconciling theoretical propositions.

Keywords: dual-goal expectancy, effort allocation, multitasking, goal importance, performance

Life skills for quality of life at old age:
The need for community wellbeing

SINGH, A. P. (Government Maharani Laxmi Bai Girls P.G. College), TYAGI, P. (Government Maharani Laxmi Bai Girls P.G. College)

Aging is virtually a universal phenomenon. The world community seems to have become increasingly aware of the multifarious issues that surround the life of the old. This concern is attributed to the swelling up of their number in the population inhibiting this globe in recent decades and its consequential demands for health, mental health and care, in the fast changing society, under the influence of modern forces of change. Quality of life (QOL) is a holistic concept. QOL is defined by WHO as an individual’s perception of their position in life in the context of culture and values system in which they lie and in relation to their goals, expectations, standards, and concerns (WHO QOL group, 1995). UNICEF used the “life skill” as psychosocial and interpersonal competencies in a person that enable him/her to deal effectively with the demand and challenges in everyday life. The impotence of the ‘healthy community’ concept has been recognized as an emergent field of research to understand the linkages between human survival, the ecosystem and wellbeing. The concept of wellbeing has been used as the state of being healthy, happy or prosperous. The community wellbeing is an emerging concept that needs exploration through empirical research to understand the indicators of wellbeing and building empathy, understanding, security and psychosocial conformity by living together in a social community. The present study focuses on exploring life skills which enhance quality of life among the old who are living in a small community and leads to community wellbeing and attributions to a positive life. The sample consists of 50 (70 to 80 years old) male and female randomly selected from Aasara old age home (multicultural) in Bhopal M.P. India. A life skill questionnaire was developed and administered to find out the correlation between life skills and quality of life. The two way interaction between gender and age reflected a significant difference in type of life skills and quality of life style. Positive life skills enhance quality of life. The quality of life contributes to community wellbeing.
Keywords: ageing, quality of life, community wellbeing, life skills

Links between short-term trajectory of depressive symptoms and effortful control

TAKAHASHI, Y. (Japan Society for the Promotion of Science /Keio University /University of Illinois / Urbana-Champaign), OKADA, K. (Tokyo Institute of Technology), HOSHINO, T. (Nagoya University)

Effortful Control, one of temperamental dimensions, is defined as the efficiency of executive attention, including the ability to inhibit a dominant response and/or to activate a subdominant response. Previous studies have reported that Effortful Control was negatively correlated with depressive symptoms. However, little is known about the links between Effortful Control and the various short-term developmental trajectories of depressive symptoms. The main goal of the present study was to examine how Effortful Control contributes to the developmental trajectory courses of depressive symptoms by using a growth mixture modeling (semiparametric group-based approach). Japanese female undergraduate students (N = 90, Mean Age = 19.82, SD = 3.44) completed the questionnaire booklet including temperamental dimensions and depressive symptom items from Times One to Four at weekly intervals. Short-term developmental trajectories of female undergraduates’ depressive symptoms with predictor variable (i.e. Effortful Control) were modeled, and three latent classes were identified by model comparison: a relatively high level group (13.0%), a middle level group (47.6%), and a relatively low level group (39.4%). Additionally, Effortful Control predicted class membership probability fairly consistently. Female undergraduate students with lower Effortful Control tended to exhibit a relatively high trajectory class of depressive symptoms. Although simple correlation analyses only showed that depressive symptoms were negatively correlated with Effortful Control, the results in the present study have additionally showed that depressive symptoms described three different trajectory courses during four weeks, and that Effortful Control could predict the membership probability for these trajectory courses. These findings may have implications for the effectiveness of identifying female undergraduate students who are at risk for further evaluations, and for the selection of intervention targets and strategies.

Keywords: effortful control, executive function, depression, temperament, developmental trajectories of depressive symptoms

Listening to the heart of Indonesian students toward university counseling service

SETIAWAN, J. L. (Universitas Ciputra)

Young people face many new experiences during their study at the university. These experiences not only challenge students’ level of development, but also bring risks of psychological distress. Some universities in Indonesia provide a counseling service in their effort to support students though their academic life. This paper describes a study designed to investigate Indonesian undergraduates’ perceptions relevant to a university counseling service. A self-report questionnaire measuring students’ perceptions of their university counseling service was distributed to 778 undergraduates from two private universities in urban areas in Indonesia. Results showed that students had poor knowledge of the counseling nature and service details. Students did not show strong favourable perceptions towards the university counseling service. The findings indicated that the publicity work of the universities’ counseling service was not adequate in getting across its message to students. In fact, the inadequacy of the publicity of the universities’ counseling service was also reported by students. University Counseling Service in Indonesia should disseminate accurate information about counseling nature and service details so that students could have more favorable perceptions towards the service. Detailed findings and further implications of this study will explored further in the paper.

Keywords: university counseling service, perceptions

Lisu literacy, culture and identity
BRADLEY, D.

The Lisu (sometimes called Yobin in India) are a tribal group living in China, Burma/Myanmar, Thailand and India, with a total population of nearly one million. About 2,700 are found in Arunachal Pradesh in the northeast of India. They have a strong group identity, and their language persists well nearly everywhere; but they also have a very positive attitude to second language learning, and many Lisu individuals are successfully bilingual or multilingual and perform well in education systems in all countries. Lisu has a well-designed orthography used in all four countries, mainly by Christian Lisu who represent some 50% of the population; all those in India are Christian. There are various basic materials available for teaching mother tongue literacy, including some specifically prepared by the community in India. Unfortunately, it is not designed for effective transfer to learning any other orthography, though it uses roman upper case letters: 25 upright and 15 inverted. The Lisu orthography is mainly taught in churches and used for reading Christian books. This means that there is little material of intermediate levels of difficulty, between basic readers and the Bible. Nearly all of the published literature is strongly Christian in its content; traditional Lisu oral literature is mostly unknown to Christians, especially those who have been Christian for two or more generations, like most of those in India. We have been printing and circulating various booklets of traditional Lisu oral literature such as the Wedding Song and the New Year Song. Other booklets of traditional stories and proverbs are also planned. Thus, we are co-opting the Christian orthography to maintain traditional culture. This is well received, even by the pastors who might feel that such literature is inappropriate in its content. This may be because of a strong positive group identity, for which Lisu language is a core value, and because it builds on prior cultural knowledge and affirms their identity. The paper will discuss reasons for the relative success of the Lisu in language maintenance and mother tongue literacy, and how this provides a springboard for content learning and second language learning.

Keywords: Lisu, Yobin, literacy, second language

LittleCounters™: Instilling number sense in free play

Early mathematics representations such as numerosity (1 unit or 2 units of something) have been linked to the acquisition of mathematics language, for example, the knowledge of count words such as one and two (e.g., Jeong & Levine, 2005; LeFevre, Clarke, & Stringer, 2002). The aim of this study is to evaluate the effectiveness of an early numeracy program, LittleCounters™ (Kotsopoulos & Lee, 2009) to increase the amount of mathematical talk used by parents during play with children between 12 and 28 months old. The adult input of families (7 boys, 8 girls) that have participated in the 5-session LittleCounters™ program was compared to that of families (14 boys, 16 girls) that did not. The parent-child dyads engaged in a 30-minute naturalistic free play session in their home using a standard set of toys (e.g., five balls, eight car counters, ten animal counters, twelve Lego blocks) which could be used and labeled in a number of ways as well as two pop-up books on colors, numbers and shapes provided. The adult speech was transcribed and coded for mathematical input such as quantity words (how many, less than), cardinality (asking for the number of items in a set without counting), counting words (one, two), counting objects in an array or in sets, and ordering numbers. The proportion of mathematical input uttered in the free play session by families which were not in the LittleCounters™ program was two per cent in terms of the total number of words spoken. In contrast, the proportion of mathematical talk by families that participated in the LittleCounters™ program was 8.5 per cent. With socio-economic status (SES) and age as covariates, our preliminary multivariate ANCOVA revealed that the differences in terms of the total frequency of mathematical talk between the two groups were significant at the .05 level. Our findings suggest that parents can be taught to incorporate early mathematical language and instructional techniques effectively into their children’s play time through the use of songs, games, stories, and movements in the LittleCounters™ program. This research is poised to make interesting
contributions in understanding the acquisition of number sense by young children.

Keywords: number sense, mathematics, early numeracy program

Locus of control and inhibited sales prospecting in a large multi-national sample

COYNE, T. (BSRP ASIA Pty Ltd.), BRYANT, T. (BSRP International Inc.), DUDLEY, G. (BSRP International Inc.)

This study examines causal attributions and the expectation of sales success across nations. We hypothesised that salespeople expecting outcomes to reflect their own actions are more resilient when prospecting, but that the influence of causal attribution may vary across countries. Participants (194 366) from eight nations participated in the study. Each participant completed a limited purpose diagnostic questionnaire designed to assess clientele-building (sales prospecting) activity. An inventory of factors reported to influence sales success were included. Two of the factors consisted of endogenous attributions. Four were exogenous. A 2x2x8 factorial ANOVA was completed to examine the effect of locus of control on clientele-building and whether gender or country of residence moderated the effect. A frequency analysis found that a significant component of the sample selected endogenous factors as being most important for sales success, but the number of participants endorsing endogenous over exogenous factors varied across countries. The factorial analyses also indicated that participants selecting endogenous success factors were significantly less likely to be reticent to make sales calls. However, this result was also significantly moderated by country of residence. This study clarifies the importance of endogenous attribution in a large multinational sample of sales professionals. It also underscores the influence of locus of control on core customer-building competencies such as prospecting. Participants endorsing external factors as most important to sales success also reported significantly higher levels of sales call reluctance. These results are consistent with earlier research which reported that perceptions of uncontrollable outcomes tend to associated with higher levels of anxiety and heightened inhibition.

Keywords: locus of control, sales prospecting, causal attribution, clientele-building, salespeople

Locus of control beliefs mediate the relationship between religious functioning and psychological health

RYAN, M. (RMIT University), FRANCIS, A. (RMIT University)

The present study investigated the correlational relationships and pathways of mediation between health, religious functioning and locus of control (LOC) in order to explain the well-established link between religiosity and health. The sample consisted of 122 Christians (79 female, 43 male) who were predominately Catholic, ranging in age from 18 to 80 (M = 45.47, SD = 15.0). Participants were recruited from churches in Melbourne, Australia, and completed a questionnaire package measuring (1) psychological and physical health, (2) the religious variables of awareness of God, instability and impression management and, (3) God, internal and external LOC domains. Awareness of God and internal LOC were associated with better health, whereas external LOC and instability were associated with poorer health. God LOC and impression management were not significantly associated with health. Sobel tests were used to analyse mediation hypotheses. Internal LOC was found to mediate the relationship between awareness of God and better psychological health, and external LOC was found to mediate the relationship between instability and poorer psychological health. The results provide empirically robust explanations for both the positive and negative influences of religiosity on mental health. Such insights provide opportunities for future research and may be useful to counsellors.

Keywords: locus of control, religiosity, religious functioning, impression management, psychological health

Loneliness and personal growth: The mediation role of self-reflection
Loneliness is recognized as a socially prevalent phenomenon that has been described consistently as very painful, distressing, and disturbing. However, several researchers found that there are surprising positive outcomes of loneliness like many other stressful and traumatic life events. Therefore the current study examined self-reflection as a mediator between loneliness and personal growth. A total of 150 undergraduates participated in the study and were asked to completed questionnaires including UCLA Loneliness Scale (Version 3), the Self-Reflection and Insight Scale (SRIS) and Ryff Scales of Psychological Well-Being (PWB). Self-reflection was positively correlated with personal growth and loneliness was significantly negatively correlated with personal growth and self-reflection. The significant relationship between loneliness and personal growth was significantly reduced in magnitude when self-reflection was included in the model. The prediction that loneliness was significantly and positively linked to personal growth and self-reflection in college students was not confirmed in the current study. Results from regression analysis indicated that self-reflection partially mediated the relationship between loneliness and personal growth.

Keywords: loneliness, self-reflection, personal growth

Loneliness, family interactions, and general mental health in the elderly

KAUR, H. (Punjabi University), KAUR, H. (Punjabi University), KAUR, A. (Punjabi University)

The aim of this research was to study loneliness and its relationship with family interactions and general mental health in Indian rural and urban geriatric population. A sample of 38 rural and 42 urban males in the age range of 65 to 85 years (mean age: rural 68 years, urban 70 years) were assessed using the Perceived Loneliness Scale (Jha, 1997), Family Interaction Pattern Scale (Bhatti, Subbakrishna, Ageria, 1986), and the General Health Questionnaire (GHQ) (Goldberg, Williams, 1988), after a brief rapport forming session. The scores were rendered to statistical analysis using t-test and correlation evaluations. The rural geriatric males were significantly lonelier than their urban counterparts; and their scores on GHQ were also significantly higher indicating poorer general mental health. The latter was true across all the subscales, namely, somatic symptoms, anxiety and insomnia, social dysfunction, and depression. The family interactions were comparable in the two groups, except for leadership pattern wherein the rural sample exhibited higher scores. In the rural sample loneliness was significantly correlated with all the measures of mental health and with family interaction patterns on the whole, with specific emphasis on reinforcement styles and cohesion in the family. Mental health was correlated with social support in the family. The urban elderly too showed loneliness related to general mental health, but specifically with anxiety and insomnia; and with the role division and leadership patterns in the family. Somatic complaints and depression were related to family interaction patterns especially to reinforcement styles. Old age is a stage when generativity-integrity must prevail as the individual self-actualizes. However when loneliness sets in there is despair and dissatisfaction; and a predisposition to mental disorders. Family plays a vital role at this developmental stage especially in collective cultures like India. The paper highlights the dimensions of family interactions determining the wellbeing of the elderly, and the role of loneliness in mental health of the elderly. The implications for counseling are discussed.

Keywords: loneliness, family interactions, elderly people, general health questionnaire, well-being

Long-term training effects of a psycho-rehabilitation technique for the children with disabilities: A cross-cultural study

KUMAR, S. (Chikushi Jogakuen University), KIM, Y. S. (Chosun University, Gwangju)

The aim of this research was to measure the long-term psycho-rehabilitation method Dousahou on the social interaction, behavior control, health maintenance, emotion expression, initiation, speech and communication, and volunteer body movements of children with
mental retardation, Cerebral Palsy, and Autism. The Questionnaire for Developmental Changes was administered among trainers and parents of these children on the fifth camp day of psycho-rehabilitation training. The psycho-rehabilitation method did support and promote health maintenance most, emotion expression least, and the usual on initiative and appearance, volunteer body movements, speech and communication, behavior control, and social interaction factors. In conclusion, the psycho-rehabilitation method was found to effectively promote health maintenance most, emotion expression least, and the usual on initiative and appearance, volunteer body movements, speech and communication, behavior control, and social interaction factors, if they regularly practice of Dousa-hou training and participate on average 3.6 times per week in camps in the Indian and Korean context.

Keywords: children with mental retardation, autism, cerebral palsy, psycho-rehabilitation model, health maintenance

Losing face and emotions: The effects of related factors in a social comparison context

HAN, K. H. (Tamkang University)

It is apparent that losing face causes distress. However, if we ask what feelings underlie losing face, the answer seems to remain unknown. In addition, face is a kind of social-contingent self-esteem. One could experience losing face and different emotions due to different factors related to that specific context. This study focused on the effects of perception (implicit versus explicit) and if there was a family member in a social comparison context. Using scenario experimental method, this study manipulated perception (implicit versus explicit) and whether the target person’s mother was (versus not) in that social comparison context. The results showed that if the message of “I’m not as good as others” was perceived implicitly by oneself, the emotions one experienced were mainly depression and shame. On the contrary, if the message was discussed explicitly by others, the emotions were anger, shame and humiliation. In addition, if the target person’s mother was in the context, besides depression and shame, one would also have a feeling of guilt when perceiving the comparison implicitly. However, if one’s bad performance was discussed explicitly in front of his mother, one would experience strong feelings of anger, hostility, humiliation as well as shame and embarrassment, but not guilt. Overall, the results were consistent with the cognitive perspective of self blame versus other blame. When one’s bad performance was perceived implicitly, the emotions mainly belonged to the self-blame category. Whereas, when one’s bad performance was discussed openly, besides self-blame emotions, one also experienced other-blame emotions. In general, the appearance of a family member could strengthen the emotions one experienced in that context.

Keywords: shame, self-esteem, losing face, self-blame versus other-blame, perceptions

Masculinity and alcohol use among young men in Sarawak: Preliminary findings

AMIT, N. (Monash University)

The objectives of this research in progress are firstly, to examine alcohol use among young men in Sarawak and secondly, to examine how they negotiate masculinity and its association with alcohol use. In this qualitative research, in-depth semi-structured interviews were conducted among 20 young men (aged between 18-30 years) from different ethnic groups in Kuching and Samarahan Divisions, Sarawak. Themes associated with masculinity and association between masculinity and alcohol use were analyzed based on grounded theory approach. The results will be discussed in two sections. Firstly, patterns of alcohol use among young adults from different ethnic groups. Secondly, themes related to young men’s negotiation of masculinity will be discussed. Some of the masculine themes are being independent, hardworking, responsible, and supportive; securing a working status; and following one’s cultural tradition. This discussion also includes association and disassociation with masculinity and alcohol use and elements of masculinity in alcohol use as experienced by them. Some elements of masculinity in alcohol use are usage of masculine-related images in persuading and
challenging alcohol use among peers, masculine images as portrayed by alcohol use, and role of alcohol use in facilitating interaction between men and women. Nature and extent of alcohol use among participants from different ethnic groups and their conception of masculinity were associated with their social and cultural context. The limitations and direction of future research will also be discussed.

**Keywords:** young men, masculinity, alcohol use

**Mastery motivation in toddlers:** Characteristics and effects of behavior evaluation

ZHANG, X. (Northeast Normal University), LIU, S. (Northeast Normal University)

The aim of this research was to examine not only the general characteristics of mastery motivation in toddlers, but also the effects of behavior evaluation on it. The method of situational experimenting was used to test 71 toddlers with three game tasks, including exploration-feedback, problem-solving, and challenge-preference, respectively. To measure effects of behavior evaluation, positive evaluation by tester and test absent conditions were set for all tasks. Also, toy with visual and auditory feedback and without feedback conditions were also set for the first task to examine characteristics of mastery motivation as a function of mastery object. The material used for first task was a newfangled toy car, and it could give out various visual and auditory feedbacks, when participants controlled it. The material for the second task was a shape matching board with different shapes of wooden fish put into it, and for the third task, were jigsaw puzzles of two levels, namely, easy and difficult. On first task: (1) the average time toddlers payed attention to the newfangled toy was over 7.5 minutes with enjoyable emotion; (2) there were more mastery behaviors in toddlers on toy feedback condition than without feedback; (3) more pleasure were derived by toddlers from a tester’s positive evaluation than without evaluation. On the second task: (1) toddlers were happier when they succeeded rather than failed; (2) whether success or failure occurred, toddlers’ emotions were better when the tester gave a positive evaluation than without evaluation. On last task: 94.4% of all toddlers would carry out the difficult task and had high persistence on it, but significant individual differences existed. Toddlers’ mastery motivation for a newfangled object with visual and auditory feedbacks was strong. And they came to experience different emotions from success and failure in mastery behavior. Positive behavior evaluation by adults could bring toddlers’ greater pleasure regarding on mastery. All of the above provide additional information to teachers and parents to promote toddlers’ mastery and emotions.

**Keywords:** mastery behaviour in toddlers, mastery motivation, exploration feedback, positive behaviour evaluation, problem-solving

**Materialism: Friend or foe? The link between materialism, subjective-well being and friendship**

JANSSON-BOYD, C. (Anglia Ruskin University), SPIERS, R. (London Metropolitan University), ANSSON-BOYD, C. V. (Anglia Ruskin University)

The aim was to investigate to what extent social support affects the relationship between materialism and subjective well being (SWB) in the United Kingdom (UK). The relationship between materialism and SWB has been found to be intricate. Researchers have found there to be either a positive (Sherman & Newman, 1978; Diener et al., 1985) or negative (Belk, 1984; Kasser & Ryan, 1993) relationship between the two. However, this has never previously been explored in the UK. New sets of scales that measure social support, SWB and materialism were developed. The scales were used to look at whether there is a positive or negative relationship between materialism and SWB in the UK, and if social support affects the relationship between materialism and SWB. The scales were merged on to one questionnaire that 173 participants filled in and completed. The results showed that there were significant negative correlations between materialism and SWB, and between materialism and social support. A multiple regression also found that when controlling for social support the influence of materialism upon SWB was reduced in strength. From the results it can be concluded
that materialists tend to feel less good about themselves. However, the decrease in SWB is also affected by the lack of social support. With a better social network, materialists are less likely to report lower levels of SWB. This supports previously conducted studies in other countries.

**Keywords:** materialism, social support, subjective well-being

**Maternal power assertion: Its role in social information processing and externalizing behavior in Turkish preschoolers**

CANDAN KODALAK, A. (Koc University), YAGMURLU, B. (Koc University), KUMRU, A. (Abant Izzet Baysal University)

The goal of the study was to investigate the relations between maternal power-assertive disciplinary techniques (both physical and non-physical forms of maternal punishment), social information processing patterns (hostile attribution bias and aggressive response selection), and externalizing behaviors in Turkish preschool children. One hundred and fifty-eight four year-old children attending different preschools in two cities of Turkey, their mothers and preschool teachers, participated in the study. They were followed throughout three years. At Time One (four years-old), maternal power-assertive child rearing was measured with self-reports (Child Rearing Questionnaire) and children's social information processing skills were assessed via behavioral assessments (the Social Perception Task). At Time Two and Time Three (five and six years-olds), teacher ratings were utilized to measure children's externalizing behaviors (Eyberg Child Behavior Inventory and Child Behavior Checklist). Children's responses to the Social Perception Task were transcribed and coded into categories. All measures displayed high internal consistencies. Data were examined through correlations and hierarchical multiple regression analyses. Findings of the study revealed that maternal physical and non-physical forms of punishment had varying effects on children’s social information processing skills and externalizing behaviors. Results were mostly in line with previous studies conducted with Western samples. The present study provides the first evidence from on the effects of maternal power-assertive discipline on Turkish children’s cognitive and behavioral development. Findings of the study are discussed with regard to Crick and Dodge’s (1994) social adjustment and social information processing model.

**Keywords:** sociocognitive development, maternal power-assertive disciplinary techniques, child rearing questionnaire, social perception, social information processing

**Meaningful being in Australia: The experiences of young Sudanese-Australians**

TIPPING, S. (max2im22), KAPLAN, I. (Victorian Foundation for Survivors of Torture, Inc.)

The aim of this paper is to provide an overview of PhD research being carried out with the Sudanese Diaspora in Australia. The project was interested in exploring the experience of meaningful being from the individual’s perspective while taking into account historical, social, political and cultural contextual factors. The study was hypothesis-generating. Semi-structured interviews were conducted with 30 Sudanese-Australians aged 18 to 30. A non-random, snowballing, stratified technique was utilised, with assistance from gatekeepers. Eight participants were re-interviewed two years after the first interviews were conducted. A template analysis was carried out, followed by an interpretative phenomenological analysis on a sub-set of the interviews. While the study was focused on qualitative data, some quantitative information was also collected enabling a comparison of the different types of data. Participants reported a broad range of internal and external characteristics in contributing to the life being experienced as meaningful in Australia. Education and family were reported as the dominant sources of meaning in life. Personal beliefs (including cultural and religious beliefs) were also important. Peace at an individual, relationship (e.g., family and community), and societal level (e.g., peace in Sudan and Australia) were also key themes. Threats to the experience of life as meaningful were identified, including separation from...
family, difficulties overcoming gaps in education, conflict with teachers and between family members, encounters with discrimination, and isolation from members of the broader Australian community. The fulfilment of basic needs, personal strengths and struggles, the immediate social world, beliefs and values, and systems and structures all play a prominent role in the lives of young Sudanese-Australians. The results suggest that many young Sudanese-Australians maintain strong links to Sudan, both on a practical level through sending remittances to family remaining in Africa and on a symbolic level through the experience of identity. Future research and project work adopting a participatory approach could explore concepts of peace held by Sudanese-Australians, including the role of the Diaspora in the peace-building process in Sudan. Further, there is also potential for a participatory peace-building project with young Sudanese-Australians, where attention is given to peace-building within and by Diaspora communities.

Keywords: Sudanese-Australians, meaningful being, Sudan, peace-building

Measuring performance: Introducing a hand held psychometric testing device

CURRIE, J. (Noarlunga Hospital, South Australia), RUTHENBECK, G. (Flinders University)

The aim of this research is to develop a small, robust, portable device to allow psychometric testing in a normal environment, away from the laboratory. The method involves a Nokia mobile phone being programmed to allow the user to perform six standard psychomotor tests. All results are time and date specific and all data – reaction times, number of errors etc., are stored electronically in the phone’s memory. This is directly downloadable to an Excel spreadsheet. The tests are: Symbol Digit Substitution, Simple and Choice Reaction Times, Reaction time with one decision-making step, Number Recall and Finger Tapping Test. The units have undergone extensive trials and have been used in a busy hospital to study ability to function before and after day surgery. No problems have been encountered. The phones have survived much abuse including “drop tests”. It has been easy to measure psychomotor performance using sophisticated tests such as Symbol Digit Substitution, Decision Making Reaction Times and error rates in an everyday environment. Multiple measurements can be made throughout the day without inconveniencing the patient. In conclusion, having an objective assessment of performance is very useful. Being able to make these assessments in the workplace or in the home is especially so. This is a useful tool in many areas of psychological and medical research. The authors are pleased to share the technology with co-workers.

Keywords: psychomotor tests, performance appraisal, mobile phones, medical research, reaction time

Measuring subjective workload using the NASA-TLX: A qualitative analysis of subscale interpretation

An operator’s perception of workload is considered a central concept within the field of human factors and ergonomics. One of the most widely-used, self-report measures of workload is the NASA-Task Load Index (TLX) (Hart & Staveland, 1988). The NASA-TLX consists of six subscales (Mental Demand, Physical Demand, Temporal Demand, Frustration, Effort, and Performance), the combination of which is assumed to provide a generic measure of overall workload. Over 20 years since its original development in the aviation field, the NASA-TLX has been favoured in a variety of research contexts for its simplistic administration and ease of interpretation by respondents. Its adaptation to vastly different fields of investigation has resulted in modifications to the original subscale descriptions, and in some circumstances, the subscales themselves. However, the process of modification of the NASA-TLX to better suit specific domains has not been well documented within the literature. The aim of this presentation is to discuss a methodology for adapting the NASA-TLX to specific research domains, using vehicle evaluation as a case study. Findings from an exercise conducted with drivers of military land vehicles will be presented, which investigated...
the range of workload definitions elicited from this unique sample group. A total of 42 drivers provided descriptions of what a rating of ‘very low’ or ‘very high’ would mean to them within each of the six workload subscales. The qualitative data were analysed with NVivo to identify consistent themes. The analysis revealed definitions consistent with the original NASA-TLX scale descriptors. However, themes relevant to the military driving domain were also identified within each subscale. These included driving conditions, vehicle comfort, elements of teamwork and level of vehicle autonomy. Eliciting definitions of the NASA-TLX subscales from a specific group is suggested as an initial step within a methodology for scale modification. Further testing is required to ensure that any changes enhance the utility of the original scale within research.

Keywords: subjective workload, operator’s perception

Medical observation chart design affects users’ decision accuracy and response time regarding patients’ vital signs

PREECE, M. (University of Queensland), PREECE, M. (The University of Queensland), HORSWILL, M. (The University of Queensland), HILL, A. (The University of Queensland), WATSON, M. (The University of Queensland & Queensland Health)

Paper-based medical observation charts are the principal means of recording and monitoring changes to hospital patients’ physiological data or vital signs (e.g., blood pressure, respiratory rate, heart rate). There is considerable variation in the design of observation charts in current use, and a lack of empirical research on the performance of observation charts in general. Improving the design of observation charts may improve the early recognition of patients who are deteriorating. This study aimed to evaluate how accurately trained novices could detect patient deterioration on 6 different observation chart designs in use or in development in Australia. Six chart designs were included in the study. In a previous study, a heuristic analysis had classified one of the charts as being poorly designed, one of the charts as being of average design, and two charts as being relatively well-designed. We also designed two further charts with reference to human factors principles of “user-friendly” design (e.g., using coloured bands to indicate physiological thresholds). Participants were shown 48 observation charts in a randomised order. Each chart design was shown four times displaying physiological data with at least one abnormal vital sign (e.g., an abnormally high blood pressure), and four times displaying normal physiological data. Participants had to classify the physiological data on the charts as “normal” or “abnormal” as quickly as they could. Decision accuracy and response time were the dependent variables. Initial results showed that chart design had a significant effect on decision accuracy and response time (both \( p < .001 \)). For both measures, participants performed significantly worse on the “poor”, “average” and one of the “well-designed” charts compared with the newly designed “user-friendly” charts (all \( p < .05 \)). Differences in the design of observation charts can affect chart users’ decisions regarding patients’ vital signs and the time it takes to make such decisions. Therefore, it is recommended that charts that are not well-designed be discarded in favour of those that can empirically demonstrate their effective design. Improving the standard of observation charts in use in hospitals may improve the recognition of deteriorating patients.

Keywords: medical observation charts, chart design, patient deterioration

Mental effort ratio: Assessing individual differences in subjective fatigue tolerance

AIDMAN, E. (Defence Science and Technology Organisation and Kingston University London), CRAMERI, R. (Defence Science and Technology Organisation)

The series of studies reported here were aimed at developing and validating a method of estimating individual differences in subjective tolerance to fatigue and physical exhaustion. Since Borg’s (1970) invention of the Ratings of Perceived Exertion (RPE), both effort perception (in short-term work) and perceived fatigue (in long-term work) have been considered as key factors influencing physical performance and its resourcing (cognitive and metabolic). The
concept of mental effort tolerance (MET; Dornic, Ekehammar & Laakasonen, 1991) has been instrumental in generating cognitive explanations for the effects of effort perception. Generally defined, MET represents the extent to which the individual is able to tolerate subjective discomfort when persisting in a difficult task (Dornic, Ekehammar & Laakasonen, 1991). Following Borg’s (1973, 1982) discovery of exercisers’ ability to detect first signs of perceived exertion, the proportion of exercise time after this detection has been found to be relatively stable (Ilyin, 1980; Aidman 1995) and individually distinct. This proportion was termed “mental effort ratio” (MER) and a psychometric procedure for its measurement has been developed using a modified hypoxemic (breath-holding) test. The paper will review a series of studies with elite endurance athletes (Aidman, 1995, 2005; Miotti, 1996) and military personnel (Aidman & Crameri, 2006) that examined the relationship between MER, endurance performance and health costs associated with it. Results to date confirm the validity of MER measurement in predicting important performance parameters, such as aerobic capacity, at the high end of fitness range. It is also useful in estimating health risks of endurance training, such as metabolic inefficiency, overtraining and burnout. This makes it an attractive practical addition to assessment protocols used for selection into physically demanding occupations. Potential applications and future development of the tool will be discussed.

**Keywords:** perceived exertion, mental effort tolerance, effort, subjective discomfort, physical demands

**Mini-markers in China: An empirical study for the use of mini-markers of the 'Big-Five'**

YANGYANG, Z. (Peking University), WANG, L. (Peking University)

Saucier’s ‘Mini-Markers’ are widely used in the ‘Big-Five’ measurement of personality, including in the Chinese version. However, no one has before examined the validation of the Chinese version. This article examines the criterion validation of the Chinese-translated version of Saucier’s Mini-Markers personality questionnaire. Participants were 492 students in a Human Resources class, who were mostly...
white-collar workers. Their personality and several workplace criteria including justice, locus of control, and turnover intention, were measured. The Chinese-translated version of Mini-Markers was used as the Big-Five measurement. The correlations between participants’ Big-Five traits and the workplace criteria were calculated. The original personality scores were transformed into standard Z scores, and the correlation calculated using both of them. Many criteria were found to have good correlations with Mini-Markers scores including procedural justice with conscientiousness, self-valued performance with agreeableness, conscientiousness with emotional stability, and job satisfaction with conscientiousness, agreeableness, and openness to experience. The validity and reliability of Saucier’s Mini-Markers has been shown to be strong. As an abbreviated version of the Big-Five measurement, ‘Mini-Markers’ saves time for researchers and practitioners, and the English version has been widely used. This article shows that the Chinese version is also reliable and valid and can be used as a convenient tool in the workplace.

Keywords: personality, big five model of personality, mini-markers, Chinese, saucier

Modification of measures on the effect of long distance work assignment on the personal, family and work domain to fit into Muslims’ cultural contexts in Indonesia

ZULAIFAH, E. (Leipzig University)

The aim of this study is to develop models of explanation on the phenomena of family structure disruption as a result of job demand. The results of the study are expected to be beneficial for developing a more family friendly policy regarding work assignment. The study is focused on finding a predictive relationship among variables in different domains: individual, family and work. In the first stage, this study tests some already developed measures, to see how they fit into the Indonesian cultural context. The study used a survey method for families. A total of 94 families in and around a city in south central Java were included in this preliminary study. The measures involved in this study are subjective well being, gratitude, acceptance, family climate, and work stress. The result of this study showed that the already developed measures widely used in other studies in western cultures have low internal consistencies when applied within the Javanese-Indonesian culture (more detailed results will be shown in the presentation). There is a need to adjust the developed measures to better suit the cultural context of the study population. Measurement of Subjective Well Being (SWB), Gratitude, Acceptance, Family Climate and Work Stress will need to be modified to show better cultural sensitivity. The modification may involve changing the construct to include more culturally relevant factors. It may also be done by still using the same factors but replacing the items to better represent the reality within the specific culture.

Keywords: family structure, family disruption, work assignment, cultural factors, work stress

Mood and false memories for end-of-life treatment decisions

SHARMAN, S. (Deakin University)

When people prepare medical "Advance Directives" to say which life-sustaining treatments they do or do not want, they later change their minds about many treatments—but do not realise it. Instead, they falsely remember that their old directive reflects their current preferences. The current experiment investigated the effects of people’s mood on their decisions about medical treatments and on their false memories for their previous decisions. Participants took part in two sessions. At Time One, they were experimentally induced into positive or negative moods. Participants then decided which life-sustaining treatments they would want if they were seriously ill, such as tube feeding if in a coma. Four weeks later, at Time Two, participants made these decisions a second time. After making their second round of decisions, they were asked—in a surprise test—to recall their previous decisions. Participants changed their minds about 16% of their decisions; for example, saying that the first time they did not want life-sustaining treatment and saying that the second time they did. As predicted, people in negative moods at Time
Two changed more of their decisions (24%) than those in positive moods (10%). When participants changed their minds, they failed to realise that they had done so for almost a third of their decisions. Overall, participants falsely remembered that 31% of their previous decisions were the same as their current decisions. Participants in negative moods at Time Two falsely remembered more of their decisions (36%) than those in positive moods (27%). These findings suggest that people’s current moods influence whether they change their treatment decisions; current decisions in turn bias recall of past decisions. Those directly involved with end-of-life care, such as policymakers, physicians, nurses, and chaplains should be informed that people often change their minds about past treatments without realising and that these changes are more likely to occur when people are in negative moods. Steps may then be taken to encourage patients’ accurate recall of their previous decisions—perhaps through eliciting more positive moods—as they consider whether or not they actually want to change their minds.

**Keywords:** end-of-life care, advance directives, life-sustaining treatment choice, treatment decisions, false memory of decisions

**Moral reasoning in clinical practice and medical education in the Pontificia Universidad Javeriana (Bogotá, Colombia) Category “Altruism and dignity, beneficence, confidentiality and duty-of-care”**

DIAZ-AMADO, E. (Universidad Javeriana), MELO, H. E. (Xaverian University), CELY, L. C. (Xaverian University), OBANDO, F. S. (Xaverian University), GUEVERA, C. L. (Xaverian University)

This research aimed to characterize the moral reasoning of medical students at the Xaverian University, Bogotá, Colombia. We analyzed the relation between five moral categories/domains (altruism, contract-confidence-justice in the exchange, consciousness, decentering of self-interest and role adoption) and four relevant bioethical categories (dignity, beneficence, confidentiality and duty of care). In this presentation the relationship between altruism and the aforementioned bioethical categories is examined. In total, 484 students participated, coming from each semester between first and tenth (please note, the medicine academic program is divided into twelve semesters and the eleventh and twelfth correspond to a year of internship). Students from seventh and eighth semesters constituted the intentional, non-probabilistic sample to test the validity and confidence of the instrument. Significant differences were found in four out of the five variables studied, with a significance level of .05. We observed that moral reasoning had a non-linear progression pattern; it depicts particular routes and several itineraries. Moreover, we noticed that different clinical situations entailed dissimilar moral reasoning which did not follow those ideals usually offered by static theories.

**Keywords:** moral reasoning, medical students, altruism, role adoption, duty of care

**Motivation and rationality of robbers: The application of Apter’s reversal theory in street crime analysis**

PIOTROWSKI, P. (Jagiellonian University)

This article deals with the issues of motivation and rationality of agents of street robbery. Most robberies are triggered by impulsive juveniles who have no intention of committing a crime or engaging in a thorough analysis of its gains or risks (de Haan & Vos, 2003). As the reversal theory supplies explanation to irrational and paradoxical behaviour (Apter, 2001), an attempt has been made to apply this theory in the analysis of crime. The author conducted semi-structured interviews with 107 agents of street robberies (of whom 55 were underage and 52 were of age). The results allowed us to define a three-type typology of street robbers: “the rational” ones, those of “bounded rationality”, and “the irrational” ones. The street robbers in the first group act purposefully and systematically. The second group - the so-called “bounded rationality” street robbers - act under the influence of alcohol or drugs, or are affected by debilitating factors, such as group pressure, and various aspects ensuing from the participation in “street culture”. The third group (encompassing about 30% of the total of subjects) is that of irrational street robbers, who
committed crime without any forethought, with no motive of a material gain and with no prior calculation of profit or risk. Their motives are unclear to external observers inasmuch as they are obscure to the robbers themselves. Apter’s reversal theory was adapted to the analysis of their behaviour. In the perspective of this theory, it transpires that a process of decision-making relating to the act of robbery should not be described solely within cognitive categories but extend to include paratelic dominance and the relation with felt arousal – hedonic tone. Numerous cases of “irrational robbery” go along one of two patterns: maintenance of a high level of arousal in a paratelic state or a meta-motivational state reversal that entails aggressive behaviour. The analysis of street robbery in the light of a three-type typology gives rise to significant implications, both theoretical and practical. Essentially, it affects the understanding of criminal motivation, and creates new perspectives for effective correction, which focuses on the roots of crime.

Keywords: rationality of street robbery, criminal motivation, juvenile offending, hedonic tone, risk decision-making

Motivational interviewing with cognitive-behaviour therapy for anxiety and depression following traumatic brain injury

HSIEH, M.Y. (Monash University), PONSFORD, J. (Monash University; Epworth Hospital; & National Trauma Research Institute), WONG, D. (Monash University), SCHÖNBERGER, M. (Monash University & Epworth Hospital), MCKAY, A. (Monash University & Epworth Hospital)

There is strong evidence that Traumatic Brain Injury (TBI) leads to psychiatric disorders, most commonly anxiety and depression, which increase in frequency over time and are associated with poorer functional outcomes. This study aims to develop and evaluate in a randomised controlled trial, a Cognitive Behaviour Therapy (CBT)-based anxiety and depression treatment program adapted for a community sample with moderate-severe TBI. It also aims to evaluate the application of Motivational Interviewing (MI) as preparatory intervention, focusing on increasing motivation to change and engagement in treatment. Participants (aged 18 years and over) with moderate to severe TBI are being randomly assigned to one of three treatment conditions to evaluate the relative effectiveness of: (1) Up to three sessions of MI followed by CBT (MI+CBT) as compared with (2) CBT only and (3) treatment as usual (Control). Assessment includes a structured clinical interview to determine psychiatric diagnoses; self-report measures of anxiety, depression, psychosocial functioning and coping style; and measures of memory, executive functions and premorbid intellectual functioning. Both interventions (CBT and MI) are guided by manuals adapted for participants with TBI, with an emphasis on flexibility to tailor therapy to individual clients’ needs and cognitive difficulties. The study is in progress. Preliminary outcome data suggest positive treatment response in participants who received MI + CBT or CBT only. Observations from individual case studies indicate a high comorbidity of depression and anxiety in this sample, and highlight the challenges in assessing and treating psychiatric disorders following TBI. Feedback from participants highlights the importance of therapeutic alliance in treatment engagement. The study results will inform clinical practice by providing evidence about relative effectiveness of interventions for individuals with TBI who suffer from anxiety/depression. Given the strong association between psychiatric disorders and functional outcome, effective psychological treatments are required to provide a means of enhancing psychosocial outcomes for this group.

Keywords: brain injury, depression, anxiety, motivational interviewing, cognitive behavioural therapy

Motor performance in autism and Asperger’s disorder: Is there a relationship between motor dysfunction and communication disturbance?

PAPADOPOULOS, N. (Monash University), RINEHART, N. (Monash University), TONGE, B. (Monash University), BRADSHAW, J. (Monash University), SAUNDERS, K. (Southern Health), MURPHY, A. (Southern Health), MCGINLEY, J. (Murdoch Research Institute)
The aim of this study was to identify the neuromotor profile of children diagnosed with autism and Asperger’s Disorder and to examine the relationship between motor difficulties and emotional behavioural disturbance, severity of autistic symptoms and communication disturbance in children with Pervasive Developmental Disorders. The Movement Assessment Battery for Children (MABC) was administered as a measure of motor proficiency, and the Developmental Behavioural Checklist (DBC) as a measure of emotional behavioural disturbance in the following groups: Asperger’s disorder (AD) (n = 22, mean age = 9.9 years, SD = 1.6); High functioning autism (HFA) (n = 23, mean age = 9.4 yrs, SD = 2.7); Low functioning autism (LFA) (n = 8, mean age = 9.8yrs, SD = 1.7) and typically developing children (TD) (n = 20, mean age = 9.9yrs, SD = 1.5). Results indicated qualitative and quantitative impairments when comparing the HFA to the AD group. The HFA group performed worse on cerebellar motor items such as ball skills and balance compared to the AD group. As predicted the LFA group was also shown to be quantitatively more impaired than the HFA group. Motor symptoms, in particular cerebellar symptoms, were shown to be associated with emotional/behavioural disturbance, autistic symptoms and communication disturbance. Results confirm previous findings implicating the cerebellum as a likely source of motor dysfunction in children with autism and may also help to distinguish AD from autism.

Keywords: Autism, Asperger’s syndrome, Movement assessment battery for children, Developmental Behavioural Checklist, Cerebellar motor items

Multidimensional relationships between prosodic features of speech sound and personality impressions

UCHIDA, T. (The National Center for University Entrance Examinations), UCHIDA, C. (Nagoya Women’s University)

This study suggests a model to explain the relationship between prosodic features and speaker’s personality impressions. This kind of model is important because it would explain the mechanism to formulate personal impressions in verbal communications. In application, the model could help speakers to control their personality impressions in their speech, and artificial voices to be synthesized with desired and distinct personality impressions. The speech stimuli were synthesized from the original speech sound using STRAIGHT algorithm. Prosodic features such as speech rate, pauses, and intonation-contours were systematically manipulated to synthesize the continua of speech stimuli for each prosodic feature. This study consists of three experiments corresponding to three prosodic features. In each experiment, 100 to 200 participants were asked to rate their impressions on randomly presented stimuli from the continua for the experiment using Big Five personality traits. Changes of each personality trait for each prosodic feature were analyzed to construct a model. The results indicated that each trait had a distinctive change pattern, while reversed U-shape patterns were their common characteristics. In other words, each personality trait could be estimated with a quadratic regression equation. In these equations, use of sensory scales, which were converted from physical scales, lead more accurate estimates. For example, intonation-contour showed clearer U-shape in approximate equations with a sensory-scale (Mel-Scale) than with physical scale (Hz). Further, by integrating these five equations, the whole personality impression could be reconstructed. Because this set of the experiments utilized a sensory scale rather than physical scales, each personality trait could be estimated with more accuracy than previous studies. Naturally reintegration of traits also showed more accurate approximate equations, and this improvement increased the possibilities for applications. With these equations, one can synthesize speech sounds with artificial personalities for certain purposes such as answering machines and “audio-help” for the users of a certain product. In addition, this model provides some implications for implicit personality theory. One can train himself to speak with a variety of personality impressions using combinations of prosodic features for different personalities.

Keywords: prosodic features, personality impressions, synthesizing sounds, implicit personality theory, personality traits
Multilevel leadership for multilevel health – an analysis of the multilevel impact of transformational leadership on employee health and well-being

WOLF, S. (Technical University Dresden), NEBEL, C. (Technical University Dresden)

Facing permanent changes and a growing number of work-related strains leaders are faced more and more with the task to support and develop employee health and well-being in the work-context. Transformational leadership has an outstanding role in this context. The positive impact of transformational leadership on employee well-being is empirically well-established by now (Arnold, Barling, Kelloway & McKee, 2007). Additionally, the impact of transformational leadership works indirectly, meaning that leaders can positively influence attributes of the job or the company and employees can benefit from those changes (Wolf & Nebel, in prep.). A systematic analysis of the impact of transformational leadership on employee health and well-being on different levels is missing until now. The current study shows additional hints for the multi-level impact of transformational leadership by concentrating on the preventive impact on team- and company-levels. We focus on the impact of transformational leadership on the genesis of team burnout regarding spill-over and cross-over effects. Subjective and objective data was collected from \( N = 1319 \) (40 teams). The research methods employed were Transformational Leadership (MLQ-5 (German version); Felfe & Goihl, 2006), Demand (FIT, Richter et al., 2008), Control (SALSA, Riemann & Udris, 1996), Self-efficacy (Jerusalem & Schwartzter, 1999), Physical Complaints (GBB-24, Brähler et al., 2004), Burnout (MBI-GS, Schaufeli et al., 1996), and Well-Being (WHO-Five, Bech et al., 2003). Multilevel Analysis (HML) was performed. The data was analyzed at the time. We hope to refer to the findings of Felfe, Franke & Korek (2009) who found transformational leadership to be stress-reducing on the team level. We analyze whether the same or similar processes can be found for reduction of burnout on individuals and on the team level. We will discuss implications of our findings for the prevention of burnout and will draw conclusions for leadership training as well as leadership culture in organizations.

Keywords: leadership, employee health, multilevel leadership, transformational leadership, well-being

Multilingual education of linguistic minorities in India: Strategies, applications and issues

PANDA, M., MOHANTY, A. (Jawaharlal Nehru University), HEUGH, K. (University of South Australia), PANDA, M. (Jawaharlal Nehru University), BRADLEY, D.

Mother tongue (MT) based multilingual education (MLE) of linguistic minorities has become a global movement (Mohanty, Panda, Phillipson & Skutnabb-Kangas, 2009). However, application of psycholinguistic framework of bilingual education as well as MLE in diverse societies raises complex issues in respect of cross-linguistic transfer of skills, pedagogic approaches to bringing in children’s MT and cultural knowledge into MLE classrooms, and socio-educational consequences of MLE. The paper presents data from different MT literacy and MLE programs for tribal children in India to reflect on these issues. The findings in respect of Bodo MT literacy in Assam, MLE programs in Andhra Pradesh and Orissa, and a cultural psychology based intervention, MLE Plus, for children’s education, cultural identities, and revitalization of languages are discussed. The MT literacy program in Bodo and MLE programs in 18 other tribal mother tongues in Andhra Pradesh and Orissa are found to be promoting better classroom achievement compared to the early submersion education in dominant languages. The MT based MLE programs have positive impact on revitalization of language and community attitude towards culture and language maintenance. The MLE Plus program in Orissa with intensive community based activities and explicit focus on linking classroom learning to children’s cultural experiences is found to have the most positive educational as well as cultural impact. These programs in India offer new insights on strategies and pedagogic principles of MLE. However, the sociolinguistic complexities of Indian multilingualism raise some issues in respect of scheduling of the second, third and other languages in MLE and
the need to develop suitable models of MLE for children with multiple mother tongues in the same classroom.

**Keywords:** mother tongue, multilingual education, linguistic minorities, India

### Multitasking and work interruptions in hospitals: Impact on employees' well-being, individual strategies, and moderators

**BAETHGE, A. (University Leipzig), RIGOTTI, T. (University of Leipzig)**

In the last decades the complexity and intensity of work has increased. Employees have to deal with a big amount of information coming from several channels. This circumstance results in an increasing rate of work interruptions and multitasking demands. The aim of this study is to get an insight on the effect of multitasking and work interruptions in real work settings on well-being and to test the moderating effects of individual skills. We chose hospitals as the setting for our study, as jobs are characterized by a high rate of work interruptions. The sample of our study included male and female nurses of German hospitals. In a pilot study we interviewed 15 nurses and monitored their shift to developing an instrument for measuring the appearance of multitasking in hospital work settings. The main study has been a daily diary study using handheld computers, using random event sampling methods to examine direct effects of work interruptions and multitasking demands, as well as coping strategies over a period of five working days. We examined the appearance of interruptions and multitasking, and parameters of well-being like mood and irritation, and also considered individual mental abilities, and preferences as possible moderating variables. The data was analyzed using multi-level analysis to test for within and between subject effects over time. The pilot study emphasized the great importance of interruptions and multitasking in hospital work. Furthermore we identified possible strategies to deal with the demands of interruptions and multitasking. The results of the main study indicate differential effects of interruptions with well-being, contingent upon type of interruption, and individual coping. The results highlight the significant role of multitasking and interruptions in hospital work settings and demonstrate their effect on well-being. Additionally we are able to give practical advices for work design with a special consideration of the aging workforce.

**Keywords:** ageing workforce, multitasking, work interruptions, hospital work, coping strategies

### Mumpreneurship: A “forced choice”?

**MORRISON, R. (Auckland University of Technology), HARRIS, C. (Auckland University of Technology), HO, M.  (Auckland University of Technology), LEWIS, (AUT University)**

Preference Theory (Hakim, 2000, 2002) and Institutional Theory (Baunach, 2002; Rubery & Fagan, 1995) are used to provide two theoretical frameworks to better understand the transition and motivation to enter into “mumpreneurship” for women who choose to depart from traditional employment and engage in entrepreneurial pursuits after having a child. Five in-depth case studies are used to explore the lives of Mumpreneurs. The competing influences of (a) genuine choice, versus (b) the societal and structural demands which contribute to these women’s decisions to depart from “traditional” work and enter into entrepreneurship, are considered. Within this context, the link between motherhood and the entrepreneurial experience is illuminated through an exploration of how the mumpreneur orients the activities of her enterprise to her family, her child(ren) and her personal aspirations. Findings suggest that the frameworks provided by both Preference Theory (which focuses on women’s choice, in affluent society, between family work and market work) and Institutional Theory (which suggests that the decision to depart from traditional, full time work is more a function of societal structures and constraints “forcing” women into particular roles and / or part time work) can be applied to our group of women. This paper points to how future work on entrepreneurship from these two theoretical perspectives can further advance our understanding of the impact of entrepreneurship on the Mumpreneur herself, her venture, her identity as a mother and her desire for a career. It is hoped that the findings generated from this research project will
highlight and inform both academic research and policy makers on important understudied groups in entrepreneurship (such as older entrepreneurs and “mumpreneurs”), as well as the holistic impact of life-stage and life-style on entrepreneurship.

### Narcissism within the team: An exploratory study

**YANG, I. W. (National Chiao Tung University), SUEN, H. Y. (Taipei Fubon Commercial Bank)**

Expanding previous research on dark side personality traits, we discuss narcissistic behavior within a team context and investigate how narcissism affects interpersonal relationships within the team and how narcissistic behaviors, attitudes or reaction lead to team performance. Specifically, we examined the effects of narcissism on self- and other-ratings of performance, interpersonal conflict and climate within the team context. Survey data were collected from 43 project teams composed of 191 senior business undergraduate and MBA student participants. To achieve course requirement, all teams were formed for one semester to complete assigned projects. Participants were asked to first hand in a written paper and then give an oral presentation at the end of the semester. Before their oral presentation, we distributed questionnaires regarding narcissism, Big Five personality traits, team climate, team conflicts, and demographics to each team member. Then, at the end of the semester, we collected overall team project grades from the instructors with the permission of each participant. The results supported some of the previous research findings that narcissism is positively associated with both self- and other-ratings of team performance after controlling for three of the Big five personality traits (emotional stability, extraversion and openness to experience). However, the current findings did not show that team conflicts and team climate for innovation moderate the relationship between narcissism and team performance. Considering the profound interpersonal implication of narcissism, we believe that more research is required on the paradoxical but charming world of narcissists.

### Need for achievement, need for power, self efficacy and university student political participation in Jakarta Indonesia

**TRIANI, R. (Universitas Katolik Indonesia Atma Jaya)**

Student participation in politics is not usually directly connected with individual purposes. They usually intend to declare their opinion in order to support the people of the nation. In this research political participation is defined as ordinary citizen activities (non-violence or/and violence) in order to influence the government in making and actuating political decisions for equal interest. This research needs to know the relationship between individual personal aspects, which is assumed to have effects on political participation (need for achievement, need for power, self efficacy) and political participation. The need for achievement can be expressed as a desire to perform in terms of a standard of excellence or to be successful in competitive situations. Need for power is described as the need to manipulate others or drive for superiority others. Self efficacy is concerned with self-perceptions of how well a person can cope with situations as they rise. This research is non-experimental. The respondents are 253 university students in Jakarta Indonesia. Four questionnaires were used in this research including the questionnaire of need for achievement (reliability: 0.923), need for power (reliability: 0.855), self efficacy (reliability: 0.926) and political participation (reliability: 0.955). Validity and reliability calculations and hypothesis testing in this research involved use of a computer program. The research result shows that there is no relationship between need for achievement and political participation, but there are relationships between need for power, self efficacy and political participation. The data shows university students in Jakarta currently have low participation in politics.

**Negative body image and its Impact on social physique anxiety and social anxiety in preadolescent children aged 10 and 11**

CASETTA, C., LEWIS, V. (University of Canberra)

This study aimed to examine the body image of children aged 10 and 11 years (n = 58). Body image in children is a growing concern due to its relationship with unhealthy behaviours and mental health concerns (Littleton & Ollendick, 2003). Gender and age differences were predicted in terms of body image perceptions and social physique anxiety (SPA). Negative body image was expected to predict SPA and social anxiety (SA) also. The Social Physique Anxiety Scale, the Figure Perception and Preference Scale, the Body Areas Satisfaction Scale and the Fear of Negative Evaluation Scale were administered to a convenient sample. Factorial ANOVA’s, non-parametric t-tests and multiple regression analyses were conducted in order to test the hypotheses. Positively, levels of SPA and negative body image were low in the sample overall. While negative body image and SPA was not found to increase with age, females were significantly less satisfied with their bodies overall and with specific body parts in comparison to males. In addition affective body dissatisfaction, in contrast to cognitive body dissatisfaction was a significant predictor of SPA and SA. Clinical implications in terms of prevention and intervention for body image concerns, SPA and SA were discussed.

**Keywords:** body image of children, body areas satisfaction scale, social physique anxiety, figure perception and preference scale, fear of negative evaluation scale

**New analysis method for projective drawings: Texture analysis, singular value decomposition, and Fourier transform analysis**

TAKEMURA, K. (Waseda University), TAKASAKI, I. (Waseda University), MATSUMURA, O. (Waseda University), IWAMITSU, Y. (Kitasato University), KIKUCHI, H. (Yokohama Aihara Hospital), YOSHIDA, K. (Yokohama Aihara Hospital)

In psychology and psychiatry, projective drawings are used to assess individual personality and holistic understanding of behavior. Especially, Koch (1949) developed a tree test, called Baum Test, for the purpose of medical practice and personality assessment. Since there is a lack of objectivity in interpretations of drawing pictures when the projective drawing techniques are used, we propose a new analysis method for the projective drawings using image processing techniques. The procedure was as follows: (1) drawing a picture, (2) scanning the picture, (3) dividing the picture, (4) the gray level histogram moment (GLHM) analysis, (5) the spatial gray level dependence method (SGLDM) analysis, (6) the gray level difference method (GLDM) analysis for the picture, and (7) the singular value decomposition (SVD) method that is a factorization of a rectangular real or complex matrix, with many applications in image processing, (8) the Fourier analysis method that can isolate individual components of a compound waveform for the image, and (9) the interpretation of the drawing picture. Image analysis methods for projective tree test were utilized to interpret psychological process of university students and patients. We analyzed the pictures for 262 university students and 23 patients with mental disorders, then interrelated statistical properties of the image analysis with the scores for psychological tests such as State-Trait Anxiety Inventory, Self-rating Depression Scale, Beck Depression Inventory, and Yatabe-Guilford Personality Test. The result suggests significant relationships between some statistical properties of the pictures and mental states such as depression and anxiety.

**Newcomers’ job expectations and adaptations during the early stage of organizational socialization: Leader-member exchange as a moderator**

YAO, Q. (Nankai University), MA, H. (Tianjin Normal University), YUE, G. A. (Nankai University)

**Keywords:** student involvement in politics, self-efficacy, need for achievement, need for power, political participation

---

1210 | Brief Oral Presentations
Job expectation is one of the important psychological variables influencing newcomers’ socializations. Researchers have proposed the met-expectation hypothesis (MEH) which addresses the positive effect of met expectations on adaptation. However, there’s still divergence on the validity of this hypothesis. Based on theory of organizational socializations, this research investigated the relations between job expectations and proximal socialization outcomes, especially the moderating role of leader-member exchange (LMX), and answered the “when” and “how” questions. Three hundred and twenty one newcomers, from nine firms in three provinces of China, participated in the research. Using longitudinal design, job expectations were measured with the self-developed Newcomer Expectations Questionnaire when newcomers were on board, and information about both proximal socialization outcomes and quality of LMX was collected from newcomers three months after organizational entry, using the Organizational Socialization Questionnaire and LMX-MDM scale respectively. Hierarchical regression technique was employed to analyze data. The results showed that: (1) When taking into account both expectations and experience, only actual experience correlated positively with socialization outcomes, which didn’t support MEH; (2) LMX moderated the relations between met expectations and socialization outcomes: when the quality of LMX was low, unmet expectations impaired newcomers adaptation, which was consistent with MEH, whereas good quality of LMX might mitigate the detrimental effects of unmet expectations on adaptations; (3) the moderating effect of each dimension of LMX was different, which supported a multidimensional structure of LMX. LMX moderates the effect of met expectations on adaptations and may give an answer to the question regarding when MEH is supported, from a perspective of interpersonal interaction.

Keywords: job expectation, met-expectation hypothesis, organizational socialization, leader-member exchange, newcomers’ adaptation

Novice driver perceptual learning of hazards: Preliminary results of a longitudinal study

We interviewed teachers who have long, multi-year experience in using the Lions Quest (LQ) social and emotional learning (SEL) program at school. The aim was to describe and understand how teachers perceive the LQ program and achievement of its educational goals. Several research syntheses and meta-analyses of SEL interventions have concluded that programs concentrating on socio-emotional competencies can result in gains that are central to the goals of all schools. However, we do not know if the skills transfer to the practice situations and what the experiences of long term use of SEL programs are. LQ curricula focuses on training of interaction skills, service-learning, and violence and substance abuse prevention. It is based on the values of equal rights, respect for the needs of others, and cooperation and peaceful resolution of conflicts. LQ is international, widely known and has been available for over 20 years. Teachers and LQ instructors (12 women and 3 men) who had long experience in using LQ program at school were interviewed. The teachers worked in elementary, lower secondary and upper secondary schools. Thematic interviews were transcribed (116 pages) and processed using qualitative, inductive content analytical procedures. The themes extracted include perceived effects of the program at the individual, class, school and communal level. At the individual level, students learned empathy and expression of emotions. They started to support each other, and become able to make decisions and solve problems themselves. Teachers learned new tools for classroom management, problem solving, giving feedback, and working with groups. The program changed their values and behaviour to be more student centered. At the class and school level, teachers perceived that group safety and ability for collaboration increased. The participants were a selected group of teachers who had used LQ for many years. Consequently, their perceptions of the effects of the program were positive. However, the experiences of teachers offer significant insider’s view on the perceived long-term effects of LQ program on children and the whole school community. The results can be useful in planning SEL interventions and...
measures to study the effects of these interventions.

**Novice teachers’ efficacy beliefs in relation to school principal support**

ALDHAFRI, S. (Sultan Qaboos University)

This study examines Omani novice teachers’ efficacy beliefs and how these beliefs are influenced by school principal support. The study undertakes a theoretical framework of social cognitive theory (Bandura, 1997). Bandura contends that there are four sources of efficacy beliefs: mastery experience, vicarious experience, social persuasion, and physiological status. The sample consisted of 376 Omani teachers from three school districts. Participants were all female teachers teaching Grades One to Four. To measure teachers’ efficacy beliefs, the researcher used the Teacher Sense of Efficacy Scale (Tschannen-Moran & Woolfolk Hoy, 2001). This scale was adapted to Arabic by some previous research. The Arabic version of the Teacher Sense of Efficacy Scale is a 24-item 5-point Likert scale. An internal consistency of ($\alpha = 0.90$) was obtained for the Teacher Sense of Efficacy Scale. To measure principal support, the researcher used a scale consisting of eight items and uses a similar 5-point Likert type scale. Similarly, a value of 0.90 was obtained for the internal consistency. The study uses multiple regressions to predict novice teachers' efficacy beliefs using demographic variables (teachers' subject, degree, and experience) and school principal support. The results showed that principal's support contributed to the prediction of teachers' efficacy beliefs over and above the effects of demographic variables. The researcher concludes that school principal support is an important variable in promoting teachers' efficacy beliefs. The author discusses implications of the findings and highlights the importance of school climate on teachers' efficacy beliefs.

**Occupational stress as threat and opportunity: An analysis of antecedents**

ESCAMILLA, M. (University Autonomous of Yucatan)

The traditional psychological approach to occupational stress reactions has been extensively focused on pathological results (Siegel & Schrimshaw, 2000; Peiró, 2008). Conversely, the positive psychology perspective emphasizes emotions, attitudes and behavior that drive well-being and more positive workplaces (Simmons & Nelson, 2007). However, as theorized by the transactional model of stress, both perspectives can be reconciled: we can appraise a threat or loss when demands exceed the resources available, but we can also appraise the situation as a challenge when seen as an opportunity for mastery, gain or personal growth (Lazarus & Folkman, 1984). The present study aimed to analyze the role played by personal characteristics such as perception (background) from patterns of existing relationships between threat and challenge appraisals. Participants were 603 professionals from human services organizations in Comunidad Valenciana (Spain); 85% were women, and the mean age of the total sample was 37.52. We ran a multinomial logistic regression analysis, Chi-Square and ANOVAs. The results show that the likelihood of having medium levels of perception of stress and challenge (Pattern One) decreases with age, increases with the resilience and increases with the category "technical assistant"; the probability of having low levels of perceived stress and challenge (Pattern Two) increases with age, with the internal locus and decreases with category "technical means", and finally the likelihood of having high levels of perceived stress and pressure and low levels of challenge decreases with age and resilience, and increases with the external locus the category of "technical means". Important factors play a role in the appraisal phase of the stress process. The intervention on personality factors is much more complex and less effective than intervention characteristics of the situation. Therefore, future research should help understand what factors or job characteristics are those who promote different patterns of stress appraisal. Implications and limitations will be discussed.

**Occupational stressors and turnover intention: A study of knowledge workers in China**

LI, Y. (Remin University)

Researchers have suggested that job satisfaction is related to both stress and stress outcomes (Sug-In Chang, 2008). However, the nature of this relationship has not fully been explained. The author contributed to a better understanding of this relationship by evaluating occupational stressors and job satisfaction, and turnover intention in a sample of Chinese knowledge workers. A sample of 687 employees was investigated using the Occupational Stress Scale (OSS), Turnover Intention Scale (TIS) and Job Satisfaction Scale (JSS) in this research. With the methods of EFA and CFA, the author obtained six dimensionalities of occupational stressors which were; work overload, co-workers, physical conditions, role conflict/ambiguity, career development barriers and work/family conflict. In addition, results indicated that only three types of stressors and turnover intention were significantly related, and their relationship was mediated by job satisfaction. The results suggest that stressors from the work environment may lead to low satisfaction and high turnover intention in modern working life, so more attention should be paid to the field of stress management.

**Older drivers crash risk to other road users in Victoria**

WILLIAMS, P. (VicRoads), LANGFORD, J. (Monash University Accident Research Centre)

This research aimed to determine the extent to which older drivers (80 years and older) pose a risk to other road users in Victoria, and to assess whether different licensing policies are associated with different harm outcomes. Separate analyses were made for the State of Victoria and nationally (including Victoria). For each driver age group (‘target drivers’), fatality rates were calculated for target driver deaths, their passenger deaths, road users external to the target vehicle but killed in the crash involving the target driver; all road users killed other than target drivers; and all road users killed (including target drivers). Fatality rates were calculated on three bases: per population numbers in each age category, per licensed driver numbers in each age category and per distance driven for each age category. The different road user fatality rates associated with drivers aged 80 years and older were compared to the rates associated with drivers from younger age categories. On a per population and per licence basis, overall, the older the driver, the less threat to other road users, particularly those external to the driver’s vehicle. On a per distance basis, older drivers appeared to be the greatest threat to other road users. Older drivers consistently posed an increased threat to their passengers. This can be attributed largely to the frailty of their (often) elderly passengers. Based on the most recent 10-year set of national fatality data, it has been shown that in the event of a fatal crash, older drivers were the most likely to be killed – and the older the driver, the greater the probability of the driver being killed. Conversely, the older the driver, the less likely that any associated fatalities involved other road users.

**Online therapy: An investigation of process and practical factors**

WEILY, S. (Monash University)

Past research has highlighted ethical and therapeutic issues regarding using the internet as a medium for psychotherapy (Pollock, 2006; Rochlen, Zack & Speyer, 2004; Schultze, 2006). However, minimal research has explored process and practical factors of the online medium. The aim of the current research is to explore and differentiate factors that contribute to beneficial and non-beneficial counselling based upon the medium of delivery, from therapists’ and clients’
organisational and individual influences in the occupational stress process: Collective efficacy and organisational identification as additional moderators in the job demand-control model

TUCKER, M. (University of Queensland), JIMMIESON, N. (University of Queensland), OEI, T. (University of Queensland)

The objective of this research is to identify those factors that mitigate or lessen the negative impact of work stressors by investigating whether group-level variables, specifically collective efficacy and organisational identification, act as additional moderators of the individual-level variables in Karasek’s (1979) job demand-control model (JDCM). The theories that serve as the foundation for this research include Karasek’s JDCM, social identity theory, and social cognitive theory. Repeated measure surveys were used to collect data from 120 participants nested within eight organisations. Analyses were completed in Lisrel and MLwiN. Multilevel hierarchical moderated multiple regression analyses were performed to assess the focal hypotheses. Three-way, cross-level interactions were found between individual-level job demand, individual-level job control and group-level collective efficacy, as well as individual-level job demand, individual-level job control and group-level organisational identification. Follow up analyses revealed that when the group-level variables, collective efficacy or organisational identification, were high, individual-level job control buffered the negative effects of high individual-level job demands. The findings of these studies provide support for the notion that certain contextual factors must be in place in order for job control to act as a buffer of the negative effects of high job demands as originally hypothesised by Karasek (1979). Thus, organisational interventions should not only focus on job design at the individual level, but also take into account the context in which individuals work and target interventions to promote collective efficacy and a shared sense of organisational identity.

Keywords: work stress, job demands, collective efficacy, organisational identification

Organisational climate management, perception of organisational change and customer satisfaction

NEVES SANTOS, J. (University of Brasília), RABELO NEIVA, E. (University of Brasília), ANDRADE MELO, E. A. (Fundacão Universa)

The purpose of this paper is to identify the relationship between organisational climate, perception of changes resulting from organisational climate research, the perception of change in the branch and the organisation, and customer satisfaction with respect to service provided. Organisational climate management is when the organisation produces changes which are recognised by the employees, as a result of a diagnosis based on a piece of Organisational Climate Research. Data were collected from employees and customers of 170 branches of a service provider organisation acting in the whole of Brazil. Data concerning the organisational climate and customer satisfaction was collected in 2007 and was provided by the company. In 2009, a five point Likert-type scale was built and validated to assess the perception of the
employee of the changes implemented by the company in the course of two years. The data was compiled at the unit level and 4000 questionnaires were aggregated into 170 units. The analysis of the data was done by structural equation modelling. Models with direct relations were tested, as well as mediational models. In this study, the perception of change mediated the relationship between organisational climate and customer satisfaction. In general, the results corroborate the tested hypotheses and indicate that the organisational climate has a direct relation with customer satisfaction and employees’ perceived changes related to management of the organisational climate. This study demonstrated the importance of organisational climate management and of conducting an evaluation of the perception of change. Furthermore, the study showed that organisational climate management can produce changes in the organisation which influence customer satisfaction. With respect to the development of future researches, such as the one developed in this study, it is recommended the replication of the present research occur in other Brazilian and international companies with the purpose of confirming the relationships identified herein.

Keywords: organisational climate, perceptions, customer satisfaction, employees’ perceptions of change, organisational climate

Organizational Climate Scale (COE): A proposal

ESCAMIILLLA, M. (University Autonomous of Yucatan (UADY)), NOVELO, R. (University Autonomous of Yucatan), ESCAMIILLLA, M. (University Autonomous of Yucatan)

Inadequate management of organizational climate, may be related to misdiagnosis and/or use of instruments that are not reliable or valid and culturally significant to the organization (Furnham, 2001). For this, the objective of this study is the validation of organizational climate scale (COE). Participants are workers from public and private organizations in Yucatan (Mexico). We ran an exploratory factor analysis (EFA) and confirmatory factor analysis (CFA). Results show seven dimensions that evaluate the organizational climate, including D1: leadership and autonomy; D2: promotion and incentives; D3: teamwork; D4: interpersonal relationships; D5: physical environment; D6: involvement; and D7: conflict management. These results show the importance of culturally appropriate instruments for measuring organizational climate for better management. Implications and limitations will be discussed.

Keywords: management, organisational climate, leadership, teamwork, conflict management

Organizational contexts that foster positive behaviour and well-being: A comparison between family and non-family businesses

ESCARTIN, J. (University of Barcelona), CEJA, L. (IESE Business School), RODRIGUEZ, A. (University of Barcelona)

Research on how specific organizational characteristics may elicit negative or positive acts (such as workplace bullying, altruism and job performance) and how such characteristics may affect well-being (including job satisfaction and work engagement) has received little attention. Likewise, there are a few studies that focus on the similarities and differences between family and non-family businesses according to their characteristics. Hence, following and extending the three-way model of workplace bullying (Baillien et al., 2009) and the stakeholder perspective (Zellweger & Nason, 2008), the purpose of this study is to investigate whether family business and non-family business contexts have a similar or different influence on employee behaviour and well-being. In the present study 287 workers from Spain participated (47% from family businesses and 53% from non-family businesses). Employees gave free descriptions of their own organization and filled out a self-administered questionnaire. The Multiple Correspondence analysis (MCA; Abdi & Valentin, 2007) was used to analyse the organizational variables associated with different degrees of workplace bullying, altruism, performance, satisfaction and engagement. Chi-square tests and Pearson correlations were performed as well. The coordinate graphs obtained from the MCA revealed that family firms are related to more positive perceptions of the organizational
context than non-family businesses. Furthermore, the results showed that family firms are perceived as having a balanced task/employee oriented focus, a positive work atmosphere and balanced power relationships/hierarchy within the organization. Finally, family firms seem to be associated with lower levels of workplace bullying and higher levels of altruistic behaviours, workplace engagement, and job satisfaction than non-family firms. These results support previous theoretical and empirical research and emphasise that the organizational context has an important impact on employee behaviour and well-being. More specifically, this study adds value on the differentiation between family and non-family firms between several relevant aspects such as workplace bullying, altruism, performance, satisfaction and engagement. Finally, the implications of the study, its limitations and areas for future research are discussed.

Keywords: organisational context, employee well-being, family versus non-family businesses, workplace bullying, job performance

Organizational identity in a turbulent institutional environment: An upper echelon perspective

LI, K. (Zhejiang University), PROF ZHONG-MING WANG, Z.M. (Zhejiang University)

This study explores the link between top management team characters and organizational identity under institutional pressures. Organizational identity is conceptualized as the collective ‘we’ articulated by the organizations themselves. Based on the upper echelon perspective, the organization can be viewed as the extension of the top management team. However, institution theorists may argue that organizations are under substantial isomorphism pressures, so this study aims at integrating the two arguments. The practical background for this study is new energy industry, which is believed to present an ideal setting for testing the two competing theoretical perspectives. A qualitative approach was employed, with content from the texts in the ‘about us’ section in the new energy firms’ website analyzed. The corresponding material was from other sources such as annual reports, interview transcripts and other public sources. A grounded approach was used for analyzing the data. Three-level coding, namely open coding, selective coding and theoretical coding were conducted to generate the link between concepts. The results identify common elements in the organization, reflecting the institutional pressure. In this case, environmental ethics seems to be a basic admission criterion of this industry. The organizational identity of the firms can be categorized into three sets: the Technician (who emphasizes technical excellence); the Craftsman (who is not extraordinarily good in terms of technology, but puts emphasis on operational excellence); and the Speculator (who just does what is required by the external parties and acts according to governmental policy rather than their own vision). The membership of each firm in the three sets is linked with the characteristics of the founding members, who are viewed as the flag-bearers of the firms. For example, the founder with a substantial technological background tends to form an organization which falls into the Technician category. Viewing organizations as human-like entities, organizational identity presents a powerful concept to explain and understand the behavior of organizations in a broader industrial background. In the background of new energy industry, which presents a turbulent and demanding institutional setting, this study explored the relationship between the upper echelon characteristics and the collective ‘we’ of the organization. The empirical results illustrate that institutional pressures do force organizations to act mimetically, but the actual organizational identities are linked more with the top management team, especially that of the founding members.

Keywords: organisational identity, institutional environment, management, upper echelon perspective, institutional pressures

Organizational innovations and dynamics of occupational stress

LEONOVA, A. B. (Moscow State University)

Organisational changes and strategies of their implementation are among the most demanding
factors of personnel adaptation and well-being in modern working life. In order to find psychological predictors for improving efficiency of innovations application we conducted a longitudinal study with the staff of a Moscow pedagogical college during the process of its reorganisation. Several indicators of occupational stress were analysed at the different stages of this process: before, during and after modernisation. The test battery consisted of overall 16 diagnostic measures including several standardises procedures of job analysis, tests for acute/chronic stress manifestations, actual well-being, quality of emotional reactions, work motivation and a checklist for subjective attitudes to innovations. Factor and regression analyses, as well as other multidimensional statistical procedures, were used for comparing the patterns of stress manifestations at different stages of the innovation process and defining crucial factors in their dynamics. The data showed a high level of stress experienced by the personnel at all stages of organisational change. This stress has been reduced to the initial level only two years after the end of college’s modernisation. The observed dynamics in the experienced stress patterns reflected the changes in motivational involvement of the staff in the process of reorganisation, from a “passive innovational readiness” at the beginning, to the “active innovational adaptation” at the final stages. The most important factor for a developing a positive stress mobilisation during the whole innovation period was the initial attitude of each person to the planned reorganisation. These findings suggest that the process of personnel adaptation to innovations can have both positive and negative effects on well-being and experienced stress depending on the level of individual motivational involvement in reorganisations and, especially, on her/his initial attitude to the coming innovations.

Keywords: organizational innovations, occupational stress, change

Organizational justice and well being: A pilot study among manufacturing employees

R IBRAHIM, R. Z. (Victoria University), OHTSUKA, K. (Victoria University)

The aim of the current study was to investigate the association of organizational justice and employee well-being. Kivimaki (2005) argues that organizational justice is a new work environment factor that impacts on employees’ health and that high levels of organizational justice might ameliorate the negative effects of job strain. Respondents comprised of 82 employees from a manufacturing company. A purposive sampling technique was adopted in this study. Data were gathered from responses to questionnaire that include three sections: The first section includes demographic profile of respondents. The second part is about terms of perceived organization justice, scales developed by Moorman (1991). The final section measures employee well being. The Job Satisfaction Survey (Spector,1997), which contains 36 items, along with The Positive and Negative Affect Schedule (PANAS) (Watson, Clark, & Tellegen,1988) and The Satisfaction with Life Scale (Diener et al., 1985) were combined to assess key aspects of employee well being. The internal consistencies of the scale were highly acceptable, \( \alpha = .91 \) (Bruck, Allen, & Spector, 2002), \( \alpha = .84 \) to \( \alpha = .90 \) (Watson et al., 1988) and \( \alpha = .87 \) (Diener et al., 1985). Reliability analysis of the instruments was consistent with previous studies; \( \alpha = .76 \) (job satisfaction), \( \alpha = .91 \) and \( \alpha = .95 \) (positive affect and negative affect), and \( \alpha = .91 \) (life satisfaction). The result showed that there was a significant correlation (\( r = .342, p < 0.01 \)) between organizational justice and employee wellbeing. Regression analysis also revealed a positive (\( \beta = .367 \)) and significant contribution of organizational justice on well being relationship. Organizational justice explained 8.4% of variance on employees’ well being. No statistically significant difference of gender was found regarding perceived organizational justice. Demographic profile of respondents was discussed. The findings of the current study found that organizational justice is a significant predictor of employees well being. Perceived low organizational justice could lead to negative consequences to both the individual and organization. Instead of organizational justice, future research should consider other factors that associate with employees well being.
Organizational justice, perceived contract breach and turnover intention: The moderating effect of social dominance orientation

ZHANG, J. (Peiking University), WANG, L. (Peking University), KONG, H. (Luxottica Group), YU, Z. (Luxottica Group)

It has generally been suggested that organizational justice is negatively related to turnover intention through perceived contract breach. However, this relationship can be different under some circumstances. The attitudes and values employees hold will have an impact on this relationship. Building on the social exchange perspective and social dominance theory, this study examined how individual's social dominance orientation (SDO: defined as the degree to which individuals desire and support group-based hierarchy and the domination of “inferior” groups by “superior” groups) affected the relationship between perceived contract breach and turnover intention. The participants were 581 employees from a manufacturing company. Measurements included social dominance orientation (i.e., some groups of people are simply inferior to other groups.), organizational justice (i.e., procedural justice, distributive justice, interpersonal justice, informational justice), perceived contract breach, turnover intention and other control variables. Results showed that general organizational justice was negatively related with turnover intention, and perceived contract breach played a mediating role in the relationship. Social dominance orientation moderated the mediated effects of perceived contract breach on turnover intention, such that for those high in social dominance orientation, the influence of perceived contract breach on turnover intention was weakened. Moreover, for those with high social dominance orientation, lower general organizational justice predicted low turnover intention, whereas for those with low social dominance orientation, lower general organizational justice predicted high turnover intention. Overall, this study highlights the important role of social dominance orientation in influencing turnover intention. It also has direct implications on how organizations and managers interact with employees through building effective psychological contract for more effective management.

Organizational practices and support as predictors of organizational citizenship behaviors

POHL, S. (Universite Libre de Bruxelles), HELLEMANS, C. (Universite Libre de Bruxelles), CLOSON, C. (Universite Libre de Bruxelles)

Given the interest in Organizational Citizenship Behaviours (OCB), it seems useful to identify the antecedents of such behaviours. According to exchange theory, prior research supports the idea that perceived organisational support (POS) is a robust predictor of OCB (Coyle-Shapiro, Kessler & Purcell, 2004). From this framework, it is interesting to empirically examine the mediating effects of POS in predicting organizational citizenship behaviour from Human Resources (HR) practices. There are also theoretical reasons suggesting that OCB could be influenced by job involvement. Yet, few studies did examine the relationships between job involvement and OCB (Diefendorff, Brown, Kamin & Lord, 2002; Cohen 2006). This study examines relationships between job involvement, POS, HR practices and OCB. The sample of the study consisted in 331 nurses. Subjects were recruited from one hospital situated in Belgium. Data for the study were obtained through the use of self-report questionnaires. The measures used to assess POS, OCB and job involvement are based on scales that appear to be reliable (Eisenberger, Huntington, Hutchison, and Sowa, 1986; Kanungo, 1982; Van Dyne, Graham and Diener, 1994). The OCB scale measures three dimensions of OCB: fidelity, obedience and social participation. To assess HR practices, we determined a set of four policies in consultation with the hospital management that affect the psychological contract (Rousseau, 1990); advancement, development, training and sharing decision programs. In testing POS's
mediating effects, we found it fully mediates the relationship between human resources practices and OCB-fidelity and partially mediates the relationship between HR practices and OCB-social participation. Contrariwise, there is not significant relationship between human resources practices and OCB-obedience. Results provide also insights into how job involvement impact OCB. An original contribution of the current study was that it confirms three components of OCB (fidelity, obedience and social participation) in Belgium. Second, these results confirm the value of perceiving OCB as reciprocating fair or good treatment from their employer but also as a consequence to personal individual variables. Nevertheless, HR practices and job involvement impact only OCB- fidelity and OCB-social participation.

Keywords: organizational citizenship behavior, human resources, perceived organisational support, job involvement, exchange theory

Outcome of psychological treatment on Dhaka University students

SHARMIN, N. (Bangladesh Clinical Psychology Association), RAHMEN, M. (University of Dhaka), RAHMAN, A. (University of Dhaka)

The present study was conducted to see outcome of psychological treatments on seven students seeking help for their psychological problems at the Guidance and Counselling Centre of Dhaka University. Seven cases seeking psychological help were selected randomly at the Students Guidance and Counseling Centre of Dhaka University for giving them psychotherapeutic intervention to see its outcome on them. Mainly, Cognitive Behavior Therapy was used to see the outcome of psychological treatment of the seven cases. However, depending on the needs of the clients, Person Centered Counselling along with Cognitive Behavior Therapy was also used. To see the outcome of psychological treatment General Health Questionnaire-12 (GHQ-12), 10-point self-rating scale, anxiety scale, depression scale and goal assessment sheet were applied and pre-intervention scores were compared with post-intervention scores. The result shows that GHQ-12 scores decreased from pre-intervention to post-intervention in all cases. The pre-intervention scores of 10-point rating scale were decreased after intervention in all seven cases. In seven cases the anxiety and depression scores decreased from pre-intervention to post intervention. Among the 25 goals of the seven clients, 4% was not achieved at all and 4% slightly achieved. The results also show that 24%, 52% and 16% goals were achieved moderately, considerably and completely respectively. Marked improvements were noticed at the post intervention phase in all cases. In five cases the post intervention scores of GHQ-12 were below the cut-off point of three and in two cases it was over the cut-off point. From the 10-point rating scale it was found that for case 1, 2, 3, 4, 5, 6 and 7 the scores decreased from 8, 8, 10, 8, 10, 10, and 10 to 5.5, 1, 5, 2.5, 3, 2 and 2.5 respectively. Anxiety and depression was decreased significantly in many cases. Among the 25 goals, 24%, 52% and 16% goals were achieved moderately, considerably and completely respectively, which is also an indication of positive outcome of psychological treatment. From the findings of the present study it is highly recommended that clinical psychological services should be extended at the Students Guidance and Counselling Centre, Medical Center and all residential halls of Dhaka University.

Keywords: psychological treatment, help-seeking, guidance, counselling, counselling goals

Parents' childrearing practices and their relation to children's academic performance

DAGOC JR., J. (Notre Dame of Dadiangas University)

This faculty research aimed to determine the relationship between parents’ childrearing practices and children’s academic performance. Specifically, this study aimed to know the demographic profiles of parents of Grade Five pupils with high and low academic performances from Notre Dame of Dadiangas University – Integrated Basic Education Department and Balite Elementary School. This research also aimed to know the extent of childrearing practices of parents of pupils with High and Low Academic Performance in terms of feeding, caregiving, observing rules, imposing discipline,
rewarding and teaching values. Determining the relationship between the demographic profile and childrearing practices of parents, as well as the relationship between the childrearing practices of parents to children’s academic performance, were also focused on in the study. The study used a descriptive correlation design. The respondents were chosen through purposive sampling. They were the parents and pupils who belonged to the upper and lower 30% in both schools. Data were gathered through a questionnaire for parents, which contained items on the profile and childrearing practices. A documented list of the upper and lower 30% of the Grade Five pupils was requested from the registrar’s office. A home visit was also conducted to gather data. The data gathered were analyzed through percentage, weighted mean, correlation coefficient through Pearson r, and t-test. The demographic profile of parents showed that exactly 50% were employed and another 50% were unemployed in the high group while the majority, or 53.92%, of the parents of the low group were unemployed; that 45.10% of the parents in the high group were professionals while only 28.43% of the parents in the low group had finished a course in college. Furthermore, larger percentages of lower educational attainments were revealed in the low group; that majority of the families earned 2,500-15,000 Philippine pesos a month as shown by 45.10% of 2,501-7,500 earners from the low group and 32.35% of 7,501-15,000 earners from the high group and that majority of the respondents had three to five children. Although the childrearing practices in both groups were interpreted as highly extensive, it showed that the parents of high performing pupils had a higher value as shown by a 4.25 factor average compared to 3.80 of the low group. The demographic profile, except occupation, and childrearing practices of the parents of both groups were significantly related to each other. The parents’ childrearing practices were significantly related to the child’s academic performance in the low group but not in the high group. Based on the findings of the study, it was concluded that there was a significant relationship between demographic profile and childrearing practices except for occupation, and that there was a significant relationship between childrearing practices and academic performance in the academically low group but not in the academically high group.

Keywords: academic performance, childrearing practices, parental employment, parental education, demographic variables

Partners Group: A multi-program collaboration to enhance the management of mental illness in a community setting

O’BOYLE, S. (EACH), MASSLER, P. (EACH)

The innovative Partners Group (EPG) has resulted from vigorous collaboration among several community programs and regulatory/funding bodies, including a PDRSS program, a local Mental Health initiative, a Respite for Mental Health Carers program (MHR), VicServ, and the National Respite Development Fund (NRDF). Members of the EPG comprise approximately 16 partners of individuals who manage significant Mental Illness in Melbourne’s outer Eastern suburbs. The group meets on Saturday afternoons at a PDRSS centre in Ringwood. The EPG is characterised by strong benevolent interest, a clear passion for community involvement, and a pro-active, pro-social attitude to improving and enhancing the support and management of mental illness in the community. Values of the EPG include a sincere interest in enhancing the management and coping resources of the individual, promoting a ready understanding of issues raised, a willingness to engage, share, and provide support. The EPG promotes readiness and eagerness to hear, acknowledge and advocate about individual carer issues. It is equally keen to discuss systemic concerns relating to mental health care, be it with a perspective to clinical, social or legal provisions, processes or arrangements. In early 2009 the EPG approached a MHR to explore the possibility of securing funding toward the provision of respite activity for its members. The MHR, funded through NRDF, assisted the EPG to provide a day outing with arrangements in place to provide transport and meals, and also to provide care for the care-recipients left at home. Subsequently, under NRDF guidelines and in the context of community capacity building, the MHR has secured further funding to allow the
EPG to periodically engage in a range of respite activities. Further collaboration between the Mental Health Services manager of a local CHS and the MHR Coordinator has secured additional funding from VicServ to secure an EPG Carer Consultant for the facilitation of group outings. These initiatives empower the EPG to decide what form respite intervention might take, thereby placing respite content and process where it belongs – with the carers. The MHR thus meets its aim in a new way to provide an innovative, flexible community respite response.

Keywords: mental illness, community, mental health care, respite

Patterns of communication and conflict resolution in couples

ARMAS-VARGAS, E. (Universidad de La Laguna)

The family and personal environment is one of the most important environments where the couple express their emotions and where they interact putting into practice a wide variety of patterns of interpersonal communication (dyadic communication). Based on a study of mothers, fathers and children in the family context (Armas-Vargas, 1999, 2000, 2006) we wished to study what patterns of communication between partners are related to self-esteem variables. The sample comprised 127 cases, 84 men (who had abused their partners) and 52 women (victims of domestic violence). The CPC-RC-COUPLE questionnaire (Armas-Vargas, 2009) was used. This is a test which consists of two forms (A and B), each with 50 items. In form A, the person evaluates himself/herself on communication with his/her partner. In form B, he/she evaluates his/her partner’s communication with him/her. The Self-Esteem Questionnaire (CAE Questionnaire; Armas Vargas, 2004) was also used. The questionnaires (A and B) have been shown so far to have validity of content and empirical value in isolating the proposed constructs. A multivarious type of analysis has been followed: factor and correlational analysis. We offer the results of the factor analysis for each factor, internal consistency (Cronbach Alpha) and the correlation between measures of the different factors of the CPC-RC-COUPLE questionnaire with the CAE. Form A includes four factors: Implicative-Resolving (19%; $$\alpha = .89$$); Explicative (13%; $$\alpha = .83$$); Reaching Agreements (9%; $$\alpha = .88$$); Excluding and Imppositive (7%; $$\alpha = .72$$); explained variance is 48%. Form B includes four factors: Implicate-Resolving (27%; $$\alpha = .93$$); Reaching Agreements (15%; $$\alpha = .87$$); Aggressive (excluding and impositive) (11%; $$\alpha = .77$$); Explicative (6%; $$\alpha = .71$$). The explained variance is 59%. Self-Esteem Questionnaire (CAE) includes four factors: I-Self (22%; $$\alpha = .87$$); Feeling of Uselessness (14%; $$\alpha = .81$$); Others (12%; $$\alpha = .82$$); Feeling of Inferiority-Negative Comparison (9%; $$\alpha = .77$$). Explained variance equals 57%.

There is a significant positive correlation between the feeling of inferiority in women and their perception of aggressive communication (excluding and impositive) on the part of their partners ($$r = .23; p \leq .001$$). Conversely, communication based on the search for agreement in a partnership is associated with a negative correlation with the feeling of inferiority ($$r = -.22; p \leq .001$$).

Keywords: interpersonal factors, emotional expression, self-esteem, aggressive communication, feeling of inferiority

Perceived acceptability of eating-disordered behaviour in young adult women with and without eating disorder symptoms

MOND, J. (University of Western Sydney), ARRIGI, A. (Central Queensland University)

Building on previous work in the field of eating disorders “mental health literacy”, we examined the perceived acceptability of eating-disordered behaviour in a community-based sample of young adult women with and without eating disorder symptoms. Participants ($$N = 264$$) were women aged 18 to 27 years recruited from a university campus in central Queensland by means of an internet-based survey. Self-report questionnaires that included vignettes of fictional persons suffering from anorexia nervosa (AN) and bulimia nervosa (BN), questions addressing the perceived acceptability of the problems described, and a measure of eating disorder psychopathology (Eating Disorder Examination Questionnaire, EDE-Q) were completed by all participants.
addressing perceived acceptability, developed by the authors, addressed the extent to which the conditions described were perceived to be acceptable or desirable personally or socially. The same eight questions were asked in relation to each vignette. Statistically significant differences in perceived acceptability between women with symptoms ($n = 37$) and women with no symptoms ($n = 227$) were apparent on all eight items for both vignettes, such that women with symptoms perceived AN and BN to be more acceptable than healthy women. Particularly pronounced differences were observed on two items. Whereas 2.2 per cent of healthy women had often or always thought that it “might not be too bad” to have AN, 37.8 per cent and of participants with symptoms had often or always thought this. Corresponding figures for the BN vignette were 5.7 per cent for healthy women and 48.6 per cent for women with symptoms. Similarly, whereas 2.2 per cent of healthy women reported that they would be moderately, very or extremely happy to have AN, 32.4 per cent of participants with symptoms gave these responses. Corresponding figures for the BN vignette were 3.5 per cent and 24.3 per cent, respectively. Although the use of a cross-sectional study design limits any conclusions concerning the direction of the observed associations, the findings suggest that the presence of eating disorder symptoms among young adult women is closely tied to the perceived acceptability of those symptoms. Hence, the findings may indicate specific targets for prevention and early intervention initiatives.

**Keywords:** eating disorders, eating disorders, acceptability

**Perceived workload mediates the relationship between self-efficacy and work engagement in nurses**

CHRISTIAN, F. (University of Surabaya)

Nursing is one of three professions that is susceptible to feelings of decreasing work engagement. The indicators are low levels of energy and mental resilience, lack of a sense of significance, enthusiasm, inspiration, pride and challenge while working. On the other side, when nurses engage with their work, they will show high levels of energy and mental resiliency, have a sense of significance, enthusiasm, inspiration, pride and challenge while working. This research found that nurses who have high self-efficacy will show high engagement with their work. When they perceive that they had higher workload, the relationship between their self-efficacy and their work engagement increased. The participants are nurses from two upper-class hospitals in Surabaya ($N = 157$). The implications of these findings for health-care worker will be discussed.

**Keywords:** work engagement, self-efficacy, perceived workload, nursing

**Perception of teachers and students regarding teaching of English composition in Indian senior secondary schools: A study**

MALIK, V. (Aastha College of Education)

This study had five aims: (1) to investigate the method of teaching composition in secondary schools; (2) to study aims of teaching composition; (3) to study whether teaching of composition aims at making learners a creative person; (4) to identify problems of English teachers on teaching composition; and (5) to gather suggestions from teachers and students regarding improvement in teaching and learning of composition. A descriptive survey method of research was used. The sample consisted of 20 teachers and 100 students randomly selected from senior secondary schools in the Kurukshetra district of Haryana (India). Two self-developed questionnaires were used. Percentages were calculated for data analysis. The study revealed that 70 per cent of teachers create a proper environment for teaching composition. Ninety per cent of teachers were not encouraging, asking students to cram essays/letters/stories and all teachers were teaching oral composition and were using translation method for teaching composition. Ninety per cent of teachers were giving instructions to students while teaching composition and all teachers were making corrections of composition in students’ notebooks. Eighty four per cent of students opined that teaching of composition was not
according to their mental level, 64 per cent students indicated that their teachers were asking them to cram essays/letters/stories, all students pointed out that their teachers was teaching oral composition and all students agreed that their teachers was correcting their composition in their note book daily. All students revealed that their teacher was translating composition. In an Indian context, although English is a foreign language, continuation of English in India is both desirable and necessary for establishing relations with the rest of world. Keeping in view this fact, teachers should not ask students to cram essays/letters/stories but should create proper environment of composition and should explore better methods of teaching composition. English composition should be taught by teachers in a manner that enables students to learn without pressure. It calls for frequent in-service training programs for teachers in Indian secondary schools.

Keywords: teaching, learning English

Performance and explanation of ways of thinking: A metacognitive analysis of solving mathematical problems

FARIA MORO, M. L. (Universidade Federal do Paraná), SOARES, M. T. C. (Universidade Federal do Paraná), SPINILLO, A. G. (Universidade Federal de Pernambuco)

This study examines the relationship between grasp of consciousness and performance on problems involving Cartesian product (Vergnaud’s categorization) in fifth and eighth graders from a public and from a private school in Brazil. In the context of current ideas about education which focuses on learning to think, contemporary literature has given fruitful attention to the so-called metacognitive processes in the acquisition of mathematical knowledge. Part of these studies, influenced by the Geneva School, analyzes the role of the grasp of consciousness in the conceptual construction in mathematics. However, these studies are mostly based on oral verbalizations, and not on situations in which the participant is asked to make her ways of reasoning explicit in writing, and specially when solving complex problems as those of Cartesian product. Forty-two participants, aged 10 to 16, solved four multiplicative and/or division problems of Cartesian product in writing and explained their solutions by answering the question "How did I think to solve this problem?" Firstly, the written answers to this question were qualitatively analyzed in order to identify categories as indicators of awareness on the part of the participants regarding their solutions to the problems; secondly, the participants’ performance on the problems, as well as the incidence by category of those written answers, were quantitatively analyzed to test the relationship on focus. The qualitative analysis of the answers identified three response categories as indicators of degrees of awareness on the part of the participants, which the statistical analysis revealed to be associated to their performance. Thus, progressively more refined explanations are accompanied by correct solutions to the problems, which are corroborated by significant differences in performance and in the presence of justifications for the solutions in both types of school. The relationship between implicit and explicit knowledge as inherent to conceptual evolution, and a teaching process directed toward reflection and comprehension on the part of students regarding mathematical concepts, may explain the results. Therefore, forms of intervention on the part of teachers that activate the metacognitive skills of students are recommended in the teaching of mathematics.

Keywords: mathematics, conceptual construction in mathematics, grasp of consciousness, problem-solving, ways of reasoning

Personality as predictor of pro-environmental attitudes and behaviours

HARDLEY, J. (Victoria University of Wellington), MILFONT, T. (Victoria University of Wellington)

Several studies have examined the influence of individual differences variables on environmental engagement. Along with gender, age and education, variables such as values, time perspective, self-construals and connectedness with nature have been linked to environmental attitudes (EA) and behaviours. Specific personality traits have also been examined.
Traits such as responsibility, conscientiousness and self-confidence have been found to relate to pro-EA, while selflessness and responsibility have been found to relate to ecological behaviours. However, to our knowledge there has been no systematic research exploring the effect of the Five-Factor Model (FFM) of personality on EA and ecological behaviours. We conducted two studies to address this gap in the literature. A total of 332 undergraduate students took part in Study One (70% female, mean age = 19, SD = 2.6), and a community sample of 150 participants took part in Study Two (54% female, mean age = 33.8, SD = 15.9). Participants completed an online survey containing FFM measures (Study One: Ten-Item Personality Inventory; Study Two: Big Five Aspect Scale), the New Environmental Paradigm (NEP) Scale, the Environmental Attitudes Inventory and ecological behaviour measures. Hierarchical multiple regressions analyses were performed to examine the relationship between the big five dimensions and EA and ecological behaviours, controlling for age and gender. Only Openness to Experience consistently predicted people’s environmental engagement in both studies. The findings are consistent with another recent study showing that Openness to Experience predicts environmentalism, and also with studies showing the link between this personality dimension and universalism and self-transcendence values, which have been shown to relate to pro-EA and ecological behaviours. Thus, those people who are open-minded, hold a more altruistic viewpoint and are innovative in their outlook and behaviour tend to be more environmentally engaged. However, the effect sizes in our studies were small to medium, suggesting that the predictive power of personality on environmental engagement is low. This is a positive finding suggesting that intervention campaigns can influence people’s environmental engagement. Theoretical and practical implications of the findings will be discussed, and directions for future research outlined.

**Keywords:** environmental attitudes, big five model of personality, ecological behaviours, environmental engagement, new environmental paradigm scale

**Personality at work: Structural validity evidence and links to workplace outcomes for a new personality tool**

MACCANN, C. (University of Sydney), BROWN, F. (Chandler Macleod Consulting), DONAGHEY, S. (Chandler Macleod Consulting)

The Humm-Wadsworth Temperament Scale (Humm) has been used by personnel psychologists for over eighty years, forming the basis for the well-known Minnesota Multiphasic Personality Inventory (MMPI). This paper presents structural and validity evidence for an adaptation of the Humm. This adaptation aims to: (a) reduce the difficulty of items’ language, (b) provide a clear and replicable structure at the dimension and sub-dimension level, and (c) produce scales with good internal consistency, test-retest reliability, and prediction of workplace outcomes. Participants were recruited via email for two online studies. Participants were drawn from two sources (a) individuals from recruitment and assessment databases of the last author’s firm who consented to future contact, and (b) client organisations of the last author’s firm. In Study One, 1895 participants (53.5% female, aged 17 to 68) responded to a large item pool developed to measure the Humm theoretical model. In Study Two, which is ongoing, participants completed personality and impression management items, as well as criterion measures (job satisfaction, turnover intention, organizational citizenship and counter-productive workplace behaviors). Participants were asked to provide an email address for their current supervisor and a co-worker, for later collection of other-report performance data. In Study One, parallel analysis, exploratory factor analysis (EFA), and confirmatory factor analysis (CFA) were used to reduce the item pool to 182 items representing 6 dimensions and 29 underlying facets of personality. The six factors represented: Emotional instability, project-focus, power-motive, self-interest, self-reliance, and extraversion. Alpha reliabilities ranged from .83 to .95 for broad dimensions, and .69 to .89 for the facet scales. Fit indices from CFA models were adequate for a 6-factor solution and good for a 29-factor solution. Study Two data will be available by the time of the conference, allowing replication of the structural model, and a test of...
whether personality scales relate to self-report criteria and performance data. Available data indicate that the new personality tool has excellent psychometric properties. Data from Study Two will determine whether the instrument also promises to be a valid tool for workplace selection and development.

Keywords: temperament, Minnesota multiphasic personality inventory, workplace selection, emotional instability, job satisfaction

Personality profile of the drug addict in Romanian young people

RASCANU, R. (University of Bucharest)

Marital adjustment was originally defined by Spanier & Cole (1976) as a multidimensional phenomenon which the Dyadic Adjustment Scale (DAS) was reported to measure adequately (Spanier, 1976). The separate dimensions of marital adjustment were reported to be the following: (a) consensus on matters of importance to marital functioning, (b) dyadic satisfaction, (c) dyadic cohesion, and (d) affectional expression. The purpose of this study is to explore if and how the behavior pattern of the women or of the man is the one influencing the dyadic adjustment of marital relationships. Ninety couples (50% males and 50% females) aged 32 to 59 years completed the Dyadic Adjustment Scale (Spanier, 1989). We selected four groups based on the scores of the two partners, and considering T scores under 30 as indicators of severe maladjustment. There are significant differences between the four groups (t Student). The groups are the following: 1. Non-distressed couples group (N = 71); 2. distressed couples group (N = 8); 3. mixed couples group: man with clinical profile, normal pattern in woman (N = 7); 4. mixed couples group: woman with clinical profile, normal pattern in man (N = 4). First, as expected, we found different patterns of behavior for non-distressed and distressed couples. Second, if only the woman has a clinical behavior pattern (low scores on affectional expression, satisfaction and consensus) the man obtained low scores on consensus. If the man has a clinical behavior pattern (low scores on affectional expression, satisfaction), the women obtained low score on satisfaction. The results discuss different patterns of marital interaction, correlatively with the behavior of the partners and their gender. These findings are important for clinicians active in family counseling and psychotherapy, as they reveal important information about the influence of the behavior of the partners on couple relationships.

Keywords: marital adjustment, dyadic adjustment scale, marital satisfaction, affectional expression, distressed couples

Personality profiling of successful elite level team sport coaches

WILLIAMS, J. (Best On Ground Performance)

Sport in Australia is a billion dollar industry and making the “right” selection of coach will have a financial and personal impact on the country, the club and the team. The hypothesis is that successful elite level long term coaches will share several common personality and motivational characteristics as tested within the Hogan inventories. As part of a larger data set collection, the results of 16 long term elite coaches completed a set of Hogan Inventory Tests (13 males and three females). All coaches were recruited from invasion sports and had been head coach at the highest level for a period of at least five years. Each had succeeded in winning or being runner up in a world championship or the highest level of their sport. The sports were Australian Football League, Basketball, Soccer, Lacrosse and Netball. Hogan inventories were selected as they are commonly used as a personality assessment tool in job recruitment and leadership training. Although the coaches varied in many aspects of the 3 Hogan inventories, there were common traits that were found. These coaches are highly competitive, very self confident, high in self expectation, highly stress tolerant, resilient, self determined, altruistic, not money driven and people’s people. Personality profiling may prove to be a useful tool in the recruitment process of elite coaches. This study is significant because in order to establish the foundations for an elite coaching competency model there is a need to establish a sporting leadership baseline data set. Long term successful coaches data can be used for psychological comparison and provide an assistance in the recruitment practices of Clubs.
and Associations. In addition, it has the potential to be expanded to provide a larger data set of assistant coaches, sacked coaches and elite players.

**Keywords:** sport psychology, elite level long term coaches, personality assessment, personality profiles, recruitment of sport coaches

**Personality traits as effective factors in tendency to addiction: Psychological comparison of addicts and non-addicts**

HOMAYOUNI, A. (Bandargaz Branch, Islamic Azad University)

Since the introduction of Diagnostic and Statistical Manual of Mental Disorders, Third Edition (DSM-III) in 1980, there has been a growing interest in the study of patients with substance use disorders (SUD). The driving force behind this field has been, and still is, the high clinical pessimism about the prognosis, and the difficulties in the clinical management of the characteristics of diagnosed patients. In this way the important matter to study is the evaluation of co-occurring personality problems and substance abuse. So the study investigated the personality traits of addicted and non-addicted people. Ninety addicted people and ninety non-addicted people were randomly selected and McCrae & Costa’s (1992) Revised Neuroticism-Extroversion-Openness Inventory was administered on them. Mean scores were compared with independent t-tests. Findings indicated that there are differences among means of personality traits in two groups. Addicted people are more neurotic and open to experience than non-addicted people and non-addicted people are more extroverted, agreeable and conscientious than addicted people. This indicates that evaluating with reliable measures, and with more attention to personality traits, can help psychiatrists and psychologists diagnose the cause of tendency to addiction, reduce the psychological problems that are related to addiction before and during drug treatment, reduce duration of treatment and enhance efficacy of treatment methods.

**Keywords:** revised neuroticism-extroversion-openness inventory, substance use disorders, addiction, personality traits, neuroticism

**Polish soccer hooligans: Euro 2012, violence and sense of alienation**

PIOTROWSKI, P. (Jagiellonian University)

Poland and Ukraine will organize Soccer Euro 2012 Championships. One of the most disturbing problems connected with the event is the presence of a soccer hooligan subculture in Poland. The data gathered by the Central Police Command revealed that in 2008 the number of soccer-related hooligan incidents was as high as 228, with 49 fans and 58 police officers seriously injured. The aim of the study is to explain the phenomenon of soccer hooliganism using the concept of sense of alienation and to emphasize the importance of prophylactic strategies to cope with it. Thirty-two boys aged 14 to 16, intensely involved in football hooligan group was diagnosed. The research techniques applied: Locus of Control Questionnaire Delta by Drwal (1980), Sherwood’s ISC inventory, Ignaczak’s WIAICH Inventory, and the Social Support Scale and Sense of Alienation Scale (both by Kmiecik-Baran). Deviant behaviours, manifested in groups of sport supporters, are explained as a way of coping with the sense of alienation, expressed in a destructive manner. The failures that hooligans experienced in environments are most vital to proper development and thus favoured high levels of physical aggression, low levels of self-esteem and external loci of control. Perceptible deficits of social support facilitated the formation of a high level of sense of alienation. For high risk group boys, the most dominant way of overcoming such a state is to form a group of a destructive character, composed of individuals experiencing similar difficulties. The sense of belonging to such a group becomes the source of support and the base for shaping identity at the same time. The sense of being rooted into the local community and identification with a group of soccer fans is accompanied by a sense of increasing alienation and inability to function in the wider social context. The research revealed that the sense of alienation can be successfully lowered by modifying the predisposing conditions. It is argued that prophylactic projects aimed at eliminating causes that promote negative phenomena can bring the expected results, whereas schemes that are repressive in their
character resulted mainly in transferring the incidents beyond the stadiums in Poland.

**Keywords:** social alienation, soccer hooliganism, locus of control, sense of belonging, self-esteem

**Portuguese college students: Different levels or different creativities?**

IBÉRICO NOGUEIRA, S. (Universidade Lusófona de Humanidades e Tecnologias)

The aim of this research was to characterize and analyze the differences in the creativity levels of students from different areas of graduation. We also intended to study the creativity differences between Portuguese and German students, to reflect about the role of the cultural and academic backgrounds in creativity development. This research involved a convenience sample of 600 participants, 200 from Psychology, 200 from Architecture and 200 from Engineering, 319 male and 282 female, ranging between 20 and 48 years of age. To assess the creativity levels we used the Test for Creative Thinking- Drawing Production (TCT-DP; Urban & Yellen, 1996). We found significant differences between the graduation areas, favoring the architects. In addition, we found statistically significant higher creativity levels in the final year students (fifth year of their graduation), by comparing them to the lower levels of graduation (third and fourth). There is a significant statistical difference between the Portuguese and the German sample, favoring the latter. We did not find any significant differences between males and females in terms of their creativity levels. We must reflect on the importance of the participant’s area of graduation for the creativity levels. We also need to reflect about the importance of the higher levels of education and its positive correlation with the creativity levels. The significant statistical difference between Portuguese and German samples, favoring the latter, leads us to reflect about the cultural differences in terms of educational goals and motives. The similarities between males and females concerning their creativity levels agree with the findings of several other studies.

**Keywords:** creativity, gender differences, education, creativity

**Positive orientation and subjective well-being of cancer patients**

KOHLI, N. (University of Allahabad)

The aim of the present study was to examine a) the relationship between positive orientation and subjective well-being and b) to identify the predictors of subjective well-being. The sample consisted of 61 cancer patients undergoing treatment at a local hospital in Allahabad, Northern India. Twenty three males and 38 females participated in the study. Their mean age was 50.13 years (SD = 14.76). More than 50% of the respondents were illiterate. Semi-structured interviews were used. The interviews lasted for about 40 minutes. Informed consent was taken. The initial section of the Interview schedule included questions pertaining to Demographics (age, gender, income, level of education), and Illness description (severity of illness, duration of treatment, perceived controllability). The later section of the Interview schedule covered items relating to positive orientation. Positive orientation was measured with the help of the Silver Lining Questionnaire which consisted of 38 items and future orientation which consisted of five items. The Subjective Wellbeing Questionnaire consisted of 24 items. A five-point rating scale was used to tap the responses. The findings showed that Positive orientation of patients (beliefs that every cloud has a silver lining and positive future orientation) correlated significantly with subjective well-being ($r = .708^{**}$ and $r = .676^{**}$ respectively). Multiple regression analysis of patient data demonstrated that family income, beliefs in silver lining and positive future orientation emerged as significant predictors of subjective well-being. The higher the family income of patients and the greater their positive orientation (strong beliefs in silver lining and more positive future orientation), the higher their level of subjective well-being was. The implications of the findings will be discussed. To unravel the mysteries of silver lining and future orientation, more studies are needed in this area.
Keywords: cancer patients, future orientation, positive orientation, subjective well-being, perceived control

Powered two-wheelers' conspicuity and human functional failures: An in-depth accident study

JAFFARD, M. (Inrets), CLABAUX, N. (Inrets), FOURNIER, J. Y. (Inrets), VAN ELSLANDE, P. (Inrets)

Until now, powered two-wheelers (PTW) have been a really dangerous means of transport despite many efforts to change this. In France, the number of PTW riders involved in accidents each year is more than 25% of people killed in accidents, despite these vehicles representing only 6.5% of the number of vehicles on the road and they drive four times kilometres less than car drivers a year (ONISR, 2007). The PTW conspicuity problem is identified in the literature as a main issue of insecurity. According to a previous study, the non-detection of PTW is involved in 60% of accident cases between PTW and another vehicle (Van Elslande et al., 2003). PTW are less detectable physically. Nevertheless, the detectability problem cannot be reduced to this characteristic. The aim of this study is to investigate different aspects of the PTW conspicuity problem in crashes in order to determine the origin, the context of onset, explanatory elements associated and to look at adapted operational solutions. The survey is based on an evaluation of the perceptive difficulties that drivers meet when they are confronted to a PTW. It makes use of the analysis performed on a sample of 184 accidents involving a PTW detectability problem by the confronted driver. Accident data were collected in the frame of the In-depth accident study (EDA) conducted at INRETS (France). Data on drivers’ difficulties and their production context variables were obtained by gathering detailed information at the scene of accident itself. Data were collected by multidisciplinary teams and covered the three components of the road system: vehicles, drivers and infrastructure. Each accident surveyed gave rise to a reconstruction in time and space of the events leading up to it. Then, a classification model of human functional failures (Van Elslande & Fouquet, 2007) allowed us to define breakdowns in the driver’s functional chain (perception, diagnostic, prognostic, decision and execution) and contextual explanatory element of these human failures (endogenous or exogenous). The preliminary results show that the non-detection of PTW could be explained at different levels: Sensorial level linked to narrowness of PTW; behavioural level linked to specific driving of PTW (e.g. lateral and frontal acceleration capacities); or cognitive level linked to attentional capacity of confronted drivers (e.g. PTW are less present on the traffic and car drivers don’t expect to meet them). Moreover, these factors are not exclusive and could often be combined in an accident situation. Yet, the implication of one factor is not most often enough to be determinant. Thus, the different factors’ impact is considered in drivers functional failures. These results, however, reveal that the lack of PTW detectability induces mainly perceptive failures, but not only these. This issue can be at the origin of difficulties in situation evaluation, in PTW behaviour understanding or in decision making. In conclusion, this study proves that the conspicuity problem is a complex issue which can be explained both by physical, cognitive or behavioural parameters. The lack of detectability has an impact on every functional level of driving. These results will be revisited from an ergonomic point of view in order to consider efficient means to fight against consequences of PTW poor detectability.

Keywords: traffic psychology, accident reconstruction, powered two-wheelers, driver’s functional chain, driving

Predicting client uptake of online family dispute resolution: An extension of the Unified Theory of Acceptance and Use of Technology (UTAUT)

CASEY, T. (Relationships Australia Queensland), WILSON-EVERED, E. (Relationships Australia Queensland), ALDRIDGE, S. (Relationships Australia Queensland)

Recent amendments to the Family Law Act have resulted in a proliferation of family dispute resolution (FDR) providers throughout Australia. However, a key issue faced by these services is client accessibility, which online delivery aims to address. In the context of a national pilot of
online FDR (OFDR), this study aimed to evaluate a model of client uptake intention. Integrating trust and personal web innovativeness (PWI) into the existing framework of the UTAUT, this study sought to identify the salient contributing factors to clients’ OFDR uptake intention. A total of 362 clients were surveyed by phone following registration for an existing national dispute resolution service. To reduce client inconvenience, exemplar items were chosen for each construct. Subject matter experts assisted in item selection. Evaluation of the model was conducted using partial least squares (PLS). Clients reported widespread access to the technologies required by OFDR. The UTAUT model and added variables (trust and PWI) accounted for a significant amount of variance in OFDR uptake intention ($R^2 = .617$, $p < .01$). Specifically, performance expectancy ($\beta = .412$, $p < .01$), effort expectancy ($\beta = .201$, $p < .01$) and trust in OFDR technology ($\beta = .537$, $p < .01$) contributed the greatest proportion of variance to behavioural intention. Social influence did not contribute significantly to intention ($\beta = .052$, $p = .278$). Domestic violence was negatively correlated with uptake intention ($r = -.161$, $p < .01$), effort expectancy ($r = -.140$, $p < .01$) and performance expectancy ($r = -1.58$, $p < .01$). Technological accessibility does not appear to be a major inhibiting factor to clients’ intended uptake of OFDR services. Further, the UTAUT was validated in this unique context. Implementations of OFDR services should consider users’ attitudes, perceived effort to use the system, trust in online technology and access to resources to maximize uptake. The negative effect of domestic violence on OFDR uptake intention, though expected, suggests further investigation. Overall the findings offer direction for future studies of the specific conditions where OFDR may be most effective and acceptable.

**Keywords:** online family dispute resolution, family dispute resolution, web innovativeness, client trust, technological accessibility

**Predicting traffic accident rates: Human values add predictive power to age and gender**

It has been well-documented by researchers in traffic psychology that age and gender predict the accident rate - males and younger drivers tend to be more involved in accidents. In the present study our aim was to test whether human values carry incremental validity in explaining traffic accidents. Human values were defined as a set of abstract beliefs related to desired human goals (Schwartz, 1992). Five hundred twenty five drivers (age range from 18 to 60, 46% females) participated in the study. Besides the rate of involvement in traffic accidents we also measured four dimensions of human values: Conservation, Self-Transcendence, Openness to Change, and Self-Enhancement by the Portrait Value Questionnaire (Schwartz et al., 2001). Hierarchical regression analysis showed that human values add a predictive power to explaining traffic accidents over that provided by the measures of age and gender. Particularly, value dimensions of Conservation and Self-Enhancement are significant predictors of traffic accident rate besides age and gender. Human values explain accident rate in a meaningful and interpretable manner, thus suggesting an important, culturally based understanding of driving accidents.

**Keywords:** traffic psychology, human values, driving accidents, self-enhancement

**Predictors of academic success: A longitudinal comparative study**

Students who learned English as a foreign language perform equally well academically in a North-American post-secondary institution as students who are native speakers of English. A 19-item questionnaire on academic success was administered to a sample of 427 English as a Foreign Language (EFL) students and 322 Native English Speaking (NES) students who entered a North American post-secondary institution for the first time during the academic year 2002-2003. Their cumulative Grade Point Averages...
(GPAs) during each of five subsequent academic years up to 2008 were analysed along nine predictors. Analyses include descriptive statistics, t-tests, one-way ANOVA, bivariate correlation, multiple regression, and discriminant analysis. The mean cumulative GPAs of EFL and NES students grouped according to the nine predictors range from 2.19 (number of employment hours) to 2.86 (number of independent study hours) and 2.22 (number of employment hours) to 3.00 (being married), respectively. When paired on each of the nine predictors, mean differences between the two groups are not significant. Coefficients of correlation between the predictors and GPAs are generally low, many are negative, yet many are significant. Variance analyses yielded significant F’s for eight predictors. Three discriminant function coefficients correctly classified 33.4% of the participants into 11 program clusters. There were 172 EFL students and 89 NES students who graduated from their program of studies. The study refutes the myth that EFL students, compared to NES students, are academically disadvantaged due to the language barrier. The hypothesis that EFL students perform equally well academically as NES students in a North-American post-secondary institution is supported. The study recommends further studies to include the variables that were not among the nine predictors, i.e., academic self-concept, motivational attitudes, such as self-efficacy beliefs and a high motive to succeed; and cognitive style.

Keywords: Academic success, English as a foreign language, Post-secondary, Students

Predictors of adaptation among adolescents from immigrant families in Portugal

NETO, F. (Faculdade de Psicologia e de Ciências da Educaçao)

The aims of this study were to investigate the degree of psychological and sociocultural adaptation among adolescents with immigrant backgrounds in Portugal and the factors that may predict adaptation. The study sample consisted of 755 immigrant adolescents from seven ethno-cultural groups (Cape Verdeans, Angolans, Indians, Mozambicans, East Timorese, Sao Tomese, and Guineans) and 320 native Portuguese adolescents. Adolescents from immigrant families reported similar adaptation to that of their native Portuguese counterparts. Predictive factors, including socio-demographic and intercultural contact variables, were significantly linked to youths’ adaptation.

Keywords: social psychology, psychological adaptation, sociocultural adaptation, adolescents’ social adaptation, immigrants

Predictors of creative performance in the workplace

IMBER, A. (Inventium)

Few studies have examined the predictors of creative performance in the workplace. We set out to examine whether a variety of predictors, which had been shown to predict creative performance in laboratory studies, actually led to more creative performance at work. Over two hundred employees across more than forty different organisations took part in the study. Employees were asked to complete a series of questionnaires, ability tests, and reaction-time tests. In addition, over four hundred of their managers and co-workers participated in the study to rate the employees on their creative performance at work. Our study revealed several predictors of creative performance, including openness to experience, creative self-identity, promotion focus, and cross application of experiences. These variables predicted behaviours such as creative problem solving ability, ability to sell in ideas to others, and ability to work collaboratively on projects requiring creative thinking. The implications of this study are significant for the field of recruitment, in that we are now able to predict the likelihood that job applicants will exhibit creative behaviours in the workplace. The findings also have important implications for learning and development for companies who are looking to identify prime employees for championing innovation within the organisation. This study also adds to the limited body of knowledge of the variables that predict creative behaviour in the workplace.

Keywords: creativity, innovation, organisations
Predictors of psychological well-being: 1150 Women

MOE, K. (University of Kentucky), BROCKOPP, D. (University of Kentucky), ABNER, J. (University of Kentucky), HATCH, J. (University of Kentucky), SCHREIBER, J. (University of Kentucky), YACKZAN, S. (University of Kentucky), HICK, M. (University of Kentucky), VARGHESE, A. (University of Kentucky)

The aim of this study was to identify predictors of Psychological Well-Being (PWB) among women undergoing diagnostic mammograms for breast cancer. As part of a larger study examining the PWB of women pre- and post-diagnosis of breast cancer, data on 1150 healthy participants (non-diagnosed) were analyzed to determine predictors of PWB in women. Participants were well-educated, exhibited normal ranges of PWB and psychological distress. Ages ranged from 23 to 87 (M = 50.16, SD = 10.84). Using simple correlations and linear regression, 15 variables were analyzed to determine predictors of PWB. Ryff’s (1989) Scales of Psychological Well-Being (SPWB) total score and six subscales represented PWB as dependent variables. Binary correlations of 15 variables as potential predictors of well-being showed that three variables (depression, r = - .63; stress, r = -.57; and perceived social support, r = .42) were significantly related to PWB. Using hierarchical regression, these three variables were strong predictors of PWB, contributing 37% of the variance in total PWB after controlling for 11 variables. PWB subscale correlations showed a hierarchy of responses suggesting that the three variables were most strongly related to Self-Acceptance followed by Purpose in Life, Positive Relations, Environmental Mastery, Personal Growth and Autonomy. Psychological distress (depression and stress) and social support appear to be key attributes in understanding women’s PWB. In relation to subscale analyses, it is difficult to discern whether or not high self-acceptance leads to increased social support and less distress or if low distress and high social support contribute to stronger self acceptance. Similar questions can be posed for each of the three variables. For example, would enhancing women’s social support and decreasing their distress give them a greater sense of self-acceptance? Findings in this study show that depression, stress, and social support are strongly related to women’s ability to accept themselves, a central feature of mental health (Ryff, 1989). An interaction effect between distress and social support, however, was not found. Therefore, future research will focus on understanding how predictors operate in different dimensions of PWB for women.

Keywords: cancer diagnosis, psychological well-being, psychological distress, social support, self-acceptance

Predictors of treatment-seeking by in-patient problem gamblers in Canada: A theoretically-driven approach

KUO, B. C. H. (University of Windsor), GILLIS, P. (University of Windsor)

Cumulative gambling literature has pointed to serious underutilization of problem gambling treatment and services by pathological gamblers worldwide. Yet the existing research on help-seeking among problem gamblers is scarce, highlighting a need for systematic empirical inquires. The present research addresses this gap by identifying and assessing a constellation of critical psychosocial antecedents of help-seeking among problem gamblers based on an a priori model previously tested with structural equation modeling by Cramer (1999). With a sample of 29 problem gamblers who attended a three-week in-patient gambling treatment program in Southwestern Ontario, Canada, this study measured 15 social, cognitive, coping, health and financial variables hypothesized to be critical to treatment-seeking behaviour for problem gamblers. The variables included: expected problems related to gambling, gambling moderation self-efficacy, help-seeking attitude, self-concealment, self and social stigma, coping, social support from friends, family and significant others, gambling-incurred debt, general health and comorbid alcohol abuse. Specifically, the study examined: a) predictors of the participants’ willingness to seek help across seven types of interventions and support; and b) changes in the predictor and criterion variables from pre- to post-treatment. The results of a series of multiple regressions showed varied patterns of help-seeking behaviours among the participants depending upon the types of help and services in question.
At pre-treatment, the regression model was effective in predicting problem gamblers’ willingness to seek psychotherapy or counselling in particular. At post-treatment, the same model was effective in predicting problem gamblers’ overall willingness to seek help. Problem gamblers’ willingness to seek most forms of help and services examined in the present study improved from pre- to post-treatment. There were statistically significant changes in the participants’ overall willingness to seek help and in their willingness to access Gamblers Anonymous in particular between pre- and post-treatment. Furthermore, the participants reported improvement with respect to overall health, social support from family members, and adaptive coping strategies. Moreover, participants reported a decrease in their tendency to conceal personal secrets and this decrease was especially pronounced among women. The findings of the study suggest the utility of systematically investigating treatment-seeking grounded in a theoretically framework. Interpretations of the findings and discussion of their implications for future research and clinical intervention are presented.

Preference of leadership styles: A cross-cultural study between Turkey and Italy

YURTKORU, S. (Marmara University), DURMU, B. (Marmara University), ERDOAN, E. (Marmara University)

Leadership has been a topic of interest since ancient times. Even though perspectives are changing, leadership still remains as a major concern for numerous nations and organisations. Especially as the borders of business world begin to disappear and people from different cultures began to be in much closer relationship, the importance of leadership styles are increasing. The perception of “ideal leader behavior” varies across countries. The aim of this study was to investigate and compare perceptions of ideal leader behaviors from two different countries: Turkey and Italy. In this study the Ohio State Leadership Behavior Description Questionnaire (LBDQ XII) was used in data collection. Discriminant Analysis was used to identify which of the twelve LBDQ dimensions accounted for the significant differences between the two subject groups. The data sets were composed of 202 Turkish and 200 Italian employees’ responses. The findings indicate that seven LBDQ dimensions: representation, demand reconciliation, tolerance of uncertainty, tolerance of freedom, role assumption, consideration, and production emphasis, discriminated between the two countries. Findings reveal that Italian employees prefer leaders that perform representation ($b=0.262$), tolerance of uncertainty ($b=0.359$), tolerance of freedom ($b=0.574$), role assumption ($b=0.673$), and consideration ($b=0.267$) behaviors more than Turkish employees. Turkish employees prefer leaders with demand reconciliation ($b=-0.108$) and production emphasis ($b=-0.269$) behaviors more than Italian employees. As a result of this research, we found the ideal leader behavior expectation of the two countries showed significant differences, as indicated in previous studies.

Keywords: leadership style, cross-cultural, Turkey, Italy

Preliminary evidence for the role of psychosocial strength in addressing problems in childhood and adolescence

BRAZEAU, J. (Centre for Excellence for Children and Adolescents With Special Needs), RAWANA, E. (Centre of Excellence for Children and Adolescents with Special Needs, Thunder Bay)

The current presentation will describe the empirical evidence that supports a strength-based approach to assessment and treatment of children and adolescents with diverse mental health problems. The initial focus of the presentation will be on the assessment of strengths and the relationship between strengths and areas of difficulties that were ascertained from a large sample of youths between the ages of 11 and 18 years of age. The presentation will then focus on two prospective studies that examined the role of strengths on treatment outcomes. The first study examined strengths as they related to outcomes in a residential substance abuse program for adolescents. The second study evaluated a
strength-based intervention for bullying that was implemented in a primary school. Results indicate that strengths tend to be negatively correlated with measures of psychopathology. However, youths with high levels of psychopathology still have areas of strength that can be used to overcome difficulties. In our studies, specific strengths were associated with improved outcomes. We have provided preliminary evidence that suggests that strengths are related to psychopathology and may play an important role in overcoming adversity. Through assessing strengths mental health professionals can identify areas of strength that may help clients overcome their problems. In addition, strength-based interventions may provide a valuable addition to traditional treatments. Ongoing research is currently underway to help further clarify these propositions.

Keywords: assessment, treatment of children and adolescents, residential substance abuse problem, adolescent psychopathology, bullying

Pride, self and culture: A cross-cultural study among Chinese and American university students

FENG, X. (Northeast Normal University), YE, Y. D. (Fujian Normal University)

Pride is a type of self-conscious emotion. Until now it has received considerably less attention from emotion researchers than basic emotions such as joy, fear and sadness. The aim of this study is: (a) To explore types of pride events; (b) to explore the characteristics of attribution between Chinese and American university students; and (c) to explore the role of self-construal when participants experience self-conscious emotions of pride using cross-cultural background. The participants are from Chinese and American universities, enrolled in psychology courses. Participants completed online questionnaires. The pride questionnaire is a modified version of the Geneva Appraisal Questionnaire (GAQ- Pride). All participants also completed a Self-Construal Scale (SCS) and a brief demographic form. Data were analyzed with the statistical software SPSS 16. An analysis of variance (ANOVA) was used to test the hypothesis. Regression analysis was used to explore the possibly mediating function of self-construal. Through content analysis, we found the characteristics of types of pride events are similar between Chinese and Americans; for example, Achievement Event is the main event type that aroused the feeling of pride. Internal appraisal is the main style of evaluation for both cultures. The feeling of pride is experienced more in public places. The feeling of pride is more related with family for Chinese students compared with American students. Chinese students mainly have interdependent-self characteristics, and American students mainly have independent-self characteristics. Culture can influence the self-conscious emotion of pride. The feeling of pride between Chinese and American university students has some coherent characteristics and some different characters. Two countries’ students have different self-construal characters, and the role of self-construal as a mediator is not significant.

Keywords: pride, self-consciousness, self-construal, Geneva appraisal questionnaire, interdependent and dependent selves

Proactive coping, positive mood and rehabilitation outcomes following orthopaedic joint replacement

KATTER, J.K.Q (York University), GREENGLASS, E. (York University)

Orthopaedic joint replacement is an increasingly common surgical procedure aimed at reducing pain and improving physical functioning. It has recently been recognized that psychological and cognitive factors can greatly influence an individual’s post-surgical recovery, above and beyond the effects of preoperative function and surgical trauma. An individual’s coping style, the way in which they typically deal with problems they encounter, may be a particularly relevant consideration in understanding how they will cope with the difficulties associated with joint replacement. Engaging in proactive coping, a coping style that is goal-oriented and involves approaching stressors as challenges rather than threats may be particularly beneficial. Individuals who engage in proactive coping have been previously shown to experience higher levels of positive emotion. Experiencing higher levels of positive emotions during stressful
encounters, such as following surgery, has been shown to help individuals to find meaning in those encounters, and successfully recover from them (Tugade & Fredrickson, 2004). It is hypothesized that older adults who engage in proactive coping would experience improved psychological and functional rehabilitation outcomes following joint replacement, and that this relation would be mediated by the experience of increased positive mood. The relation between proactive coping, mood, and psychological and functional rehabilitation outcomes was examined in a longitudinal study of 228 older adults undergoing rehabilitation following joint replacement surgery. Shortly after admittance to a rehabilitation centre, participants completed a series of self-report measures, including assessments of proactive coping and mood. Subsequently, on the day prior to discharge, trained medical professionals assessed the success of a patients' rehabilitation. Support for the proposed mediation model was found, where proactive coping style was associated with increased vigour, which was in turn associated with improved functional and psychological outcomes. A similar relationship was not found for the experience of negative mood. Improved rehabilitation outcomes may be experienced by individuals who engage in proactive coping, due in part to their increased positive mood. Theoretical and practical implications of the association between proactive coping, mood and rehabilitation outcomes are discussed in the context of interventions to foster proactive coping in older adults.

Keywords: proactive coping, mood, joint replacement

Problem coping style as a mediator between dispositional optimism and adjustment to university

HEALY, M. (University of New South Wales)

This study examined the relative influence of dispositional optimism, and problem coping styles on adjustment to university for first year university students. The study examined adjustment by both Australian-born students and international students. Participants were 1097 first year students at the University of New South Wales, Australia. Students completed measures of dispositional optimism, adult attachment, attachment to parents and peers, coping styles, and adjustment (psychological, social, academic). Results indicated that dispositional optimism, attachment relationships with parents and peers and problem coping styles were associated in expected directions with adjustment for both local and international students. Success at university, demonstrated by academic achievement, showed a statistically significant association with the constructs examined. In the current sample optimistic students reported more adaptive coping skills, had more positive attachment relationships with parents and peers and adjusted more quickly to the transition to university. Finally, optimism, coping and relationships with parents and peers in facilitating adjustment applied equally to both local and international students giving support to the cross-cultural applicability of the core constructs.

Keywords: dispositional optimism, coping styles, adjustment, adult attachment

Problems faced by primary school students belonging to socio-economically disadvantaged sections of Indian society

YADAV, R.J. (Kurukshetra University), SHARMILIA, (Kurukshetra University), KADIAN, M.S. (Kurukshetra University), KUMAR, P. (Shri Krishna College of Education)

This investigation, conducted in India, aimed to: (1) study the academic/educational problems of primary school students belonging to socio-economically disadvantaged family backgrounds; (2) study the personal problems of primary school students belonging to socio-economically disadvantaged family backgrounds; (3) study school related problems of primary school students belonging to socio-economically disadvantaged family backgrounds; (4) to study teachers’ related problems of primary school students belonging to socio-economically disadvantaged family backgrounds; and (5) study parents’ related problems of primary school students belonging to socio-economically disadvantaged family backgrounds. A descriptive
survey method was used. The study sample consisted of 200 students belonging to socio-economically disadvantaged family backgrounds of six government schools of Jhajjar district of Haryana, India. A researcher-developed questionnaire and Chi-Square test was used for analysis of the data. The study indicated the following main problems faced by Schedule Caste students, who are socio-economically disadvantaged in primary school: (1) children develop fear regarding school and teachers; (2) these children are afraid of corporal punishment given by teachers; (3) lack of facilities in school; (4) books of stories are not made available to children; (5) frequent corporal punishment is given to children; (6) these children have to do domestic work; and (7) lack of environment and adequate space for studies at home. In India, in spite of efforts made in this direction, there exist numerous problems in the field of elementary education due to existing socio-cultural conditions/contexts and socially disadvantaged communities/weaker sections. The major proportion of children belonging to these backgrounds do not complete their education up to elementary school-level and either remain out of school or prematurely dropout from school without completing elementary school-level education. Therefore, there is still a need for further thinking in this context.

**Keywords:** primary school, socio-economic disadvantage, schedule caste, India, elementary school

### Process Experiential Emotion Focused Therapy - An inquiry of peer supervision 'in-mode'

TUDGE, S., JOHNS, H. (Essendon Community Counselling Service)

Supervision is increasingly being required of trained psychologists to promote high quality counselling, continuous learning and psychological health. Group supervision models can provide invigorating and challenging professional development opportunities, allowing practitioners to enquire, observe, practice and learn in ways that cannot be achieved in one-on-one supervision. The aim of this study was to determine the effectiveness of a peer supervision framework using Process Experiential Emotion Focused Therapy (PEEFT) in mode. Effectiveness is indicated by improvements in the psychologists counselling competencies. Within a participatory inquiry methodological framework data was collected from a Melbourne peer supervision group. Five Melbourne psychologists with varied backgrounds met monthly in an informal setting for two and a half hours practicing peer supervision in a context of trust and exploration. The structured format comprised discussion on preparatory reading, analysis of issues from case examples and an experiential exercise. PEEFT methodology requires the therapist to notice and track the client’s emotional and physical sensations using an empathically-attuned, client-centred, and interventionist approach. Group participants self selected as supervisor, therapist or observers according to ‘what is emotionally present’ and participated in triad work. Within a safe and respectful environment practitioners practiced PEEFT techniques, reflected and gave feedback on the process while remaining ‘in-mode.’ Theory was applied in a sensitive, honest and supportive manner during evaluation. A formal evaluation of the peer supervision process used in the group was conducted after an 18 month period. All psychologists reported a heightened sense of self-awareness, self-efficacy and satisfaction associated with skills development and consolidating theory through the experiential process. The effects were found to occur at both a professional and personal level with improved competencies within supervision and counselling sessions. The PEEFT model of peer supervision was found to be successful due to improved counselling competencies. The ‘in-mode’ framework provided an innovative, efficient, effective, and satisfying model of training and supervision for psychologists working in various counselling positions.

**Keywords:** supervision, group supervision, process-experiential emotion-focused therapy

### Process-experiential emotion-focused therapy (PEEFT) - Supervision “in-mode”

KRUPKA, Z. (La Trobe University), HARTE, M. (La Trobe University), KRUPKA, Z. (La Trobe University)
The Process-Experiential Emotion-Focused Therapy (PEEFT) approach to therapy uses specified client markers or indicators of experience, to direct the therapist’s choice of process interventions or tasks. Traditionally, supervision in this area tends to focus on the appropriate use of these tasks, the analysis of client emotional processing and the developing relationship between the client and counsellor. While the PEEFT counselling method is expressive and process-oriented, the supervision experience is potentially content “heavy” and directive. The aim of this study is to explore an “in-mode” model of supervision consistent with PEEFT markers and tasks. This presentation is structured to include a brief overview of the work in the area so far and report on a participatory line of inquiry the supervisee’s experiences. As part of a PEEFT supervision group (circa 2005), involving psychologists and psychotherapists, there has been an exploration of PEEFT markers, to inform a supervision practice that is more process based. For example, tasks such as empty chair and two-chair work are used to debrief the therapist, “bring the client more to life,” and to clarify for the counsellor those blind spots and dilemmas they are experiencing in the counselling relationship. The issue of distinction between therapy and supervision was also investigated. In addition, innovative Professional Development (PD) Days have been developed. These days incorporate triad work, theoretical discussions around application of tasks and live supervision. A pioneering advance sees supervision conducted in a ‘fish-bowl’ group setting and ‘in-mode’, providing the supervisee with an opportunity to personally explore their reactions to clients and group members to contribute to the supervision process. Supervision becomes less concentrated on the “unknown client’s story” and more on the counsellor’s and supervisor’s “known” experiencing. As this exploration continues, a theory of PEEFT supervision is developing that: supports the counsellor’s work with the client, enhances their own experience of the tasks and highlights the processes operating in the counselling relationship.

Keywords: counselling, process-experiential emotion-focused therapy, emotional processing, supervision, professional development

Procrastination in the workplace: What demotivates performance?

LEYBINA, A. (Raffles Educational Corporation College)

Workplace procrastination has recently become academically topical. The works of Choi (2005) and Dingfelder (2006) have addressed workplace productivity but not the influence of underlying motivation in the same manner Temporal Motivation Theory (Steel, 2007) has done in the analysis of procrastination. This study aimed to define a motivation structure of workers and hypothesized that this motivational structure has a direct and contrasting relationship with the level of worker procrastination. One hundred and forty seven Russians of different trades participated in the study. Various methods and questionnaires were used including “Personal Motivational Structure” (V.E. Milman), “Motivation of Professional Activity” (C. Zamfir), “Value Inventory” (S. Schwartz) and “Professional Performance” which was developed and validated. To determine underlying redundancies among the motives, the data were factor analyzed. A principal components method (VARIMAX rotation) was used to extract factors and a multiple regression analysis was conducted to assess the influence of motivation types on procrastination level. The procrastinator motivation structure was then built. There were four factors retained in the motivational structure of Russian workers; “Creation Factor”, “Prosperity Factor”, “Altruistic Factor” and “Reinforcement Factor” (stability for factor analysis yielded the value .785). The value of R² was .68, which was highly significant F (12.23) = 24.02, MSresidual = 23.58, p < .001. The standard error of estimation was 4.86. It was found that the motivational structure of workers with high work procrastination was three times more consistent than that of workers with low or average work procrastination. Nevertheless, no significant differences were found establishing a homogeneous relationship among the three motivational structures rs=.81 (p < .001) for high and low procrastinators and rs =.75 (p < .005) for high and average procrastinators. The connection between motivational components and levels of professional procrastination was revealed and correlated with underlying motivation factors. It
was demonstrated that procrastinators have higher adaptive abilities, i.e. they can switch motivations easily to procrastinate, but in general their motivation is similar to employees with low and average levels of procrastination. Although the majority of independent variables alone correlated significantly with the activity level, only activity motivation, creativity, achievements and stimulation accounted for a significant amount of unique variance of procrastination.

Professional counsellors’ experiences and perceptions of multicultural counselling in Malaysia: A qualitative examination

AGA MOHD JALADIN, R. (Monash University)

This research in progress explored the experiences and perceptions of 11 multicultural counselling practitioners with regard to the field of multicultural counselling in Malaysia. Semi-structured interviews were conducted with 11 professional counsellors in Malaysia. These counsellors were registered with the Malaysian Board of Counsellors and were holders of a practising license. They came from different work settings and different ethnic, religious, gender, and age groups. Based on a qualitative analysis using NVivo 8, participants noted that aspects of being a multiculturally competent counsellor in Malaysia included open-mindedness, flexibility, active listening, knowledge and awareness of cultural issues, skilfulness in making cultural interventions, self-awareness, and broad exposure to diverse life experiences. Most of the participants also stated that the challenges to becoming multiculturally competent included lack of knowledge regarding other cultures in Malaysia, lack of skill when dealing with clients who presented culturally sensitive issues in Malaysia such as lesbian and gay issues, and lack of support and training in multicultural counselling competency. However, many participants agreed that the current national movement towards “One Malaysia”, which emphasises national unity by encouraging mutual respect and trust among the different races in Malaysia, has had a great impact towards increasing their awareness and understanding regarding diversity and multicultural issues in the Malaysian context. These results indicate that multicultural counselling is a rapidly emerging profession in Malaysia. Continuing support for practising counsellors, counsellor educators, training institutions and government and non-government bodies, to promote and enhance current theoretical understanding and practice of multicultural counselling, is needed. Future research directions for improving the current education and training of counsellors are also discussed.

Keywords: multicultural counselling practitioners, cultural interventions, multicultural counselling competency, training, counselling competency

Profile of time perspective and subjective well-being among Taiwanese

GAO, Y. (Fu Jen Catholic University)

A balanced time perspective (BTP; Boniwell & Zimbardo, 2004) is usually operationally defined as a combination of high scores on past positive (PP), present hedonistic (PH) and future (F) in conjunction with low scores on past negative (PN) and present fatalistic (PF) in terms of the Zimbardo Time Perspective Inventory (ZTPI; Zimbardo & Boyd, 1999). In this study, we investigated profiles of time perspective and its correlation with subjective well-being (SWB) in Taiwan. Participants comprised 420 Taiwanese young adults (278 females and 142 males) recruited from five universities in northern Taiwan. The 56-item Zimbardo Time Perspective Inventory (ZTPI: Zimbardo & Boyd, 1999) and five-item Satisfaction With Life Scale (SWLS; Diener, Emmons, Larsen & Griffin, 1985) was translated from English into Chinese by the researchers. The data contained sufficient shared variance for factor analysis (KMO = .79) and Bartlett’s test of sphericity (χ² = 2412.613, p < .001 for ZTPI; χ² = 967.572, p < .001 for SWLS) identified the possibility to perform factor analysis. A 25-item modified Chinese Version Zimbardo Time Perspective Inventory and five-item Satisfaction With Life Scale Chinese Version
was used in this study. Results showed 81 participants holding a BTP profile and 319 participants without a BTP profile. Compared with non-BTP group, the group with a BTP profile had significantly higher scores on SWLS ($t = 5.662, p < .001$). Besides this, the five temporal frames (PP, PN, F, PH and PF) were correlated with SWB. There were no significant correlations between PF and SWB. People with higher scores for PP, F and PH had greater subjective well-being ($r = .420, p < .001$; $r = .277, p < .001$; $r = .139, p < .01$, respectively). Individuals with more PN had less subjective well-being. Most of these results are consistent with the findings reported by Drake, Duncan, Sutherland, Abernethy and Henry (2008). The relationship between BTP and SWB exists across different cultures.

Promoting effects of complete model essay and incomplete model essay learning on pupils’ narrative writing

QI, Z. (Liaoning Normal University), YAO, W. (Liaoning Normal University)

In the past, in composition teaching, pupils were generally only provided with complete model essays, and rarely were incomplete model essays used. However, the authors believe that the results of learning from some types of incomplete model essays may be better than the results of learning from complete model essays. In order to verify the hypothesis, authors established an evaluating indicator of pupils’ narrative writing, and designed one complete model essay and eight different types of incomplete model essays. A total of 300 third-grade pupils were randomly divided into ten groups with one group being the control group and the other nine being experimental groups. At the beginning of the experiment, the experimenters presented a narrative with the same subject to the ten groups. After pupils completed the composition ten minutes, the control group did not learn anything via model essay, and the other nine experimental groups respectively learned one type of incomplete model essay. After 30 minutes, the experimenters presented a subject to the ten groups as the same as before, then let pupils complete the composition. According to the evaluating indicator of pupils’ narrative writing, the pre- and post-narrative writing performances were assess, and the total scores and sub-scores calculated. Compared with the control group, narrative writing performances of experimental groups were all significantly promoted. The differences among post-narrative writing performances of the nine experimental groups were significant. After third-grade pupils had learned the different types of narrative model essays, the narrative writing performances all improved significantly. In regards to the total score, the “added the end ” incomplete model essay learning group performed best, “fill the contents” incomplete model essay learning group was second, complete model essay learning group was third, and the “added elements” incomplete model essay learning group preformed the least.

**Keywords:** complete model essays, incomplete model essays, student narratives, composition teaching, narrative writing

Promotion regulatory focus, affective commitment and manager-rated performance predicting intention to leave in retail banking employees

VOIGT, E. (Monash University), HIRST, G. (Monash University)

The aim of the study was to examine interactions between regulatory focus of promotion, affective commitment and manager-rated performance in relation to intention to leave. The study included a national sample of 785 retail banking employees across 181 branches. Participants completed an online questionnaire and responses were matched to individual performance as rated by the manager. Descriptive statistics and correlations were calculated for all variables. Data was then centered to reduce possible concerns with multi-collinearity. Controlling for age, organisational tenure and job satisfaction, hierarchical moderated regression analyses were conducted to test the three hypotheses proposed. The manager-rated performance-intention to leave relationship is influenced by level of promotion focus ($\beta = -0.07, p < .05$). With increasing
performance ratings, high promotion focus individuals indicated reduced intention to leave, but those with low promotion focus tend to become more likely to consider leaving as performance increases. Results also indicated that the affective commitment-intention to leave relationship is influenced by level of manager-rated performance ($\beta = -0.05, p < .05$). As performance increases, individuals with high affective commitment indicate reduced intention to leave, but those with low affective commitment indicate higher intention to leave. The relationship between affective commitment and intention to leave was not significantly moderated by promotion focus ($\beta = -0.05, p = 0.07$). The findings indicate that a combination of promotion focus, manager-rated performance, and affective commitment are useful factors to consider in relation to understanding intention to leave. More specifically, the findings are useful to advance understanding of strategies for retaining high performing employees. Practical and theoretical implications of these unique findings, together with suggestions for future research are discussed.

**Keywords:** intention to leave, promotion focus, staff retention, bank, affective commitment

**Prospective links between playing violent electronic games, hostile attributions, normative beliefs and aggression in pre-adolescence**

SCHULTES, M. T. (University of Vienna)

Playing electronic games is a popular leisure activity of pre-adolescents, yet many of these games are age-inappropriate and contain violence. A large number of studies have shown the negative effects of violent games on aggression (Anderson et al., 2004; Möller & Krahé, 2009; Polman, Orobio de Castro & Van Aken, 2008). As causal relationships are still questionable, the present study uses a longitudinal approach to investigate the prospective links between playing violent electronic games and aggression. Since research on girls’ use of electronic games is often overlooked, the present study analyzes the longitudinal associations for girls and boys separately. A short-term longitudinal study was conducted in two waves of data collection with a time lag of six months. The longitudinal sample comprised 169 pre-adolescents (38% boys) aged 11 to 14 years at Time One ($T_1; M = 11.80, SD = 0.64$). Participants were asked to name their five favorite electronic games, which were then categorized according to their age appropriateness and violent content using the European classification system for electronic games, PEGI. Hostile attributions and normative beliefs were measured via instruments developed by Möller (2006). Aggression was assessed with a measure developed by Little et al. (2003). A multiple group longitudinal mediation analysis was conducted using game preference at $T_1$ as the independent variable, aggression at Time Two ($T_2$) as the dependent variable, and attributional style at $T_1$ and normative beliefs at $T_1$ as mediating variables. The results revealed important gender differences in that consuming age-inappropriate violent electronic games over a period of six months caused higher aggression amongst girls. Unexpectedly, no effects of electronic game usage could be observed for boys and there were no mediational effects of attributional style or normative beliefs in both groups. The present study reveals that girls preferring age-inappropriate violent games belong to a group of “high-risk-players”. Girls had a higher vulnerability for the effects of violent electronic games on aggression. Playing violent games at $T_1$ was a risk factor for displaying aggressive behavior at $T_2$ in girls only. Based on these results, further female-oriented research on electronic games is recommended.

**Keywords:** electronic game usage, pre-adolescents, aggression, gender differences, violent games

**Prospective memory deficits in ecstasy/polydrug users**

HADJIEFTHYVOULOU, F. (University of Central Lancashire), FISK, J. (University of Central Lancashire), MONTGOMERY, C. (Liverpool John Moores University), BRIDGES, N.

Previous research has revealed that recreational drug users believe themselves to be impaired in aspects of real world memory including prospective memory (PM). However, it remains
unclear whether these self-perceptions are accurate. The impact of ecstasy-polydrug use on PM was investigated in a sample of ecstasy-polydrug users and non-ecstasy users. Laboratory PM tasks were devised and added to the existing self-report measures of PM to test whether any impairment on different aspects of prospective memory was present in ecstasy-polydrug users when compared to the control group. Laboratory measures included tests sensitive to time and event based PM and long term episodic PM. Self report measures included long term episodic, short term habitual, internally cued PM, strategies people adopt to remember and finally retrospective memory. Ecstasy/polydrug associated deficits were observed on both laboratory and self-report measures of PM. The present study extends previous research by demonstrating that deficits in PM are real and cannot be simply attributed to self misperceptions.

Proximological approach in the psychology of health

GLOZMAN, J. (Moscow University)

The aim of this research was to study the influence of family on a patient’s health and personality, as well as the influence of chronic disease on the caregiver’s health and quality of life. The method included the Luria comprehensive neuropsychological battery, Spilberger State-trait Anxiety Inventory, Wylie Self-concept Assessment, Scales of Quality of Life (for the patient and their care-giver), and Inventory of Internal Representation of Disease. Trait anxiety correlated with the duration of disease and the family situation of the patient: the patients living alone without wife or children were more anxious than those living in families. Internal representation of defects correlated more with emotional disturbances than real motor deficit. Significant correlations were seen between quality of life scores and duration of disease and the score of cognitive disturbances, which proves an objective value of subjective measures. Interdependence between quality of life of the patient and their caregiver was revealed in Russian, French and Spanish studies using the same Questionnaire of Quality of Life. The burden of care interferes with economical well-being, physical health, psychological functioning and social well-being of caregivers. Patients with less cognitive disturbances, lower depression and anxiety, and balanced type of internal representation of disease, show better results in rehabilitation and lower interference with the quality of life of their caregivers. In conclusion, health concepts should be one of the main orientations in psychological rehabilitation, because the subjective factors are as much or even more important than objective ones for the disease progression or regression. The quality of life and internal representation of one’s own disease are integral components of the psychology of health. The patient-caregiver dyad should be viewed as a unit when detecting problematic situations and targeting of appropriate and efficient interventions by professional practitioners.

*The work is supported by a grant of the Russian Fond of Fundamental Researches # 07-06-00039

Psychobiological origin of mental health: The effect of returning to the evolutionary dietary/blood lipid pattern

WILCZYNSKA, A. (University of Silesia), DE MEESTER, F. (TsimTsoum Institute), BARGIEL-MATUSIEWICZ, K. (University of Warsaw)

Experimental studies indicate that ω3 PUFAs play an important role in neurones’ structure and function. The brain is quite rich in ω3 PUFAs and several studies suggest a role of ω3 PUFAs in neurotransmitter synthesis, degradation, release, re-uptake and binding. The main aim of this study was to review the latest accumulated results in the field and to propose a physiological and evolutionary explanation for the effect of dietary lipids on psychological behavior and human well-being, on the assumption of the Columbus Concept that stands for the return of the evolutionary dietary/blood lipid pattern. The study consisted of overviews of psychological,
From the social conflicts between East and West Germans after German unification, it can be inferred that prejudicial attitudes could be a potential problem for Korean reunification. The dual-process model suggests that prejudicial attitudes are comprised of both explicit (conscious) and implicit (non-conscious) attitudes. Within this framework, past data suggest that South Koreans explicitly and implicitly preferred South Korea over North Korea, and while explicit attitudes could be influenced by context effects (e.g. positive news about unification efforts), implicit attitudes were not similarly influenced (Kim, 2003). However, recent research suggests that implicit attitudes could be influenced by associative exposures, implying that the pairing of North Korea or North Koreans with positive valences could change implicit attitudes. The purpose of the present studies was to investigate ways to reduce South Koreans’ explicit and implicit prejudicial attitudes toward North Korea and North Koreans. Three studies were conducted. In Studies One and Two, we investigated whether explicit and implicit attitudes toward South and North Korea could be altered by exposure to positive or negative news concerning the relationship between the countries in a laboratory (Study One); and whether attitudes could be altered with experience of a real, positive development in the two countries’ relationship (Study Two). In Study Three, we investigated the effects of associative priming on explicit and implicit attitudes by exposing participants to subliminal associations between North Koreans and positive valences. Explicit attitudes were affected by context effects both in the laboratory (Study One) and in response to real events (Study Two) in the expected direction, but implicit attitudes were not affected in both studies. In Study Three, implicit attitudes were less pro-South Korean as a result of exposure to association of North Koreans with positive valences, while explicit attitudes were not affected. The data suggest that explicit attitudes are influenced by context effects while implicit attitudes are influenced by associative exposures. Understanding of the characteristic of implicit and explicit attitudes could lead to strategies that are effective methods in reducing the explicit and implicit prejudicial attitudes, to overcome potential social consequences of Korean unification.
Psychological assistance for preschool children with mild perinatal pathology of central nervous system

SULTANOVA, A. (Russian Academy of Education), IVANOVA, I. (Russian Academy of Education)

The urgency of this research was caused by the progressing prevalence of perinatal pathology of nervous system among children population of the developed countries. Generally the psychological research has focused on studying the effects of grave damage to the central nervous system such as infantile cerebral paralysis and mental retardation. The practical influence of mild perinatal pathology of the central nervous system (CNS) on the mental ontogenesis is not studied, consequently, there are not assistance programs for these children. Our research was devoted to this problem. The investigation consisted of the following stages: (1) The analysis of the features of mental development of children with mild perinatal pathology of CNS in comparison with healthy children. (2) Development and implementation of the assistance programs. (2) Assessment of the program’s effectiveness. Ninety two children (5 to 6 years old) were investigated: children considered healthy but with mild perinatal brain injury in the anamnesis – 52 persons; healthy children – 40 persons (the control group). The research revealed the typical deviations of mental development of the children with perinatal pathology of CNS: neuropsychological dysfunctions (fatiguability, psychic inertness, fluctuations of tempo in mental processes, change of the pace of activity etcetera), emotional and behavioral disturbances (emotional lability, change of the emotional sensibility, aggressiveness and negativism etcetera), some negative features of the development of their mental functions – speech, attention, perception, verbal memory, verbal-logic thinking, and also the reduced self-control capability. The program of psychological assistance for these children was worked out, it included three component parts: neuropsychological correction, psychological help to children and their families, socio-psychological work in the educational environment. The repeated diagnostics spent after this remedial course has shown substantial improvement of indicators of development of mental functions and social adaptation of children. Parents and educators reported a decrease of behavioral and emotional disorders in children. Thus according to the data of research, the perinatal injury of the central nervous system even in case of a favorable outcome negatively influences upon the mental health of children. Also this research allows us to assert that an integrated psycho-socio-pedagogical assistance is the effective for improving of mental development of these children.

Keywords: central nervous system, brain injury, children

Psychological capital and authentic leadership: Examining their impact on both extra role and deviant workplace behaviours

WILSON-EVERED, E. (Relationships Australia), VAN OLST, A. (Monash University), COLEMAN, G. (Monash University)

Contemporary organisations are challenged more than ever to find innovative, cost-effective ways of improving productivity, performance and customer service. The purpose of this study was to examine the relationships between two emerging constructs; Psychological Capital (PsyCap) and authentic leadership and the organisational outcomes; extra-role behaviour and employee deviance. Arguably, psychological capital, comprising hope, resilience, optimism and self confidence, could emerge in the presence of authentic leadership and lead to engaging in extra role behaviours. Conceivably, the converse is likely, such that where leader authenticity is low, psychological capital will be diminished and counterproductive or deviant behaviours more likely. One hundred and seventy seven employees from a diverse range of organisations completed an online survey measuring levels of PsyCap, perceptions of their leaders’ authenticity and reported frequencies of the two contrasting organisational behaviours. Hypotheses were tested using a series of regression equations. As predicted,
PsyCap shared a positive association with extra-role behaviours and a negative association with deviance. Authentic leadership also demonstrated a significant positive association with PsyCap. Contrary to predictions PsyCap did not mediate the relationships between authentic leadership and the two workplace behaviours. The results of this study provide empirical support for the relationships between PsyCap, authentic leadership and two central organisational outcomes. To successfully survive and prosper through the current financially challenging times, organisations that can promote both PsyCap and authentic leadership are likely to encourage employees to go beyond their current role to benefit the organization. The ongoing investment in employees’ psychological resources, combined with the development of genuine, transparent leadership arguably creates a foundation for sustained competitive advantage and a superior organisational experience.

Keywords: productivity, organisational performance, customer service, psychological capital, extra-role behaviour

Psychological contract breach and work attitudes: The role of age

BREYER, T. (University of Rostock), NERDINGER, F. (University of Rostock), KLUTH, J. (University of Rostock), PUNDT, A. (University of Rostock), MARTINS, E. (University of Rostock), CURTH, S. (University of Rostock)

Demographic development which is characterized by an increasing life expectancy and a simultaneous decrease in birth rates, means that the share of ‘older’ employees in companies is steadily increasing. We assume that the changed age structure in companies has an impact on the relationship between employees and employers, whereby this relationship is operationalized in terms of psychological contracts (PC). One subsequent aspect is the breach of psychological contracts (PCB). There are findings confirming that PCB is related to work attitudes. Based on Socio-emotional Selectivity Theory, we presume that older people evaluate PCB less negatively. Therefore, we presume that age could moderate the relationship between PCB and work attitudes. The aim of the study is to identify differences between younger and older employees in the perception and the effect of PCB. Therefore we investigated the effects of a perceived PCB on employees’ work attitudes (job satisfaction, affective commitment and turnover intentions) in general, and tried to determine age as a moderating variable for the relation between PCB and employee attitudes towards their work. The analysis is based on data collected from employees (N = 461) of different German companies by means of an online and a paper-and-pencil survey. We conducted correlation and regression analyses to test our hypothesis. The results prove the moderating effect of age on the relation between PCB and two of the three named work attitudes. The age of the employees alleviates the effect of PCB on work satisfaction as well as on turnover intention. However, the moderator hypothesis for the relation between PCB and affective commitment must be rejected. There is evidence that the impact of PCB on employees’ work attitude differs from older to younger employees.

Psychological discrimination on different cultural exchange: City custom comparison of Shanghai, Tokyo, and Seoul

YAN, M. (Humanities Institute of Shanghai Normal University)

Three East Asian countries: China, Japan and South Korea share common Chinese character culture tradition. However, the Chinese culture tradition changes from time to time, generation to generation. In addition, after the Chinese culture spreads to East Asian countries, it also combines with the native culture and produces the different custom activities. Then, the different cultural exchange psychology emerges. Shanghai is located at the central China Yangtze River estuary. In the Ming dynasty and Qing dynasty, it was only a small, ordinary coastal city. After 1840’ China and United Kingdom Opium War, Shanghai opened as a port, accepted the Western civilization and imported
Abstracts of the 27th International Congress of Applied Psychology

Brief Oral Presentations

In the different cultural exchange aspect, the South Korean culture slightly owes the compatibility, but the Japanese culture presents the multiplicity and compound. Since Buddhism has spread to Korea, it occupies the dominant position is the Mahayana Buddhism throughout. Afterward, into the Korean time Confucianism presented after the national leadership idea, also repels Buddhism. Japan and South Korea are treating the Kong Zi theory aspect. In South Korea, only the stressed that the intrinsic judgment and the moral supreme have the very strong speculation about Zhu Xi’s theory, and what is considered as legitimate is Confucianism. However Japan’s scholars not only have accepted Zhu Xi’s theory, but have also widely accepted the intense realistic criticalness Wang Yangming’s theory. Japan’s Confucianism has not looked like South Korea’s Confucianism, and becomes the ruling class the absolute behavior way. Japan and South Korea have practiced the centralization system, but afterward Japan onto the place decentralization path, but South Korea was still has been maintaining the powerful centralization system.

Psychological follow-up of top level athletes in France: Place and role of the scientific associations

ROSNET, E. (INSEP)

France institutes a legal medical follow-up in 2004 for top-level athletes which includes a psychological examination since 2006. The paper presents the place and role of the scientific associations during the preparation of the law and since its application and focuses upon the ethical aspects. The concerned athletes are ranked at international level and received financial support from the Sport Department. Young talents are also subject to the law. The global population is around 6000 persons. The medical follow-up includes one psychological examination each year (2 each year for under 18 athletes) among different medical examinations like cardiac echography and biological analysis. In case of any examination suspecting a medical problem threatening the athlete’s health, he/she
can be prevented from licence. The paper analyses the process that drives to the law from an organisational point of view and according to ethical criteria. Difficulties encountered concern firstly the relationships between medical and psychological associations during the conception of the law, secondly the way to define the characteristics of the psychological examination according to ethical criteria, and thirdly the way examinations are performed. The actual organisation of the psychological examination will be exposed. Some examples of difficulties encountered on field will be provided and partial results concerning fencing will be presented. The role of scientific associations is very important during laws’ conception and application in order to secure ethical aspects.

Keywords: athletes, legal medical examination, France

Psychological measures of hardiness and self-handicapping predict outcomes from elite military training

TEMBY, P. (Defence Science and Technology Organisation), DROBNJAK, M. (Defence Science and Technology Organisation)

Psychological tests have a long history of use in the selection of military personnel. In recent years, there has been renewed interest in examining the ability of personality-based measures to predict outcomes from military training (Hartmann et al, 2009). For example, research has found that measures of hardiness predict outcomes from United States Army special forces training (Bartone et al, 2008) and measures of self-handicapping predict outcomes from British Army training (Richards et al, 2002). The aim of this study was to examine the ability of hardiness and self-handicapping measures to predict outcomes from elite military training in an Australian sample. Using a prospective research design, self-report measures of hardiness (Dispositional Resilience Scale, 30-item) and self-handicapping (Self-Handicapping Scale, 25-item) were administered to 139 military personnel (mean age = 27.9 years) prior to attempting a three-week military training course and then correlated with course outcome for each participant (successful versus unsuccessful). Hardiness scores were significantly higher for successful ($M = 72.1, SD = 6.9$) than for unsuccessful candidates ($M = 67.5, SD = 6.7$), $t = 3.3, p < .001, d = 0.68$. Self-handicapping scores were significantly higher for unsuccessful ($M = 36.6, SD = 10.6$) than for successful candidates ($M = 30.3, SD = 8.8$), $t = 3.2, p = 0.002, d = 0.61$. Logistic regression analyses confirmed that hardiness and self-handicapping scores significantly predicted course outcome. This study has found that individuals who successfully complete an elite military training course are significantly higher in psychological hardiness and lower in self-handicapping than individuals who are unsuccessful. The effect sizes suggest these factors play a moderate but significant role in predicting success in stressful environments. The study replicates the findings from previous research into these constructs and extends previous research by investigating both measures in an Australian sample. We recommend that future research continues to explore psychological factors that predict success in high-stress occupations to assist the development of reliable screening tools for personnel selection.

Keywords: Military personnel selection, Self-handicapping, Hardiness, Military training outcomes, Personality-based measures

Psychological resilience as a predictor of well-being among spouses of persons with dementia

O’ROURKE, N. (Simon Fraser University - Vancouver Campus), KUPFERSCHMIDT, A. (University of British Columbia)

The current study examines the degree to which psychological resilience predicts the well-being of spouses of persons with dementia one-year later. From these analyses, two pairings of canonical variates emerge as significantly correlated. The first captures significant percentages of variance of each of the facets of resilience (i.e., commitment to living, perceived control, and challenge) as well as higher socioeconomic status, family income; this canonical variate predicts the physical and mental health of caregivers one-year later. The second is defined by the absence of commitment to living and predicts lower life
satisfaction for women with less formal education and more health conditions. These findings suggest that psychological resilience as initially reported is a harbinger of both the mental and physical well-being of spousal caregivers over time.

Keywords: resilience, dementia, caregivers, caregivers, life satisfaction

Psychological resources and depressive symptomatology in students with and without migration in their family

Migration is present around whole world and it is considered a stressful life event that is accompanied with multiple psychological processes of adjustment and adaptation that have an impact in health. This study sought to identify if there were differences in psychological resources (affective, cognitive and social resources) and depressive symptomatology in students with families that have or have not had the experience of migration. The participants were 287 Mexican college students, 51% of whom had the experience of migration in their family and 49% who had not. Psychological resources were measured with the Psychological Resources Scales (affective, $\alpha = .82$; cognitive, $\alpha = .71$ and social, $\alpha = .77$) by Rivera Heredia & Andrade Palos (2006) and depressive symptomatology was measured with the Center of Epidemiologic Studies Depression Scale (CES-D) (Radloff in 1977), validated in Mexico by Marino, Medina-Mora, Chaparro & Gonzalez-Forteza (1993). The scales were applied in the classroom, with agreement from the participants. With a t-student analysis the following significant differences ($p \leq .05$) were found: students with migration in their family had less self-control, more difficulties with sadness, more presence of self-reproaches and more difficulty asking for help when they needed it, than students without the experience of migration in their family. In regards to depressive symptomatology, students with migration had less positive affect, more sadness, more isolation and more suicidal ideation than the other group. These results demonstrate the need to develop, apply and evaluate intervention programs for this vulnerable population. They should be directed to increase affective, cognitive and social resources.

Keywords: migration, depression, psychological resources, self-control, self-reproaches

Psychological theories of help-seeking by male victims of intimate partner abuse: Implications for psychological practice

TILBROOK, E. (Edith Cowan University), ALLEN, A. (Edith Cowan University), DEAR, G. (Edith Cowan University)

In this study we aimed to explore the factors that influence male victims’ decision-making about seeking help in relation to intimate partner abuse (IPA). Our second aim was to examine male victims’ help-seeking within three theories of help-seeking developed in relation to female victims of IPA: ‘Survivor Theory’, ‘Reclaiming Self Theory’ and ‘The Decision to Leave Model’. Semi-structured interviews were conducted with male victims ($N = 15$), service providers ($N = 8$), and close friends and family of male victims ($N = 6$). Participants identified 11 barriers to men seeking help following IPA, and four facilitating factors. Participants also described men’s help-seeking decision-making processes. The help-seeking processes described by participants are consistent with those outlined in the three theories developed to explain women’s help-seeking. As with women victims, a male victim’s decision about seeking help involves an evaluation of his options to ensure his safety and reclaim his sense of self within the constraints of adhering to his existing gendered world-view. The main implication for psychologists who work with male IPA victims is: what has been learnt about the help-seeking behaviours of female victims of IPA can be applied to men but strategies to engage men and work with them must be applied within the context of contemporary understandings of masculinity.
Keywords: male victims’ decision-making, intimate partner abuse, help-seeking, masculinity, sense of self

Psychological therapy of a case with marital conflict, insomnia and hypertension

NARASAPPA, K. (University Malaysia Sabah)

A 33 year old married Malay Muslim lady referred to our unit with chief complaints of giddiness, fainting attack and insomnia. A detailed history revealed that the patient was diagnosed as having hypertension since 2002 and receiving medication. She was admitted to Accident and Emergency 34 times in two years with complaints of fainting attacks and giddiness. She also had complaints of insomnia with fear of death due to hypertension. Each admission lasted for one to four days. All investigations including EEG, chest x-ray and CT scans were reported to be normal. A detailed psychological evaluation, interview with psychological tests such as GHQ, STAI and NEO-P, were administered. Test results revealed anxious personality traits with significant psychological distress. The patient underwent 12 sessions of psychological treatment over the period of three months. She was accompanied by her husband for treatment even though she received individual sessions of psychological therapy. Her severe interpersonal conflicts with ambivalence, her insomnia and anxiety were treated successfully. She was advised to come for follow-up once a month and it continued for six months with good recovery.

Keywords: insomnia, hypertension, anxiety, fear of death, interpersonal conflict

Psychological wellbeing in the community

ENGLAND, M.

This paper outlines and explains the approach and operation of the APS Sydney Branch Community Wellbeing Award. This award exists to support community groups to plan and implement projects that encourage psychological wellbeing in the community. The paper explains the theoretical underpinnings of the award and provides an example of its operation and outcome. The award provides a means of understanding and encouraging measures to promote psychological wellbeing in the community. The value of the award is evidenced by the participation and outcomes shown in the example of its operation provided.

Psychological wellbeing: United Kingdom and Malaysian fire fighters

A. MALEK, M. D. (Universiti Malaysia Sabah), KAMIL, I. S. M. (Universiti Malaysia Sabah)

Sources of occupational stress and their impact on job satisfaction and psychological wellbeing were examined in a questionnaire survey of 436 United Kingdom (UK) fire fighters and 617 Malaysian fire fighters. The role of coping strategies and work motivation as moderating factors were also tested. Sources of occupational stress had significant negative correlations with job satisfaction and wellbeing. Hierarchical regression analysis was used to examine the moderating effect of work motivation and coping strategies on job satisfaction and psychological wellbeing and found differences between the UK and Malaysian fire fighters. Models of job satisfaction and psychological wellbeing for both cultures were produced.

Keywords: stress, well-being, work motivation, job satisfaction, Firefighters

Psychology into the schoolroom

KRANE, H. (Icita Publications, RMIT University)

The aim is to develop a teacher-training program for Victorian Secondary Schools that will include, in addition to certain school subjects, a ‘therapeutic-psychological approach’ in the classroom. Whilst the teacher is not designated the role of educational psychologist or sociologist, he will have a background knowledge in this area. The method of applying this psychological approach involves having students co-operating in the development of
learning materials and their own studies. This is likely to include the re-design of methods of learning. Appropriate training is meant to ensure that any interventional involvement of the teacher is not invasive but consultative. In the likelihood of needs of a personal nature arising as formal learning is proceeding, the interaction between the various proponents in the classroom is expected to have a lasting ‘therapeutic’ effect on the students to cope with ‘change’. In conclusion, the Secondary School student of the present and future is entering an age in which professional and vocational ability is insufficient to cope with an ever increasing number of inter-personal and social problems. Developing formal education with a modicum of psychological and social support may offer these students a greater preparation to deal with their immediate environment and sustenance of the greater environment (the world).

**Psychometric analyses of time perspective in Taiwan**

GAO, Y. (Fu Jen Catholic University)

This study investigated the reliability and cross validity of the Zimbardo Time Perspective Inventory (ZTPI; Zimbardo & Boyd, 1999) in terms of five subscales: Past Negative (PN), Past Positive (PP), Present Hedonistic (PH), Present Fatalistic (PF) and Future (F) in a Taiwanese sample, using both classical and multidimensional Rasch analysis. Participants comprised 420 Taiwanese young adults (278 females and 142 males) recruited from five universities in northern Taiwan. The 56-item Zimbardo Time Perspective Inventory was translated from English into Chinese by the researchers. The approach used for the statistical analysis combined classical and multidimensional Rasch analysis. Fit indices are represented by two forms of the mean square (MNSQ), Outfit (unweighted MNSQ) and Infit (weighted MNSQ). Mean square (MNSQ) ranging from 0.5 to 1.5 is considered acceptable (Linacre, 2009). The fit statistics of all items were near 1.0 and remained within the acceptable range (all MNSQ ranged from .86 to 1.14). This means that the data closely fitted the multidimensional IRT model. According to the results of both classical and modern psychometric approaches, the modified ZTPI-Chinese Version was empirically validated and shown to be a reliable measure in Taiwan.

**Keywords:** time perspective, Zimbardo Time Perspective Inventory, Chinese, validity, Classical Test Theory

**Psychometric properties of the Farsi version of the Multidimensional Inventory for Religious-Spiritual Well-Being (MI RSWB 48)**

ZAREAN, M. (University of Social Welfare and Rehabilitation Sciences), MAHMOOD-ALILU, M. (Tabriz University), BEYRAMI, M. (Tabriz University), HASHEMI, T. (Tabriz University), ELHAMi ASL, M. (Tabriz University), AAYAT MEHR, F. (Tabriz University)

Regarding the importance of the role of religious/spiritual factors in the individual’s well-being and also the importance of its assessment, this study was carried out to investigate the psychometric properties of the Farsi Version of
the Multidimensional Inventory for Religious-Spiritual Well-Being (MI RSWB 48; Unterrainer, 2007). In this cross-sectional, descriptive, and correlative study, a sample of 320 undergraduate students (204 girls and 116 boys) from Tabriz University were asked to complete the MI RSWB 48, the General Health Questionnaire (GHQ-28), Problem Solving Styles, and Alport's External/Internal Religious Orientation Scale. Data were analysed using Pearson’s correlations, t-tests, multiple regression and internal consistency statistical methods. Findings showed high internal consistency (alpha = 0.81) for the total score of the MI RSWB 48 and its factors (0.57 to 0.86). Also, results supported concurrent as well as predictive validity of the Farsi version of the MI RSWB 48. According to the reliability and validity scores reported above, it seems that the MI RWSB 48 has satisfactory psychometric properties in an Iranian university student sample.

Keywords: Farsi, psychometric, MI RSWB 48, religious, spirituality

Psychometric studies with the Test for Creative Thinking - Drawing Production (TCT-DP)

ÍBÉRICO NOGUEIRA, S. (Universidade Lusófona de Humanidades e Tecnologias)

We intend to present some of our studies carried out with Test for Creative Thinking-Drawing Production (TCT – DP; Urban & Jellen, 1996), in a Portuguese sample of college students. This test focuses on a more holistic concept of creativity than the mere quantitatively oriented, traditional divergent thinking tests. We will analyze the psychometric properties of TCT-DP, namely reliability and factorial structure. We also intend to discuss the implications of these results on creativity evaluation. This research includes a convenience sample of 600 participants, 200 from Psychology, 200 from Architecture and 200 from Engineering, 319 male and 282 female, ranging between 20 and 48 years of age. To assess the creativity levels we used the TCT-DP. The factorial structure analysis presents five dimensions that explain 60.58% of total variance (Kaiser-Meyer-Okin = .74; Bartlett’s Test of Sphericity = .000). The Cronbach’s alpha coefficient for the total items is .69. The inter-item correlation matrix analysis suggests an important debate about the pertinence of some items for further research. We need to reflect about the pertinence of excluding some of the criteria/items in the adaptation of the TCT-DP for the Portuguese population.

Keywords: creativity, creativity evaluation, drawing production, creativity, test for creative thinking - drawing production

Psychosocial risk in Colombian firms of production and services sector

URIBE-RODRIGUEZ, A.F. (Universidad Pontificia Bolivariana-Pontificia Universidad Javeriana Cali), RENTERIA, J. (Pontificia Universidad Javeriana Cali)

The aim is identifying psychosocial risk factors in productive sector organizations and health in Colombia. A joint study (qualitative and quantitative) and transactional (descriptive, not parametric) was done. Intentional non-probabilistic sample comprised of 20 companies. Those who make up the sample are persons of both sexes with an age range between 21 and 38 years. We performed the adaptation, validation by judges, pilot testing and implementation of quantitative survey for Identifying Psychosocial Risk Factors prepared by Bocanument and Berja (1993), with the aim of identifying risk factors characteristic present in the population study. Similarly, to categorize the level of hazard risk, the Pre-set levels of risk for psychosocial risk area developed by Duke and Uribe (1999) were used. A questionnaire measuring biopsychosocial factors was used. It was found that the most relevant data driven by the survey of risk identification, are related to the job rotation, are associated with factors related to work organization (excessive working hours, overtime, non-rotating shifts, inadequate planning of work activities by the organization), the content of the tasks to develop, the presence of psychological and physical factors (stress, headaches, anxiety, fatigue and sleep difficulties), and mental burden (simultaneous demands of several tasks in a short period of time, lack of support from the heads, teamwork and under). All these factors were presented in the sample with a medium hazard level. After
the application of the instruments it was found that the above factors affect work dynamics and therefore work climate perceived by workers in the workplace. Contributing to the welfare and health of employees within an organization is very important and necessary in business, because these are the raw materials that can be achieved for the respective functions of all processes, and thereby to meet the proposed goals for this reason it is essential to have a psychological state, physical and emotional stable and perform optimally effective in their work. It is therefore necessary that psychosocial risk is interpreted as warning signs that indicate that workers are in a state of mental and physical discomfort and maintained in that state, the chances of developing a disorder of another kind are substantially increased. Finally it was concluded that psychosocial risk factors affect and are associated with employee turnover, generating self-employment conditions unsuitable for the subject to enhance their performance and productivity within the organization.

Keywords: psychosocial risk factors, organizational performance, organizational productivity, employee turnover, hazard risk

Purpose and passion: Why are organisation mission and values so important for employee engagement?

PARKES, L. (Voice Project, Macquarie University), LANGFORD, P. (Macquarie University)

Previous research by the authors has demonstrated the powerful impact of organisational purpose on employee engagement, in both commercial and not-for-profit organisations. Despite hypotheses to the contrary, mission and values were just as engaging in both sectors. The current study continues this research by investigating whether the social and ethical value of the organisational purpose moderates the relationship between purpose and engagement, or whether it is mediated through social identity and perception of fit. Organisational climate surveys were completed in 2008 by 3079 employees from 302 predominantly Australian-based, commercial organisations across a wide range of industries. The survey content included the Mission and Values scale from the Voice Climate Survey (Langford 2009), as well as items measuring Social Responsibility, Philanthropic and Ethical CSR. Employees also rated the extent to which their values and ‘personality’ matched those of the organisation and other employees in the organisation. Employee Engagement was assessed as an aggregate of job satisfaction, organisational commitment and intention to stay in the organisation (Langford, 2009). Hierarchical regression analyses showed that after belief in the mission and values of the organisation, evaluation of the social and ethical value of that purpose explained little further variance in employee engagement. The interaction between belief in mission and values and evaluation of organisational purpose was not significant. However, perceived organisation-fit was a stronger predictor of employee engagement, and partially mediated the relationship between organisational purpose and employee engagement. Employees’ belief in the purpose, mission and values of their organisation is a powerful motivator, particularly driven by employees’ sense of fit between their own and the organisation’s values. This relationship between purpose and engagement was not affected by the social or ethical value of that purpose.

Keywords: organisational purpose, employee engagement, organisation fit

Putting the horse before the cart: Clarifying the content domain and measurement of employee engagement

LANGFORD, P. (Voice Project, Macquarie University)

Much is being discussed by researchers and practitioners regarding the antecedents, consequences and practical uses of employee engagement. The content domain of the construct, however, is still unclear, and without further clarity little can be confidently concluded regarding the relationships between engagement and other practices and outcomes. The present study investigated the interrelationship between 12 closely-related constructs that have been previously suggested to represent components of employee engagement. Data was gathered from 1701
employees from 180 organisations. Each employee responded to a randomised set of previously published items measuring the engagement-related constructs of job satisfaction, organisational commitment, intention to stay, vigour, dedication, absorption, positive affect, discretionary effort, organisational citizenship behaviour, proficiency, adaptivity, and proactivity. Exploratory and cross-validated results indicated substantial overlap between many of the a priori measures. A single factor explained a large percentage of variance in responses, supporting the previously argued presence of a single overarching construct that could reasonably be labelled as employee engagement. Exploring factors with eigenvalues greater than one, a clean two-factor solution was found representing factors of attitudinal engagement (encompassing three lower-order factors of organisation commitment, job satisfaction and intention to stay) and behavioural engagement (encompassing three lower-order factors of effort, proficiency and proactivity). An 18-item measure of both attitudinal and behavioural engagement, comprising three items for each of the six lower-order factors, was developed and cross-validated against manager-reported organisational outcomes. An even shorter 9-item measure representing only attitudinal engagement showed similar predictive validity as the 18-item measure. The study concludes that the presented factor structure and measure of employee engagement provides both theoretical and statistical rigour to meet the needs of researchers, as well as the brevity and ease of use required by practitioners. It is hoped that the study may contribute to a convergence in the understanding and operationalization of the construct of employee engagement.

Quantitative analysis of client-counselor interaction in psychotherapeutic counseling

NAGAOKA, C. (Kyoto University), KOMORI, M. (Osaka Electro-Communication University)

A Client in a psychotherapeutic counseling session benefits from the client-counselor dialogue in that it enhances ability to solve problems, make decisions, and affect desired changes in attitude and behavior. It is expected that an empirical investigation of the process of client-counselor dialogues can contribute to development of dialogue theory, or engineering application. The present study analyzed quantitatively verbal and nonverbal behaviors of a client and a counselor. Four 50-minute counseling sessions were analyzed, of which two were negatively evaluated and two were positively evaluated (high evaluation counseling). In addition, two 50-minute ordinary advice sessions between two high school teachers and the clients from the high evaluation group were analyzed. All sessions represented role-playing. This study analyzed (a) the proportion of total duration of utterance/pause of a client or counselor/teacher to each session. The results indicated that the proportion of total duration of client’s pause corresponds to the evaluation of the session, and that temporal change of the proportions in the four counseling cases showed similar temporal pattern. We also analyzed (b) body movement synchrony, through a video analysis of client-counselor/teacher dialogues. The results indicated a correspondence between the degree of body movement synchrony and the evaluation of the session, and a consistent temporal pattern among the four counseling cases. Three judges labeled (c) the counselor’s or teacher’s turn-taking into (i) utterances with an answer to the speaker’s questions at beginning part of the utterance, (ii) utterances with back-channels at beginning part of the utterance, (iii) utterances with laughter at beginning part of the utterance, and (iv) others. The results indicated that occurrence of (i)-(iii) in the two high evaluation counseling cases showed a similar time-series pattern, and that this time-series pattern corresponded to the temporal pattern of body movement synchrony and the proportion of total duration of utterance/pause. The results suggested that these indicators ((a)-(c)) can act as effective indicators of the evaluation of counseling as well as ordinary dialogue. The present study suggested that the professional skills of a counselor, which have been described qualitatively by experts, can be approached by analyzing client-counselor dialogues empirically.
Abstracts of the 27th International Congress of Applied Psychology

**Rasch analysis of depressive symptoms for Aboriginal and general children in Taiwan**

CHANG, H. T. (National Chiao Tung University), LIU, Y. L. (National Chiao Tung University)

This study used Rasch analysis to examine sex and ethnicity differences on depressive symptoms for children from eastern Taiwan. Subjects were 1189 sixth graders from eastern Taiwan. Thirty percent of subjects were aboriginal children. The Chinese version of the CDI was employed in this study. The reliability of the questionnaire was estimated at 0.87 (which can be similarly interpreted as Cronbach’s α). Infit and Outfit MNSQ were ranged between 0.5 and 1.5, indicating that the Rasch model fitted pretty well. Rasch analysis (1960) with Construct-Map software was performed on CDI to examine ethnicity and sex differences. The results were summarized as follows: (1) The Aboriginal girls (-0.0265) reported the most severe depressive symptoms, and the next were the aboriginal boys (-0.07949) and non-aboriginal girls (-0.23848); finally, non-aboriginal boys reported the less server symptoms; (2) There were no sex and ethnicity differences in the overall patterns of Rasch model. Group and Sex showed non-significant differences in Rasch model; (3) Within item level, ethnicity differences were found in the items such as schoolwork earning and self-determination; (4) Within item level, sex differences were also found in the items such as interpersonal relationship, appetite, negative emotion, appearances, self-determination and lack of interest. This study found that there were no significant sex and ethnicity differences in the overall patterns of the Rasch model. (The melancholy degree is situated between -3 to 1.5). However, within item level, the Aboriginal Children reported higher levels of Depressive Symptoms than non-aboriginal children in the following items: schoolwork learning and self-determination. Girls reported higher levels of depressive symptoms than boys in the following items: self-perception, emotional intelligence, physical attractiveness, interpersonal relationship and problem solving ability. Aboriginal girls reported the highest symptoms than the other groups, particularly in negative emotions (e.g. cry, suicide, repugnant of self).

**Reaction times to visual cues in the driving environment**

TRETEN, P. (Luleå University of Technology), NILSSON, R. (Luleå University of Technology)

The purpose of this paper is to map the driver’s ability to notice and comprehend visual cues in relation to the point of focus at its onset. Ten drivers in a high-fidelity driving simulator drove two15 km driving blocks through rural and urban traffic and the driver’s focal positions were observed and measured at the onset of the visual cue, in which, the time to notice, time to react, and comprehension time where studied to see what type of correlation there was between focal distance and location in the vehicle. Results showed that the visual cues found in the lateral field of view were noticed quicker than in the horizontal which agrees with earlier literature. In more demanding driving situations, e. g. high traffic load in town, are drivers less likely to notice visual cues that are commonly found in the instrument cluster. In conclusion, should visual cues be implemented so that they can be presented adaptively, in accordance to the driving situation. That is, the information can be more effective if intelligently shown to the driver in ways that take into consideration the driving condition and how it relates to the driving situation, thus, helping the drive respond to the information intuitively so that the risk for distraction is minimized.

**Keywords:** driving simulation, visual cues, focal distance, driving situations

**Reasons and functions of creative crisis**

BABAEVA, J. (Lomonosov MSU), KONONEN, A.

In spite of its severity, creative crisis isn’t just a negative phenomenon, it has a range of positive functions and becomes an important stage in
the creator’s personality development. The study sample ($N = 75$) comprised art school students, art school graduates no longer working in the arts, and people established as artists (actors, writers, musicians etc). Participants were interviewed, administered the Rokeach Value Survey (RVS), and were provided with the Symbol of Creativity technique and a modified version of the Life-line technique. The art school students and those established as artists ranked creativity high in the RVS. They demonstrated wide range of creativity interpretations, from specialised professional meaning to general universe fundamentals. Almost all participants, including students, reported that they had experienced creative crisis. The analysis of early childhood events related to creativity specified some preconditions of later creative crises. Participants noted the following reasons for creative crisis: lost sense of creativity, “genre crisis”, loss of creative self, inability to cope with hard life situations, lack of understanding and support from others, etc. In line with our hypothesis, participants noted both negative and positive aspects of creative crises. Positive functions identified include signal, diagnostic, developmental, protective and creative. Positive perception of creative crisis is connected mostly with an understanding of its positive functions. Negative perception depends on subjective evaluation of its possible consequences (including distant ones) and on individual experiencing of emotion. Self-esteem plays an important role in the subjective perception of creative crisis because according to participants, it is easily damaged by crisis. The study results reveal the importance of developing adequate techniques of psychotherapeutic help to people experiencing creative crisis and identify what will help to decrease the amount of psychological breakdowns among representatives of creative professions.

**Keywords:** creative crisis, creativity interpretations, self-esteem

**Reducing collusion with individualism in counselling: Disclosing student’s stories for individual, family, and school benefits**

HAHS, A. (Haileybury College), COLIC, M. (St John’s College, Melbourne)

This presentation focuses on the issue of how to maintain confidentiality in the counselling setting while avoiding collusion with individualism. The aim is to create conversations about this dilemma with other practitioners as well as outlining feedback from high school students that have entered into counselling. Theory informing confidentiality and disclosure arguments will be discussed, and practical tips given on how to share young people’s stories in school settings for both individual and community benefits. Qualitative data was collated via focus groups ($n = 42$) and individual interviews ($n = 10$). Young men ($n = 25$) and young women ($n = 27$) aged between 16 and 18, and from a range of cultural backgrounds, participated in a number of interviews at two Melbourne high schools. Open and closed questions were used in the semi-structured interviews. The oral answers were recorded in a written format. Overall, 48 out of 52 participants stated that they would partly disclose their stories if they viewed it would benefit others. The remaining four participants indicated that they would fully disclose their stories including their identities. All 52 participants said they would like to collaborate in choosing the disclosed information and how it would be disclosed. The participants gave several tips on how their stories could be shared with others, including: professional development to teachers and students, newsletters, posters and multi-media sites. The results also include several quotes from the participants. In conclusion, the findings from the focus groups and individual interviews suggests that the majority of students were willing to partly disclose their stories explored in counselling, especially if it benefited individuals, families and schools. Other schools are encouraged to generate similar discussions to explore how they may be able to reduce collusion with individualism in counselling while honouring confidentiality.

**Keywords:** disclosure in counselling, collusion with individualism, students, confidentiality, sharing stories

**Relation between self perceived employability and career exploration of Chinese University students in Hong Kong**
CHEUNG, R. (City University of Hong Kong)

Self perceived employability of university students attracts the attention of academics and practitioners alike. Building on the work of Rothwell, Herbert and Rothwell (2008) on a scale assessing the self-perceived employability of university students in England and current career exploration research (e.g. Flum & Blustein, 2000), this study aims at exploring the relation between self perceived employability and prior career exploration in the Hong Kong context. A cross sectional quantitative design is adopted. The research aims at obtaining a sample of over 600 final year students from three local universities in Hong Kong, drawn from different academic disciplines like business, social sciences, and engineering. They will be asked to fill in a set of questionnaires which consist of the self perceived employability scale, career exploration survey (Stumpf et al., 1983), as well as demographic variables. Scales have been translated and adapted to use in a Hong Kong/Chinese context. The reliability and validity of the scales of self perceived employability and career exploration as applied to the Hong Kong sample will be presented. Through multiple regressions, the extent to which self perceived employability is explained by prior career exploration for the last months, after blocks of demographic and educational factors are controlled for, will also be analyzed. Conclusions will be made on the extent of prior career exploration as an antecedent of self perceived employability of Chinese University students in the Hong Kong context as compared to other individuals and educational variables, with reference to the local employment situation. Implications on both theory building and career guidance related to employability of university students will be analyzed. Further research on employability of university students in Chinese societies will be suggested.

Keywords: employability perception, career exploration, career exploration, employment, career guidance

Relations between job-related anxiety and job satisfaction according to basic personality traits

ZALEWSKA, A. (Warsaw School of Social Sciences and Humanities)

This study examined the relationship between job-related anxiety and overall job satisfaction from the perspectives of three distinct approaches to well being: ‘bottom-up’, ‘top-down’, and ‘transactional’. The latter model is boosted with elements of greatest significance of the aforementioned two approaches. The models of these relationships, postulated in three theories, were verified in two studies. In each study the level of overall job satisfaction (Work Description Inventory), situational job-related anxiety (4 items from Job Affect Scale) and persistent job-related anxiety (Mood at Workplace Questionnaire) were investigated among 240 employees (120 males). Additionally, neuroticism and extraversion (NEO-FFI) were measured in the first study and in the second study emotional reactivity and activity (Formal Characteristics of Behavior – Temperament Inventory) were also measured. Analyses done from the perspective of ‘bottom-up’ theories showed that two forms of job-related anxiety were negatively correlated with overall job satisfaction in both studies. Data analysed from the perspective of the ‘top-down’ model demonstrated that neuroticism and emotional reactivity affected job-related anxiety and job satisfaction. Moreover, persistent job-related anxiety mediated the relationship between neuroticism or emotional reactivity and overall job satisfaction. However, situational anxiety was a mediator only between reactivity and job satisfaction. Data analyses within the transactional model indicated that overall job satisfaction depended on a second order interaction between job-related anxiety and two considered individual characteristics in both studies (namely neuroticism and extraversion or emotional reactivity and activity). These studies have made an important contribution to the well-being literature by revealing the possible methodological problems and measurement artefacts of ‘bottom-up’ and ‘top-down’ approaches. In addition, they provided evidence supporting the adaptive role of anxiety and individual properties as its moderators.

Keywords: job-related anxiety, job satisfaction, bottom-up, top-down, transactional
Relations of quality of attachment with anxiety and depression in college students

HADDADI KUHSAR, A. A. (University of Tehran), HADDADI KUHSAR, A. A. (University of Tehran), GHOBARI BONAB, B. (University of Tehran)

The aim of the present study was to investigate the relationship between quality of attachment with anxiety and depression in Tehran medical sciences and Iranian medical science universities. To accomplish the stated goal, 513 students from Tehran Medical Sciences University and Iranian Medical Sciences University were selected by means of proportional sampling procedure. Adult Attachment Scale (Collins, 1996) and Symptom Checklist-90R (Derogatis, 1973) were utilized for data collection. Analysis of data with utilization of multiple regression revealed that anxiety and depression of college students can be predicted from the magnitude of their quality of attachment. Moreover, data revealed that students with anxious attachment were higher in depression and anxiety than individuals with a secure attachment style. Individuals who could depend on their partners and find them available were lower in anxiety and depression. The authors concluded that insecure adult attachment was associated with anxiety and depression.

Keywords: quality of attachment, anxiety, depression, Adult Attachment Scale, Symptom Checklist 90-Revised

Relationship between alexithymia and coping strategies in stressful situations

GHOREYSHI RAD, F. (Azarbaijan University of Tarbiat Moallem)

Coping strategies are used to manage conflict and illness and can have adaptive or maladaptive effects on health status. The typical features of alexithymia include difficulty with identifying and describing feelings, difficulty with distinguishing feelings from bodily sensations of emotional arousal, a constricted fantasy life and an externally oriented cognitive style. There is controversy in the literature as to whether alexithymia reflects a deficit in the cognitive processing of emotions or a defensive coping style. Previous studies with clinical populations reported a strong association between alexithymia and a maladaptive (immature) ego defense style. The objective of the present study is to examine the relationship between alexithymia and coping strategies (three general and two sub-styles) to cope with stressful situations in a group of non-clinical populations students. The study sample consisted of 200 participants aged between 19 and 21 years enrolled in the academic year of 2008 to 2009 in Tarbiat Moalem University of Azarbayjan in Iran. The Toronto Alexithymia Scale (TAS-20) was used to measure alexithymia, along with the 48-item Coping Inventory (Endler & Parker, 1990), to measure coping strategies in stressful events. The results reveal the significant difference between females’ and males’ coping strategies, and suggest that self-rated alexithymia and adaptive coping strategies are generally inversely related.

Keywords: alexithymia, coping strategies, stressful situations, gender differences, emotional processing

Relationship between attachment styles and sexual behaviors in adults

GHOBARY BONAB, B. (University of Tehran), FAGHIHI, A. (University of Qom)

The aim of the current study was to collect and analyze published studies related to attachment and sexual behaviors. In the current study, relevant articles in the field of psychology in relation to attachment and sexual behaviors have been reviewed. The sample consisted of 27 electronic sites in the field of psychology which were reviewed. Meta-analysis was used to summarize the results of the review. The results of the current meta-analysis revealed that individuals with an insecure attachment are not exhibiting functional sexual behaviors, and they are not getting satisfaction from their own behaviors. Moreover, individuals who have been abused sexually during their childhood, have insecure attachment styles. These individuals feel low in self worth, and have lost their trust in others as an available, responsive, and responsible attachment figures. Review of the literature in the field of attachment revealed
that individuals with anxious and avoidant attachment styles demonstrate specific patterns of sexual motives and behaviors. Individuals with an anxious style use their sexual behaviors as an instrument to get acceptance, affection and security. Unfortunately, these motives make individuals vulnerable to deviant and dysfunctional sexual behaviors. These tactics backfire most of the time by damaging intimacy in sexual relations, promoting mental dissatisfaction, and causing psychological divorce in the long run. Individuals with an avoidant approach show problems in commitment and maintaining an intimate relationship with their partners. Their discomfort with functional social relations with others may lead them to dysfunctional sexual behaviors including masturbation and self-stimulation. In contrast, individuals with secure styles tend to show functional and satisfactory relations with the partners. Their sexual behavior is enhancing their satisfaction, intimacy and commitment.

Keywords: attachment style, marital satisfaction, sexual behaviour, intimacy, affection in relationships

Relationship between Chinese workers’ work values and their attitudes toward marriage and childbirth

WANG, C. K. (Soochow University), LO, K. Y. (Soochow University)

The purpose of this study is to examine the relationship between Chinese worker’s work value and their attitude toward marriage and childbirth. Chinese people traditionally cherish marriage and childbirth. However, many young workers in China and Taiwan tend to reject marriage and childbirth, which is having a strong social and financial impact on these countries with growing ageing populations. It is hypothesized that those who hold non-traditional marriage and childbirth attitudes should emphasize individual oriented work values more and emphasize social oriented work values less, than those who have traditional marriage and childbirth attitudes. Based on Young’s Bicultural Self Theory, the authors developed Chinese indigenous work end value, and instrumental value, scales and surveyed 1031 Chinese and Taiwanese urban workers. Respondents were clustered into traditional or non-traditional marriage and childbirth believers based on cluster analysis of their responses to three questions about intentions of keeping single, cohabiting without marriage and marriage without children. A discriminant analysis suggested that male traditional marriage and childbirth believers emphasized competition, aggression, safety and security more, and emphasized autonomy and flexibility work values less, than male non-traditional marriage and childbirth believers. Female traditional marriage and childbirth believers put less emphasis on self-competence, autonomy, flexibility, acceptance of the mandate of heaven, responsibility and discipline, but put more emphasis on social respect, competition, aggression, forgiveness and humble work values. Results support the hypothesis. Workers who have more individual oriented work values tend to hold non-traditional marriage and childbirth attitude. Those who put more emphasis on social oriented work values tend to have traditional marriage and childbirth attitudes.

Keywords: work values, marriage, traditional versus non-traditional values, individual-oriented values, social-oriented values

Relationship between home environment and self-derogation among higher secondary school students: A study in a developing country

GEORGE, S. (Monash University)

The focus of the study is the relationship between home environment dimensions and self-derogation among adolescents in India. Results were derived from a survey with 400 Grade 11 students from ten secondary schools in Kerala state, India. The proportionate random sampling technique was followed to select the sample, which consisted of three pairs of subsamples: male-female, rural-urban, and government-private school. Self-derogation data were collected by administering an established scale (Raj, 1991). A 50-item questionnaire was developed to collect data regarding four dimensions of home environment: material facility, parental attitude, study habits, and family relations. Pearson correlations measured relationships at the whole sample and
subsample levels. Further tests of significance of difference were adopted to test whether correlations were significantly different among the three pairs of subsamples. The study revealed a high negative correlation between home environment overall, and self-derogation, within the whole sample. The correlation analyses involving the four dimensional components of home environment established negative substantial relationships between self-derogation and each of study habits, parental attitude and family relations; but a low, negligible relationship with material facility. The strengths of these correlations were significantly different within the full sample. Correlation coefficients significantly differed between male-female subsamples with girls showing stronger relationships of self-derogation with home environment. Although boys showed a negative substantial correlation ($r = -0.50$), the other subsamples showed significantly stronger negative correlations (range, $r = -0.87$ to $-0.92$). Correlations also differed significantly between rural-urban subsamples with urban students showing stronger correlations, but there were no significant differences in correlations between the private-government subsamples. The study establishes that self-derogation, which is detrimental to effective development, is associated largely with unfavourable home environment dimensions relating to parental attitudes, family relations, and study habits; but not to material facility. It reveals that emotionally congenial family interactions and a cognitively stimulating environment are essential for healthy overall development of a positive self-concept during adolescence.

**Keywords:** home environment, self-derogation, family relations, adolescent development, parental attitudes

**Relationship between procrastination and counterfactual thinking: Achievement motivation as mediator**

FANG, P. (Capital Normal University), JIANG, Y. (Beijing Sport University), MA, Y. (Capital Normal University)

Procrastination appears cause difficulty because sometimes it results in poor performance and reduced physical/mental health. The present study investigates the relationship between procrastination and its related factors. The study will provide a theoretical basis and empirical support for correcting procrastination behavior of students. The experimentation and questionnaire are used on 234 university students. The results indicate that individuals who use downward contrast counterfactual thinking feel more relaxed, and those with upward assimilation counterfactual thinking feel more anxiety. Different counterfactual thinking has different effects on procrastination. Furthermore, achievement motivation affects the influence of counterfactual thinking on procrastination. From the study, it is concluded that counterfactual thinking can influence procrastination. Achievement motivation mediates the relationship between counterfactual thinking and procrastination.

**Keywords:** procrastination, counterfactual thinking, achievement motivation, poor performance

**Relationship between sexual function and marital adjustment in married women and their husbands**

ALIAKBARI DEHKORDI, M. (Payame Noor University)

The aim of present research is to identify the relationship between sexual function with marital adjustment in married women and their husbands. For most of adults, happiness in life is more dependent on successful marriage and satisfactory marital relations than life’s other aspects. Desiring sex that can provide extreme satisfaction will have an important and fundamental role in success and constancy of family foundation. By identifying sexual function and its components can result in sexual satisfaction and ultimately marital satisfaction that has important effects on a couple’s adjustment. In this research, 60 couples that were resident in Tarbiat Modarres University’s married dormitory were selected by random sampling. The necessary information was collected by a questionnaire of women’s sexual function (FSFI; Rozen, 2000) and a marital adjustment questionnaire (Spainer, 1976). These two tests have high reliability and validity. To analyze data statistically, Pearson’s correlation coefficient and multivariate regression were
employed. The findings are that there is a significant positive correlation between women’s sexual function and its components with women and their husbands marital adjustment. Also, women’s sexual function components explain 25% of their marital adjustment variance and 34% of their husband’s marital adjustment variance. In conclusion, in regard to the results of the research that sexual function has role in predicting marital adjustment, it seems that by paying attention to women’s sexual function quality, providing correct information, necessary training and enhancing the rate of women sexual function, we can help to their life constancy and marital adjustment.

Keywords: marital adjustment, married women, sexual function, life constancy

Relationships between quality of life, self-efficacy, self-esteem, food craving, mood and weight-loss in an older obese population

CORSER, D. (University of the Sunshine Coast), STATHAM, D. (University of the Sunshine Coast)

In Australia, the greatest increase in obesity has occurred in the 55 to 64 age group. Obesity is directly related to several health issues and costs an estimated $21 billion per year. Also, it has been identified as a national health priority. This study examines psychological issues influencing weight loss in an older obese population and aims to evaluate the efficacy of a short-term multi-disciplinary weight loss program. Participants were recruited through a private rehabilitation centre and were required to have a Body Mass Index greater than 30, aged 50 years or over, be medically stable, well enough to exercise, and not participating in another weight loss program. Three groups participated: (1) a treatment seeking group, (2) a non-treatment seeking control group, and (3) a waiting list control group. Psychological influences on weight loss were assessed with the Obesity-Related Well Being Questionnaire, Weight Efficacy Life-Style Questionnaire, Food Craving Experience Questionnaire, Rosenberg’s Self-Esteem Questionnaire, and the Depression Anxiety Stress Scale. Each group completed the battery and was weighed initially and six weeks later. The treatment group was also tested at three, six and twelve months. The treatment group participated in a six week structured group program, meeting weekly with psychologists, dietitians, exercise physiologists, occupational therapists, and physiotherapists. The psychology component followed a cognitive-behavioural therapy model, aiming to deliver education and training in several areas relevant to obtaining and maintaining weight-loss. Data collection for this project is currently in progress. Collection will be finalised and data analysed before July 2010.

Keywords: weight loss, body mass index, self-esteem, obesity, food craving

Relevance of assessment centres in competency assessment and importance of handling post-assessment data

GUPTA, S. (Institute of Management Technology)

Competencies are statements about the characteristics that result in effective, superior performance in a job. Competencies are vital for understanding human potential and hence assessing them becomes important. Assessment Centres have been widely used for assessing competencies which are identified by an organization, and research shows that although predictive coefficients of Assessment Centres are generally high, some Assessment Centres have low predictive validity. In fact the observed validity coefficients of Assessment Centres reviewed in one research ranged from -.25 to .78 (Gaugler, Rosenthal, Thornton & Bentson, 1987). These kinds of results affect their usage by practitioners. This research is aimed at answering two questions including (1) Are Assessment Centres essential for assessing Competencies, given their high cost factor? Can competencies be assessed by other methods or combinations of a few methods for cost-effective results? (2) If Assessment Centres are essential then how can they be made more valid and effective so that greater number of organizations can benefit from them? This paper carries out a critical analysis of the relevance of Assessment Centres by interviewing professionals in a number of organizations who are responsible for Assessment Centre
initiatives. An attempt is made to arrive at a realistic picture of how much Assessment Centres are being used in India by Indian and Multinational organizations and whether the high costs involved justify their use. Results support the general research conclusion that Assessment Centres are highly effective tools of assessment but require careful implementation of the processes. Considerable care and attention should be given to how the results will be used and how the results will not be used. Proper handling of post-assessment data is very critical and can go a long way in creating job-related, fair and legally defensible Assessment Centre programs. Final conclusions are yet to be drawn as interviews are still being conducted.

**Keywords:** competence, assessment centres, human potential, competency assessment

**Religious Community Mass Syndrome (RCMS) Huj And Simhastha: Demographic and attribution analysis**

SINGH, A. P. (Government Maharani Laxmi Bai Girls Postgraduation College)

Community Mass Syndrome (CMS) was first reported in the fifteenth century as “Tarantism” in the context of normal behavior in Germany and, in the rest of Europe, it was known as “St. Vitus’s dance”. It was similar to the ancient orgiastic rites used to worship the Greek God Dionysus. The Lady Guadalupe Festival has been celebrated since 1531 in Mexico where millions of people participate in religious mass, discussion, music, dance, parties and relaxing. The Feast of Fools was a very popular medieval celebration for Roman Catholics. It was not categorized under mass psychogenic illness. Community Mass Syndrome is being interpreted as normal behaviour where hundreds to millions of people of more or less the same community are motivated towards a certain type of behaviour acceptable in society with one, or more than one, common goal (Singh, 2005). One of the types of CMS is Religious Community Mass Syndrome. The aim of the present study is to investigate the difference between demographic structure (age and gender) and attributions among the participants of Huj and Simhastha Religious Community Mass syndrome. The Simhastha has a history of eight hundred years of participants including pilgrims, devotees and participants from various communities assemble. In Huj, since 12th century, hundreds to thousands of Muslim pilgrims have participated in Mecca in Saudi Arabia, the gigantic celebration of faith. The present study involves 200 participants (100 male and 100 female), stratified randomly selected using a two-by-two design of gender (male/female) and age (of three age groups 20-plus, 30-plus and 50-plus), from India and who participated in Simhastha and Huj, in order to find out the effect of gender and age group on attribution. A questionnaire was prepared to assess the attributions. The first part of study focuses on gender and age and the second on type of attributions behind mass syndrome. The results are based on an analysis of variance and qualitative analysis and reflect the difference between age, sex and state and trait attributions between the sample of Huj (Muslim) and Simhastha (Hindu) Religious Community Mass Syndrome. There was a difference amongst the participants’ demographic picture and attributions of RCMS of Huj (Muslim) and Simhastha (Hindu) participants.

**Keywords:** religious behaviour, community mass syndrome, trait attributions behind mass syndrome, celebrations of faith, Indian community celebrations

**Reports of wins and risk taking: An investigation of the mediating effect of the illusion of control**

MARTINEZ, F. (university of Lyon)

Two experiments examined the relationships between the knowledge that another person has won in a gamble, the illusion of control and risk taking. The first study thus aims to test a causal model where the illusion of control is a mediator of the effect of reports of others’ wins on one’s risk-taking behavior. The second experiment examined what motivated the increase in participants’ personal illusion of control when they knew the gain of another player. In a first study, 24 participants, randomly assigned to one of two groups and played a computer-simulated French roulette game individually. In the experimental group, participants were informed of the amount won by the previous winner. In the control group, this information was omitted.
In a second study, 36 participants were randomly assigned one of three groups. The first experimental group and the control group were identical to the groups in Experiment 1. In a second experimental group, participants were still told of another person winning but, in addition, they were informed that this person acknowledged that her win was fortuitous. Results from the first experiment validated a causal model where the knowledge of another person's gain increases the illusion of control, measured with betting times, expectancy and self-reports on scales, which in turn encourages risk taking. Results from the second experiment confirmed that the increase in risk taking observed upon learning that another player had won in a gamble was contingent on the belief that this previous winner controlled the outcome of the gamble like in a skilled task. Reports of wins are interpreted as a skill-related cue. When participants thought that the previous winner did not control the outcome of his gamble, the knowledge of his gains no longer increased participants’ risk taking. Mediation analyses replicated results observed in the first experiment. Thus, Experiment 2 demonstrated that it is the belief that the previous winner could exert control over the outcome of the gamble that presumably led participants to experience higher levels of illusion of control and take higher risks when gambling in the knowledge that the previous gambler had won.

Keywords: gambling, risk taking, illusion of control

Research on the impact of communication openness to organizational commitment based on superior-subordinate relationships

LIU, Y. (Renmin University of China), HUANG, X. (Renmin University of China), DING, G. (Renmin University of China), YAN, S. (Renmin University of China)

This research is established in Chinese settings and, by measuring a sample of 315 employees from Chinese enterprises, it attempts to examine the impacts of communication openness on organizational commitment and the mediating effects of leader-member exchange and Guanxi in this process. Also, we explored the impacts of age, education, position level on these variables. We applied Simple Random Sampling by random sampling and sending questionnaires via e-mail to improve recovery of our questionnaires. Measurements applied in this study are from western researchers’ literature or developed in the Chinese context as follows: Communication Openness Measure Scale, developed by Rogers (1987,) for Communication Openness; JOM scale, developed by Liden & Maslyn (1998), for Leader-member Exchange (LMX); Guanxi with Supervisor Scale, developed by Kenny Law (2001), for Guanxi; and, an 8-item scale by Meyer & Allen (1997), for Organizational Commitment (OC). The above variables are measured by a 5-point Likert scale ranging from 1 = “strongly disagree” to 5 = “strongly agree”.

Statistical methods in this paper mainly include: Reliability and Correlation Analysis and Regression analysis. The main findings are showed as follows: firstly, communication openness is significantly related to LMX, Guanxi and organizational commitment; secondly, Guanxi fully mediates the relationship between communication openness and organizational commitment; and, thirdly, LMX doesn’t mediate the relationship between communication openness and organizational commitment directly. This research finds that personal Guanxi between supervisor and subordinate plays an important role in Chinese enterprises. The suggestions for Chinese enterprises from the result are as follows: Chinese enterprises should build effective formal communication networks to ensure that any information can be transmitted without obstacles; and, supervisors should be more open to subordinates, especially in strengthening the initiative of communication. In addition to formal LMX, supervisors need to keep good personal Guanxi with subordinates and spend time showing care to them, in order to win subordinates’ commitment and increase employees’ organizational commitment.

Keywords: Chinese enterprises, leader-member exchange, communication networks, employee organizational commitment, superior-subordinate exchange

Risk and resilience for mental health problems in childhood and early adolescence: Evaluation of a risk screening tool
HAMMOND, S. (Australian Catholic University), HUDGSON, A. (Australian Catholic University), VONARX, R. (Bell Primary School)

This study investigated the psychometric properties of the Darebin Risk Assessment Screening Tool (DRAST), a newly developed screening tool designed to assist teachers in identifying students who may be at risk for developing social, emotional and behavioural problems. The DRAST covers both risk and protective factors. The primary aim of this study was to establish reliability and validity to support the use of the DRAST within schools. The sample consisted of 206 students in grades one to six, recruited from primary schools in a Northern metropolitan Melbourne schools network. For 147 students, data consisted of pre-existing anonymous DRAST screening assessments only. For the remaining 59 students, parents completed a demographic questionnaire and the Strengths and Difficulties Questionnaire (SDQ) for their child and classroom teachers completed the DRAST, SDQ and Student Behavior Survey (SBS). Principal component analyses revealed a four factor structure for both risk items and protective items, with adequate reliability observed for the total risk and protective scores, and for most of the newly derived factors. Significant relationships were found between the DRAST factors and parent and teacher ratings of problems, adjustment and resources. Protective factors were found to be more significant predictors of problems or adjustment than risk factors. Overall, the results indicate that the DRAST is a reliable and valid screening tool, as the total risk and protective scores were found to be adequate for identifying students at risk for developing problems. However more refinement of the tool is needed, especially for risk factors. Future research with a larger sample is needed to examine additional psychometric properties such as test-retest and inter-rater reliability and to develop normative data.

Keywords: risk factors, resilience, risk assessment, children's mental health, adolescent mental health

BERNADET, S. (Laboratoire de Psychologie EA 4139), MICHEL, G. (Laboratoire de Psychologie EA 4139)

Over the past few years, prevalence of risk-taking behaviors has not remarkably increased but new dangerous practices seem to have emerged among adolescents in France (for example, asphyxial games, binge drinking). Several researches considered individual factors leading adolescents to seek risky situations. However, few of them came to distinguish profiles of risk-taking depending on the type of declared dangerous practices. The objectives were to distinguish different risk-taking profiles among adolescents and specify involved individual features (personality, perceived stress, coping strategies) in each profile. Two hundred and seventy six middle and high school students, aged between 12 and 16, participated. Self-assessment included an Exploratory Questionnaire on risk-taking behaviors, Junior Temperament and Character Inventory (Luby, 1999), Coping Across Situation Questionnaire (Seiffge-Krenke et al., 2008), Children Depression Inventory for Children (Kovack & Beck, 1977), and the State Trait Anxiety Inventory for Children (Spielberger, 1983). Preliminary results underline three profiles of risk-taking. Of the adolescents, 26.1% reported at least one antisocial behavior, 31.2% declared at least one antisocial behavior and at least one substance use behavior and 10.5% reported at least one antisocial behavior associated with at least one substance use behavior and one dangerous game. High depressive and anxious symptomatology, high novelty-seeking, use of avoidant coping strategies as well as low individual and social maturity were associated with adolescents engaging several forms of risk-taking behaviors. Likewise in regards to Jessor’s General Syndrome of Deviance, this study shows that selected individual factors might be indicators of a general syndrome of risk-taking. Adolescents presenting this kind of psychological functioning would be more likely to seek risky situations in several fields in their life. These results would help to define well-focused preventive strategies.

Risk taking behaviors in adolescence: Different psychological profiles
Road-rail level crossings: Expectations and behaviour

EDQUIST, J. (Monash University Accident Research Centre), RUDIN-BROWN, C. (Monash University Accident Research Centre), LENNÉ, M. (Monash University Accident Research Centre), NAVARRO, J. (Monash University Accident Research Centre)

Road-rail level crossings are a dangerous point in the rail network, as the relatively controlled environment of the railway is opened to the unpredictable behaviour of road users. One potentially dangerous interaction is a mismatch between the warning signals provided, and road users’ expectations of warnings. Little is known about how road users expect crossing signals to behave, particularly when the crossing controls do not work as anticipated. The behaviour of 52 road users was examined in a driving simulator experiment. Participants performed several drives containing four railway crossings, including one in which the crossing warning signals did not perform as expected. After the drives, participants were interviewed about their behavior in the experiment, and when driving in the real world. Participants’ expectations of the warning times provided by railway crossing signals were generally in accord with standard practice warning times. The appearance of an alternative warning system was generally well understood, and may offer safety benefits as judged by participants’ predicted behavior. However, participants’ descriptions of how they would behave at crossing with malfunctioning signals did not match their behavior when they encountered this situation in the simulation. There is scope to improve the information provided to road users at road-rail level crossings, and their understanding of the behaviour required of them.

Keywords: road-rail level crossings, unpredictable driving behaviour, railway crossing signal warning times, driving simulation, road users

Role of empowerment on self-efficacy and organizational effectiveness in South Korean organizations

KIM, S. (Ajou University), YOU, B. (Ajou University), KIM, D. Y. (Ajou University)

Empowerment, defined as providing employees with autonomy in tasks, positively influences job satisfaction and organizational effectiveness (Spreitzer, 1999). Thus many companies have tried to systemize empowerment. However, empowerment may not always have positive outcomes if it does not promote the employee’s belief that they are capable of performing adequately to attain goals (i.e. self-efficacy). Additionally, empowerment may be influenced by the effects of organizational characteristics, such as the level of hierarchical structures and bureaucracy in which employees may not experience the positive effects of empowerment due to the lack of latitude in their role within the organization. It was thought that public organizations would be most subject to such effects, followed by large, then medium-sized, organizations and that the positive effects of empowerment would be most apparent in medium-sized organizations. This research aims to see whether self-efficacy would mediate the relationship between empowerment and organizational effectiveness, and between empowerment and job satisfaction, and whether these mediation effects would differ by organization type. Two-hundred and seventy nine employees (96 from medium-sized, 60 from large, and 123 from public organizations) participated in the survey. They reported on empowerment, self-efficacy, job satisfaction, and organizational effectiveness variables (i.e. organizational commitment, organizational citizenship behavior and innovative behavior). Self-efficacy fully mediated the relationship between empowerment and job satisfaction, and between empowerment and organizational effectiveness in both medium-sized and large organizations, but partially mediated in the public organization. Analysis of the moderating effect of organizational type revealed that, compared to public organizations, the indirect effect of empowerment on job-satisfaction and organizational effectiveness was stronger and more positive in medium-sized organizations. The large organization did not show significantly different relationships compared to the other organizations. Data showed that self-efficacy was a mediator of the relationships between empowerment and job satisfaction, and between empowerment and organizational effectiveness variables. Also, increasing empowerment in medium-sized organizations
may influence organizational effectiveness and job satisfaction to a greater extent than in public organizations. Therefore, organizations may need to deliberate the level of empowerment given to employees in light of the resulting effects on self-efficacy and the characteristics of the organizational structure.

Rumination and depression: The effects of a depression attention control training program on reducing rumination and depression

SALEHI FADARDI, J. (Ferdowsi University of Mashhad), BAGHERINEJAD, M. (Ferdowsi University of Mashhad)

The goals of this research were to investigate: (a) the relationships among rumination, anxiety, and depression in a sample of Iranian students, (b) the relationships between negative attentional bias with depression and rumination; and (c) the efficacy of a Depression Attention Control Training Program (DACTP) on reducing negative attentional bias, rumination, and depression. The research included three studies. In the first study, participants (N = 119; 37% male) completed Beck Depression Inventory-II (BDI-II), Ruminative Response Scale (RRS) and Beck Anxiety Inventory (BAI). In the second study, participants (N = 52; 20% male) completed the BDI-II, RRS, BAI and Depression-Stroop Test. In the third study, participants (N = 16; 100% female) from the previous study who obtained the highest scores on both rumination and depression were randomly allocated to a training (experimental) or a control group. The experimental group received four sessions of training with the DACTP. All participants completed the BDI-II, RRS and Depression Stroop Test at pre- post-training and a 70-day follow-up. From the first study, the results of a hierarchical regression analysis indicated that, after controlling for age, gender, and anxiety, increases in rumination were associated with increases in depression. From the second study, the results indicated that, (a) compared to non-depressed participants, depressed participants showed less attentional bias for positive- and concern-related stimuli; (b) negative attentional bias was positively related to depression, but the relationship was limited to depressed females; (c) positive- and concern-related attentional bias were negatively related to depression and rumination; and (d) increases in negative attentional bias were associated with increases in rumination, even after age, gender, education, classic Stroop test, anxiety, and depression had been controlled. From the third study, the results indicated that participants in the DACTP group showed reductions in post-training negative attentional bias and rumination (reductions in depression approached significance; p = .06). The findings support the role of attentional bias in rumination and depression and suggest the feasibility and benefits of depression attention control training in reducing rumination and depressive mood.

Keywords: Rumination, Depression, Depression attentional control training, Beck Depression Inventory, Anxiety

Rumination and gender differences in depression (response style approach)

JANATIAN, S. (University of Isfahan), YOUSEFI, Z., JANATIAN

The purpose of this study was to examine the etiology of the difference between males and females in the prevalence of depression among students at the University of Isfahan. The statistical population was all students at the University of Isfahan. The sample consisted of 100 students (60 females and 40 males) that were randomly selected from all the campuses who all responded to a depression scale. The results of variance analysis showed that there were not any differences in problem solving and rumination between female and male students but there was a significant difference between females and males in distraction (p < 0.05). From the results, it can be concluded that females could experience more depression than males. It seems while doing problem solving, they do rumination, and that is the reason they experience more depression than male students.

Keywords: depression, gender differences, distraction, rumination, problem-solving
Safety climate in the construction industry – Interaction and influence of levels of climate in a dynamic industry

HARTLEY, R. (Business School, Loughborough University), CHEYNE, A. (Loughborough University)

The concepts of safety climate and culture are now applied extensively within many industries to explain risk taking behavior. Therefore, the development of a strong positive safety culture is a goal for many organizations. However, such a goal may be problematic within a dynamic construction industry where employees and site of work can change frequently. In an attempt to address this potential problem, this research aims to elucidate the complex nature of safety climate within the construction industry and see how an interaction between climates and hazard exposure can influence safety behavior and workplace accidents. Questionnaires were completed by employees of a large company within the construction industry. The questionnaire used a number of established and specifically developed scales to assess the influence of various levels of climate and hazard exposure on safety behavior and workplace accidents. The questionnaire was sent to 2250 employees. Responses were obtained from 983 employees, a response rate of 43.7%. The scales were subjected to confirmatory factor analysis, before modeling the relationships between variables using Structural Equation Modeling. A model was developed demonstrating the influences of different climates and hazard exposure on worker risk taking behavior. The model proposes that organizational climate and professional climate, influence coworker climate (colleagues and supervisors) and this, in turn, influences the risk taking behavior of workers. This model explains 45% of the variance in individual risk taking behavior. Construction industry safety climate is a complex, fragmented phenomenon. Worker behavior is influenced by a number of climates within the workplace, with organizational climate, co-worker climate and professional climate all influencing risk taking behavior. The findings have implications for organizations trying to manage both climate and risk taking behavior; the construction environment provides more of a challenge than more stable workplaces. By understanding the influence of different cultures in this sector, organizations will be more able to influence and manage them.

Keywords: safety, construction industry, work environment, risk taking, organisational climate

Season of birth and mood seasonality

MILFONT, T. L. (Victoria University of Wellington), TILYARD, T. (Victoria University of Wellington), NATALE, V. (University of Bologna), TONETTI, L. (University of Bologna)

Previous research has shown that mood seasonality is modulated by season of birth (Natale, Adan, & Chotai, 2007). Italian and Spanish individuals born during spring or summer had significantly higher mood seasonality than people born during autumn or winter. Significant gender differences were also observed, with female participants showing higher mood seasonality than males. The present paper reports preliminary data investigating the robustness of these findings by considering New Zealand participants, who live in a different hemisphere and experience different seasonal patterns than participants from previous studies. A study was conducted with 636 New Zealand-born participants with ages ranging from 18 to 30 years old (M = 22 years, SD = 3.6; 68.7% female), who completed the Seasonal Pattern Assessment Questionnaire (Rosenthal et al., 1984), plus socio-demographic questions. A two-way ANOVA was conducted to examine the effects of month of birth and gender on mood seasonality, with age entered as a covariate. A significant effect of gender was observed (F(1, 597) = 43.6, p < .001), with females scoring higher than males. A marginally significant effect of month of birth was also observed (F(11, 597) = 1.71, p < .07), with mood seasonality being higher for those born in August (winter) than in February (summer). No significant interaction was found between month of birth and gender. In line with Natale et al.’s (2007) findings, we observed a significant main effect for gender, indicating that women experience greater mood seasonality than men. In contrast, these preliminary results showed only a marginally significant main effect for month of birth on mood seasonality, and New Zealand participants born during a winter month had significantly higher mood seasonality than...
those born during a summer month. This reverse pattern of findings may be due to differences in climate features in New Zealand, such as different hemisphere, rain and wind patterns. Additional studies with larger samples from the southern hemisphere are necessary to fully understand the influence of season of birth on mood seasonality.

Keywords: mood, season of birth

Secondary school teachers’ job satisfaction in relation to their organisational climate

YADAV, R.S. (Kurukshetra University), MALIK, V. (Aashta College of Education, VPO- Damla), YADAV, B.S. (Kurukshetra University)

The aims of the current study were to examine the relationship between job satisfaction and organisational climate of secondary school teachers; and to study the job satisfaction differentials of secondary school teachers at different levels of organisational climate. A descriptive survey method was used and the sample consisted of 120 teachers. The hypotheses formulated were: (1) there exists no significant positive relationship between job satisfaction and organisational climate of secondary school teachers; and (2) there exists no significant difference in job satisfaction of teachers at different levels of organisational climate. The study was delimited to Kurukshetra district of Haryana State (India) and six secondary schools. Tools used were the Job Satisfaction Questionnaire (JSQ) for teachers by Parmod Kumar and D.N Mutha, and Organisational Climate by M.L Sharma. Correlation coefficients and t-tests were used. The study revealed that (1) job satisfaction of secondary school teachers was found to have no significant relationship with organisational climate and its different dimensions; and (2) no significant difference was found in the job satisfaction of teachers belonging to different organisational climate groups. Job satisfaction plays an important role in an individual’s life and it depends on many factors. Job satisfaction is the results of various attitudes possessed by an employee towards his/her job. These attitudes are related to factors such as wages, conditions of work, advancement opportunities, prompt settlement of grievances, fair treatment by employers and other benefits. Organisational climate results from the cumulative effect of ways in which the principal interacts with teachers; and the way teachers interact with each other and with the principal. Job satisfaction and organisational climate of teachers are of paramount importance and have bearing on their teaching performance. Therefore, needed facilities should be created in schools and teachers should also be provided with the required facilities.

Keywords: secondary school, teachers, job satisfaction, organisational climate

Self, other, and past experience in the process of perspective taking

GERACE, A. (Flinders University of South Australia), DAY, A. (Deakin University), CASEY, S. (University of South Australia), MOHR, P. (University of South Australia)

Perspective taking, the main cognitive component of empathy, is considered to be a significant part of human interaction. Within counselling and clinical practice, perspective taking has a particularly important and complex role to play in the clinician-client relationship. However, despite extensive investigation into the outcomes of this construct (for example, sympathy, altruism), the process by which people take another’s psychological point of view has received comparatively little attention. The purpose of this study was to investigate what the individual does when attempting to take the perspective of another person. Specifically, the aims were to identify the specific strategies people use to accomplish this task, to consider how and why these strategies are chosen, and the relationship between the strategies and subsequent outcomes. Twelve community volunteers were provided with an induction to recall and describe an example of their own perspective-taking experience. A semi-structured interview guided participants through their recollection. Adopting an interpretive phenomenological approach, analysis resulted in the generation of several themes relevant to both the perspective-taking process and the wider empathic experience. Two superordinate process themes emerged, use of other-
information and use of self-information, from which several subordinate themes emerged. Of particular interest were those falling under the use of self-information theme, which included the use of past experiences, and a theme of shifting perspectives, which involved simultaneous consideration of self and other perspective. These strategies were considered important determinants of the effort required to apprehend another’s perspective. While past experience was related to greater ease of the process, the latter strategy often resulted in some difficulty for the participant, as they had a unique, and in some cases conflicting, perspective to that of the other person. Implications for understandings of empathy more generally, and application to counselling and clinical areas are discussed. In particular, the advantages and challenges which result from the ways in which the person undertakes the process of perspective taking are focused upon.

Keywords: perspective taking, empathy, counselling practice, psychological point of view, shifting perspectives

Self-concept of secondary school students in relation to their classroom environment, academic achievement and gender

YADAV, R.S. (Kurukshetra University), SINGH, P. (Kurukshetra University)

The study was conducted with the following objectives: (1) to discover the relationship between self-concept and the classroom environment of students; (2) To examine the relationship between self-concept and academic achievement of students; and (iii) to investigate the difference between self-concept of male and female students. Accordingly, the following hypotheses were formulated: (i) there exists significant differences between self-concept and the classroom environment of students; (ii) there exists significant differences between self concept and academic achievement of the students; and (iii) there exists significant differences between self-concept and gender of the students. A descriptive survey method was used. The sample consisted of 100 students (50 males and 50 females) selected on a random basis from four schools. The Self-Concept Scale of Sarswat, and the Classroom Environment Scale of Abdur Rehman were used. Academic achievement was measured using marks from the annual exam of the IXth standard. Correlations and t-tests were used to analyse the data. The study revealed that students’ self-concept and classroom achievement were significantly correlated. It indicated that a better educational/classroom environment led to higher self-concept among students. Similarly, self-concept and academic achievement of students were significantly correlated. Boys had a significantly higher self-concept than girls.

Keywords: self-concept, secondary students, classroom environment, academic achievement, gender

Self-control, burnout, psychological well being and integrity

TRIANI, R. (Universitas Katolik Indonesia Atma Jaya)

This research aims to find out the connections between Self-control, Burnout and Psychological Well Being as independent Variables and Integrity of employees as a dependent variable. Robbins (2003) stated that integrity refers to honesty and trust, and is a positive hope that someone will not take advantages of other party. Two factors that influence integrity are personal and social factors. The questionnaire was constructed based on Edward Hoffman questionnaire which consists of overt and covert integrity. Self-control refers to the ability to keep firm control over one’s own behavior. This questionnaire was constructed based on four dimensions of Self-control by Baumeister et al. Burnout is a syndrome resulting from prolonged exposure to stress, consisting of physical, emotional, and mental exhaustion plus feelings of lack of personal accomplishment. The questionnaire was constructed based on Maslah Burnout Inventory. Psychological Well Being was measured by Ryff Psychological Inventory that covers six areas of well-being: Autonomy, Environmental Mastery, Personal Growth, Positive Relations with Others, Purpose in Life, Self-Acceptance. This research was non-experimental research. For hypothesis testing, the researcher used the Pearson Product Moment Correlation method. The validity, reliability and hypotheses testing in this research
involved use of the SPSS 15.0 computer program. The results showed that there are connections between Self-control, Psychological Well Being and Integrity, but there is not any connection between Burnout and Integrity.

Keywords: self-control, burnout, psychological well-being, integrity, Ryff Psychological Inventory

Self-regulation and activation of hierarchical goals with feedback changes

TSUCHIYA, K. (Nagoya University), YOSHIZAWA, H. (Gifu Shotoku Gakuen University), NAKAJIMA, M. (Mie University), YOSHIDA, T. (Nagoya University), HARADA, C. (Nagoya University)

Previous research has indicated that goals affect the individual’s adaptation (e.g., Deci & Ryan, 2000), and that the activation of specific goals can lead to success at self-regulation (e.g., Bargh, 2006). However, few studies have explored how goal activation both affects and reacts to decision making in the real world. In the present study, based on the supposition of hierarchical structure of goals (e.g., Austin & Vancouver, 1996), we aimed to identify goals that vary with feedback change and goals that contribute to self-regulatory success. Participants (n = 461) were presented with one of four different vignettes involving situations where they needed to regulate their impulses (i.e., buying, eating, antisocial behavior, and interpersonal conflict). Each participant was presented with five scenes from one vignette (one neutral scene and four different feedbacks). For each scene, participants completed the superordinate and subordinate goal scale that was developed based on the taxonomy of human goals (Ford, 1987), and completed their behavioral response whether they would regulate their impulse or not. A series of ANCOVAs revealed that the activations of specific goals varied by feedback. A series of ANCOVAs, in which the independent variable was whether participant succeeded in self-regulation, revealed that the activation of specific goals differed whether one achieved self-regulatory success. Specifically, the goals that affected the success of self-regulation did not necessarily correspond to the goals which changed in activation as a result of feedback. These results indicated that the activations of specific goals were derived from the situational change. Moreover, the activation of goals differed whether one succeeded in self-regulation. The results provide evidence for the adaptive style of goal settings; people who do not succeed at self-regulation lack the flexibility of goal activation with feedback changes. In the future, how this goal flexibility affects our adaptation should be examined.

Keywords: goal activation, self-regulation

Self-regulation and personality factors of decision making effectiveness in extreme professions’ specialists’ activity

INDINA, T. (Russian Academy of Education), MOROSANOVA, V. (Russian Academy of Education)

Research is devoted to discovery of specific personality and self-regulation factors of decision making in emergency professions’ specialists activity (life savers, firefighters, bodyguards). Self-regulation, according to Conscious self-regulation theory (Konopkin, 1970) is understood as an ability to initiate, organize, support, and manage external and internal activity which is goal-oriented. The following were used: Self-regulation profile questionnaire (SPQ; Morosanova, 1994), NEO-PI-R (Russian version; Oryol & Senin 2003), Personality factors of decision making (Kornilova, 2004), Decision making model, which includes practical tasks on decision making in lifesavers’ professional activity (Indina, 2008). The research sample included 180 men who were extreme professions specialists in the age range of 24 to 60 years. To estimate effectiveness of the decision making experimental model “Decision making in emergency situations” was elaborated. The model allowed us to estimate six basic parameters of decision making: Search for information, Situation assessment, Subjective task representation, Alternatives construction, Choice of the alternative, Decision implementation. General effectiveness of decision making was esteemed by summarizing indexes of all six parameters. The results indicate significant connections between personality and regulation factors and decision making parameters. General effectiveness of decision
making, according to research results, depends on development of conscious self-regulation processes (including Modeling of significant conditions and Result estimation) and personality traits (Rationality, Openness, and Agreeableness). Regulation-personality profiles for specialists with high and low effectiveness of decision making were built. Specialists with high effectiveness of decision making are characterized by developed Result estimation, Modelling of significant conditions, Programming of actions and Goal planning regulation traits. Personality characteristics of highly effective in decision making specialists include Rationality, Openness and Agreeableness. For specialists with low effectiveness of decision making low level of basic self-regulation processes and high level of Neuroticism and Risk readiness are typical. It was concluded that personality traits and development of a conscious self-regulation system plays key role in effectiveness of decision making in extreme professions’ specialists’ activity.

Selling cars successfully: A retrospective analysis of the predictive utility of salesperson personality and bio-data

This study aimed to examine the predictive utility of personality using the Five Factor model (FFM) and bio-data factors in determining sales success. It looked at how an individual’ s score on the factors – Openness, Conscientiousness, Agreeableness, Extroversion, and Neuroticism of the FFM and which bio-data factors will be predictive of sales success. The records of 107 (99 males, 8 females) salespeople working in the sales-force of a car sales company were used. Participants’ data was extracted from the business records of an organizational psychology firm. All participants were sent an online invitation to complete a questionnaire comprising demographics; bio-data, Saucier’s Mini Markers and the International Personality Item Pool (IPIP) questionnaire.

There was a positive correlation between IPIP extraversion measure and sales success as defined by total number of cars sold in the last calendar year ($r(105) = .24, p < .01$). A negative correlation was found between Saucier’s measure of agreeableness and sales success defined as total dollar sales in the last calendar year ($r(105) = -.22, p < .05$). There was a positive correlation between length of employment and sales success ($r (105) = .27, p < .05$), sporting achievements and sales success ($r (105) = .28, p < .01$), work hours and sales success ($r (105) = .26, p < .05$). There was a negative correlation between lack of promotion and sales success ($r (105) = -.26, p < .05$). When assessing a salesperson’s performance it is important to note that there are many aspects of personality and bio-data measures that may interplay. It is expected that the outcome of this research after further confirmatory analysis will assist individuals in terms of career selection, development of coaching programs, and commercial entities in the recruitment and development of potential salespeople.

Keywords: big five model of personality, bio-data factors, sales success, international personality item pool, recruitment of salespeople

Service integration success factors: A case study review of a regional youth health service integration process

WINDLE, K. (Deakin University), WINDLE, K. (Deakin University), VON TREUER, K. (Deakin University), MCGILLIVRAY, J. (Deakin University)

Headspace Barwon is a consortium of agencies that came together under the banner of ‘headspace’ to provide an integrated health service system to youth in a regional area. The aim of this study was to conduct a retrospective review of the service integration process engaged in by headspace Barwon and identify best practice service integration success factors. Eleven interviews and four focus groups involving 17 people were conducted with voluntary representatives from a range of stakeholders including. A thematic content analysis was conducted. Factors identified to facilitate the service integration included pre-existing regional health networks, design collaboration with both sector and community
representatives, establishing a shared service vision and integration model, early establishment of complimentary partnerships with high stakeholder buy-in, implementing common Information Technology (IT) systems, establishing common language between agencies, co-location, lack of any one-agency domination, and early generation of brand awareness. Factors identified as challenges to the service integration included competing models of service delivery between agencies, lack of inter-agency interaction, concerns over confidentiality with shared IT, anxiety and fear regarding change, lack of staff buy-in to the integration system, loss of pre-identity, change fatigue, and external pressure to implement changes quickly. A number of elements of headspace Barwon service’s integration process are aligned with existing literature on best practice service integration and may be applied to future service integrations and change management planning.

Sexual orientation and suicide risk in the Philippines: Evidence from a national survey of young adult Filipinos

MANALASTAS, E. J. (University of the Philippines Diliman)

This paper explored links between sexual orientation and suicide risk in the Philippines, to replicate similar findings found in the global lesbian, gay, bisexual and transgender (LGBT) psychology literature. I examined data from the 2003 Young Adult Fertility and Sexuality Survey, a national population-based study of N = 8,042 Filipino men and N = 8,922 Filipina woman ages 15 to 24, using logistic regression analysis. Significant links between suicide risk (that is, suicide ideation and suicide attempt) and sexual minority status were found across three measures of sexual orientation (same-sex attraction, sexual behavior, and romantic relationships) for both male and female Filipino youth. These effects were partly mediated by depression, recent suicide attempt of a friend, and experiences of threat and victimization, as predicted by the Minority Stress Model. Similar to findings in global LGBT psychology, sexual orientation is significantly associated with suicide risk in the Philippines, with lesbian, gay, and bisexual Filipino youth reporting higher suicide ideation and attempts than heterosexual counterparts.

Sexual risk behaviour, general psychopathology and psychosexual symptoms among Victorian men who have sex with men (MSM) at risk of HIV transmission: Building our understanding of the psychological motivations for HIV risk behaviour

EARLE, M. (The Alfred)

This study aimed to build upon international literature informing HIV prevention policy and initiatives, by examining rates of and psychological factors contributing to HIV-risk behaviour (unprotected anal intercourse with multiple partners) among Victorian men who have sex with men (MSM). Specifically, it measured sexual risk behaviour, general psychopathology and psychosexual symptoms among Victorian MSM attending a specialist, sexual risk-reduction clinic, which have been identified in the literature as associated with HIV-risk behaviour. It then compared these rates with those in the general community and in HIV-risk studies internationally. All MSM attending the Clinic because of their sexual risk behaviour completed a demographic/sexual health/sexual behaviour questionnaire, the Personality Assessment Inventory (PAI, Morey, 2007), the Sexual Compulsivity Scale (SCS, Kalichman & Rompa, 1995) and the Sexual Sensation Seeking Scale (SSSS, Kalichman & Rompa, 1995) at Intake. Preliminary data suggested rates of general psychopathology were higher in the sample group than in the general community, including depression, anxiety, borderline features, drug and alcohol use and suicidality. Rates of sexual risk behaviour, general psychopathology, Sexual Compulsivity and Sexual Sensation Seeking, were also comparable to or greater than those reported in similar HIV-risk studies. High levels of comorbidity were observed. Notably, the clinic group showed high rates of treatment
readiness. Consistent with international trends, HIV-risk behaviour among MSM in Victoria attending a specialist sexual risk-reduction clinic was high, and was contributed to by a comorbid and complex mix of general psychopathology and psychosexual symptoms. Despite the sample bias and size limit generalisability, indications were that Victorian MSM seeking help for their sexual risk behaviour require specialist psychological intervention, and because of their self-awareness, motivation and treatment-readiness, are highly likely to benefit from it. Some clinical and public health implications of this work will be discussed.

Simulated scenarios of accidents: A good tool for young drivers’ training

The overall representation of young drivers in car crashes is a recurrent problem in developed countries. In order to prevent this over-representation, in France, young people can start early driver training at the age of 16, but the positive effects of this possibility are not manifested. We thus assessed the driving skills of traditionally trained novices, early trained novices, and experienced drivers, to evaluate whether early training improves young drivers’ skills. Three groups of healthy male volunteers had to drive the simulator, 12 were experienced (licensed for more than three years), 12 were traditionally trained and 12 early trained (licensed for less than one month). Participants were confronted with five accident prototype scenarios introduced in an urban circuit. We checked the number of collisions and measured each driver’s response (brake) time, speed and vehicle position on the lane. No significant differences appeared across groups regarding number of collisions and obstacle detections as revealed by the analysis of response times. We demonstrated the limits of traditionally trained drivers’ position control, which was more conservative. Early trained and experienced drivers were more susceptible to try an efficient evasive action. The exposure gained by early trained drivers appears to favor the development of visuo-motor coordination. The literature shows that the way novice drivers with poor driving experience (traditionally trained) scan the visual scene may partially explain their poorer performances. Taking the training period to improve young drivers’ risk detection ability and to develop the skills necessary to deal with simulated accident scenarios is an approach that we recommend. Simulators should be regarded as a promising pedagogic tool.

Slower adaptation and simulator sickness in older adults when engaging in driving tasks in driving simulators

KAWANO, N. (Nagoya University), IWAMOTO, K. (Nagoya University), UMEGAKI, H. (Nagoya University), SUZUKI, Y. (Nagoya University Hospital), NODA, A. (Nagoya University), IIDAKA, T. (Nagoya University), KUZUYA, M. (Nagoya University), OZAKI, N. (Nagoya University)

Although driving simulators (DS) provide a safe and cost effective environment for evaluating driving ability, DS applications are not without certain limitations when used to assess older drivers. An important issue is the age-related adaptation deficits to simulation environments. In order to examine if adaptation deficits affect DS performance, we focused on two markers of adaptation: frequency of simulator sickness and the effect of simple repeated tasks on performance. We asked older adults with intact cognitive functions (n = 17) and normal young adults (n = 15) to perform two types of PC-based DS (Toyota Central R&D Labs, Inc.) tasks: the road tracking and the car-following tasks. In order to learn the operating system, the participants first practiced driving freely on a straight, two-lane road with no other traffic for a maximum of five minutes. Then, they were asked to perform the experimental task of controlling the speed and position of a car by manipulating the steering wheel, accelerator, and the brake pedal for five minutes, while watching the driving scene on a screen. The trial was repeated four times (trials One to Four). There was a significant trend (p < .10) for the frequency of simulator sickness to be higher in
the older adults (n = 5) than in the young controls (n = 1). Data of 14 older and 14 younger adults were analyzed, after excluding three older adults that suffered simulator sickness, who did not complete the test and a younger adult whose data was lost due to technical problems. Results of comparing the DS performance between the groups showed slower adaptation in older adults in the road tracking task, but not in the car-following task. In the road tracking task, the performance of older adults improved from the first trial to the fourth trial, whereas those of young adults did not change. By the fourth trial the performance of older adults was similar to young adults. The current study demonstrated that normal aging increased the frequency of simulator sickness, as well as the detrimental performance of the simple, repeated, task of road tracking. These findings indicate the limitations of using DS for screening older individuals for driving safety. Although DS have a better face validity than pencil-and-paper tests for assessing driving skills, the participant’s capacity to adapt to environmental changes should be taken into consideration when using DS.

Social and psychological factors affecting people’s perception of mental illness: A study of Saudi in Abha City

AL-GHAMDI, S. (King Khalid University)

Little is known about the perception of mental disorders and stigma in Saudi Arabia. The aim of this paper is to focus on the social and psychological factors that can affect people’s perception of mental illness (or disorders). It can be admitted that most people in this country still believe that when a person has been labeled with a mental illness, they can never fully recover and will be socially isolated. In addition, they believe that the medicine given is like illegal drugs and that they will be addicted to it. Moreover, many think that people with mental illness will lose the respect of others as well as their roles in society. It is the main aim of this paper to examine the knowledge, attitude and beliefs about cause of mental illness and mental disorders among people who suffer as well as among normal people.

Keywords: mental illness, stigma

Social cohesion in an ecological ordering of a rural municipality in México: From theory to practice

The aim of this paper is to present a theory-methodological proposal of psychological work in ecological and territorial orderings through actions that allow the identification of different levels (and further development) of social cohesion as a key concept in the development of sustainability in rural communities. Social cohesion can be defined as the capacity of a society to ensure the well-being of all its members, minimising disparities and avoiding marginalisation. It considers four aspects: social capital, social integration, social inclusion and social ethics (Feres, 2006). Its measurement allows the community characterisation of its social cohesion in any of the four levels. This knowledge allows further work in increasing social cohesion of communities. The research project is being worked under a participatory action research framework in 13 communities of a rural municipality of Tzucacab in Yucatan, Mexico. Groups of men and women, with different ages, jobs, religions, etc., have participated in interviews and participatory workshops. It has been complemented with observation and documental analysis. The research has finished its first phase: the diagnosis at the 13 communities. The results presented in this paper show how the theory-methodological proposal was developed and applied at the communities and presents the social cohesion levels that characterise the different communities considering the combination of the four aspects mentioned above. The second phase is now beginning with the work through different participatory actions in every community to join efforts to increase their social cohesion considering their actual status as a starting point. Nobody would deny
the importance these days of sustainable development and pro-environment/ecological work, but it is a very complicated issue that needs interdisciplinary efforts. Despite this, the psychology discipline is not as involved in this kind of professional area as it could be. In spite of its importance, many social and psychological aspects are usually left behind and other biological, economic and engineering topics have been over worked. This paper presents an example of an opportunity for psychologists’ professional development in issues pertaining to the environment.

**Social comparison and self-appraisal effect on the feeling of pride**

FENG, X. (Northeast Normal University), ZHANG, X. (Northeast Normal University), TIAN, L. (Shandong Normal University)

The present study aims to examine the four different types of social comparison and self-appraisal that may influence the feeling of pride in the background of Chinese culture. Our sample consisted of 138 university students (31 males and 107 females). Participants had a mean age of 18.96 years ($SD = .81$), ranging in age from 18 to 21 years. They were randomly assigned to four conditions (mere public, praise, social comparison praised followed by a stranger and private no-feedback). Participants were asked to play an intelligence game at first. Participants played the game independently. They received different feedback when they finished the game. Each participant was alone with the experimenter at the time of the manipulation of priming social comparison. There were four situations: 1. Mere public condition; 2. Praise condition; 3. Social comparison condition and stranger effect; 4. No feedback. Later, they completed a series of questions. There were 12 items to measure participants’ feelings about their performance and their perceptions about the task, such as: How good was your performance do you think? How proud do you feel about how you did on the task? How do you appraise your performance compared with others? The results were: 1. Participants experienced different intensities of pride. Social comparison played a significant effect on the feeling of pride. The participant in the social praise comparison condition followed by a stranger had the highest level of the pride. The no feedback group of participants had the lowest level of pride. 2. Self-appraisals and others appraisals had significant correlations with the pride. 3. Self-appraisal based on comparison with others and self-satisfaction was a predictor for the feeling of pride. Social comparisons affected the feeling of pride. The level of pride increased across comparison conditions. Self-appraisal and self-satisfaction can predict the feeling of pride. Our findings support pride being influenced by self-appraisal.

**Keywords:** pride, social comparison, self-appraisal, self-satisfaction, public praise

**Social desirability responding impact in training report evaluations**

ENRIQUEZ, F. (National Autonomous University of Mexico), DOMINGUEZ, M. A. (Universidad Iberoamericana)

The purpose of this research was to prove that social desirable responding (SDR) not only affects self-report measures, but also other kind of scales. In work settings there is empirical evidence that people’s self-impressions are inflated. This self-enhancing tendency has been empirically established for peoples’ own perception of their task performance (Robins & Paulhus, 2001), but the question which arises is: What happens when evaluating “others” performance? The SDR would be equally important to control when assessing “others” performance? Based on a non-probabilistic sample of 487 workers, enrolled in training courses, we evaluated the impact of SDR in the appraisal of course instructor’s performance. In order to evaluate SDR we use the Balanced Inventory of Desirable Responding (BIDR), version 7 (Paulhus, 1998) in conjunction with a scale explicitly developed to evaluate instructor’s performance, based on nine items in Likert type format, named the Training Evaluation Questionnaire (CEC). We use two types of instruction in order to induce or control SDR based on a specific social demand situation. The results show that the experimental and control group differ significantly ($t = -5.5; g/f =$
57 p = 0.000) indicating that when inducing SDR, the scores in BIRD and in CEC where higher than in the control group (standard instructions). Using a Pearson correlation, between the two scales, the correlation indices run from .15 to .25 for the total sample, but when considering only the experimental group, the indices increase and run from .37 to .46, indicating a significant association between the two scales. In other words, there is an effect of SDR in the CEC when manipulating an instruction to induce a social demand situation, when assessing a third person’s performance. In this sample, every two of ten performance evaluations present a SDR. The presence of SDR in this type of report suggests that people inflate the rating estimation of instructor’s performance just to “appear more friendly” or more desirable to others, causing erroneous estimations and affecting possible improvements in training projects.

Keywords: socially desirable responding, self-impressions, performance appraisal, training, task performance

Social goals and academic engagement among Filipino students

KING, R. (University of Hong Kong), WATKINS, D. (The University of Hong Kong)

Much of the research on achievement goal theory has focused on the roles of mastery and performance goals in academic engagement, thus the role of other goals like social goals have been neglected. Academic engagement refers to the commitment of the student to the school experience, and it has been conceptualised as a multifaceted construct that includes cognitive, behavioral, and emotional components. Behavioral engagement refers to involvement in academic tasks and includes such behaviors as persistence, effort, and asking questions. Emotional engagement involves affective reactions to the school. Cognitive engagement refers to psychological investment in the learning process shown through deep learning strategies. The aim of this research was to investigate the effects of different kinds of social goals (social approval goals, social affiliation goals, social status goals, social responsibility goals, and social concern goals) on the different facets of academic engagement. Participants were 1300 Filipino secondary school students who answered questionnaires assessing their social goals, achievement goals, social support, and academic engagement. Hierarchical regression analyses were employed to investigate the effects of social goals on academic engagement after controlling for demographic variables (age and gender), social support, and achievement goals. Even after controlling for demographic variables (age and gender), social support (teacher support, peer support, and parental support), and achievement goals (mastery goals and performance goals), social goals were still found to be predictive of the different components of academic engagement. The different kinds of social goals are also important in understanding academic engagement. We recommend that researchers consider investigating these constructs instead of focusing exclusively on mastery and performance goals in the achievement goal theory. Social goals may especially be salient for collectivist societies like the Philippines.

Keywords: social goals, academic engagement, students, Filipino, mastery

Social goals and their effects in academic engagement in learning in Chinese university students

LI, X. (The University of Hong Kong)

Filial piety, friendship and discipleship are traditionally valued by Chinese people. Children respect their elders and strive to satisfy the wishes of their parents. Tao and Hong (2000) indicated that Chinese students have strong social reasons to achieve academically as the values of Chinese achievement have a high collective and social nature (Yu, 1996). Smith (2003) argued that Asian students are extrinsically motivated, based on the desire to please teachers and parents, and intrinsically motivated to perform as well as possible. Salili (1996) argued that Chinese students’ achievement motivation is socially oriented. Social-oriented goals are especially important for Chinese students, but they have not attracted enough attention in the previous studies,
especially in the ones based on Chinese samples. The relationships between students’ social goals, and motivation and engagement as well as the roles of social goals in students’ achievement have not been examined well among students in universities in China. In this study, Martin’s (2005) Motivation and Engagement Scale-University/College (MES-UC), as well as subscales (social approval, social concern and social status) in Dowson and McInerney’s (2004) Goal Orientation and Learning Strategies Survey (GOALS-S) were administered to 832 university students in China. The results showed that Chinese student’ self-belief and learning focus are significantly related to academic achievement; anxiety is significantly related to achievement but in the opposite direction. Social status oriented goals is significantly related to achievement and they act as mediating variables between self-belief, learning focus, anxiety and achievement. These results partly supported Dowson and McInerney (2001)’s argument that that social oriented goals of Australian students directly affect their psychological processes when they strive to achieve. For social approval and social concern, there is not a mediating effect from them between MES-UC and students’ achievement. It is concluded that social status oriented goals of Chinese students directly affect their psychological processes when they strive to achieve. For social approval and social concern, there is not a mediating effect from them between MES-UC and students’ achievement. These findings are discussed in the context of the special importance of social goals in Chinese students, and the roles of these goals in understanding students’ engagement and learning.

Stigmatisation of employees with depression: Exploring the role of managerial characteristics and organisational climate

MARTIN, A. (University of Tasmania), HOWARTH, E. (University of Queensland), HOBMAN, E. (University of Queensland)

This study is an investigation of how levels of managers’ cognitive, affective and behavioural stigma towards employees with depression are affected by the managers’ depression experience, as well as the mental health climate of the respective organisation. Drawing on social contact theory, it was hypothesized that managers would report less stigma if they had a personal experience with depression, or an experience with a significant other with depression. It was also predicted that managers who are more reticent to seek help would have more stigma towards employees with depression. Additional hypotheses involved the mental health climate of the organisation having both a main and a moderating effect on stigma. Participants (N = 223) assumed the role of a manager in a company, managing an employee suffering from depression. Using a vignette, the mental health climate of the organisation was manipulated to be supportive or unsupportive toward employees with depression. Participants’ ratings of stigma toward depressed employees were measured, as was the participants’ own level of experience with depression, their experience of a significant other with depression, and their reticence to seek help. Contrary to that hypothesized, personal experience with depression was positively related to affective stigma. Experience with a significant other with depression was related to lower levels of cognitive stigma. Help-seeking reticence was positively associated with cognitive and behavioural stigma. Consistent with predictions, it was found that those in the unsupportive mental health climate had more cognitive and behavioural stigma than those in the supportive mental health climate. Statistical testing of the model indicated that there were differences between the two mental health climates, but overall no moderation was seen. These results pose important implications for organisations, such as workplace training in depression management.

Keywords: social contact theory, depression, organisational mental health climate, employee depression, help-seeking

Strategy training and transfer in teenagers with or without learning disabilities

CLERC, J. (Université Nord de France, Lille3)

Memory strategy training in young people has long been a topic of interest for researchers.
Since the work of Flavell (1970), the possibility of enhancing memory scores by the use of a correct strategy training procedure has often been challenged. Many authors showed that training constitutes a good way of allowing children to become more strategic and consequently, at least in certain cases, exhibit better recall scores (Pressley & Hilden, 2006). Among others, the sorting strategy (Coyle & Bjorklund, 1997) has been intensively studied. This strategy, which belongs to more general categorization strategies, consists in physically sorting items in their relevant categories during the time of examining material in order to be able to recall it later. Sorting is well-known in children between 5 and 10 years of age, probably because of its impressive development during this period. Little is known, however, about what happens in teenagers and especially teenagers who manifest learning disabilities, even if other strategies like rehearsal (Hulme & Mackenzie, 1992) or use of a mental image (De la Iglesia, Buceta & Campos, 2004) have been studied in learning-disabled persons. Since sorting is only possible once the child acquired the logical properties of categories and since these properties are clearly abstract ones, we should observe difficulties in the use of sorting, not only in typically-developing children before 10—as is the case— but also in older children with learning disabilities. Based on the assumption that learning-disabled teenagers encounter specific difficulties with the sorting strategy, our experiment allowed us to compare strategic and recall scores from three groups: a group of teenagers with identified learning disabilities (50 < IQ < 70), a group of teenagers with probable - but no identified - learning disabilities and who belong to a special school for children with family and/or social problems (French “Maison d’Enfants à Caractère Social”), and a group of typically-developing teenagers. Each of these three groups was separated in an experimental group which received training in a sorting strategy as well as recall tests, and a control group which only received recall tests but no strategy training. A pre-test/training/post-test design was used, in which the “Letter-Number-Sequencing” (L-N-S) subtest of the WISC-4 served as recall baseline during the pre-test, then training and/or recall were proposed and tested across three training sessions of two trials each (six trials), and finally the L-N-S subtest was again proposed as a post-test. The strategy score consisted in the Adjusted Ratio of Clustering (ARC score, Roenker, Thompson & Brown, 1971), recall during the training sessions directly assessed the efficacy of strategy use, and the L-N-S final score served as an assessment of transfer of the sorting strategy in a different task than that where it was trained. Results showed that both groups of learning-disabled teenagers (“identified” and “supposed to be” learning-disabled) benefited from strategy training, as is evidenced by the significant better strategy and recall scores in trial 6 than in trial 1 for experimental participants: control participants did not enhance any of their strategic or recall scores between trials 1 and 6. Furthermore, sorting strategy was transferred to the “L-N-S” subtest as was visible in the significant difference between pre and post-test scores: again this was only true for experimental participants, however. Surprisingly, the pattern was reversed for typically-developing teenagers: neither did experimental participants (who were constrained to listen to strategic training) sort or recall better in trial 6 than 1, nor did they transfer the sorting strategy. On the contrary, control participants performed better in trial 6 than 1 for both sorting score and recall score. Nevertheless, they did not differ in their “L-N-S” pre and post-test scores. Clearly, strategic training with sorting has helped learning-disabled teenagers to both better master the requested strategy and better recall the verbal items at use. Sorting strategy, a kind of categorization strategy, then seems subject to refinements and progression after the age of 10, which is classically considered to be the age at which this strategy is definitely acquired and nearly perfectly used (Schneider, Kron-Sperl & Hünnerkopf, 2009). Our results shed some light on the evolution of this particular memory strategy in teenagers who frequently encounter difficulties, and even failures, in school everyday activities. Such teenagers seem to actually benefit from training in the use of a sorting strategy, probably because they usually lack the abstract categorical knowledge which constitutes a pre-requisite to the use of a categorization strategy like the sorting one: the training would have permitted them to identify the categories, and as a consequence, to use them for correctly sorting items. Finally, contrary to what is often held as true, our learning-
disabled participants also revealed the ability to transfer the trained strategy in another task, namely the “L-N-S” task. Strategic and recall performances of typically-developing teenagers showed that these young people, who certainly had acquired the sorting strategy for many years, seem to have been disturbed by systematic strategy training. Specifically, trained typically-developing teenagers did not enhance their strategic and recall scores, whereas it was the case for untrained ones: it could be the case that the strategy training we used here caused a conflict with the spontaneous way our participants produced the strategy. Finally, this conflict was present in the strategic score itself as well as in the recall score.

Stress and resilience of Chinese government officers following the 2008 Wenchuan earthquake

YANG, Y. (Beijing Normal University), ZOU, H. (Beijing Normal University), YAO, (Beijing Normal University)

This paper established a method to analyze the stress that government officers were under after the Wenchuan earthquake. In addition, main factors which affected individual resilience after the earthquake are also appraised. The semi-structural questionnaire method is applied in this study 17 months after the earthquake. The questionnaires are based on the responses of government officers from Beichuan – the heaviest disaster area. Twenty six officers of different levels from the county assisted us to complete the study by using their own working experiences and knowledge about the disaster. Beichuan county is the only Qiang nationality autonomous county in China. The catastrophic disaster resulted in 15,645 dead, 1,023 missing, and 26,916 injuries, which account for one eighth of the whole population in the county. As for the government officer, nearly a quarter of them (466 people) are dead or missing. The stress that government officers are under derives mostly from two aspects. On the one hand, their family members, relatives and friends may die or be missing. On the other hand, they are frequently suffering from overtime work and relocation of working place due to reconstruction of the city in other regions. According to the study, the main factors which affect individual resilience are degree of damage, individual characteristics (including gender, age, personality, coping style, life meaning), social support, collective efficacy, and national policy. The resilience status of the government officers are affected by various factors with respect to the degree of damage, the individual characteristics, the social support, and national policy.

Keywords: earthquake, disasters, social support

Stress, coping, and burnout among Chinese nurses

RAMOS, H. M. (IWHO, University of Nottingham Malaysia Campus), PAN, Y. (University of Nottingham), SANTOS, A. (University of Nottingham)

The issue of nursing stress and coping are a big concern in the area of health care (Kickaldy & Martin, 2000; Lambert & Lambert, 2001) as stress can often lead to negative outcomes such as illness, job dissatisfaction, increased turnover, absenteeism and decline in the quality of care. The main aim of the study is to look into stressors, coping strategies and their relationship to burnout amongst a sample of Chinese nurses. The goal of the study is fourfold. First it aimed to identify key stressors in the nursing practice. Second it looked into how coping moderated the relationship between stress and burnout. Third, it investigated the effects of different coping strategies on specific stressors to identify which coping strategies would moderate the stress-strain relationship and in which direction. And fourth, it aimed to identify themes in coping strategies used by these nurses. The data was collected from 370 Chinese nurses in a general hospital in Southeast China using the Expanded Nursing Stress Scale (ENSS), the ways of Coping scale (WCS) and the Copenhagen Burnout Inventory (CBI). Factor analysis identified several overarching themes amongst different nursing coping strategies. Results also indicate that overall stress predicts burnout in all three burnout domains (personal, work-related and client-related). Coping acted as a moderator for the stress-strain relationship for
all three dimensions of burnout. The moderating effects of individual coping strategies differ for different nursing stressors – some helped alleviate the aversive effects of stress while others worsened them. Areas for development and improvement of support for nurses will be presented further in detail. Implications of the study suggest the need to train nurses to develop diverse and appropriate coping skills to handle specific nursing stressors. Furthermore, setting up communication networks among doctors, patients and their families could be very helpful in improving relations between the providers and recipients of healthcare.

Stroke prevention: Modification of risk factors depending on personality factors, stress coping strategies and affective syndromes in patients with transient ischemic attacks

LETTLER, S. M. (Department of Neurology With Stroke Unit), MAYRHUBER, M. (Department of Neurology With Stroke Unit), OBERNDORFER, S. (Department of Neurology With Stroke Unit), KAMFL, A. (Department of Neurology With Stroke Unit), HINTERBERGER, G. (Department of Neurology With Stroke Unit)

Medication taking behaviour is an important step to optimizing the use of secondary preventive therapies in patients with transient ischemic attacks (TIA) and stroke. However, the importance of specific neuropsychological factors including personality factors, stress coping strategies and affective syndromes in medication taking behaviour in patients with TIA has not been investigated in detail. Sixty patients with TIA in anterior or posterior circulation are included in this study. The index event is classified as a TIA if neurologic symptoms resolve within 24 hours and neuroimaging (Cerebral Computed Tomography and or Magnetic Resonance Imaging) is negative. Vascular risk factors assessed at baseline and three months after the index event include hypertension, diabetes mellitus, hyperlipemia, obesity, smoking status and alcohol consumption. Neuropsychological testing includes a stress coping test, personality test, affective questionnaires (anxiety and depression) and health behaviour questionnaire within 48 hours after admission and three months thereafter. Our data will document the adherence to secondary stroke prevention therapies in regard to specific neuropsychological factors. Our results may improve the quality of care after stroke and may reduce the risk of future cerebrovascular events.

Keywords: quality of care, strokes, neuroimaging, stress coping, neuropsychology

Structure and measurement of teachers’ learning procrastination

FAN, Q., CHENG, J. (Suzhou Human Talents Exchanging Center)

The 21st century is a so-called “century of learning”. Learning, both for students still in school and adults who have left school, is attracting more and more attention. We have been in charge of a project of the Ministry of Education of China from 2005, which researches adults’ learning behavior. We have found out that learning procrastination is a common phenomenon among adult learners, even teachers. Based on document retrieval, open survey and structured interview, we have put forward a “5-factors hypothesis” about the internal processes of learning procrastination. Then we have verified the hypothesis through factor analysis. The main behavioral expressions of learning procrastination have been revealed as follows: (1) negative cognition to learning task; (2) being in low spirits; (3) weak will; (4) weak motivation; and (5) the habit of delaying. According to the principle of psychometrics, we have developed the Teachers’ Learning Procrastination Questionnaire. As a reliable and effective tool, it could be academically or practically used in the fields of educational psychology, learning guidance, teachers’ education and adults training.

Keywords: teachers, learning procrastination, structure and measurement

Student emotional and psychological support: A case study of a residential international school
The aim of this study was to better understand how well the pastoral care program, as well as the overall school community, provided emotional and psychological support to academically gifted students by identifying the organization’s strengths, challenges, and opportunities for growth. Using a case study methodology, I collected data from multiple stakeholders, including students, staff, and the faculty in order to analyze complex and dynamic organizational issues. In particular, I collected narrative data (for example, interviews), textual data (for example, written documents) & observational data (for example, staying on campus). Using this methodology allowed me to seek various representations of the issues and to pursue a multifaceted understanding of the phenomenon. Results demonstrated that although the pastoral care program and overall school community provided some psychological and emotional support to a portion of the student body, many students and the faculty were confused about the nature, purpose, and goals of the program. Additionally, the school operated from two different visions and philosophies, which sometimes created situations that became negative and divisive. However, where there was congruence between student and faculty expectations and roles, community agreement on how difficult situations should be handled, and a common vision between individuals and the group, students and faculty felt psychologically and emotionally supported. The opportunities for growth focused on how to build capacity for the community with a focused emphasis on the pastoral care program by developing congruent expectations, increasing consistency, and adding new evidence-based interventions at all levels of the system – individually, relationally, systemically, and philosophically. This research provided important insights and recommendations that opened up optimistic conversations and opportunities for the community to make intentional and integrated positive changes in order to significantly improve the psychological and emotional well-being of the community. The results of this study have led to further ongoing program development and research using an Appreciative Inquiry model.

Keywords: pastoral care program, student well-being, community change, appreciative inquiry model, narrative data

Student perceptions of plagiarism

GULLIFER, J. (Charles Sturt University), TYSON, G. (Charles Sturt University)

Plagiarism is perceived to be a growing problem and Universities are being required to devote increasing time and resources to combating it. Theory and research in psychology show that a thorough understanding of an individual’s view of an issue or problem is an essential requirement for successful change of that person’s attitudes and behaviour. The aim of the present study was to develop a better understanding of how students construct plagiarism by using group discussion to explore the range of opinions regarding students’ perceptions of plagiarism. In the pilot study, seven focus groups were held with first and third year students across discipline areas and modes of study. A thematic analysis revealed six themes of perceptions of plagiarism that are outlined under six main headings: confusion, fear, perceived sanctions, perceived seriousness, academic consequences, and resentment. These dimensions and the relationships between them were developed into a concept map. The current study was a pilot to a research program aimed at exploring these relationships.

Keywords: plagiarism, student perceptions, perceptions, academic consequences

Students’ conceptions of generic skills development in a university in Hong Kong

CHAN, W. (University of Hong Kong)

This paper aims to present the development of a survey from the findings of a pilot study of students’ conceptions of generic skills development in a university in Hong Kong. Twenty-nine interviews were conducted with 93 undergraduate students in a research-intensive university in Hong Kong. Students were asked to describe their understanding of generic skills development and relevant experiences in their
university education. Students’ definitions of the term “generic skills” and opportunities in the university they had experienced about developing such skills were identified. Generic skills were conceptualized by students as skills that could help them tackle stressful or unknown situations. Students identified critical thinking and communication skills as the most important skills to help them solve problems. Students indicated the dispositions to obtain information, to analyze information critically, and to make rational decisions as the skills related to critical thinking. Effective communication involved not only conveying ideas but also the ability to be assertive when collaborating with others. Students indicated more awareness of generic skills development when these were described explicitly as the objectives or outcomes of teaching and learning activities. They perceived more positive development when they were asked to reflect upon their learning experiences. These students also described that by developing these skills in and through university education they would be able to develop confidence in handling stressful and unknown situations in life. Undergraduate students conceived of generic skills as the tools to increase their chances of success in the changing world or unknown future. Critical thinking and communication skills were identified as overarching attributes of more basic generic skills. Also, teaching and learning activities with clear objectives and learning outcomes and that foster self reflection might help to enhance positive development. These findings suggest assessing achievement of basic skills and self-efficacy in uncertainties as evaluation of generic skills development in undergraduate students.

Keywords: skills development, generic skills, learning experiences, self reflection, self-efficacy

Study habits of secondary school students in relation to their sex, parental level of education and place of residence

YADAV, R.S. (Kurukshetra University), KUMAR, P. (Shri Krishna college of Education, Karnal), YADAV, P. (Patudi College of Education)

The aim of this study was to study the effect of sex, parental level of education and place of residence on study habits of students. A descriptive survey method was used. The study was confined to 200 ninth grade students of Government and aided schools of the Gurgaon district of Haryana (India). The sample consisted of 50 male and 50 female urban students; and 50 male and 50 female rural students; selected from five different senior secondary schools. A questionnaire created by the researchers was used. The mean, standard deviation, standard error of means and t-ratios were calculated to identify any significant differences between means. Frequencies and percentages were also calculated. The study revealed that female students had better study habits than the male students in English, Social Studies, Mathematics, Science and Hindi. The students whose parental level of education was higher had better study habits than those of low parental level of education in English, Social Studies and Mathematics. Parental educational level had no effect on students’ study habits for Science, Hindi and General Reading. Urban students had better study habits than the students belonging to a rural place of residence for English, Social Studies and General reading but no difference existed among students in Mathematics, Science and Hindi in relation to their place of residence. Rural female students had better study habits than rural male students in Mathematics and Hindi; but in English, Social Studies and General Reading, rural male and female students did not differ in their study habits. Similarly, urban female students had better study habits than urban male students in English, Social Studies, Mathematics, Science and Hindi, but not in General Reading. Study habits affect academic achievements of students. Therefore, students should be helped to develop good study habits, and teachers, in particular, can do a lot in this context.

Keywords: study, secondary students, gender, rural students

Study on the job and tacit knowledge structure of salespersons in insurance

SHUHUA, Z. (Shenyang Normal University), XIAOKUN, W. (College of Shenyang Technician)

Tacit knowledge is one of the hot topics in contemporary knowledge management research. From the strategic resource view,
compared to explicit knowledge, tacit knowledge is the most important resource of competitive advantage for not only the organization but also the personal. Though some research and discussion towards tacit knowledge and its frameworks has been carried out by former researchers, the swatch of salespersons in insurance has been touched upon only a little. This research takes salespersons in insurance as subjects being investigated and probes into the tacit knowledge of their job deeply. We collected the questionnaire items by the interview method on the basis of the extensive literature, and formed a questionnaire of tacit knowledge of salespersons’ job. We surveyed 750 salespersons, two swatches, as subjects investigated and explored and validated the structure of the tacit knowledge of salespersons’ job. In addition we explored the relationship between tacit knowledge level and the demographic variables. We achieved the following results: the structure of the tacit knowledge of salespersons’ job is composed of six factors; the questionnaire of the tacit knowledge of salespersons’ job has superior reliability and validity; the Cronbach's Alpha based on standardized items is 0.866, the split-half reliability is 0.849 and the repeated measurement reliability is 0.902; and the exploratory and confirmatory factor analysis shows the questionnaire has good structural validity. We achieved the following conclusions: 1. After exploratory and confirmatory factor analysis, we found that the structure of the tacit knowledge of salespersons’ job is composed of six factors: organizing and harmonizing, active attitude, market seeking, communication sensing, self restricting and sales planning. 2. The questionnaire of the tacit knowledge of salespersons’ job has superior reliability and validity. The correlation coefficients between the dimensionalities indicate that the content validity is superior. The regression analysis shows the questionnaire has a good predictive validity. 3. The total score of the tacit knowledge of salespersons’ job and the organizing and harmonizing, market seeking and self restricting in the three levels of their sales’ years have significant differences. The more sales years, the higher the total score and the organizing and harmonizing score, market seeking score and self restricting score. The total tacit knowledge levels and those of each dimensionality have no significant differences based on sex, speciality and record of formal schooling.

Keywords: tacit knowledge, insurance salespersons, contemporary knowledge management, market seeking, active attitude

Successful treatment of an 80-year old man with a 65 year history of obsessive-compulsive disorder: A case study

JONES, M. (The University of Sydney), WOOTON, B. (The University of Sydney), VACCARO, L. (The University of Sydney), JONES, M. (The University of Sydney), MENZIES, R. (The University of Sydney)

Exposure and response prevention (ERP) is proven to be a useful treatment for adults with Obsessive Compulsive Disorder (OCD). However, there is currently limited empirical evidence to suggest that this treatment is effective for the treatment of OCD in older adults (those aged over the age of 65). The current case study aims to address this gap in the literature. The participant was an 80 year old man with a reported 65 year history of OCD. He had previously received non-specific psychological treatment as well as pharmacological interventions but had failed to benefit from these approaches. At the time of the current treatment the participant was medicated on 50 milligrams of Sertraline and had been stable on that dose for four years. This medication dosage remained stable throughout the treatment and follow-up period. Treatment consisted of 11, 50 minute weekly individual treatment sessions of ERP, conducted by a clinical psychologist. The participant was assessed on the Yale-Brown Obsessive Compulsive Scale (YBOCS), the Global Assessment of Functioning (GAF) scale, and the Obsessive Compulsive Inventory (OCI) at pre-treatment, post treatment, and at seven month follow-up. At seven month follow-up the scores on the Y-BOCS had reduced 65% from 20 (moderate), to seven (subclinical). On the GAF scores improved from 65 at baseline to 85 at the seven month follow-up. On the OCI total scores reduced 45% from 38 at baseline to 21 at seven month follow-up. Scores on all OCI subscales reduced over the course of the treatment. On the checking subscale, scores reduced 56%. The results of this case study add to the preliminary evidence that ERP appears to be an acceptable
and successful treatment for older adults, as it is with younger adults. Modifications may need to be made to traditional ERP for this age group however due to the existence of medical comorbidities and cognitive decline. These will be discussed. Further research is required to assess the effectiveness of this treatment for geriatric OCD patients.

Sunset and moonrise: Athletes’ experiences and reflections in the twilight of their careers

MCGRATH, S., ANDERSEN, M. (Victoria University)

The aim of this study is to describe and explore the thoughts, emotions, behaviors, and the intra- and interpersonal experiences and reflections of athletes who are, at the time of the investigation, in the twilight of their sporting careers (i.e. when interviewed, are considering retirement within the next two to four years). Participants involved are aged between 30 and 45 years of age. The study involves at least four interviews with each athlete over an 18-month period (beginning, 6 months, 12 months, and 18 months). In an attempt to provide, a holistic account of the athletes’ lives, particular attention is paid to the athletes’ perceptions and experiences (hopes, dreams, disappointments, high and low points) of their past, current, and future sporting careers. Areas such as adversities, resiliency, identity, personal development, and future plans are explored. Furthermore, an interpretative narrative to their life stories (Denzin, 1989) has been applied, as the researchers engage, explore, and interpret the subjective experiences of the athletes. The study is on-going, and the first round of interviews has been conducted. By the time of the conference, the second round of interviews (at 6 months) will have been completed and analyzed. This presentation will provide a glimpse into longitudinal research in progress, and preliminary interpretations of the cases (so far) will be presented.

This research will increase our understanding of how the potentially turbulent and stressful pre-retirement period of athletes can be better managed and, by extension will allow us to improve the mental health and well being services available to athletes.

Keywords: pre-retirement period of athletes, athletes’ perceptions and experiences, interpretative narrative, athletes, athletes’ well-being

Supporting services and quality of life in people with multiple sclerosis

DADKHAH, A. (University of Social Welfare and Rehabilitation), AZIMIAN, M. (University of Social Welfare and Rehabilitation Sciences)

Multiple Sclerosis (MS) is one of the most common non-traumatic and weakening diseases of the central nervous system, which causes many somatic, psychological and social problems; and mainly has an unpleasant effect on different aspects of the patient’s, and their families’, quality of life. This study has been performed in order to evaluate the relationship between supporting services and different aspects of life quality in MS patients in Tehran city. This was a coherence type study which was done by simple random sampling from active existing files in the Iranian MS association and Sina MS super-specialist clinic. Among these, 60 files were selected. By estimating sample volume in coherence research, sample volume was determined. Life style was evaluated by a standard questionnaire containing 54 questions (The Multiple Sclerosis Quality of Life-54 Instrument) and for evaluation of the type and quality of supportive services, the researcher’s questionnaire used 46 questions. The relationship among variables was assessed by the statistical test of Spearman correlation coefficient. The findings indicate that there are significant relationships between supportive services and these items: promotion of somatic health, decrease in somatic/emotional limitations in performance of the role, increase in psychological health, fatigue decline, increase in health sense, optimization of cognitive and social performance, decrease in anxiety regarding health, improvement in health condition and promotion of life style from the
patients’ point of view. There is no significant relationship between supportive services and increase in sexual performance of patients and pleasure from their sexual performance. According to the results of this study some procedures and activities can be used for increasing supportive service levels in MS patients who need these services in order to promote their quality of life.

Keywords: multiple sclerosis, quality of life, supportive services, somatic health, central nervous system

Surveillance study for intervention to prevention of street crime: The relationship between the information and the perception

OKIBAYASHI, Y. (Yamaguchi University), FUKUDA, H. (Yamaguchi University)

The main purpose of this study was to investigate the aspects of criminal cases in recent Japan. As the lifestyles of Japanese people have changed, the pattern of criminal cases has been changing. It is therefore important to conduct an investigation of actual conditions. This investigation consisted of two phases. The first was to count the number of criminal cases, which corresponded to several domains. The second was to analyse the data, which were gathered in the first phase. The aim of the second phase was to find the features that were difficult to discover by only counting the number. A further purpose of this study was to investigate the relationship between the actual criminal cases and people’s perceptions of the criminal cases. Most people feel anxiety when they know the information about the criminal cases in their daily life. Although most people feel anxiety, anxiety does not consist of only one component. Anxiety has many aspects and consists of many components. It is important to identify the components and examine how the components relate to each other. The further purpose of this study was to investigate the individual differences of participants when they know the information about the criminal cases. The participants of this study were about 250 undergraduate students. Participants were asked to answer some multiple-choice items and to write how they felt about the contents of the report. The result of this study was that several types of anxieties were found. Moreover some components of anxiety were related to each other. A more sophisticated study is needed to clarify the detailed relationship between information and perception.

Keywords: criminal cases, anxiety

Survey on attitudes toward driving and giving up driving of the elderly in regional cities

NIHEI, M. (The University of Tokyo), SHINO, M. (The University of Tokyo), KAMATA, M. (Institute of Gerontology)

The car has an important impact on the daily life of the elderly and their social activities and participation. However, physical depression caused by aging is also a cause of traffic accidents and they will all have to give up driving one day. The aim of this study is to clarify the effect on daily life of car dependency and the impact of having to stop driving among the elderly. We also aim to proposition for substitute methods of transportation to continue for elderly going about their daily life after having to surrender a driver’s license. We carried out a questionnaire survey and a follow up group interview. In this investigation, we sent 1,338 questionnaires to the over 60 year olds in regional cities that include areas with public transit convenience and inconvenience. The recipients of the questionnaire were chosen based on random sampling using the Basic Resident Register for the two regional cities. We extracted three kinds of areas with different degrees of public transport convenience in each city. The questionnaire contained the following contest. (a) Profile of recipient: state of health, usage of public transport, (b) Driver’s license holder: driving frequency and purpose, when is it time to give up driving?, notice symptoms about their body functions and driving abilities, (c) Those who had surrendered their license: reason and process, any feelings of unease or about post-driving mobility. We received 767 questionnaire returns, that is, 57.3% of the number sent out. Percentage of respondents
broken down by having car license were driver’s license holder 62.4% (N = 474), non-holder 34.2% (N = 260), and those who had surrendered their license 3.4% (N = 26). From one target area called limit village, more of the respondents (around 48%) were over-75 years old than in other areas. There was little difference among areas in the frequency of going out of the house, but there was in the purpose of going out. Trips related to farming were high in areas outside city centers, while “commuting to work” was high in city centers. “Daily shopping,” was cited in both areas. The mode of transportation often included driving one’s own car, but in city centers, “on foot” was a common response. Persons living in limit villages used cars more commonly than in the other areas, broken down into other people’s (family’s or neighbor’s ) cars (23%) or own car (44%). Although some respondents used public transport, centers that were near to a train station of the train had little use in each district. Overall satisfaction about their current mobility was high (around 90%). The frequency of going out among recipients decreased as they became older and the necessity of the public transport increased. In addition, the need to travel to a hospital increased along with aging. The consciousness of giving up driving so as to become old and the number of years during which they could drive were limited. The investigation revealed that aging and physical infirmity was significantly related to driving ability. In addition, respondents living in a “graying area” have a strong need to drive, are anxious about the risk of giving up driving and need an encouraging improvement in the mass transportation system.

**Keywords:** transport, elderly drivers, driving, depression, public transport

**Systematic case studies of four depressed young women counselled with process-experiential emotion-focused therapy (PEEFT)**

HARTE, M. (La Trobe University)

There is a consensus amongst counselling researchers of a need for investigations that employ collaborated systematic qualitative methodology into “what works” in therapy. Process-Experiential Emotion-Focused Therapy (PEEFT) is an integrative, evidenced-based, manualised, experiential therapy developed in the mid 1980’s by Greenberg, Elliott and Rice. PEEFT emphasises the quality of the client-therapist relationship and offers interventions/tasks to assist clients to deal with emotional experience in the present moment. Experiential treatments have been found to be effective with depression, anxiety and trauma in adults. This presentation reports on a study of in-therapy experiences and treatment effects of four severely depressed young women (20 to 26) counselled with PEEFT. The study investigated “change processes” using established psychometric measures and observations in 12-session PEEFT treatment modules with the four young women in a naturalistic counselling setting. The design is consistent with the flexible framework, presented by Elliott and Zucconi in 2005, for guiding individual and collaborative research for the international investigation on the effectiveness of person-centred and experiential psychotherapies. Further, this study utilised expanded single case designs that take an interpretive approach to examining client change and its causes. In general, these designs aim to: (1) demonstrate that change occurred, (2) examine the evidence for concluding that therapy was responsible for the change, (3) examine alternative explanations for the change, and (4) examine which processes in therapy might have been responsible for change. A simple thematic analysis highlighted themes of change from the client’s perspective. Clinical significance was determined. After six sessions, three of the women’s level of depression was measured as within mild to moderate ranges. The fourth young woman experienced an unplanned pregnancy and miscarriage during the therapy but her depression reduced by the end of her sessions. All four women described reduction in other reported concerns and major shifts in their perceptions of themselves and their world view. The systematic case study methodology, within a participatory inquiry, allowed in-depth personal accounts of the women’s journeys through depression via PEEFT counselling.
Taboo trade-offs, moral outrage and the moral limits of markets

WASTELL, C. (Macquarie University), MACMILLAN, C. (Macquarie University)

The Sacred Value Protection Model (SVPM) proposed that taboo trade-offs evoke a strong moral reaction in people who resist secular encroachments on their sacred values. It is also suggested that a substantial minority of participants are susceptible to trading off their sacred values when exposed to reframing strategies which convert taboo trade-offs into routine or tragic trade-offs. This suggests that the sacred-secular barrier is quite permeable. The present study examined these key issues using a sample of one hundred university students. Participants evaluated both routine and taboo trade-offs as well as being asked to re-evaluate their reactions after considering policy revision material. It was found that taboo trade-offs do elicit strong moral reactions in participants. In particular, participants expressed significantly greater moral outrage when contemplating taboo trade-offs compared to when thinking about routine trade-offs. The study also found that reframing taboo trade-offs as routine trade-offs was not effective in subverting sacred values. Specifically, taboo trade-offs were reframed using policy revision information that was designed to alleviate concerns about the possible extreme consequences that result from allowing taboo trade-offs to occur. Following exposure to the policy revision information, participants were asked to re-evaluate the permissibility of taboo trade-offs and no significant reduction in moral outrage was found. The results of this study are in contrast to other related studies in that the policy revision material did not change the reaction of participants and yet similar levels of moral outrage were elicited. Further refinements to the policy revision material component are outlined based on relevant models of the underpinnings of sacred values.

Taoists’ personality characteristics and its relation to their subjective well being

XIAOJUN, L. (Hua Zhong Normal University), ZONGKUI, Z. (Hua Zhong Normal University)

The purpose of the study was to understand Taoists’ personality characteristics and their relation to subjective well-being (SWB), and by comparison, to offer reference for modern people’s lives. Sociometric rating and questionnaire methods were applied in this study. The Cattell Sixteen Personality Factor Questionnaire (16PF) and Satisfaction With Life Scale were used to conduct a survey of 33 Taoists from Wudang Mountain Taoists’ College of Hubei Province. The data were mostly analyzed by MANOVA using SPSS12.0. The results indicate that: (1) Taoists’ scores in reasoning, emotional stability, rule-consciousness, social boldness and perfectionism were significantly higher than those of university samples; while their scores in liveliness, vigilance, openness to change and self-reliance were significantly lower than those of the university sample; (2) Taoists’ scores in life happiness ($t = 2.95, p < 0.01$) and positive emotion ($t = 3.55, p < 0.01$) were both higher than those of the university sample; while their scores on negative emotion were not significantly different from that of the latter; and (3) The regression analysis showed that emotional stability, apprehension, vigilance and tension all entered in the regression equation of Taoists’ SWB. From these results can be drawn the following conclusions: (1) Taoists’ personality characteristics are significantly different from those of general university students on a number of dimensions; (2) the degree of life satisfaction and positive emotion of the Taoists are higher than those of the general university students; and (3) the four factors; emotional stability, apprehension, vigilance and tension are predictably important to Taoists’ SWB.

Keywords: Taoist, personality, well-being, satisfaction, 16PF
Teachers' agency in professional development: Its constructs, characteristics and developmental mechanisms

ZHANG, N. (Academy of Beijing Educational Science), SHEN, J. (Ministry of Education of the People's Republic of China)

In the field of teacher education, teachers progress from a passive development stage to an active development stage. During this transformation, the degree to which teachers can exercise their agency is critical. The purpose of this study is to theoretically explore the role of teachers’ agency in professional development, including its definition, construct, function, consequence, development and predictors. With the base of theoretical construction, the current study used interview and questionnaire methods and the author conducted the study with a sample of 522 elementary school teachers from four provinces in mainland China. The purpose of the study was to examine the role of Chinese elementary school teachers’ agency in their professional development. The Teachers’ Agency in Professional Development Questionnaire included two dimensions: personal agency and contextual agency. The questionnaire was shown to possess good construct validity by confirmatory factor analysis, acceptable criterion validity and good internal reliability. The mean of Chinese elementary school teachers’ agency in professional development is in the moderate level. The Teachers’ personal agency score is statistically higher than their contextual agency score. For teachers with more than ten and less than twenty years of work experience, their personal agency score was statistically higher than teachers with less than ten years of work experience. The expert teachers’ personal agency score was higher than that of experienced teachers and novice teachers; their contextual agency score was higher than that of experienced teachers. Teachers from rural key schools all scored higher on their personal agency and contextual agency than did urban key school teachers and rural ordinary school teachers. Teachers who had made master goals all scored higher on personal agency and contextual agency than did teachers who had made performance goals and teachers without goals. Compared with the low agency teacher group, the high agency teacher group had two more predicted paths that influenced their personal agency. The first is from environmental factor supports to teacher perceived efficacy. These factors are mediated by teacher professional developmental satisfaction and then from teacher perceived efficacy to teacher personal agency. The second is from general personal agency to teacher perceived efficacy mediated by teacher personal agency. Compared with the low agency teacher group, the high agency teacher group had two more predicted paths that influenced their contextual agency. First, from general contextual agency to teacher contextual agency directly, and second, from general contextual agency to teacher contextual agency mediated by teacher perceived efficacy.

Teachers socialization and job satisfaction: A field study from Chinese kindergartens

MA, H. W. (Tianjin Normal University), YAO, Q. (Nankai University), YUE, G. A. (Nankai University)

Previous research has well documented that teacher socializations are positively correlated with teachers’ job satisfactions (JS). However, most of these researchers focused on job satisfaction for the job itself and excluded other job aspects like supervisors and colleagues. In addition, most of them aimed at teachers from primary or middle schools and little is known about teachers from kindergartens. Regarding these, this research treats JS as a multidimensional structure and explores its relations with the socialization process. Three hundred and twenty seven teachers from 11 kindergartens in Tianjin, China, participated in this research. The socialization degree was measured by Content of Teacher Socialization Questionnaire, which included four dimensions (organization, organizational politics, role and task), and JS were measured with the Job Satisfaction Survey, which described job from nine aspects (reward, promotion, supervisors,
interests, colleagues, job itself, personal interaction, et al.). Multivariable regression technique was used to analyze data. The results showed that: (1) Knowledge of kindergarten teachers about their organization was positively related with each dimension of JS; (2) task mastery of kindergarten teachers correlated positively with work fairness factors like reward, promotion, procedure et al., but negatively with interpersonal factors like supervisors, colleagues et al.; (3) role clarity only had positive correlations with interpersonal factors; (4) knowledge about organizational politics only had negative correlations with contingent reward. The relations between JS and socializations depend on the contents of each variables and the well accepted conclusion that the better teachers are socialized the higher their JS, is not always the case.

Keywords: teacher socialization, teacher job satisfaction, organizational politics, kindergarten teachers, task mastery

Teachers’ burnout and job satisfaction: Based on data from rural China

XIAOJUN, L. (Hua Zhong Normal University), CUIYING, F. (Huazhong Normal University)

The professional existence actuality of primary and middle school teachers in rural areas of central China was investigated in this study. Meanwhile, the developmental trend of professional existence actuality between pretest and protest had been explored. Participants were 1312 teachers and 1791 principals from primary and secondary schools in rural areas of central China, who completed the Job Burnout Questionnaire, the Professional Satisfaction Questionnaire and the Teachers’ Evaluations Questionnaire. Longitudinal tracking research design (interval time was 12 months) was employed in the present study. The data were mostly analysed by t test and MANOVA. The results indicated that 1. In China, three dimensions of job burnout of primary and secondary school principals in rural areas were significantly lower than the general level; the degree of job satisfaction was high (67%), but satisfaction relating to wages and treatment were significantly lower than the general level at only 14.5 percent; 2. Rural primary and secondary school teachers’ degree of professional satisfaction and evaluations of interpersonal relationships (71.4 %) were high, while the degree of satisfaction relating to their income and welfare (5.1%), promotion chances (7.5%), social status (10.6%) and their schools (27%) were all significantly lower than the general level. 3. The two results showed consistently that the job burnout of principals was low, their degree of professional satisfaction was high, but they were discontented with their promotion chances. Conclusions that can be drawn from the study are 1. Using job burnout and degree of professional satisfaction as indicators, the professional existence actuality of primary and secondary school principals and teachers in rural areas of central China was good in general; and 2. The existence actuality of principals and teachers presented a downward trend.

Keywords: teachers, burnout, job satisfaction, China, rural

Teachers’ experiences of job satisfaction and work-life balance: The mediating role of motivation and support

HUMPHRYS, K. (Griffith University), BROUGHS, P. (Griffith University)

Teaching is an emotionally labour intensive job which requires individuals to engage in nurturing / social behaviours while negotiating professional and bureaucratic guidelines. As a result, the motivation to teach, and the support the networks developed, may play a role in teachers’ experience of job satisfaction and work-life balance. This study aims to test the theory that resources such as motivation and support (supervisor, colleague, family and friend) actually mediate the relationship between job demands and involvement, and job satisfaction and work-life balance (WLB) as opposed to the traditional associations suggested by demands-resources or person-environment fit models. Five hundred and seventy members of the Queensland Teachers’ Union responded to a survey on Teacher Demands and Work-Life Balance. Work demands, Job involvement, Motivation, Support, Job satisfaction and WLB were measured (Boyer, Carr, Mosley & Carson, 2007; Canman, Fichman,
Jenkins & Klesh, 1983; Kanungo, 1982; O’Driscoll, Brough & Kalliath, 2004). Preliminary analyses were run using hierarchical regression to examine the relationships between Job demands, Job involvement, Motivation, Support, Job satisfaction and WLB. In addition, Structural Equation Modelling (SEM) was used to further assess the mediating role of motivation and support in the theorized model. As predicted Job demands and Job involvement were significantly associated with Job Satisfaction ($F(2) = 70.7, p < .001$) and WLB ($F(2) = 3.29, p < .05$). Motivation and supervisor support significantly mediated the relationship between demands / involvement and Job Satisfaction ($\beta = .178, p < .001$; $\beta = .238, p < .001$, respectively). As such, the overall models incorporating motivation and supervisor support yielded good fit ($\chi^2(1) = .009, p = .925$; $\chi^2(1) = .018, p = .893$, respectively). No mediating effects were found for the relationship between demands / involvement and WLB or for colleague support, family support and friend support. While the data reported here is cross-sectional, Time Two data collection is currently underway and results will be tested and reported over time. The findings from this study contribute to the modelling of organizational and individual outcomes such as job satisfaction and work-life balance, specifically for professions where the boundaries between work and home are blurred. In contrast to traditional theories of demands, resources and outcomes, this study suggests that resources such as motivation and supervisor support actually act to mediate the relationships between demands and outcomes.

Keywords: teaching, work-life balance, job satisfaction, teacher demands, job support

Teachers’ experiences of long term use of Lions Quest SEL program

LINTUNEN, T. (University of Jyvaskyla), TALVIO, T. (University of Helsinki)

We interviewed teachers who have long, multi-year experience in using the Lions Quest (LQ) social and emotional learning (SEL) program at school. The aim was to describe and understand how teachers perceive the LQ program and achievement of its educational goals. Several research syntheses and meta-analyses of SEL interventions have concluded that programs concentrating on socio-emotional competencies can result in gains that are central to the goals of all schools. However, we do not know if the skills transfer to the practice situations and what the experiences of long term use of SEL programs are. LQ curricula focuses on training of interaction skills, service-learning, and violence and substance abuse prevention. It is based on the values of equal rights, respect for the needs of others, and cooperation and peaceful resolution of conflicts. LQ is international, widely known and has been available for over 20 years. Teachers and LQ instructors (12 women and 3 men) who had long experience in using LQ program at school were interviewed. The teachers worked in elementary, lower secondary and upper secondary schools. Thematic interviews were transcribed (116 pages) and processed using qualitative, inductive content analytical procedures. The themes extracted include perceived effects of the program at the individual, class, school and communal level. At the individual level, students learned empathy and expression of emotions. They started to support each other, and become able to make decisions and solve problems themselves. Teachers learned new tools for classroom management, problem solving, giving feedback, and working with groups. The program changed their values and behaviour to be more student centered. At the class and school level, teachers perceived that group safety and ability for collaboration increased. The participants were a selected group of teachers who had used LQ for many years. Consequently, their perceptions of the effects of the program were positive. However, the experiences of teachers offer significant insider’s view on the perceived long-term effects of LQ program on children and the whole school community. The results can be useful in planning SEL interventions and measures to study the effects of these interventions.

Team work with members from different cultures and disciplines at university

BEHRENS, K. (Griffith University), EGEA, K. (The University of Queensland)
The aims of this research were to investigate first year webdesign students’ approach to team work, their team work preferences and their experience of team work, and to identify strength and weaknesses of working in teams in the university environment. In particular the role of working in cross cultural and cross discipline teams was investigated with regard to communication, task management, relationships and culture. The cohort of first year webdesign students in the School of Information Technology and Electrical Engineering at Queensland University participated in the study in semester one 2009. As part of the course requirement students completed online questionnaires regarding their attitude to team work at the beginning, in the middle and at the end of the semester. In the questionnaires the students rated various team work attributes. At the end of the semester students were also asked to submit an individual reflection on their team work experience. The responses of 280 students were used in a quantitative and qualitative analysis. There were 126 female and 141 male students, while 25 did not indicate their gender. The majority of students were aged under 20 years and indicated to be Australian. There was however a large number of international students in the course and most students were working in teams with members from other cultures and other disciplines. The ratings of students working in cross discipline teams were generally higher than those working in teams from a single discipline, indicating greater awareness of team work attributes. However the ratings of students in cross cultural teams did not differ from those working in all-Australian teams. It was concluded that students are capable of working well with members from other cultures and are effective in their teams. Students effectively address issues regarding communication, task management, relationship building and culture in cross cultural teams. However, to be successful in their team work when working with team members from other disciplines, students needed to address various team work issues, such as task plan clarification and team member responsibilities.

**Keywords:** university students, team-work, cross-cultural, cross-discipline

**Terror management and implicit group identification: The effects of mortality salience on overlapping mental representations of self and ingroup**

**WATANABE, T. (The University of Tokyo), KARASAWA, K. (The University of Tokyo)**

In this article, we test the prediction derived from terror management theory that mortality salience would increase self-ingroup overlap. The theory provides the notion that people support their cultural worldview when mortality is salient. Although previous research has established death-related thoughts led to positive evaluation (Greenberg, Pyszczynski, & Solomon, 1990) and explicit identification (Harmon-Jones, Greenberg, Solomon, & Simon, 1996) toward ingroup, it remains unclear how they implicitly identify their ingroup under the fear of death. The present research addresses this question about overlapping mental representations of self and ingroup. Specifically, our prediction is that mortality salience would result in enhanced implicit ingroup identification in minimal groups. Thirty-nine undergraduates participated in the experiment. They completed the computer-based tasks, which consisted of personality questionnaires and a response time task. Half of the participants were reminded of death-thoughts, and the other half answered questions about their eating habits. Later, they were categorised into two groups ostensibly based on art preference (Tajfel, Billig, Bundy, & Flament, 1971). Following this minimal group procedure, they rated 60 trait descriptions about self, ingroup and outgroup. Participants next completed the response time task on the same traits, indicating whether or not a presented trait was characteristic of ingroup and outgroup members, respectively. If judgments on the group are facilitated by matches with self-judgments and inhibited by mismatches, it is interpreted that mental representations of the two concepts are overlapping (Smith & Henry,
In this study, response time facilitation was calculated by subtracting responses for self-group matching traits from responses for mismatching traits based on questionnaire ratings. We then conducted a 2 (MS: mortality salient vs control) x 2 (target: ingroup vs outgroup) x 2 (valence: positive vs negative) analysis of variance with repeated measures on the last two factors. This analysis found a main effect for target ($F(1, 37)=3.24, p<.10$), and the predicted interaction for MS x target ($F(1, 37)=6.32, p<.05$). Pairwise comparisons revealed mortality salience increased self-other overlap only in the ingroup condition. Response time analysis showed ratings of self-ingroup matching traits were faster when mortality was salient. This result is in line with our hypothesis that mortality salience increases self-other overlap to defend their cultural worldview. Since participants were given no information about their ingroup, self-conceptions are applied to ingroup conceptions (Cadinu & Rothbart, 1996). Future research needs to replicate these findings and further investigate self-other relationship under a group setting.

Keywords: terror management theory, group identification, mortality salience, ingroup, minimal group

The 1-2-3 Magic Program: Mid-term outcome of implementation in the home

BAILEY, E. (Southern Cross University), VAN DER ZWAN, R. (Southern Cross University), PHELAN, T. (ParentMagic Inc.), BROOKS, A. (Southern Cross University)

The aim of this project was to establish the outcomes for both parent and child of implementation of the 1-2-3 Magic program (a brief parenting intervention; Phelan, 1984) in the home. Empirical evidence suggests a robust link between negative parenting techniques and attitudes and the development of child behaviour difficulties (Smith & Farrington, 2004). The 1-2-3 Magic program aims to provide parents with positive techniques that facilitate successful child rearing and prevent the development of behaviour difficulties. Whilst the program has been available in Australia for some time and efforts have been made to establish short-term outcomes associated with its implementation in the home (e.g. Bailey et al., 2009), longer-term outcomes remain largely undefined for Australian families. This paper reports the mid-term findings from a project designed to address that situation by conducting the first longitudinal evaluation of the 1-2-3 Magic program using an Australian sample. Families with a child aged 6-12 years participated in a controlled trial of the intervention program. Parents/caregivers of those families were randomly assigned to either an immediate treatment group, or a wait-listed control group. Parents/caregivers in the treatment group began immediately a practitioner-directed education course, consisting of two 3-hour group sessions. The control group commenced training subsequent to the first follow-up assessment, after an interlude of two months. We report here data pertaining to the 8-month, post-intervention follow up and discuss mid-term outcomes for both parent/caregiver and child following implementation of 1-2-3 Magic in the home. For parents/caregivers, trends in levels of parental stress, confidence in parenting ability and use of positive parenting techniques over time will be discussed. For children, medium-term trends in behaviour change will be presented. The present study provides further insight into the suitability of the 1-2-3 Magic program as an intervention for Australian families. The potential benefits of the intervention as an 'entry-level' parenting program are also discussed. Ongoing research is focused on establishing the long-term outcomes associated with the implementation of the 1-2-3 Magic program in the home.

Keywords: positive parenting, parenting intervention, child rearing

The antecedents and impact of organisational identification after a university merger

TANG, N. (Shanghai Jiaotong University), WANG, Q. (Shanghai Jiaotong University)

Employee’s identification with the organisation has been recognised as an important and critical...
factor for understanding organisational behavior (Lee, 1971; Ashforth & Mael, 1989). Organisational identification will be even more important after a merger. University mergers have been a hot topic and phenomena in the last two decades in China, yet few empirical studies have studied the merger’s impact. In this paper, we look at the antecedents and impact of organisational identification after a university merger. This paper has two studies. In the first study, one university merger was used as the study focus and 119 employees and faculties were surveyed on their organisational identification with the former and new organisations, their organisational commitment, social accounts and satisfaction with the merger. Meanwhile, supervisors were asked to evaluate the performance of those employees and faculties. In study 2, an experimental method was used to see if there were priming effects of identifications with the former and new organisations. The first study showed that: (1) satisfaction with the merger and social accounts were antecedents of organisational identification with the new organisation; (2) the identification with the former organisation significantly influenced the after-merger job performance, while the impact of the identification with the new organisation on job performance was moderated by organisational commitment. The findings of the experiment revealed that the priming effect of the identification with the former organisation was not significant while the identification with the new organisation could be primed. This finding has some implication for how to foster identification with the new organisation after a merger. Social account and satisfaction with the merger are antecedents of post-merger organisational identification. Organisational identifications with the former and new organisation have different mechanisms on the post-merger job performance and the identification with the new organisation could be primed.

The assessment of posttraumatic stress disorder in emergency service workers

KEMP, R. (University of New South Wales), BOSTOCK, D. (University of New South Wales), PATERSON, H. (University of Sydney), BRYANT, R. (University of New South Wales)

Emergency service workers are routinely exposed to distressing events. As a result, the management of compensation claims related to the development of posttraumatic stress disorder (PTSD) is an important issue for emergency service organisations. The aim of this study was to review the quality of the diagnostic assessment reports prepared by clinicians who had assessed emergency service workers in connection to a PTSD related workers compensation claim. Access was granted to the files relating to a group of Australian emergency service workers who had made PTSD related compensation claims and the assessment reports were evaluated relative to the diagnostic criteria for PTSD in the DSM-IV-TR. Assessments were conducted by psychologists (80%) and psychiatrists (20%). In the majority of cases (81%), the assessor determined that the worker was suffering from PTSD but only one report met the minimum standard in that it showed evidence that all symptoms were (a) assessed (the assessor asked the claimant whether they had experienced the symptom); (b) justified (the report included examples provided by the claimant); and (c) endorsed (the claimant stated that they had experienced the particular symptom). Only one third of assessors’ reports addressed the possibility of malingering. This study suggests that the assessment reports fail to meet minimum assessment standards based the DSM-IV-TR. The implications of these findings are discussed in relation to both the welfare of the emergency service workers and their employers’ management of compensation claims.

Keywords: post-traumatic stress disorder, emergency workers, malingering, workers compensation, workers welfare

The challenges and successes of psychological service delivery to rural South West Queensland

MANN, W. (Centacare), DU PREEZ, J. (University of Southern Queensland)
General Practitioners and mental health clinicians recognise and acknowledge the expertise of psychologists in the diagnosis and management of the full range of mental health problems. This presentation highlights the challenges of recruiting and retaining sufficient numbers of psychologists by a particular service provider, while also outlining a particularly effective strategy implemented over the past decade. Continuing difficulties are identified with some options suggested as part solutions. Data is presented illustrating the scope of the challenges faced: nature and extent of mental health problems; scale of demand and geographic are covered; comparative research involving other service providers. The organisation has been recruiting and employing qualified and experienced psychologists for South West Queensland region for the past 13 years. The challenge to the organisation to offer effective and continuous services hinges on the difficulties of recruitment and retention of staff in these areas. The practice of sponsoring psychologists from abroad, who meet the standards of the Australian Psychological Society as well as the Queensland Board of Psychology, has proven to be an effective strategy. This has allowed for effective service delivery in this region as described by the community, GPs and consumers in a recent survey. Service delivery remains a challenge due to numerous reasons to be explored. Of particular note is the challenge of managing a situation in which overseas-trained psychologists with a particular cultural orientation are required to serve an ever changing multi-cultural population in the South West Queensland region. A future based exploration of ways to support these psychologists—personally and professionally—whilst delivering an effective service within this multicultural environment is outlined.

Keywords: diagnosis, general practitioners, overseas-trained psychologists, recruiting psychologists, psychological service providers

The aim of the present brief oral presentation is to quantitatively review prospective high risk longitudinal studies ascertaining the childhood neurodevelopmental precursors associated with schizophrenia. In addition, the current presentation aims to explore essential research questions such as whether the observed neurological, neuromotor, neurocognitive, social and behavioural deficits present prior or post diagnosis? Do they represent a continuous developmental decay? To what extent these neurodevelopmental deficits are sensitive and specific vulnerability markers for schizophrenia? This presentation evaluates the findings of 18 high risk studies and quantifies the factors that significantly differentiate between high risk and normal control children. Inclusion in the review was determined by several criteria. The results are presented under obstetric, neurological and neuromotor, cognitive, social and behavioural domains. In addition, the identified discriminating variables are presented in accordance with childhood developmental stages and relative to their effect sizes. The strengths and limitations of the studies and measurements are discussed. Additionally, recommendations for further studies are provided to strengthen the research methodology by using standardised neuropsychological measurements in order to acquire results that are true positive (specific to the development of schizophrenia), replicable and statistically significant. The accurate identification of predictive neurodevelopmental precursors of schizophrenia provides valuable insights regarding the developmental pathways of schizophrenia spectrum disorders. Indeed the identification of childhood neurodevelopmental variables may be markers of genetic liability to schizophrenia. In addition, the true positive identification of these endophenotypes is a major advancement in scientific knowledge guiding the development of effective early preventative intervention programs.

Keywords: childhood neurodevelopment, schizophrenia, interventions, development

The condition of Chinese adolescents' parental monitoring and its effect on their social adjustment
This study aimed to extend the former construct of parental monitoring to three factors: parental knowledge, negative feedback and autonomy granting, as well as to explore the condition of Chinese adolescents’ parental monitoring, its effect on their social adjustment, and the moderating effect of Neuroticism. A total of 2340 students participated in this study. Parental Monitoring Questionnaires, Adolescents’ Social Adjustment Assessment Questionnaires and NEO-R were used. The results showed that: (1) there were significant differences between grades and sex in adolescents’ parental monitoring. That is, parental knowledge about girls was significantly higher than boys, the negative feedback of boys was significantly higher than girls; parental knowledge and autonomy granting of children from lower grades was significantly higher than those from higher grades, and negative feedback of Grade Eight was significantly higher than Grade Ten and Grade Eleven. (2) The adolescents’ parental monitoring could be categorized by three styles, including democratic, controlling and Laissez-Faire, whose proportion were 38%, 30% and 32%, respectively. (3) The three styles differed significantly in all aspects of adolescents’ social adjustment. (4) Neuroticism served as a moderating factor in the relationship between parental monitoring and negative social adjustment. In general, results demonstrated that the condition of Chinese adolescents’ parental monitoring is balanced. The effect of parental monitoring is moderated by adolescents’ neuroticism character.

Keywords: parental monitoring, parental knowledge, parental negative feedback, adolescents’ neuroticism, adolescents’ social adjustment

The construction of an off-line meta-cognitive regulation test and its application on personnel selection

Higher level processes such as monitoring and controlling of cognitive behavior have been pervasively emphasized in recent years, and meta-cognitive regulation was regarded as one of the hot points of contemporary psychological studies. The significance of scientific research on meta-cognitive regulation is momentous both in theoretical and practical fields. According to the object, area and time of regulation, meta-cognitive regulation could be decomposed into two components: on-line regulation and off-line regulation. On-line regulation happens during a certain task, while off-line regulation takes place out of a certain task situation. The purpose of the present study was to explore the psychometric structure of off-line meta-cognitive regulation, and to construct an assessing instrument with high criterion-related validity. The data of this study were collected from a large-scale Information Technology company in China. In Study One, 260 employees participated in the preliminary test. By using a self-developed questionnaire, a three-factor structure of off-line meta-cognitive regulation was obtained, which included global-planning, insight and generalization. After a retest study with 115 participants, the structure of off-line meta-cognitive regulation was confirmed. In Study Two, in order to examine the criterion-related validity of the off-line regulation questionnaire, hierarchical linear regression and hierarchical logistic regression were conducted by the researcher. The following findings were obtained: The managers are different from the common staff in particular regulation factors. Managers have a higher generalizing level than others in sales departments, while managers in support departments have higher insight levels than others. On the other hand, for common staff, the level of off-line meta-cognitive regulation fails to predict employees’ performance in the sales department. However, for staff in the support department, level of global-planning predicts the creative activities reversely. According to the results, we may suggest that the off-line meta-cognitive regulation questionnaire has good psychometric qualities, and the procedures of administrating and scoring are objective and standardized. It can be applied to practical use such as personnel selection and promotion.

LI, J. (Beijing Normal University), LI, Y. (The Chinese University of Hong Kong)
The contextualised assessment tool for risk and protection management: Validation and evaluation of a scale for examining the strengths of youth at-risk

CARROLL, A. (The University of Queensland), BOWER, J. (The University of Queensland), ASHMAN, A. (The University of Queensland)

The Contextualised Assessment Tool for Risk and Protection Management (CAT-RPM) is a 95-item on-line tool that aims to identify risk and protection across six domains (self, family, school, peers and leisure, community, and significant life events) in at-risk youth. Items target information about the operating frameworks, relationship base, and leisure time activities of participants in these six domains, and a visual representation of the balance of risk and protective factors emphasises the young person’s strongest domain. Cultural relevance to Indigenous young people has also been taken into account. The present research investigated the reliability and validity of the CAT-RPM with Australian high school students aged 12 to 18 years. In total 387 participants (196 males and 169 females, mean age of 14.95 years) from nine high schools across three states in Australia participated in the trial of the CAT-RPM. Using the school’s Index of Relative Socio-Economic Disadvantage (IRSED) rating as a guide, participants who attended schools located in a range of socioeconomic areas were recruited. Participants completed the tool on-line during class times using the school computer facilities. Principal Components Analysis forcing two factors was conducted to determine the content validity of the instrument. Levels of risk and protection were measured according to a process of weighting the severity of items and establishing their multiplicity. Psychometric properties of the on-line tool were sound with adequate alpha levels for the various scales. To establish whether there were differences in risk and protection management among males and females, Indigenous and non-Indigenous, and junior and senior school students, t-tests were conducted. The final product is a strengths-based, culturally relevant assessment tool with strong psychometric properties, measuring the balance of risk and protective factors for at-risk youth. The CAT-RPM can assist both professionals and young people in identifying optimal support networks and most appropriate interventions to facilitate change. It is useful in a case management model of assisting young people at risk.

The dark side of leadership: Prevalence of potential leadership derailers in a management population

WEBSTER, V. (Griffith University), MYORS, B. (Griffith University)

Currently there is a paucity of research on the ‘dark side of leadership’. Potential derailers might achieve short term objectives but can, over time, lose the support of colleagues and subordinates and potentially lead to serious problems in the workplace. This study will analyse the prevalence of extreme preferences toward derailment behaviours and the relationship between personality and motivation drivers with the use of these quasi-leadership tactics. De-identified archival data on the leadership profiles of 301 executives, managers and line managers (193 males and 108 females), across a range of industries and occupations, were used. Two-hundred and eleven were from the private sector and 90 from public sector. The majority of participating managers were Australian, with a small proportion from New Zealand, United Kingdom, South Africa and Asia. The data were collected for the purposes of selection, promotion and/or leadership development. The Global Personality Inventory (GPI) (Schmit, Kihm & Robie, 2000), an on-line self report leadership profiling tool, was used, and responses were scored against the appropriate management norm, using proprietary software. The independent variables were: Achievement Drive, Affiliation, Socialised Power, Personalised Power and Self Management. The dependent variables were Prevalence of leadership derailers, e.g. ego-centred, intimidating, manipulating,
micromanaging and passive-aggressive. This data supported the hypothesis that there is a significant proportion of the management population who are likely to use quasi-leadership tactics to achieve their objectives. One-hundred and eighty six (62%) reported a strong to extreme preference (seventieth percentile or higher compared to the norm) for using at least one derailing behaviour. Eighty two reported a strong preference to use at least two derailers; 35 reported a strong preference to use at least three derailers; 12 reported a strong preference to use at least four derailers; and eight reported a strong preference to use all derailers. Using correlation analyses, significant relationships were found between all independent variables and the dependent variable, in the predicted direction. These results confirm there is a significant prevalence for using potential leadership derailers in this management population, supporting the need for further study into the variables leading to and the impacts of derailers on leadership style.

The development and evaluation of crisis communication training for health professionals

KIKKAWA, T. (Keio University), KATO, F. (Keio University), NAKAMURA, M. (Ryutsu Keizai University), SUGIURA, J. (Aichi University of Education), NAGAOKA, T. (Sanno University)

The aim of this research was to examine the structure and outcome of a crisis communication training program for health professionals. Despite the attention paid to health crises in recent years (e.g. outbreaks of E-coli and swine flu), relatively little attention has been paid to communication skills in general, and the crisis communication skills in particular, of health professionals. Poor communication can lead to fiascos during crises. The author and colleagues have been developing and evaluating a training program in this area. Twenty-five officials of a Japanese ministry voluntarily participated in the training. The program consisted of five sessions, which occurred approximately monthly. Each session began at 18:30 in the meeting room of the ministry and ended at 19:30. Effectiveness was evaluated in terms of changes in cognitive complexity, changes in confidence in communication skills, and perceived need for training in communication skills. Independent evaluators (i.e. medical doctors and a journalist) also observed participants and evaluated their performances. No significant changes in cognitive complexity were found. However, confidence in communication skills increased slightly, and perceived need for communication skills increased. In addition, the independent observers noted the active engagement of participants in the training and commented favorably about the relaxed atmosphere during training. We expected that cognitive complexity would increase as the training proceeded. The absence of significant change in this regard is likely due to a self-selection bias. That is, the cognitive complexity demonstrated by participants at baseline was higher than expected, resulting in a ceiling effect. Relatively higher interest in crisis communication in this volunteer sample may have been associated with increased communication skills. Given the absence of similar training programs, these results underscore the relationship between training in communication skills and increased confidence in and perceived need to learn about communication skills. It is necessary to improve this training program so that the needs of health professionals and the public will be met in the event of health crises.

*Keywords: cognitive complexity, communication skills, communication skills, crisis professionals, health professionals*

The development and preliminary validation of a religiosity assessment instrument to be used in the Muslim population

PURWONO, U. (Universitas Padjadjaran, Bandung), FRENCH, D. (Purdue University)

There has been increasing interest in understanding the role of religion in the lives of children and adolescents. The effectiveness of this research is constrained by difficulties associated with measuring youth religious involvement, particularly in the Muslim population. This study reports on the
The development and validation of the Chinese Psychological Hardiness Inventory: An emic-etic approach

LAI, C. M. (The Chinese University of Hong Kong), YOU, J. (The Chinese University of Hong Kong), FU, K. (The Chinese University of Hong Kong), LEUNG, F. (The Chinese University of Hong Kong), CHEUNG, F. (The Chinese University of Hong Kong)

The present study aims to develop and validate the Chinese Psychological Hardiness Inventory (CPHI). Hardiness is a global psychological quality theoretically defined as consistent pattern of behaviors, motives, and feelings where individuals view potentially stressful situations as normal aspects of life and opportunities for growth rather than threats (challenges), they keep believing in their own capability to change the situation (sense of competence), and can be involved in a social relationship (social commitment). The indigenously developed CPHI comprises 32 items with dichotomous scales originally drawing from the 541-item pool of Chinese Personality Assessment Inventory-2 (Cheung, Leung, Song, & Zhang, 2001). The scale was administrated to about 100 Hong Kong college students, 1360 normative individuals and 730 psychiatric patients aged 18 to 45 from Mainland China and Hong Kong. All items in CPHI were checked and approved to be comprehensible by both mainland and Hong Kong Chinese. The CPHI showed high internal consistency, temporal reliability and valid factor analytic structure. Hierarchical regression analysis demonstrated the concurrent validity of the CPHI in predicting various aspects of life satisfaction after controlling for the effect of life stressors. Analysis of variance suggested the concurrent validity of CPHI, in which the hardiness level of the normative sample was substantially higher than that of the psychiatric sample. Logistic regression further established its incremental validity to predict suicidal tendency among depressive patients beyond the severity of depression. Norms of the CPHI was provided on the basis of over 1300 normative participants. The CPHI extends the foreign construct of hardiness (Kobasa, 1979) to collectivistic Chinese culture, and at the same time avoids the problems of translation and cultural irrelevance. It is a comprehensive, efficient, reliable and valid measure of hardiness.
that taps the psychosocial adjustment level of Chinese under stress from a combined emic-etic approach.

Keywords: Chinese Psychological Hardiness Inventory, hardiness, stressful situations, competence, depression

The development of inequity aversion in Japanese children

MORI, K. (Kwansei Gakuin University), YUKIHIRO, R. (Kyoto Gakuen University)

In this study, we investigated the developmental sequence of inequity aversion preference in Japanese children. Forty-nine Japanese elementary school children (aged 6 to 12) participated in the experiment. Each child was asked to allocate virtual tokens to himself/herself and to his/her partner (a graduate or undergraduate student). A pair of even and uneven token allocations was displayed on a touch-screen and the participants selected the pair of their choice. A total of eight pairs were displayed in a sequence; these pairs differed in terms of the absolute, relative, or joint amount of payoff. At the end of the experiment, tokens won by the participants through the series of choices were exchanged to stationery. A principal component analysis on the choices in the eight pairs extracted three principal components that accounted for 70% of the item variance. The three components consisted of the following types of pairs respectively: (1) The unequal allocations were advantageous and the payoffs obtained from them were more than those from the equal ones; (2) the unequal allocations were disadvantageous but the payoffs obtained from them were not less than obtained from the equal ones; and (3) the unequal allocations were disadvantageous and the payoffs obtained from them were less than those from the equal ones. A 3 (component) × 3 (grade group) × 2 (sex) ANOVA on the rate of equal choice revealed significant main effects of component and grade, and a component × grade interaction effect. In other words, participants in higher grades were averse to disadvantageous inequality even when they could obtain a larger payoff from it. Besides, participants showed a strong aversion to disadvantageous inequality with low payoffs and reluctance to abandon advantageous inequality regardless of their grade. No other significant effects were detected. Our results revealed that the aversion to disadvantageous inequality showed a strong development with age; on the other hand, aversion to advantageous inequality remained at low levels. In conjunction with recent findings, the results of this study suggest that advantageous inequality aversion may be evoked selectively (i.e. only within ingroup members) and is scarcely developed among people in general.

Keywords: inequity aversion preference, unequal allocations, inequality, ingroup members, payoffs

The development of the perception of “overt” and “covert” prosocial behavior in Japanese children

YAMAMURA, A. (Osaka university)

Although a large number of studies have investigated “overt” prosocial behaviour (e.g., helping, contribution), few have investigated “covert” prosocial behaviour (e.g., caring, waiting). Ninomiya (1993) suggests that teachers and nurses perceive covert behaviour as prosocial in Japan, however few studies have investigated covert behaviour in childhood. Therefore, the purpose of this study was to examine the development of perception of “overt” and “covert” prosocial behaviour and the correlation between the perception of each behaviour and empathy. Children aged 10 (n = 97) and 12 (n = 80) completed a 16-item empathy scale. They were asked about their “concern of empathy” and “perspective taking”. Participants also responded to four prosocial episodes in which a friend was distressed. The characters in the stories were two helpers who are prosocial – one helped immediately (overt behaviour) and the other kept an eye on distress (covert behaviour). The questions about each of the characters concerned the degree of prosociality (8 items). An ANOVA showed that the 10 year-olds estimated the overt prosocial behaviours as being more prosocial than the covert prosocial behaviour and that the 12 year-olds estimated the covert prosocial behaviours as being more prosocial. In addition, for the 12 year-olds, the perception of covert prosocial
behaviours had significant plus correlation with “concern of empathy” and “perspective taking”. This effect showed few significant correlations. These data suggest that, in childhood, the perception of others’ covert prosocial behaviour is developmental. It appears that prosocial behaviours are variable in children. Yarrow et al. (1976) pointed out that prosociability appears not to be a unitary concept. Their report supports this study.

Keywords: prosocial behaviour, overt behaviour, covert behaviour, empathy

The differential impact of psychosocial and physiological factors on the self-management of type 1 diabetes in young people

SMITH, L. (University of Sydney), OVERLAND, J. (Royal Prince Alfred Hospital, Sydney), JOHNSTON, C. (The University of Western Sydney), HATHERLY, K. (The University of Sydney), WALLER, D. (The University of Western Sydney)

Attaining recommended levels of metabolic control can be a challenge for many people with Type 1 Diabetes (T1D). This is particularly so during adolescence due to the physiological and psychological changes taking place during this period. This study aimed to investigate the differential impact of psychosocial and physiological determinants of metabolic control. A sample of 158 Australians with T1D, aged 8 to 19 years, and their families, were recruited independent of their source of care as part of a longitudinal, cross sectional exploratory study. Data were gathered regarding demographic, physiological (self-monitoring of blood glucose, adherence to insulin regimen, rates of hospitalization) and psychosocial (negative affect, coping, self-efficacy and knowledge of diabetes) information. A capillary sample was taken for glycated hemoglobin (HbA1c) determination. Multiple regression procedures were performed, using backward elimination, to determine those factors contributing to metabolic control. Participants’ attitudes and beliefs about coping, negative affect and self-efficacy were significant predictors of metabolic control ($ps < 0.05$; adjusted $R^2 = .302$) and contributed more to the variance in the data than physiological measures such as self-monitoring of blood glucose and rates of hospitalization ($ps > 0.05$). Adherence to insulin regimen was the only physiological measure to remain in the final regression model ($p = 0.007$). Young people with T1D reporting high acceptance and low avoidance behaviours, confidence in their ability to manage the condition, who are not depressed and who are adherent to their treatment regimen, are more likely to achieve acceptable levels of metabolic control. Research models incorporating both psychosocial and physiological markers of self-management of Type 1 Diabetes can provide a clearer view of those factors which are most important to achieving optimal self-management of T1D. Healthcare focusing on physiological self-care behaviours may not adequately address those aspects of T1D self-management that can have long term effects on health and quality of life.

Keywords: type 1 diabetes, self-care, metabolic control, self-monitoring, self-efficacy

The dual social impact of university outreach programs on enrollment in higher education

ADDI-RACCAH, A. (Tel-Aviv University), ISRAELASHVILI, M. (Tel-Aviv University)

In order to increase the enrollment of low socioeconomic status (SES) students with higher levels of ability in higher education, many universities and colleges initiate outreach programs. In spite of their popularity, little is known concerning the programs’ contributions and long-term effects. Based on a follow-up study of adolescents who were enrolled in such a program twenty five years ago, the current study addressed two questions: 1) Did participation in the outreach program lead low-SES participants to enroll in higher education? 2) To what extent did the participants attribute their present personal achievements to their experiences within the outreach program? Using several methods for data collection we were able to approach 198 adults who had participated (72%) in an outreach program 25 years ago, or who served as a comparison group (28%). These ex-students studied in two large high schools located in low-SES neighborhoods of metropolitan Tel–Aviv–Jaffa. The participants
completed questionnaires on various aspects of their participation in the program in the past as well as various aspects of their current life and self-perceptions. The findings indicate that currently (ex)participants in the program have more advance academic degrees in comparison to non-participants. Moreover, interviews with a random sample of ex-participants show that those who have continued to higher education partially attribute their academic education to the outreach program in that it enhanced their confidence that higher education is attainable. However, those participants who have not been enrolled in higher education perceived it as their personal failure and lack of effort at school. No significant differences were found between these two groups in attitudes regarding the social and economic merits of higher education. Outreach programs might have dual social impact. On one hand they can significantly foster the enrollment in higher education of the low-SES population. On the other hand they might also operate as a social mechanism that preserves the prevailing social order, which favors the more advantageous groups in society. Namely, by attributing failure for not enrolling in higher education to personal capacities, the participants who did not continue to higher education legitimatize social inequality.

Keywords: low socioeconomic status, university outreach programs, higher education, social inequality, failure attributions

The effect of coloured overlays on reading Japanese characters for Japanese students with/without Scotopic Sensitivity Syndrome

IMAIZUMI, S. (Chiba University), KOYAMA, S. (Chiba University), HIBINO, H. (Chiba University), SINGU, Y. (Chiba University)

Scotopic Sensitivity Syndrome (SSS) is also known as Irlen Syndrome. People with SSS perceive abnormal brightness and visual distortions from text while reading. In the present study, we conducted a survey on the prevalence of SSS in Japanese students. Since coloured overlays were reported to ease reading of English text (Irlen 2005; Wilkins 2003), we also examined whether the overlays of various colours could ease reading of Japanese text. In the survey, 152 students (45 males and 107 females) completed a questionnaire, which contained the diagnostic criteria of SSS by Iren Institute. The questionnaire included 14 questions regarding their reading and lifestyle. In the experiment, 33 students (13 males and 20 females) who participated in the above survey read Japanese and English texts with or without coloured overlays. Six students met the diagnostic criteria for possible SSS. The stimuli were 11 sets of 144 Japanese characters (Hiragana) in a 12 x 12 characters grid. The students read ten sets with coloured overlays (Irlen Overlay), and read one set without the overlay. The colours of the overlays were purple, peach, rose, orange, yellow, green, light blue, blue, bluish gray, and gray. After reading all the Japanese texts, they were asked to evaluate how easy they were to read with each coloured overlay by using the normalized ranking method. In the same way, they read English texts with or without coloured overlays, and evaluated how easy they were to read. In the survey, 36 students (10 males and 26 females, 23.7% of the total) met the criteria for possible SSS. In the experiment, light blue, bluish gray, gray, and green were ranked significantly more highly than the other colours ($p < 0.01$) by the normal students. The results were very similar for English characters. Light blue and bluish gray were also ranked highly in the six students with possible SSS. Interestingly, some students with possible SSS ranked blue and purple highly, although those colours were ranked low in the normal students. Our study suggested that approximately 20% of students may have SSS in Japan. Overlays in some colours may ease their reading.

Keywords: scotopic sensitivity syndrome, visual distortions, reading ease, colour overlays on text

The effect of distraction on forced-choice symptom validity tests amongst individuals with mild-moderate traumatic brain injury

LEIGHTON, A. (University of Western Australia)

Measures designed to assess test-taking effort, called Symptom Validity Tests (SVTs), are critical for accurate neuropsychological assessment. It
Abstracts of the 27th International Congress of Applied Psychology

Brief Oral Presentations

has recently been suggested that some SVTs that purport to assess effort alone may actually require a degree of cognitive ability (Batt, Shores, & Chelachuk, 2008). Subsequently, these tests may misclassify truly impaired individuals as feigning or exaggerating, and thus may be unsuitable for use with impaired individuals. The present study compared the performance of Healthy Adults (HA; \( n = 74 \)) to those with mild-moderate Traumatic Brain Injury (mmTBI; \( n = 47 \)) on two well-validated SVTs: the Word Memory Test (WMT) and the Test of Memory Malingering (TOMM). These groups were further randomly allocated to one of three conditions: full effort (FE), full effort with distraction (FED) or simulated malingering (SM). SM groups were given instructions to feign impairment adapted from Tombaugh (1997). Conversely, the FE and FED groups were asked to optimize their efforts. In addition, the FED group completed an auditory distraction task during the learning phase of each SVT. Results indicated that participants in the FED condition had significantly lower scores on the WMT, but not the TOMM, when compared to those in the FE condition for both the HA and mmTBI groups. Participants in the SM condition scored significantly lower than both the FE and FED groups regardless of TBI history. With regard to classification accuracy, sensitivity was identical (88%) for the WMT and the TOMM in both the HA and mmTBI simulating groups. Only one (4%) of the participants across FE and FED groups was misclassified as giving sub-optimal effort on the TOMM (96 to 100% specificity). Conversely, false-positive rates for the WMT were unacceptable, with eight of 26 (30%) of HA in the distraction condition misclassified as giving inadequate effort, and 11 of 19 mmTBI (58%) in this condition similarly misclassified (42 to 70% specificity). The TOMM test results were consistent across FE and FED conditions, supporting it as a true test of effort, whilst the WMT produced unacceptable false positive rates under conditions of distraction and hence may not be suitable for use as a measure of effort for persons with significant cognitive impairment.

The effect of intervening variables on strain for Japanese workers

NODA, T. (Tezukayama University Graduate School), NAKAGAWA, T. (University of Tezukayama Graduate School), MORISHITA, T. (University of Tezukayama)

Coping, social support and social skill are known as intervening variables between stressor and strain. The purpose of this study was to examine which of those variables reduces strain the most and how stressor and intervening variables effect strain on Japanese workers. The participants were 241 Japanese workers (184 males and 57 females) who completed five questionnaires to measure stressor, strain, coping, social skill and social support. Factor analysis was conducted on stressor, coping and social support. Multiple regression analysis was used to examine how well strain can be predicted from other variables and factors. Finally, an unpaired t-test was used to compare the difference between male and female workers. As a result of factor analysis on stressor, six factors (overwork, role ambiguity, role conflict, job aptitude, evaluation and workplace environment) were extracted. For coping three factors (self-subjective type, avoidance type, others-subjective type) were extracted and for social support two factors (positive support, moralistic support) were extracted. Multiple regression analysis indicated that stressor significantly enhances strain while social skill reduces strain, however coping and social support were not significant predictors of strain. With regard to two factors of social support, the result showed that the positive support from fellow workers reduces strain. In contrast, it showed that avoidance type coping increases strain regarding three factors of coping. An unpaired t-test showed that male workers were more likely to feel overworked and role conflict, while female workers were more likely to feel workplace environment as a stressor. The results also showed that males tended to use self-subjective type coping and females tended to use avoidance type coping, and that males had higher social skill than females. These results suggest that social skill reduces strain the most among three intervening variables and that the positive support from fellow workers also reduces strain. In contrast,
avoidance type coping seems to increase strain. Finally, there seem to be sex differences in stressor, social skill and coping, which may mean that we need different stress managements for each sex.

The effect of invulnerability and Theory of Planned Behavior (TPB) on drinking and driving among young Chinese drivers

WU, A. M. S. (University of Macau), CHAN, D. C. N. (University of Macau)

Though scarcely studied, a large proportion of traffic accidents are alcohol-related and thus driving after alcohol use poses risk on both personal and public health in Chinese societies. Young adults are more likely to engage in drinking and driving and thus are of particular concern. The aim of this study is to investigate both the direct and indirect influences of the three Theory of Planned Behaviour (TPB) components (attitude, norm, behavioral control) and invulnerability, on young Chinese drivers’ drinking and driving. This study is a self-administered online questionnaire survey. The Chinese questionnaire template was created by an online survey program (www.surveymonkey.com), and the survey hyperlink was posted at popular Chinese public forums for young people in Macao. One hundred and twenty-four licensed drivers (aged from 19 to 35 years) fully completed the questionnaire online with informed consent of participation given. Among the respondents, 39% had driven after taking alcohol in that period of time. The results of correlation analysis showed that intention to drive after drinking was positively correlated with attitude, subjective norms, perceived behavioral control, invulnerability, and prior driving behavior after drinking (ps < .05). The result of path analysis revealed the significant indirect effect of invulnerability on intention, through promoting a favorable attitude and a greater perceived behavioral control of driving after alcohol use. The present findings suggest that irrational beliefs of invulnerability to danger as well as the three TPB components are potential targets in safety campaigns for Chinese people.

The effect of job stress on medical scheme claims and member well-being

PIENAAR, J. (North-West University), MOSTERT, K. (Department of Industrial Psychology), ROTHMAN, I. (Afriforte Pty Ltd.), ROTHMANN JR., I (Afriforte Pty Ltd.), HAGEMAN, G. (Energi)

The aim of this research was to determine the impact of job stress on medical scheme claims and physical health risks. A measuring instrument embracing the job demands-job resources model was implemented in a closed medical scheme environment in the financial industry in South Africa. The member population of medical aid is 120 000. Participation was voluntary and a total of 3230 members completed the survey in a nine month period. Medical Scheme Insured Benefit claims data was available for the entire sample whilst objective physical health data was available for 1264 members. Physical health data included blood glucose and cholesterol levels, blood pressure, Body Mass Index, dietary index, exercise profile, and cardio-vascular disease risk. Firstly, structural equation modeling was used to fit the data to a conceptual model. Secondly, MANCOVA was used to determine differences in claims between risk factors while controlling for certain factors. Lastly, logistic regression was used to determine odds ratios for risk factors. Burnout, stress and associated distress states resulted from high job demands and low decision latitude and recognition. The relationships were moderated by perceived supervisory support at work. These work variables (demands and lack of resources) contributed to 62% of distress states, which in turn was responsible for 64% of stress-related ill health symptoms. Work variables (demands and lacking resources) were responsible for 40% of the stress-related ill health symptoms experienced by participants. Stress-related psychological ill health was the best predictor of medical aid claims. Members experiencing high levels of stress-related psychological ill health
Abstracts of the 27th International Congress of Applied Psychology

symptoms claimed on average 3135.17 Rands (approximately 418.69 United States Dollars) more than members experiencing low levels of psychological ill health symptoms over a six month period. The odds of suffering from chronic medical conditions also increase substantially if high risks for burnout were evident. Members at higher risk of burnout also posed risks in terms of productivity, attendance levels, exercise, medicine usage, doctor visits, and being overweight. Strategically, ways to mitigate job stress (consisting of high job demands and a lack of job resources) in combating medical aid inflation should be facilitated. Employer groups are crucial and should act as strategic partners of the medical aid provider. This is mainly because job stress does not only affect medical expenses but also affect organizational effectiveness and competitiveness and the quality of life and health of members/employees.

Keywords: job stress, medical scheme claims, body mass index, organisational effectiveness, burnout

The effect of learning hydrocarbon covalent bond structural formulae by correct and incorrect combined worked-examples

QI, Z. (Liaoning Normal University), DEZHI, X. (Liaoning Normal University)

In previous studies, few researchers paid attention to the role of incorrect worked-example in worked-example learning. Furthermore, they drew different conclusions. We thought that the outcomes would be better when using the combination of correct and incorrect worked-examples compared with the correct worked-examples only in worked-example learning. This hypothesis was tested by three experiments in this research which used hydrocarbon structural formulas of organic chemistry as the materials. High school students from Grade One were recruited to participate in this research. Single-factor design was implemented in each experiment. All the hydrocarbon structural formulas were selected from a chemistry textbook of Senior Two level. A total of 293 subjects were assigned to the three experiments (79 participated in Experiment One, 116 participated in Experiment Two and 98 participated in Experiment Three). They all participated in the pre-test, worked-example learning, and the post-test in quiet classrooms. The results were the following: (1) Experiment One showed that the effect that combination of correct and incorrect worked-example learning was significantly better than single correct worked-example learning; (2) Experiment Two showed that the scores achieved from the combination group, which contained equal number of correct and incorrect worked-examples, were significantly better than the scores achieved from the combination group in which the number of correct worked-examples was larger than that of incorrect ones. At the same time, the scores achieved from the combination which contained equal number of correct and incorrect worked-examples were significantly better than the scores achieved from the combination group in which the number of correct worked-examples was smaller than that of incorrect ones (the proportion of correct and incorrect worked-examples was 2:6 or 6:2 in this study). In addition, the scores achieved from the combination group in which the number of correct worked-examples was larger than that of incorrect ones were higher than the scores achieved from the combination group in which the number of correct worked-examples was smaller than that of incorrect ones (but this was not a significant difference); (3) Experiment Three showed that the effect was most significant when correct and incorrect worked examples were matched; the effect obtained from the combination group in which correct worked examples were put before the incorrect ones was worse than the effect of the matched group; the effect obtained from the combination group in which correct worked examples were put after the incorrect ones was the worst. The conclusion derived from this study is that the learning outcomes could be promoted when using appropriate incorrect worked-example in worked-example learning.

Keywords: worked-example learning, correct worked-examples, incorrect worked-examples, learning outcomes, combinations of worked-examples

The effect of mindfulness training on performance in closed-skill sports: The power of mild acceptance
MEEÛS, M. (Technical University Lisbon), BOEN, F. (Catholic University Leuven), DE CUYPER, B. (Catholic University Leuven)

The purpose of this experiment was to examine the effect of mindfulness training on performance in closed-skill sports, during which athletes have much time to reflect in between their physical activities. One experimental group was composed by 27 participants, who followed an eight-week course in mindfulness. It was compared with a control group of 36 participants who did not follow any training in mindfulness. In the pretest (that is, just before the start of the mindfulness course) and in the posttest (that is, after the end of the course, eight weeks later), participants completed three motor tests: a darts test, a golf putting test, and a sinusoid test. Repeated measures ANOVAs showed that the experimental group improved significantly more on the golf putting test than the control group. A similar result was found for the number of errors made on the sinusoid test. The order in which the tests were performed (first golf putting test or darts test) also had an impact. The experimental group that performed first the darts test improved significantly more in the number of errors, compared to the other groups. No significant group effects were found in the darts test, neither in the extent of errors on the sinusoid test. It is concluded that mindfulness might have a positive effect on specific motor skills in closed-skill sports. Further research is needed to corroborate these preliminary findings.

**Keywords:** mindfulness training, motor skills, closed skill

### The effect of neighborhood crime prevention on public perception of crime

This study examines the effects of neighborhood crime prevention on inhabitants’ perception of crime and public safety in a suburb of Tokyo. A questionnaire survey was conducted in November 2007 in Ichikawa city, Chiba. Data was obtained from a randomly-sampled of 1184 adults (aged 20 to 69). The questionnaire included the variables of seeing the patrol and crime map, as well as four outcome variables: perceived risk, fear of crime, evaluation of public order and residential satisfaction. Hierarchical multiple regression analysis revealed that civilian patrol is associated with higher perceived risk and lower residential satisfaction, whereas inspecting a crime map bulletin board was strongly associated with higher perceived public order and residential satisfaction. Fear was affected by neither the patrollers nor the crime map bulletin board. Civilian patrol seems to be successful in attracting public awareness of crime, whilst the intervention may undermine sense of community and residential satisfaction. Disseminating crime maps might help general public to adjust their perceived risk to objective crime rate.

**Keywords:** crime prevention, neighbourhood crime, fear or crime, community satisfaction, public order

### The effect of providing information on increasing users of parking lots for bicycles: A single case study on a Japanese university campus

OKINAKA, T. (Kwansei Gakuin University), SHIMAZAKI, T. (Kwansei Gakuin University)

Illegal parking of bicycles near the station, store and on campus is at issue in Japan. They are obstacles to the mobility of pedestrians and wheel chairs. Also, they damage the landscape of a community. Though much effort had been devoted to decreasing illegal parking, few empirical studies are available. The aim of this study was to increase the number of users of a bicycle parking lot from the applied behavior analytic perspective. The number of bicycles in a parking lot on the campus was measured over 6 weeks. Information was provided that included the time required to travel between parking lot and lecture room, with a campus map and the merit of using parking lots (e.g., secured parking). This information was provided through placards set in a campus, handbills posted to illegally parked bicycles, and the university website. Single case experimental design (ABC
design) was used to evaluate the effects of these interventions. Furthermore, parking lot staff assessed the social validity of this intervention by completing a 7-point scale questionnaire and free description. Providing information in the way this study used did not increase the number of users of the parking lot for bicycles. And although staff of the parking lot assessed the goal of this study as highly important, the result and appropriateness of the study's procedures were not satisfactory. Other subsidiary data was also obtained.

Keywords: information provision, bicycle parking, applied behavioral analysis

The effect of psychosocial factors on marital adjustment: An Indian perspective

SHRIVASTAVA, M. (Higher Education Department)

Marriage and family are not only optional, they are essential as they meet man’s deepest need for companionship, affection and sexual expression (Kumar and Rohtagi, 1987). Veenhoven (1983) equated marriage to an indispensable heaven. Marriage makes a person feel wanted, needed, approved of, secure and complete to a degree which cannot be thought of in any other human relationship (Coleman, 1964). Adjustment state, in which the needs of the individual and the claims of the environment are fully satisfied, is the process by which this harmonious relationship can be attained (Eysenck, et al., 1972). There are many psychological and social factors which can affect marital adjustment. Psychological factors including intelligence, self-disorder, interest, feelings, attraction etc., are the main features. Age, religion, income, education, etc. are considered social factors. The psychological factors selected for the study were self disorder and intelligence, and the social factors of age and income. Thus the aim of the study was to determine the relationship between psychosocial factors and marital adjustment and to investigate the relationship between psychosocial factors and marital adjustment.

The sample consisted of 200 Indian couples from Bhopal and Jabalpur town in Madhya Pradesh, India. Randomly selected couples were divided into two categories on the basis of their age. The first group was called lower age group (25-35 years) and the second group was called the higher age group (36-50 years). To study the effect of psychological factors on marital adjustment three standardized tests were used – the Marital Adjustment Questionnaire (developed by Dr Pramod Kumar and Kanehan Rahetogi), the Self Disorder Inventory (developed by Veerendra Sinha), and the Raven Progress Matrices (developed by Raven). All three tests were administered on the 200 couples, who were asked to fill out their questionnaires independently and without discussing answers. There was no significant difference in the level of marital adjustment in the lower age group; however the higher age group showed nominal difference in the level of marital adjustment by gender. The difference was calculated in the level of self disorder of the lower age group. The self discloser was higher in wives compared to the husbands, whereas in the higher age group husbands disclosed themselves more than wives. The difference was found in both the groups for the psychological aspect of intelligence. Economic level plays an important role in marital adjustment. The psychological features play an important role in marital adjustment in all age groups in Indian culture.

Keywords: psychosocial factors, marriage, marital adjustment, Indian perspective

The effect of the gender composition of organisations on male and female perceptions of ‘glass cliff’ situations

HALLFORD, D. (Deakin University), WEBB, J. (Deakin University)

The glass cliff refers to the higher likelihood of women being placed in precarious leadership appointments during times of organisational crisis. The current study aimed to investigate male and female perceptions of the fairness, prevalence and problematic nature of glass cliff appointments and the extent to which these perceptions depend on the gender composition of an organisation. A 2 (gender: male and female) x 3 (gender composition of organisation: majority male, majority female or equal gender composition) between subjects design was used in this study. Two hundred and four participants,
comprising 139 women (mean age = 26.04, SD = 7.32) and 65 men (mean age = 28.66, SD = 7.32) each read a hypothetical glass cliff scenario depicting a female appointed to a leadership position in a time of declining organisational performance. Three scenario conditions were used which differed only in their description of the gender composition of the organisation, being either majority male, majority female or equal gender composition. Participants then responded to items measuring their perception of the general, distributive, procedural and interpersonal fairness of the appointment, and its prevalence and problematic nature. For exploratory purposes, a measure of modern sexism was also included. A MANOVA analysis conducted on the fairness measures revealed that although females found the glass cliff appointment more unfair than males on measures of distributive, procedural and interpersonal fairness, these differences were not found to depend on gender composition. Neither females nor males found the hypothetical appointment overall to be particularly unfair, prevalent, or problematic. Exploratory path analysis revealed that the obtained gender difference in fairness perceptions was mediated by levels of modern sexism. The present findings suggest that individuals do not find glass cliff situations to be unfair, prevalent or problematic, but that there are gender differences in the evaluation of the fairness of glass cliff situations, and these differences are related to modern sexist attitudes. However, there is currently little evidence that such differences depend on the gender composition of organisations. Furthermore, these findings suggest that neither females nor males may accurately perceive women’s overrepresentation in the context of poor prior organisational performance, nor the potentially deleterious consequences they hold for female leaders.

Keywords: glass cliff, leadership, fairness

The effect the experiences of volunteer HIV counsellors have on their own well-being: A case study

VAN DER MERWE, K. (North-West University), VAN ASWEGEN, L. (Midvaal Local Municipality)

The aim of this qualitative interpretive research was to explore the experiences of HIV counsellors and how these experiences influence their psychological well-being. A case study design was used. In depth interviews were conducted with nine Sotho speaking volunteer HIV counsellors working in primary health care clinics in the Sedibeng region of Gauteng, South Africa. Additional data was collected through observation. Transcribed interviews were analysed through a process of open coding and these data were integrated with data from observations and literature to construct a textured description of the experiences of the participants in which the focus was on the psychological wellbeing of the volunteer HIV counsellors. The data indicated that the participants were not overwhelmed by the many stressors of their challenging occupations. They succeeded in developing their own ways of stress relief especially through the practise of their spiritual beliefs and other means like participating in community activities and meaningful relationships with significant others. They experienced personal growth and empowerment in general, but especially in the field of health and sexuality. The female participants were increasingly able to negotiate safer sex. Participants’ lives were enriched through the regard they received from their communities, and being in a position to give information and advice they gained from their training and exposure to information. The participants experience feelings of self-worth in that they were able to contribute to their communities and this added meaning to their own existence. It became clear that their character strengths such as wisdom, courage, humanity, justice and transcendence enabled them to function and grow in their difficult situation.

Keywords: psychological well-being, HIV, occupational stress, volunteer counsellors, stress reduction

The effectiveness of systematic model interventions in decreasing schizophrenic patients’ re-hospitalizations in Razi Psychiatric Hospital, Iran

...
RAHEB, G. (Welfare and Rehabilitation University), EGHLIMA, M. (Welfare and Rehabilitation University), FAHLIYANY, M. A. (Welfare and Rehabilitation University)

The aim of this research is to assess the effect of a systemic intervention model on reducing the frequency of re-hospitalizations in schizophrenic patients. This is applied research using a quasi-experimental method. The sample group includes schizophrenic patients in Razi psychiatry center and their families. The method of sampling is randomization. The intervention in the experimental group included: psychological training of families and psycho-social support services for patient after hospitalization. This research used Student’s t tests, Chi-Square tests and Mann-Whitney U tests for data analyzing. The results showed that the use of a systematic intervention model has reducing effects pm the rate of schizophrenia patient’s re-hospitalizations. The systematic intervention model effects schizophrenic patients, their families and their environments and improves the patient’s quality of life and reduces the frequency of re-hospitalization.

Keywords: systemic model intervention, schizophrenia, psychological training, psycho-social support, quality of life

The effectiveness of two treatments to enhance academic self-concept of low-achieving secondary school students in mainland China

LAN, Y. (The University of Hong Kong)

This study is designed to investigate the effectiveness of internally-focused performance feedback and attributional feedback in enhancing academic self-concept of low-achieving junior middle school students who continue their study in secondary vocational education (SVE) of China. Participants were year-one SVE students who were once low-achievers in junior middle school. Three classes of students participated in the 16-week intervention program: two classes were experimental and one was acted as a control. One experimental class received the internally-focused feedback approach only and the other received the internally-focused feedback approach and attributional feedback approach simultaneously. The control class received no treatment. The researcher-administered intervention significantly enhanced the targeted academic self-concept (English self-concept) and modestly enhanced Chinese self-concept, a related facet in the same domain. The intervention had no significant impact (either positive or negative) on the other academic domain (math self-concept) and general school concept. The results demonstrated that the combined approach enhanced participants’ academic self-concept better than a single enhancing approach. The research demonstrated the multidimensional nature of academic self-concept. Strong measurement (e.g., SDQ series) was adopted in designing intervention programs that effectively enhanced and addressed low-achieving participants’ self-concept. In addition, the combined treatment, internally-focused performance feedback and attributional feedback, worked better to enhance low-achieving students’ academic self-concept than merely using one of them. Further applications are discussed in detail.

Keywords: academic self-concept, internally-focused performance feedback, attributional feedback

The effects of a breath-training program on reducing the stress-symptoms of chronic heart disease patients

SRISAYEKTI, W. (Padjadjaran University), FARDIANI, F. (Padjadjaran University)

This study was intended to see whether the Indonesian traditional breath-training program 'Merpati Putih' had therapeutic aspects for patients with Coronary Heart Disease (CHD). The aim was find out whether the training had the effect of reducing stress symptoms of CHD patients in Bandung, Indonesia. This study was a continuation of the empirical findings reported by the members of the organization of the ‘Merpati Putih’. Twenty clinically stable CHD patients (determined by a doctor), including ten males and ten females, 40 to 60 years old ($M = 50.1; SD = 4.8$), participated in this study. They were diagnosed with CHD with Artery Coronary Stenosis greater than 75% in at least one coronary artery, recommended by cardiologists
for regular medical treatment despite whether or not they had received Percutaneous Coronary Intervention and Coronary Artery Bypass Graft. The study consisted of 13 sessions, twice a week, two hours per session. Interrupted time-series with multiple replications design (Cook & Campbell, 1979) was applied. The stress symptoms were measured by an adapted questionnaire for stress symptoms (Severin, 2002), a sphygmomanometer for blood pressure, and manual measurement using a stop watch for the heart beat. Results showed that the breath-training program reduced stress symptoms (questionnaire $X = 225.878^{**}$, $\alpha = 0.05$; blood pressure $X = 154.224^{**}$, $\alpha = 0.05$; heart beat $X = 28.938$, $\alpha = 0.05$). The Indonesian traditional breath-training program ‘Merpati Putih’ had therapeutic aspects for patients with CHD. The social supports provided by other participants should be discussed. The results should be further investigated before the training is implemented and recommended for the CHD patients.

Keywords: breath training, stress symptoms, chronic disease, medical treatment, Indonesian traditional program

The effects of anxiety on attentional control functions and its implications for driving performance

WONG, I. (CARRS-Q, Queensland University of Technology), MAHAR, D. (Queensland University of Technology), TITCHENER, K. (Queensland University of Technology)

Attentional failure has been demonstrated to be a leading cause of traffic crashes. Recent crash statistics from the South Australia police department revealed inattention to be a major contributing factor in as many as 60% of fatal crashes in the year 2008 (South Australia Police, 2008). Further, experimental and naturalistic observation studies have also identified attentional failure to be a significant predictor in driving errors and lapses (Shahar, 2009; Wilson, Chattington, & Marple-Horvat, 2008). Emerging research has highlighted the important influence psychological factors, such as anxiety, have on attentional control in cognitive and motor performance. The purpose of this investigation was to explore the impact of anxiety on attentional control functions, and its potential implications for driving performance. Seventy-five Australian drivers completed the Parametric Go/No-Go and n-back tasks, as well as the State-Trait Anxiety Inventory and the Driver Behavior Questionnaire (DBQ). A series of ANOVAs revealed that highly-anxious individuals maintain accuracy at the expense of processing efficiency (i.e. response time) for the inhibition, set-shifting as well as updating function of the Central Executive. While hierarchical Multiple Regression has shown that the deficit in processing efficiency (response times) on the Central Executive functions partially mediated the anxiety – driving lapses relationship reported in previous literature, the current study provided evidence to support the potential of Attentional Control deficits in accounting for the influence of anxiety on driving performance. A new model of Attentional Control that incorporates the role of pre-attentive processes and dual-task coordination was proposed to provide a framework for future research to explore the effects of anxiety on task performance.

Keywords: traffic accidents, attentional failure, driving, processing efficiency whilst driving, central executive functions

The effects of cognitive appraisal of being teased on self-esteem and loneliness

HAYAMA, D. (University of Tsukuba), SAKURI, S. (University of Tsukuba)

Previous studies (Kowalski, 2000; Storch et al., 2003) have demonstrated that an experience of being teased damages the psychological functioning of the target (e.g., low self-esteem, high social anxiety, and high loneliness). Kowalski et al. (2001) suggested the effects of being teased are changed by how a target evaluates the experience and Lazarus’ model of cognitive appraisal toward stressors (Lazarus, 1966) is useful to assess evaluation of being teased. Cognitive appraisal includes primary appraisal and secondary appraisal. The purpose of this study is to examine the effects of cognitive appraisal of being teased on self-esteem and loneliness. One hundred and eighty two college students (76 male and 106 female) participated in this study. First, they completed a
questionnaire about their cognitive appraisal of being teased (5 point scale), such as evaluation of threat (e.g., “Being teased is very painful”, 4 items), importance (e.g., “It is important for me to react well to teasing”, 3 items), and effectiveness (e.g., “I’m good at reacting to teasing”, 3 items). They also completed a self-esteem scale (Rosenberg, 1965), and the UCLA loneliness scale (Russell et al., 1980). Cluster Analysis revealed participants were classified into three clusters based on cognitive appraisal of being teased. The first cluster (n=80) is called the “indifference cluster” and is characterised as low threat, low importance, and low effectiveness. The second cluster (n=49), called the “threatened cluster” is characterised as high threat, moderate importance, and low effectiveness. The third cluster (n=53) is called the “adaptive cluster” and is characterised as high threat, moderate importance, and high effectiveness. Concerning frequency of being teased, the indifference cluster scored significantly lower than the other two clusters. One-factor analysis of variance indicated participant in the threatened cluster (M=2.15) scored significantly higher on loneliness than participants from the adaptive cluster (M=1.88). Additionally, participants from the adaptive cluster (M=3.52) scored significantly higher on self-esteem than participants from the threatened cluster (M=3.12).The results of this study supported Kowalski’s idea that cognitive appraisal (Lazarus) is useful to examine the effects of being teased. The first cluster (n=80) is called the “indifference cluster” and is characterised as low threat, low importance, and low effectiveness. The second cluster (n=49), called the “threatened cluster” is characterised as high threat, moderate importance, and low effectiveness. The third cluster (n=53) is called the “adaptive cluster” and is characterised as high threat, moderate importance, and high effectiveness. Concerning frequency of being teased, the indifference cluster scored significantly lower than the other two clusters. One-factor analysis of variance indicated participant in the threatened cluster (M=2.15) scored significantly higher on loneliness than participants from the adaptive cluster (M=1.88). Additionally, participants from the adaptive cluster (M=3.52) scored significantly higher on self-esteem than participants from the threatened cluster (M=3.12).The results of this study supported Kowalski’s idea that cognitive appraisal (Lazarus) is useful to examine the effects of being teased. The first cluster (n=80) is called the “indifference cluster” and is characterised as low threat, low importance, and low effectiveness. The second cluster (n=49), called the “threatened cluster” is characterised as high threat, moderate importance, and low effectiveness. The third cluster (n=53) is called the “adaptive cluster” and is characterised as high threat, moderate importance, and high effectiveness. Concerning frequency of being teased, the indifference cluster scored significantly lower than the other two clusters. One-factor analysis of variance indicated participant in the threatened cluster (M=2.15) scored significantly higher on loneliness than participants from the adaptive cluster (M=1.88). Additionally, participants from the adaptive cluster (M=3.52) scored significantly higher on self-esteem than participants from the threatened cluster (M=3.12).The results of this study supported Kowalski’s idea that cognitive appraisal (Lazarus) is useful to examine the effects of being teased. The first cluster (n=80) is called the “indifference cluster” and is characterised as low threat, low importance, and low effectiveness. The second cluster (n=49), called the “threatened cluster” is characterised as high threat, moderate importance, and low effectiveness. The third cluster (n=53) is called the “adaptive cluster” and is characterised as high threat, moderate importance, and high effectiveness. Concerning frequency of being teased, the indifference cluster scored significantly lower than the other two clusters. One-factor analysis of variance indicated participant in the threatened cluster (M=2.15) scored significantly higher on loneliness than participants from the adaptive cluster (M=1.88). Additionally, participants from the adaptive cluster (M=3.52) scored significantly higher on self-esteem than participants from the threatened cluster (M=3.12).The results of this study supported Kowalski’s idea that cognitive appraisal (Lazarus) is useful to examine the effects of being teased. The first cluster (n=80) is called the “indifference cluster” and is characterised as low threat, low importance, and low effectiveness. The second cluster (n=49), called the “threatened cluster” is characterised as high threat, moderate importance, and low effectiveness. The third cluster (n=53) is called the “adaptive cluster” and is characterised as high threat, moderate importance, and high effectiveness. Concerning frequency of being teased, the indifference cluster scored significantly lower than the other two clusters. One-factor analysis of variance indicated participant in the threatened cluster (M=2.15) scored significantly higher on loneliness than participants from the adaptive cluster (M=1.88). Additionally, participants from the adaptive cluster (M=3.52) scored significantly higher on self-esteem than participants from the threatened cluster (M=3.12).The results of this study supported Kowalski’s idea that cognitive appraisal (Lazarus) is useful to examine the effects of being teased. This study examined the effects of participating in community activity on self and collective efficacies. Many schools in Japan encourage students to participate in community activities as class work. Usually, students’ participation is mandatory, but sometimes it is voluntary. Students of a junior high school answered the same questionnaire twice at two separate times. The first time (April, the beginning of the spring term) the base rate for self and collective efficacies was measured. During the term, there were mandatory and voluntary community activities. Students in the first grade had to participate in a community activity for planting flowers as class work in June. Students could then participate in the voluntary activity of cleaning the local park in early July, though few students chose to participate. Students answered the second questionnaire at the end of the spring term (end of July). Data from 411 students in the first sample and 412 in the second sample were obtained. Only 123 responses gave valid data that could be matched between the two sample sets due to anonymity reasons. Participants (n=20) and non-participants (n=103) of the volunteer activity were compared. A 2 (participation) x 2 (time) ANOVA with efficacies as dependent variables was conducted. Results showed that the main effect of participation was significant, implying that participants had higher self and collective efficacies than non-participants. The interaction effect was also significant: participants got higher efficacies throughout the term, while non-participants decreased in their efficacies. However, examining the effect of mandatory activity on non-participants of the voluntary activities, those who joined the mandatory activity did not decrease their efficacies throughout the term. This result indicated that mandatory activity had an effect to preserve non-participants from losing motivation to join the community activity. The results suggested that voluntary activity encourages those who have high motivation from the beginning. But only voluntary activity winnows out the motivation of the other people. Mandatory activity is also important for preserving people who do not have high motivation at the beginning from losing self and collective efficacies, otherwise they lose more motivation. The combination of voluntary and mandatory activities would be effective in environmental education programs in school in Japan.

The effects of perceived social support on minority stress in lesbians and gay men

CONDREN, M. (York University)

Lesbians and gay men are regularly faced with several stressors related to their minority status. Negative external events, stigma consciousness, internalised homophobia, and self-concealment are widely reported among sexual minorities, and are associated with negative mental health outcomes. Perceptions of stressors and the resources to deal with them are important in the coping process. In the present study it is hypothesised that social support from sexual minority and heterosexual sources will alleviate perceptions of stressors in gay men and lesbians. Self-identified gay and lesbian students at a large Canadian university participated in an internet study of perceived social support and stressors. Support from other sexual minorities as well as support from heterosexuals was examined. Because support from parents may be of particular importance to university and college students, it was assessed separately. Students also reported their experience of four minority stressors: negative external events, stigma consciousness, internalised homophobia, and self-concealment. Source and amount of perceived support were studied in relation to these four minority stressors. The effects of high perceived support from sexual minorities, high perceived support from heterosexuals, low perceived support from sexual minorities, and low perceived support from heterosexuals on the four minority stressors were examined. Theoretical and practical implications of the findings are discussed, including the importance of the perceptions of stressors and resources in the experience of minority stress. Particular attention is given to the role of social support from various sources in interventions to increase well-being among lesbians and gay men. The present study should contribute to theoretical
conceptions of stress, particularly the transactional theory of stress.

The effects of the amount of information and the cognitive style on the sport decision making of badminton athletes in decision-making speed and accuracy

YE, H. (Beijing Sport University), CHI, L. (Beijing Sport University)

This article examines the effect of amount of information and cognitive style on badminton decision making. Badminton athletes of varying abilities were studied in the decision-making speed and accuracy. This study used a testing system of decision-making ability of badminton players which was designed independently and examined the effect of amount of information and cognitive style on speed and accuracy of intuitive decision-making. The results indicate that: (1) Between different decision-making tasks of varied amount of information, there is a significant difference in the correct response rate; (2) The average reaction time and the correct reaction time of the large amount information decision-making tasks are less than the small one; (3) The correct rate of the large amount information decision-making tasks is higher than the small one; (4) The correct response rate of high sports level athletes is significantly higher than the lower one, but there is no significant difference in reaction time. In conclusion, badminton players develop decision-making speed earlier than the decision-making accuracy and in the large amount of information task, the decision-making speed and accuracy of badminton players were lower than in the small amount of information task.

The effects of video analysis of the nonverbal behaviour of handball coaches on the coach-athlete relationship

MEEÛS, M. (Technical University Lisbon), SERPA, S. (Technical University Lisbon), DE CUYPER, B. (Catholic University Leuven)

The purpose of this experiment was to study the impact of video feedback on the coaches’ nonverbal behaviour, and its relation with their athletes’ anxiety and perception of coaches’ behaviour and emotions. One experimental group was composed of 45 athletes and four coaches, and one control group by 58 athletes and five coaches. The measures included one adapted Coaching Behaviour Assessment System (CBAS), one adapted Coaching Behaviour Questionnaire (CBQ), and the Competitive State Anxiety Inventory-2 (CSAI-2). The participants responded to the questionnaires twice with seven weeks in between responses. The coaches’ behaviour in competitions during halftime breaks and timeouts was video recorded. Each coach received a frequency table with the answers of his team in the first series of responses, compared with his own answers. The coaches also saw a video of their behaviour during their interventions in competition. Repeated measures ANOVA’s showed that athletes of the experimental group became significantly less anxious and that they perceived their coaches significantly more positively than athletes of the control group. The self-perception of coaches of the experimental group improved significantly more, compared to the self-perception of coaches of the control group. One-way ANOVA’s showed that goalkeepers in both conditions were significantly more anxious in the pre-test. In both conditions, goalkeepers perceived their coaches less positively than the field athletes in both pre- and post-test. It is concluded that an intervention using video feedback might have positive effects on the anxiety level and coach perception among athletes, and on the self-perception of coaches. It is also concluded that goalkeepers perceived their coach less positively and were more anxious compared to field athletes. Further research is needed to corroborate these findings.

The evidence of the procedure meanings of Chinese connectives Dan and Buguo

ZHOU, L. (Capital Normal University), LIU, H. (Chinese People’s Public Security University)

The present study aims to find out evidence about constraints on Chinese adversative connective Dan and Buguo imposes on utterance interpretation by using event-related brain potentials (ERPs) technology. We perform two ERPs experiments in the Language Acquisition Lab of Capital Normal University in China. The 20 participants are university students and the stimuli, which are testing sentences, are presented randomly through the software called STIM 2. ERP data or the electro-encephalogram of the two experiments and are processed by the software called Scan 4. The results indicate that the response accuracy rates of the sentences with Dan / Buguo are apparently higher than those without Dan / Buguo under different conditions, and that the response times of sentences with Dan / Buguo are faster. The behavioral data and ERPs data support each other to explain the cognitive role of Dan / Buguo in language understanding, which helps the participants get to the appropriate interpretation of the utterance more quickly. Based on the theories of brain and neural science and cognitive pragmatics, we discuss the two kinds of data, the behavioral data and ERPs data in order to clarify and explain more scientifically the role of Dan / Buguo in language interpretation. We believe that Dan / Buguo encodes procedural meaning and the proposition introduced by them has the contextual effect of contradiction and elimination. We point out that Chinese connective Dan / Buguo plays a positive role in language interpretation.

Keywords: utterance interpretation, language interpretation, event-related brain potentials

The experience of cross-racial adoption: Transformations in parents’ racial identity

CHEN, Y. L. (Social Science Research Council, National Science Council), LAMBORN, S. (University of Wisconsin), LU, H. (University of Wisconsin)

Recent research has shown that Euro-American adoptive parents have experienced social prejudice and discrimination when their adoptive children are from another race (e.g. Friedlander, Larney, Skau, Hotaling, Cutting, & Schwam, 2000). Due to these parents not being from ethnic minorities, they typically have not experienced these issues prior to adoption. The purpose of this research is to investigate how Euro-American parents re-explore their racial identity after facing social prejudice and challenges in developing their child’s racial and ethnic identity. Themes from the current study were compared with existing conceptualizations of Euro-American racial identity development (e.g. Hardiman, 1982; Helm & Cook, 1999; Ponterotto, 1988). Between 2004 and 2008, Americans adopted over 31,000 children from China, which currently is the highest number of adoptions to the United States from one country (United States Department, 2009). Over 90 percent of the adoptive parents were European Americans and most of them had goals for their children’s racial and cultural socialization (Rojewski, 2005). Therefore, this study focused on Euro-American parents’ experiences in raising children from China. Fourteen Euro-American parents were recruited through Chinese language and cultural school for children adopted from China. At the time of the interviews, the children were between the ages of 6 and 11. The parents were well educated, economically stable, and lived in predominantly white, middle class, suburban communities. A phenomenological design was used to purposefully select a small sample of information-rich cases (Patton, 2002). Each parent completed a one to two hour intensive interview. Questions focused on the parent’s efforts at cultural socialization and how the parent’s own racial identity had been affected by adopting a child from China. Audiotapes were transcribed and then coded separately by three research team members to identify key passages. Our research team met several times to discuss and come to consensus on these passages. Next, team members individually identified essential features of the data at the next level of analysis. The team met over several sessions to discuss this step and come to a consensus. Key themes from the interview reflected a progression through the adoption process and how it ultimately affected personal
identity growth in the parents. Central topics included adoption memories, cultural socialization practices, challenges to the child’s cultural socialization, and personal racial identity growth of the parents. In particular, the parents indicated that they had been changed by adopting a child from China by being more sensitive to inequalities in American culture and by adhering more strongly to a universal, humanistic view of the world. This study provided essential features from in-depth interviews with Euro-American parents to show how their own racial/ethnic identity was transformed by the experience of including a child of Asian background in the family. The results confirmed many aspects of previous white racial development models, but also suggested that most participants have developed a strong interest in embracing multiculturalism and have cultivated a differentiated worldview about another country, China.

The grounding principles for the modern pedagogy: Ontopsychological approach

DMITRIEVA, V. (Saint-Petersburg State University), VEREITINOVA, T. (Saint-Petersburg State University)

The goal of this paper is to present the novelty of the achievements of the ontopsychological school in the area of pedagogy and educational psychology. The aim is to describe the methodology, goal and guiding principles of ontopsychological pedagogy, providing examination of the cases. A child is a project of nature, which is actuated in the individualized (distinct) place within defined historic processes. If the ambient environment wants him to be a great man, a great scientist, a good citizen, then it must provide him with instructions, that is must create the conditions for the child. The child, with his needs, absorbs the prevailing rules of the surrounding ambient environment in order for him to become and to formalize himself. However society gives only the general principles of how thinking must proceed and what is good and what is evil. It lays the groundwork for the future conscience development. However the question is whether the structures of this conscience in conformity are synchronous with the plan of nature, plan of life? Are they going along with the in-itself of Being? Are they consistent with the original life implanted in that particular child, that is the ontic In-itself? The ontopsychological method has discovered an objective criterion of the functionality of a human being and therefore proposes a new vision in the area of pedagogy. How can psychology be more efficient for the pedagogy of the future society – society of the new economy and information society? As our educational model seems to be too far removed from the every-day reality of our children and that is changing too rapidly. Through individualization and isolation of the impulses of the basic life project of any individual it is possible to discover how the project of nature of a life-child wants to actualize itself in existence, and using the instruments of ontopsychological school it is possible to offer to an individual victorious strategies that will be useful and functional at the individual as well as social levels. Today, thanks to the internet, every young person can share his views with the rest of the world. The great majority of young people in the world do not read the information disseminated by official institutions, by university, and by the in general. They read only about themselves, their problems and their anger. Nevertheless every young person claims the right, the fact, and the evidence that “I exist”. This is where psychology can be more active and more efficient and the way it might be will be demonstrated in terms of this paper.

The impact of conflict in teams affective outputs

AKEL, N. (Universidade de Brasilia), PUENTE-PALACIOS, K. (Universidade de Brasilia)

The main aim of this study was to develop and empirically test a predictive model of the role of conflict in the effectiveness of work teams. Effectiveness was measured through affective criteria, namely satisfaction and commitment to the team. Two studies were carried out. The first sought to construct and validate the Intragroup
Conflict Scale. The second study investigated, in a first phase, the relationship between the interdependence of tasks, results, and conflicts. In a second phase, Study 2 analyzed the relationship between conflicts, satisfaction, and commitment. For the first study, the data were collected from a sample of 200 students and workers. The analysis of the data was done by factor analysis. For the second study, data were collected from 125 police officers belonging to 25 teams of the Federal Police of Brasilia. The analysis of the data was done by linear multiple regression. The results showed the theoretical adequation of Intragroup Conflict Scale and its statistic reliability, with a two-factor empirical structure (task conflict $\alpha = 0.85$; relationship conflict $\alpha = 0.91$), both accounting for 52.19% of the variance. Regarding the relationship between the variables of the model proposed in study 2, it was found that the interdependence of tasks and results contributed to explain both task conflict ($R^2 = 0.07$) and relationship conflict ($R^2 = 0.05$). In addition, it was found that task conflict was negatively related to satisfaction ($B = -0.61$) and commitment ($B = -0.46$), while relationship conflict had no significant impact on effectiveness indicators. The results showed the reliability of the Intragroup Conflict Scale, and therefore it can be considered a good tool for diagnosis of conflict in teams. The predictive model was observed, the level of task and results interdependence predicted the conflict level in work teams and also it was verified that conflict has a relevant participation in explaining the affective links between members and their team. Therefore, the diagnosis of conflict level provides relevant information for managers in organizations.

**The impact of intangibility on perceived risk of online games**

LEE, Y. H. (National Taiwan University of Science and Technology), CHEN, S.-L. (Tamkang University, Taipei), HSIEH, C.-L. (Hsing-Wu College), LEE, Y. H. (National Taiwan University of Science and Technology)

Increasing evidence proves persons nowadays will likely spend their leisure time with online games. This study investigates the intangibility influence on perceived risks (including social risk, time risk, financial risk, physical risk, performance risk and psychology risk) among online gamers. The self-completed market survey questionnaire employs two measures: the Intangibility Scale and the Perceived Risk Scale. Data were gathered in the biggest-sized metropolitan area, Taipei, in north Taiwan, and interviews all took place either at Cyber Café People (with a total of 1018 participants) or via online questionnaire (totaling 400) with voluntary participants. Structural Equation Modelling analysis was used. Cronbach $\alpha$ was adapted to measure reliability and had acceptable reliability. The estimates of Composite Reliability and Average Variance Extracted demonstrated that the measurement model had acceptable internal consistency. Convergent validity is indicated when the path coefficients (loadings) between each latent-trait factor and its manifest indicators are statistically significant. All factor loadings in the Correlational Factor Analysis were significant, and moreover exceeded .5, supporting the convergent validity of the scale items. Regarding the fit statistics for the full model, the hypothesized model was estimated and all the other statistics were within the acceptable ranges, which indicate a good model fit. Results reveal significant positive relationships between Intangibility and all dimensions (social risk, time risk, financial risk, physical risk, performance risk and psychology risk of Perceived Risk among participants in online games). This work suggests possible result explanations and discusses finding implications.

**The impact of LMX on staff nurses’ organisation-based self-esteem: A mediating effect of perceived organisational support**

KAO, Y.T. (I-Shou University), YUAN, S.-C. (Chung Shan Medical University), WANG, S. M. (Cheng Ching Hospital), LI, C.H. (Chung Shan Medical University)
Due to the high turnover rate, it is important to understand the working conditions among staff nurses in the nursing profession. This longitudinal study aimed to examine factors related to nurses’ organisation-based self-esteem, especially focusing on the mediating effect of perceived supervisor support and the cross-level effect of the head nurses’ political skill. Around 1160 staff nurses from three hospitals participated in the study. Both the staff nurses and head nurses were asked to fill out the questionnaires. Each participant was assigned a unique code to ensure that data collected at the three stages could be matched. The number of valid responses for each stage were 813, 945, and 893 respectively. Among them, about 396 staff nurses completed the questionnaires at each stage. The valid data was analysed and the results of hierarchical regression analysis indicated that there was a full moderating effect of perceived supervisor support on the relationship between leader-member exchange and organisation-based self-esteem. Furthermore, the findings of hierarchical linear modeling revealed a significant main effect of head nurses’ political skill on staff nurses’ perceived supervisor support. According to these results, we concluded that both leader-member exchange and head nurses’ political skill contribute to staff nurses’ perceived supervisor support. In addition, the high quality of the leader-member relationship sends the message about the support from the supervisor that promotes the members’ self-worth and enhances their organisation-based self-esteem.

Keywords: leader-member exchange, LMX, nurses, organisation-based self-esteem, organisational support

The impact of meaningful work on disadvantaged youth

SCHIRO-GEIST, C. (University of Memphis), BROADBENT, E. (University of Memphis)

The aim of this research was to describe how a program of providing meaningful work at the University of Memphis has affected attitudes toward work and career thoughts. In the summer of 2009, as part of the Economic Stimulus Package in the United States of America (USA), 166 young workers were employed with federal funds at the University of Memphis. They were provided with meaningful work experiences, technology training, seminars on how to apply for jobs, and individual and group counseling around work behaviors. A number of career related instruments, such as the Career Thoughts Inventory, FACES and the Semantic Differential were administered pre and post the 10 week work period at the University. Significant results were obtained in the area of improved attitudes towards work and self as worker. Young, disadvantaged youth can benefit from a meaningful, even if brief, work experience. These youth not only made a salary, but through some significant work related interventions, improved their attitudes towards work and themselves as workers. The results of this model program will be replicated in the summer of 2010 and, hopefully, will be disseminated as a model program for improving career thoughts.

Keywords: career thoughts inventory, meaningful work for youth, youth attitudes towards work, youth work interventions, work behaviors

The impact of organisational climate on field placement experiences of university students

DHARMAPURI, S. (Deakin University), FULLER-TYSZKIEWICZ, M. (Deakin University)

Although accumulated research findings highlight the importance of organisational climate for employee wellbeing and job satisfaction, the majority of these studies have looked at populations of full-time and/or experienced employees. The present study builds on prior research by evaluating the relative importance of key climate variables on postgraduate university students’ experience of field placement, a population characterised by relative inexperience and who tend to exhibit an inordinate amount of stress in relation to work. Eighty post-graduate psychology students from Australian universities completed an online questionnaire measuring organisational climate
variables (support, workload, role clarity, recognition and level of autonomy) and placement-related outcomes (job satisfaction and job stress). Dominance analysis (Azen & Budescu, 2003) was used to determine which of the climate measures was the most important (or dominant) predictor of two key outcome variables (placement satisfaction and placement-related stress). While standard multiple regression analyses revealed that the organisational climate variables accounted for 43% variance in job satisfaction and 26% variance in job stress, dominance analyses further revealed that recognition was the most dominant predictor of job satisfaction whereas workload was the most dominant predictor of placement-related work stress. Interestingly, level of autonomy was poorly related to self-reported satisfaction and stress, suggesting that it may not be an important climate variable in inexperienced work populations. Present findings of most relevant predictors of key employee outcomes are discussed in comparison with results for populations of full-time and experienced employees, and also in light of current practices with regards to organisational set-up for field placement of university students.

Keywords: postgraduate students, field placement, job satisfaction, job stress, organisational climate

The impact of protestant spirituality on the well-being of people in Hong Kong

NG, E. (Victoria University), FISHER, A. (Victoria University)

There is compelling evidence that religion is a potent force in society, shaping both individuals and the larger society. The most recent WHO Melbourne charter also regards spirituality as one important protective factor for mental health and well-being. Although literature demonstrates that the relationship between religion and well-being is generally positive, information about the mechanism of the religious influence on well-being is still far from clear. The primary objective of the present study is to examine how Protestant spirituality affects the well-being of people in the context of Hong Kong. 324 Chinese from four Protestant communities, representing four major kinds of Protestant spirituality, and one social center in Hong Kong were recruited to participate in a survey examining the association between various dimensions of religiosity and well-being variables. Path model analysis demonstrated the complex relationship between various spirituality dimensions (religious belief, practice and experience) and well-being variables, manifested in life satisfaction, mental health, social trust and sense of community. While some spirituality-related variables may directly predict sense of community and mental health, the relationship between spirituality-related variables and life satisfaction and social trust are mainly mediated through sense of community and mental health. Furthermore, well-being at the community level (feeling sense of community and social trust) affects well-being on the personal level (life satisfaction and mental health). These findings not only show that the influence of religion on people’s well-being can be richly diverse, but also match quite well with the emerging literature on the salutary effect of social capital on health and well-being. Thus, when studying the effect of religion, the multi-dimensions of religion and the religious context cannot be overlooked when drawing any conclusion regarding the cost and benefit of religion.

Keywords: spirituality, religiosity, well-being, sense of community, mental health

The impact of Theory of Mind intervention on school children’s peer experience

ZONGKUI, Z. (Hua Zhong Normal University), XIAOJUN, S. (Hua Zhong Normal University), HUASHAN, L. (Hua Zhong Normal University)

The relationship between children’s peer interaction and Theory of Mind (TOM) in childhood was examined in the current research with the guidance of the lifespan perspective. Whether a TOM intervention was effective was examined as well as whether the intervention could predict change in peer experience. Sociometric nomination, sociometric rating and questionnaire methods were applied in this study. Forty children in an elementary school from Grade three to Grade six completed the Friendship Quality Questionnaire, and Peer Nomination, Class Play, Situational Story, and
self-made Theory of Mind tasks. Longitudinal tracking and intervention research design were employed in the present study. The data were mostly analysed using t-tests and ANOVAs. The results of the study found that 1. The training of 20 children from Grade three to Grade six was effective in promoting Theory of Mind, 2. There was a significant positive correlation between the pretest and posttest on Peer Interaction and TOM, 3. The differences between friendship quality scores between the pretest and the posttest vary significantly in the experimental and the control group. The difference between the scores in the experimental group is significantly greater than that of the control group and the difference between the pretest and the posttest of fifth and sixth grade groups is significantly higher than that of third and fourth grade groups. 4. The difference between the pretest and the posttest of TOM can significantly predict the difference between the two tests of Friendship Quality. This study illustrated that the intervention of TOM is effective with the level of the TOM increasing after receiving the training. The difference between the pretest and the posttest of TOM can significantly predict the difference between the two tests of Friendship Quality.

Keywords: theory of mind, school children, peer experience, friendship, peer interaction

The impacts of objective and subjective caregiving stressors on caregiver mental health: A six-month prospective study of caregivers of older Chinese people with dementia

YAN, E. (The University of Hong Kong)

Guided by Pearlin’s (1999) stress process model, this six-month prospective study investigated the impacts of objective and subjective caregiving stressors (patient problem behaviors and caregiver burden) on caregiver mental health in a sample of caregivers of older Chinese with dementia residing in Hong Kong. A consecutive sample of 122 family caregivers of dementia patients was recruited from local non-government organizations. Caregivers provided information on their demographic characteristics, patient behavior problems as measured by the Cohen Mansfield Agitation Inventory, and caregiver burden as measured by the Zarit Burden Interview. At six months following the initial contact, 108 caregivers were successfully contacted and responded to the Short Form General Health Questionnaire (GHQ-12). Family caregivers reported poor mental health, 81.5% of the respondents reported a GHQ-12 score above the cut-off point (greater than two). A series of regression analyses was conducted to determine the relationship between patient problem behavior, caregiver burden, and caregiver mental health. In the first two regression models, patient problem behavior was associated with caregiver mental health ($B = .26, p < .05$) and caregiver burden ($B = .42, p < .01$) respectively. In the final regression model, a full mediation was observed where the addition of caregiver burden to the regression for caregiver mental health reduced the relation of patient behavior problem to caregiver mental health ($B = .03$). This study found evidence that subjective appraisal of stress mediated the relationship between stressor and mental health. Specifically, the relationship between patient behavior problems and caregiver mental health was mediated by caregiver burden. For intervention programs for dementia patients and their caregivers to be effective, service providers should provide assistance that can reduce objective stress as well as assistance to help caregivers modify their subjective perception of the stressful situation.

Keywords: stress process model, caregiver burden, patient problem behaviors, general health questionnaire, dementia

The importance of exploring the relationship between cultural values and job stress among Sri Lankan migrants in Australia

AIMAN, L. (Deakin University), THOMAS-RAJAPAKSA, R. (Deakin University)

This paper discusses the importance of understanding the relationship between cultural values and job stress among Sri Lankan migrant employees in Australia. It is important to study this group as the number of migrants entering Australia and consequently entering the Australian workforce, is increasing every year (Australian Bureau of Statistics, 2007). Despite
this there remains a dearth of research regarding migrant groups, and specifically regarding the relationships between cultural values and job stress. As a result little is known about the general wellbeing of Sri Lankan migrants in the workplace. The current paper will present the rationale for the examination of factors influencing the wellbeing of Sri Lankan migrants in the workplace and present the aims of the proposed research. Further, the appropriate methodology to study migrants in the workplace will be presented. The implications of such a project include the better understanding of employment factors related to Sri Lankan migrants and policy suggestions for employers with a culturally diverse workforce.

Keywords: cultural values, job stress, migrants, workplace

The importance of gender identity disorders in Iran (Case study: Shahid Navab Safavi Center, Tehran)

GOLKARIAN, P. (University of Tehran), AREFNAZARY, M. (University of Tehran), AZHDEHOFAR, L. (Azad University of Tehran)

Sexual disorder therapy involves a psychic-based recognition but the cure of sexual dissatisfaction doesn't include the change of Sexual Identity; however, identity is considered too important to adopt a recognized disorder to his/her distressed identity. According to the cultural and social situations of Iran, and in spite of removal of legal preventives, executive remedies, recognition, guidance and support for Gender Identity Disorder (GID) is still unknown amongst the public. The purpose of this research is to present a psychic profile of GID, their individual satisfactions in life, their social compatibility and finally some remedies which are proposed by experienced people in related departments and organizations (such as Behzisty Department, Naja, Country Ministry etc). In the first step we monitored 200 suffered people in Shahid Navab Safavi center via a directional open-response interview approach. We gathered valuable information about participants’ disorder reputation, their family, mental, social, economic and medical troubles and also their personal opinion on social and cultural adaptation. A parallel interview was conducted between experienced people in related departments and organizations to help us to present a set of remedies to make sense. As a result, all the information is categorized in seven specified groups: individual, family, social, economic, therapeutic, facilities and medical services, life improvement and their compatibility. Studies have shown that when the problem is recognized the first problem for those who suffered GID is individual and family troubles. Economic troubles and lack of facilities and services come after. The only organization that is responsible to support them is Behzisti with the cooperation of Legal Medical Department who check them and make some counseling sessions, then present them for operation. Studies have indicated that medical services do not have the good qualities which are needed and the injured people often have problems in immediate adaptation.

Keywords: gender identity disorder, sexual disorder therapy, sexual identity, social compatibility, social and cultural adaptation

The influence factors and mechanism of societal risk perception

ZHENG, R. (Chinese Academy of Sciences), LI, S. (Chinese Academy of Sciences), SHI, K. (Chinese Academy of Sciences)

The degree of risk that individuals assign to societal problems involving possible harm helps shape their attitudes toward public policy on such issues. So it is of great value in theory and practice to investigate societal risk perception of people especially in a Socio-economic transition period. A total of 2,485 people participated in the survey (43% males and 57% females). Their ages ranged from 18 to 83 (median = 36.3) and they were all come from Beijing. In general, the sample is in line with the region’s population characteristics. The major findings are listed: Firstly, a scale of societal risk perception was designed and two factors were identified (Dread Risk and Unknown Risk). Secondly, structural equation model was used to analyze the influence factors and mechanism of societal risk perception. Risk preference, government support and social justice could influence societal risk perception directly. Government support fully moderated
the relationship between government trust and societal risk perception. Societal risk perception influenced life satisfaction, public policy preferences and social development belief. From the result, we can conclude that: 1) Daily life hazards, instead of macroscopically problems, capture the preoccupation of current China; and 2) By describing the societal risk and examining the structured model, we can account for the influence factors and mechanism of societal risk. Recognition of both direct and indirect effects through the modeling of exogenous and endogenous relationships improves the ability to capture the myriad determinants of the citizenry’s perspective on hazard management.

Keywords: hazard management, risk perception, government trust, social justice, socio-economic transition

The influence of emotional state on coping with exam stress

BARGIEL-MATUSIEWICZ, K. (University of Warsaw), WILCZYŃSKA-KWIATEK, A. (Silesian University)

The aim of this research was to describe the connection between emotions and strategies applied in an exam situation. The study was a randomized controlled trial using a convenience sample of 90 fully informed and consenting young people just before an important exam. The instruments comprised of the Emotional State Inventory and Ways of Coping Questionnaire, both of which are based on Lazarus’ (1984) theory. The results show that there is a connection between emotions and strategies applied in an exam situation. There is positive correlation between the emotion group called Challenge Emotions (excitement, satisfaction, willingness) and the following escape strategies: wishful thinking ($r = .32, p < .01$), and keeping distance ($r = -.22, p < .05$). There is a negative correlation between the emotion group called Benefit Emotions and one escape strategy which is wishful thinking ($r = -.41, p < .01$). There is a positive correlation between the emotion group called Threat Emotions (anxiety, uncertainty, hopelessness) and the following escape strategies: wishful thinking ($r = .59, p < .01$) and keeping distance ($r = .31, p < .01$). There is a positive correlation between the emotion group called Harm/loss Emotions (anger, disappointment, sadness) and the following escape strategies: wishful thinking ($r = .51, p<.01$) and keeping distance ($r = .30, p < .01$).

There is a negative correlation between the emotion group called Threat Emotions and the following confrontation strategies: fighting ($r = -.33, p < .01$), problem solving ($r = -.32, p < .01$) and acting according to the schedule ($r = -.33, p < .01$). There is negative correlation between the emotion group called Harm/loss Emotions and the following confrontation strategies: fighting ($r = -.23, p < .05$) and acting according to the schedule ($r = -.41, p < .01$). On the basis of the presented study it is possible to claim that emotions of challenge, emotions of benefit, emotions of threat and emotions of harm/loss are connected with applying different strategies of coping with exam stress. Emotions of challenge and emotions of benefit help applying confrontation strategies, while emotions of threat and emotions of harm/loss are connected with using escape strategies. The conclusions from the study may be helpful for people who experience the situation of exam stress.

Keywords: emotions, coping strategies, exam stress, escape strategies, confrontation strategies

The influence of affective reactivity, sensation seeking and risk perceptions of risky driving behaviours

WONG, I. (CARRS-Q; Queensland University of Technology), TITCHENER, K. (Queensland University of Technology)

Reinforcement Sensitivity Theory (RST) proposed that the Behavioural Inhibition System (BIS) and Behavioural Approach System (BAS) are instrumental in understanding an individual’s
tendency to engage in risky behaviours. Previous studies have reported individual differences in BIS and BAS to be associated with challenging health behaviours such as substance use and gambling. Specifically, findings from previous research suggest that BAS sensitivity appeared to contribute to engagement in risky behaviours through the heightened tendency to seek out novel and potentially rewarding experiences. The current study aims to apply the predictions of RST to a range of risky driving-related behaviours, such as speeding, drink driving and drink riding. An additional focus of the present study is the effects of sensation seeking on the perception of risk for these risky behaviours. Approximately 300 participants from the State of Queensland, Australia, will be surveyed using an online questionnaire designed to assess participants’ levels of BIS, BAS sensitivity, sensation seeking, and risk perceptions of a range of risky driving related behaviours, such as drink driving and not using a seatbelt. Data generated from the sample will be analysed using regression techniques to assess the relationship between BIS/BAS sensitivity, sensation seeking, and risk perceptions of risky driving behaviours. Findings from the current study will contribute to the literature of Reinforcement Sensitivity Theory and report the application of the theory to the traffic psychology domain. Our findings will also contribute to the existing body of literature identifying personality traits that might make individuals more likely to engage in risky behaviours.

Keywords: risky driving behaviours, reinforcement sensitivity theory, behavioural inhibition system, behavioural approach system, risk perception

The influence of generation on the relationship between organisational climate and intention to leave

GERBER, T. (Victorian Department of Health), VON TREUER, K. (Deakin University), FULLARTON, C. (Deakin University), JOHANSEN, S. (Deakin University)

Recent literature has suggested that generational differences may account for some variance in findings between Organisational Climate (OC) and Intention to Leave (ITL). The current study examined the association between OC and ITL and explored whether generation is a mediator of this relationship. Participants consisted of 202 Allied Health Professionals from metropolitan and rural health agencies. The majority were female and came from a variety of age groups. Participants completed the Work Environment Scale (WES; Moos, 1994), two items as a measure of ITL as well as demographic information including gender, age group and generation. Multiple linear regression analyses revealed that OC factors as a whole contributed 36.1% of variance in ITL. Three factors, namely Supervisor Support, Job Involvement and Physical Environment were each found to contribute unique variance in ITL. Subsequent mediation analysis found that generation did not mediate the relationship between OC factors and ITL. The results provide evidence for OC as a significant contributor to employees’ ITL. Specifically, it was found that Supervisor Support, Job Involvement and Physical Environment contributed unique variance in ITL. These results imply that organisations should focus retention strategies around OC factors rather than customising strategies according to generational differences.

Keywords: organisational climate, intention to leave, supervisor support, job involvement, physical work environment

The influence of meditation on well-being: The mediating effect of psychological acceptance

CHU, L. C. (Chung Shan Medical University)

Past empirical evidence has demonstrated that meditation is not only beneficial to mental health (Carmody & Baer, 2008) and the regulation of cognitive and emotional functioning (Segal, Williams, & Teasdale, 2002), but is also effective in eliminating perceived stress and related symptoms (Carmody & Baer, 2008). Very few studies have attempted to understand mediating processes underlying the relationship between meditation and well-being. These benefits of meditation may be attributed to its acceptance nature. Psychological acceptance is people’s willingness to experience...
thoughts, feelings, and physiological sensations, especially those that they evaluate negatively, such as fear, without having to avoid them or let them determine their actions. These characteristics can enable people to disengage effectively from automatic thoughts, habits, and unhealthy behavioral patterns, thus fostering informed and self-endorsed behavioral regulation, something which has long been associated with the enhancement of well-being. Past research has found that people with higher psychological acceptance tend to have better mental health (Bond & Bunce, 2003; Donaldson-Feilder & Bond, 2004). This study therefore expects that the longer people engage in meditation, the higher the level of their psychological acceptance should become. Psychological acceptance therefore appears to be an effective mediating variable in terms of the relationship between meditation and well-being. This study extends previous research by proposing and testing a model that examines the mediating effect of psychological acceptance on the relationship between meditation and well-being. We used a cross-sectional survey research design and convenience sampling to collect data. The study’s participants were full-time working adults employed by public and private enterprises in Taiwan. We distributed 350 questionnaires, directing 175 mostly towards students of the Zen Buddhist Association who had jobs. All participants were asked to evaluate their meditation experience, psychological acceptance and well-being. The sample returned 271 responses, 135 from males and 136 from females, with a mean age of 35.58 years, an effective questionnaire rate of 77%. These participants employed in industry sectors such as hi-tech, finance and insurance, business and professional services, traditional manufacturing, medical and government. From the regression analysis, it was discovered that psychological acceptance was positively associated with well-being as job satisfaction, mental health, and physical health ($\beta = .27, p < .01$; $\beta = .64, p < .01$; $\beta = .55, p < .01$). In addition, meditation experience was positively associated with psychological acceptance ($\beta = .36, p < .01$). Furthermore, this study confirmed that meditation experience was positively associated with well-being as job satisfaction, mental health, and physical health ($\beta = .24, p < .01$; $\beta = .46, p < .01$; $\beta = .47, p < .01$). Finally, this study showed that under meditation experience the predictor of well-being as job satisfaction, mental health, and physical health were partially achieved through the mediating effect of the psychological acceptance. The findings confirm that meditation not only generates a direct effect for balancing its practitioners' well-being, but also has an indirect effect in terms of enhancing their well-being by storing up high psychological acceptance. The therapeutic efficacy of psychological acceptance has received increasing attention from every type of proposal for stress-management training. However, it is important to ask whether intervening to foster more psychological acceptance can help improve well-being in the future. Future studies should compare and evaluate the relative effectiveness of a variety of such stress interventions on psychological acceptance.

Keywords: meditation, perceived stress, well-being, psychological acceptance, job satisfaction

The influence of orthodontic treatment on self esteem and perceived attractiveness

HOWE, E. (University of Sydney), CHIU, Y. (University of Sydney), KENTJUNG, R. (University of Sydney)

With the increasing popularity of orthodontic treatment for occlusal anomalies with aesthetic improvement but minimal benefits for oral function, dentists argue that such treatment is important for social and psychological wellbeing. Since elective orthodontic treatment may be recommended as a preventive measure for social or psychological problems, the aim of this study is to review current literature pertaining to the assertion that orthodontic treatment is of value in improving self-esteem and perceived attractiveness. Searches in Medline database (1950 to 2009), EBM reviews, and PsycINFO were performed using “malocclusion”, “orthodontics”, “self-concept”, and “body image” as sub-headings, with “psychosocial”, “self-esteem”, and “perceived attractiveness” as keywords. Included were studies investigating the association between orthodontic treatment and change in psychosocial measures, such as self-esteem, self-concept, body image, facial
Abstracts of the 27th International Congress of Applied Psychology

appearance, perceived attractiveness and aesthetics. Articles with orthognathic surgery as the treatment modality were excluded. The search yielded 219 articles, of which 24 met the inclusion criteria. Many studies support the association between orthodontic treatment and improved dentofacial aesthetics; however, limited evidence exists for the influence of orthodontic treatment on self-perceived attractiveness. There is conflicting evidence concerning the influence of orthodontic treatment on self-esteem. This might be explained by the lack of rigorous definition of constructs, unreliable measurement strategies, lack of control of confounding variables, poor patient randomisation and a dearth of longitudinal studies. Rigorous research to explore the influence of orthodontic treatment on self-esteem and perceived attractiveness is required, employing a standardised approach, reliable measures, appropriate control of potential confounding variables and a longitudinal research design with pre- and post-treatment assessment.

Keywords: occlusal anomalies, orthodontic treatment, self-esteem, perceived attractiveness

The influence of regulatory focus of supervisors and subordinates on LMX and the performance of the subordinates

WU, X. (Beihang University), WU, Z. (Tsinghua University), WU, Y. (Tsinghua University), LI, R. (Beihang University)

Regulatory focus theory proposes that people have two distinct self-regulatory foci: promotion focus and prevention focus. The major purpose of this study was to examine the effect of regulatory focus of supervisors and subordinates on leader-member exchange (LMX) quality perceived by the subordinates, and the task performance and contextual performance of the subordinates. This study investigated (1) the different effects of promotion focus and prevention focus on task performance and contextual performance, (2) the effect of difference and/or interaction of regulatory focus of supervisors and subordinates on LMX and performance, and (3) the mediating role of LMX between regulatory focus and performance. Participants of this study included 249 employees and their supervisors. Participants were recruited from multiple industry and company types in China. Subordinates rated their own regulatory focus and LMX, and supervisors rated their own regulatory focus and the task performance and contextual performance of their subordinates. Data were matched in pairs for statistical analysis. Some of the key findings included: (1) promotion focus of both the supervisors and the subordinates was positively related to the contextual performance of the subordinates, and prevention focus of both the supervisors and the subordinates was positively related to the task performance of the subordinates; (2) there was an interaction effect of the regulatory focus of the supervisors and the subordinates. When the regulatory focus scores for the supervisors and the subordinate were both higher, the outcome scores were higher; (3) The similarity of regulatory focus of the supervisors and the subordinates moderated the relationship between regulatory focus of the subordinates and certain dimension of LMX; and (4) LMX partially mediated the relationship between regulatory focus and the performance of the subordinates. In conclusion, regulatory focus is an important antecedent of employee performance, and both the level of regulatory focus of the supervisors and the subordinates and the interaction of regulatory focus of the supervisors and the subordinates play critical roles.

Keywords: regulatory focus, leader-member exchange, promotion focus, prevention focus, task performance

The influence of resilience on the appraisal of academic stressors as threatening and challenging

KATTER, J.K.Q (York University)

Throughout their education students encounter many difficult situations that must be dealt with effectively in order to avoid negative psychological, physical, and academic consequences. According to the transactional model of stress and coping, when individuals are faced with an actual or anticipated stressor an evaluative thought process is triggered where the potential impact of the situation to their own well-being is appraised. Threat appraisals
involve assessing the potential for harm or loss in the future, while challenge appraisals reflect the anticipation of gain or growth from the situation (Lazarus & Folkman, 1984). One factor that may influence the way in which an individual will appraise stressors and consequently cope with them is trait resilience, which refers to the personal qualities that allow a person to thrive in the face of adversity (Connor & Davidson, 2003). It is hypothesized that higher levels of trait resilience, compared to lower levels of resilience, will be associated with the appraisal of upcoming tests and exams as more challenging and less threatening. Three hundred and four university students completed an online study in the week prior to the end of the academic term. Participants completed a series of personality measures including trait resilience, and were then randomly assigned to either a resilience boosting writing exercise, or a control exercise. Participants then appraised their own upcoming tests and exams as threatening and as challenging. A MANCOVA was preformed to examine the association between the personality measures, writing exercise and appraisals. Results reveal the hypothesized association between trait resilience and appraisals, such that resilience was positively related to appraisals of challenge, and negatively associated with appraisals of threat. Further analyses to examine the mechanism through which resilience affects appraisals suggest that affect may play a role. The research findings suggest that resilient individuals are more likely to appraise upcoming stressful events as challenges, rather than as threats, due in part to the association of resilience to affect, such that resilient individuals appear to have more positive affect and less negative affect than non-resilient individuals. Theoretical and practical implications of the association between resilience and appraisal are discussed.

Keywords: trait resilience, appraisals, stress coping

The general aim of the study was to investigate adolescent emotional well-being and the parent-adolescent relationship as a precursor to adolescent emotional well-being. The research was conducted at two secondary schools located in the Gauteng province in South Africa. A quantitative cross-sectional survey research design was followed. Convenience sampling was used. Participants included Grade 9 to 11 learners who fitted the selection criteria. Validated psychological measuring instruments were used to gather information at the schools. The results indicated that the parent-adolescent relationship was a predictor of the emotional well-being of this total group of adolescents and attachment-anger and family satisfaction-cohesion were the best predictors. Significant differences between genders on emotional intelligence and fortitude and between cultures on emotional intelligence, fortitude and positive affect were found. The emotional well-being of adolescents correlates with aspects of the parent-adolescent relationship and the parent-adolescent relationship could serve as a predictor of adolescent emotional well-being.

Keywords: adolescent emotional well-being, parent-adolescent relationship, attachment anger, family satisfaction, emotional intelligence

The influence of time pressure and number of attributes on information processing in purchasing decisions

WANG, D. (Shandong Normal University), HU, Y. (East China Normal University)

This research employed the technology of information board, used a commodities purchasing decision as the experimental task, and explored the influence of time pressure (high time pressure, low time pressure and no time pressure) and the numbers of attributes on decision makers’ information processing. The study included two experiments. A preparative experiment tested the time of decision making under different time pressures via simulated commodities purchasing tasks programmed with a computer. The formal experiment explored the influence of time pressure and the numbers of attribute on information processing, on the basis of preparative experiment. The results showed that (1) on the depth of information search and
average decision time, time pressure and the number of attributes had a significant main effect and interaction. (2) on the mode of information search, time pressure and number of attributes had a significant main effect, but no significant interaction. And decision makers usually applied a decision strategy according to alternatives under no and low time pressure. However they mostly applied a decision strategy according to attributes under high time pressure.

Keywords: Purchasing decisions, Time pressure, Decision making, Information processing

The influence of work behavior on meaningful performance

JATNIKA, R. (University of Padjadjaran)

This research is a causal study which is conducted to determine the effect of work behavior on meaningful performance. Meaningful performance is the performance generated by the fulfillment of serving a better work environment, which is conducted without the burden and caring, which is run by lasting to realize a better future (Jatnika, 2006). Meaningful performance will not only produce high performance but also the one that will make individuals have meaning in their work. These individuals will eventually be respected, be models for other parties, and be able to improve self-actualization. Therefore work is not only an activity to get some income, but also a part of the individual’s definition of himself, so that individual can improve self-actualization. Conceptually meaningful performance is influenced by the work behavior (quality of interpersonal relationship, acceptability of leadership, quality of team-work development and quality of work atmosphere development). The measurement in this research is done using questionnaires given to 327 top managers, middle managers and supervisors on service companies in Indonesia. The data obtained were analyzed using path analysis that will be exposed to the variables that significantly affect the meaningful performance. The results of data analysis show that meaningful performance is influenced by work behavior: quality of interpersonal relationship, acceptability of leadership, and quality of team-work development. The quality of work atmosphere development does not affect the meaningful performance significantly.

Keywords: work quality, work behaviors, meaningful performance, work environment, team-work

The interaction of job demands and job resources in a matrix organisation

O'DONNELL, M. (University of New South Wales), BROWN, M. (University of Melbourne), BENSON, J. (University of South Australia), GLENNIE, M. (University of New South Wales)

The paper makes use of the Job Demands - Resources model to explore the impact of the introduction of a matrix organizational structure in one large public research-focused organization in Australia. The findings represent the outcome of a qualitative research project exploring the interaction of job demands and job resources in a large scientific research organization. Exploratory semi structured interviews were held with research scientists across six divisions and at different levels of the organization. Staff members were interviewed for approximately one hour. The interviews were digitally recorded, transcribed and analysed using NVIVO software. A total of two focus groups comprised of six staff and 20 individual interviews were undertaken in 2009. The qualitative stage of the research allows for the identification of a range of organization specific job demands and resources. These will be explored further during the second quantitative stage of the project. The newly introduced matrix organizational structure had greatly increased the workloads of supervisors who were responsible for substantially larger numbers of research staff. The electronic system used to record the working time of scientists created considerable job dissatisfaction. The system did not permit scientists to record their actual hours worked. This resulted in an unwillingness to work above standard working time. Many junior scientists experienced reduced career guidance from supervisors who were often unable to comment on the quality of their science. Research scientists also experienced increased role conflict. Senior
management encouraged a focus on commercialization, and staff performance was also increasingly assessed against success in securing external funding. The criteria underpinning promotion decisions, however, continued to be dominated by research publications. Relationships with co-workers and team dynamics were often positive. Nevertheless, the organizations culture was widely viewed as competitive and many female interviewees highlighted difficulties with career advancement and with being accepted in a male-dominated environment. The paper found support for the argument that increasing job demands combined with reduced job resources results in withdrawal behaviours and declining levels of employee motivation and commitment.

Keywords: job demands-resources model, job resources, organization specific job demands, employee motivation, employee commitment

The investigation of forgiveness among original and nuclear families and its relationship with marital satisfaction

HOSSEINI, A. (Melbourne University)

This study investigated forgiveness in original and nuclear families as well as its relationship with marital satisfaction. The research has been conducted on 200 families (couples including 100 wives and 100 husbands) in Tehran, Iran. They were selected according to convenient sampling. It was a descriptive study and the tools used were: demographic questionnaires, family forgiveness scale (FFS) and questionnaire of marital satisfaction (ENRICH). The results of the study showed that there was a significant positive correlation \( r = 0.38 \) in forgiveness between two generations and also between forgiveness and marital satisfaction \( r = 0.51 \). In addition, there was a significant positive correlation between forgiveness and age, marital duration and education levels of couples. However, there was not a significant relationship between the number of children and forgiveness. According to the findings we can say that forgiveness may be effective in preserving family health.

Keywords: forgiveness, marital satisfaction, nuclear families, couples, family health

The measurement of workplace socialisation: An evaluation of the validity of the Thomas and Anderson Socialisation Questionnaire (TASQ)

WEINAND, C. (Deakin University), VON TREUER, K. (Deakin University), WINDLE, K. (Deakin University)

Researchers report positive relationships between newcomers' socialisation on important work outcomes such as job performance, job satisfaction, commitment, turnover, mental health, task mastery and intentions to stay. Consequently, the measurement of workplace socialisation is important. Few studies utilise consistent measures of socialisation and even less studies report upon the factor structure, other validity results and reliability. The aim of this study was to examine the proposed four factor structure (social, role knowledge, interpersonal support, and organisational knowledge) of the Thomas and Anderson Socialisation Questionnaire (TASQ) as originally reported by Thomas and Anderson (1998). Furthermore, generalisability of the factor structure will be tested in a different sample. Correlations between the TASQ and subscales with a similar established instrument may also support the validity of this instrument. This sample comprised of 215 employees from 17 different Australian-based organisations. The TASQ was used as the measure of socialisation and the Work Environment Scale (Moss, 1981) factors of job involvement, supervisor support and co-worker cohesion were measured. The factor analysis revealed four factors: social, role knowledge, interpersonal support, and organisational knowledge which was consistent with Thomas and Anderson’s (1998) findings. However, there were variations in the item loadings in the social subscale. The TASQ subscales were compared with the subscales of the Work Environment Scale and results revealed significant correlations between the subscales. Based on inspection of the items, it was suggested that the 'social' subscale can more accurately be relabelled as ‘co-worker cohesion'. Cronbach's alphas were; social (0.87), interpersonal support (0.88), role knowledge (0.90), and organisational knowledge (0.87).
With some recommended changes the TASQ was found to be a reliable and valid measure of workplace socialisation that is generalisable to other groups.

**The mediating effects of emotional intelligence and coping strategies on problem behaviours in adolescents**

HANSEN, K., DOWNEY, L. (Swinburne University), BIRNEY, J. (Swinburne University), STOUGH, C. (Swinburne University)

Early adolescence is a time of transition during which the individual experiences not only profound physical, emotional and cognitive changes, but also changes in terms of societal expectations regarding appropriate behaviour patterns and preparation for taking on adult roles. This transition from childhood to adolescence can be a challenging time for many young people. While many adolescents navigate this period without experiencing major difficulties, some individuals may experience psychological and behavioural problems. As many as 14% of Australian children under the age of 15 have some form of mental or behavioural problem (Australian Bureau of Statistics, 1997), and such problems may have "flow-on" negative consequences into adulthood. In light of this, the establishment of methods to identify individuals who are at risk for developing problem behaviours and strategies for the amelioration of these behaviours is of critical importance. It has been proposed that the recently emerging concept of Emotional Intelligence (EI) may offer a measure that has predictive value for identifying those at greatest risk for problem behaviour. This study explored the mediating effect of Emotional Intelligence (EI) and coping strategies on problem behaviours in Australian adolescents. One hundred and forty-five adolescents (60 males and 85 females with a mean age of 12.02 years) completed self-report instruments of EI, stress coping strategies, and problem behaviours. The relationship between Emotional Management and Control and engagement in internalising behaviours was found to be mediated by the use of non-productive coping strategies. Mediation models of externalising, anxious/depressed, withdrawn/depressed, and aggressive behaviours illustrated significant overlap with adolescents’ abilities to manage and control strong emotions and engage in non-productive coping strategies. The results are discussed in regards to how coping strategies are utilised in adolescence may produce more or less adaptive patterns of coping during adulthood. The development of emotional abilities may be required to improve coping outcomes for adolescents, which in turn may produce better psychological outcomes for adolescents in the long-term.

**Keywords:** emotional intelligence, problem behaviour, coping strategies, adolescence

**The microcredit and its users: A comparative study between Argentina and Spain from a psychological perspective**

PRADO GASCO, V. J. (Universidad de Valencia), QUINTANILLA-PARDO, I. (University of Valencia), ALTAMIRANO, P. (University of Cordoba), DE MARIA, M. (University of Cordoba)

The aim of the study was to compare some of the main important dimensions of a microcredit between two countries and to analyze and compare the consumer profile of a microcredit. The sample comprised 100 subjects. Interviews, questionnaires and discussion groups were used to collect a range of information across the following dimensions: 1) consumer profile (age, genre, work situation, education level, marital status, job experience, experience in leadership, experience in creating organizations, market research, motivation of solicitude, country, among other dimensions); 2) characteristics of the microcredit (financial sources, interest rates, quantities, beneficiaries, financial institutions, grace period, commission among other dimensions); 3) process of solicitude and concession; and 4) situation of the microcredit (number of operations, quantities, refund rates, default rate, delay in the refund, among other dimensions). A descriptive analysis and meta data was produced using SPSS 16.0. Differences between both countries have been observed in most of the analyzed dimensions, nevertheless not in the sub-dimensions. There seem to be lots
of similarities in the demographic profile of microcredit's clients between both countries (considering age, education, marital status, experience). On balance, in the Spanish context, the microcredit characteristics have more likeness with the traditional credits, with a bigger presence of private financial institutions (banks), while Argentina's microcredits have a major relationship with the original approach of the Grammen Bank and their running is public.

In Spain, this kind of financing has a relative short history when compared to Argentina, and nowadays it has been strongly affected by the economic crisis in the country. The solicitude process in Argentina's case has lower levels of bureaucracy and depends entirely on public institutions; however, this is completely different in the Spanish case. Finally higher rates of refund have been observed in the last years in the Argentina's case comparing with Spain.

**Keywords:** microcredits

**The mobilization and root causes of mass incidents in China: Case studies**

WANG, E. (Chinese Academy of Sciences), ZHANG, S. (Chinese Academy of Sciences), ZHOU, J. (Chinese Academy of Sciences), LIN, J. (Chinese Academy of Sciences)

Mass incidents in China refer to the conflicts between some collective groups and their administrative authorities. There are tens of thousands mass incidents that have occurred every year during past decades. A new characteristic was observed since 2004: While officials intervene in an ordinary civil or security conflict, the conflict soon turns to the authorities. It infers that discontent accumulates in people. This present study tried to explore why and what people feel discontent about and how a mass incident is mobilized. Four cases of mass incidents that occurred in 2008 and 2009 were chosen as the subjects of this study. We interviewed the local cadres and residents, asking the same questions, such as what public policies the local government made in recent years and how they thought the public policies worked. Comparing the responses of the cadres and residents, we tried to determine policy failures and improper administrations. Results indicated that: 1) residents complained that they were victims of some policies, while cadres considered their policies benefitted most people; 2) nonfeasance of authorities was considered as a most dissatisfactory administrative behavior by residents; 3) relative deprivation of some social groups and collective identification may be a mobilization of mass incidents, and rumors before and during the incidents play a catalyzing and magnifying role; 4) policy failures and improper administrations were the root causes of mass incidents. We also found that the conflict aims of mass incidents were restricted to official properties (vehicles and/or buildings) and collectives hardly injured official staff. They rarely destroyed private materials. Mass incident is a strategy of disadvantaged social groups to put pressure on authorities for declaring or protecting their interests. Policy failures and improper administrations are knowledge-based errors of policy makers and official staff, so officials are hardly self-aware their failures immediately. Social scientific scholars as the third party may be an intermediary between collectives and authorities, and be a detector to help governments find their policy failures and improper administrations.

**Keywords:** mass incidents, civil conflict, mass mobilization, disadvantaged social groups, collective behaviour

**The moderating effect of an innovative climate on the relationship between work-related stress and job satisfaction**

PIYASENA, N. (Deakin University), FULLERTYSZKIEWICZ, M. (Deakin University)

An innovative climate has been suggested to be a job resource by which organisations can assist experienced employees alleviate the negative effects of work demands on job satisfaction. However, considering the job environment of inexperienced employees may be quite different to experienced employees, the aim of the current study was to test the relevance and impact of an innovative climate on job satisfaction in inexperienced employees. In an attempt to better understand how an innovative climate impacts job satisfaction, a secondary aim was to explain how an innovative climate leads to job satisfaction using autonomy, support, job
clarity and organisation-based self-esteem (OBSE) as potential mediators. For the study, 80 university students currently enrolled in postgraduate studies in psychology and undertaking placement as part of their university degree were invited to complete an online questionnaire measuring organisational experiences and climate. In contrast to prior studies (which have sampled experienced/full-time employees), current results suggest that high levels of innovation may strengthen the negative relationship between work-related stress and job satisfaction. The results also revealed that the relationship between an innovative climate and job satisfaction is significantly mediated by OBSE and partially mediated by job clarity. It was concluded that low innovative climates as opposed to high innovative climates act as a buffer against the negative impact of work-related stress on job satisfaction for inexperienced employees while a high innovative climate exacerbates this effect. Therefore, the effect of an innovative climate on the relationship between work-stress and job satisfaction established in past research based on experienced employees cannot be generalised to inexperienced employees. The findings of the current study also reinforce the need to provide sufficient structure with clear policies and procedures for inexperienced employees in order to reduce work-related stress and enhance job satisfaction.

Keywords: innovative climate, work stress, job satisfaction, inexperienced employees, organisation based self-esteem

The moderating effect of parent gender on hazardous alcohol use among college students who are the Adult Child Of Alcoholics (ACOAs)

KELLEY, M. (Old Dominion University), PEARSON, M. (Old Dominion University), TRINH, S. (Old Dominion University), KLOSTERMAN, K. (Friends Research Institute), KRAKOWSKI, K. (Virginia Consortium Program in Clinical Psychology), KULNIS, A. (Old Dominion University)

Approximately 11% of all children in the United States (US) live with at least one parent who abuses or is dependent on alcohol or other substances (US Department of Health and Human Services, 2008). Among college students, approximately 25% meet the criteria for being an adult child of an alcoholic (ACOA; Grant et al., 2004). History of alcohol abuse in one’s family of origin is linked to offspring risk for alcohol abuse (King & Chassin, 2007; Warner, White, & Johnson, 2007; Zhou, King, & Chassin, 2006). Whether maternal or paternal alcoholism is linked to greater risk is not known. We examined whether the effect of ACOA status on hazardous drinking was moderated by which parent was suspected of alcoholism. Surveys were completed by 687 undergraduate students attending a large university in southeastern Virginia. Based on their Children of Alcoholic Screening Test (CAST; Jones, 1983) scores, 24% (162 of 687) were categorized as ACOAs (CAST score ≥ 6); 66% (451 of 687) were categorized as non-ACOAs (CAST score ≤ 1). The remaining 11% (74 of 687) were indeterminate (CAST score two to five); data from indeterminate respondents were not examined in the following analyses. Using the Alcohol Use Disorders Identification Test (AUDIT; Babor, Higgins-Biddle, Saunders, & Monteiro, 2001), 27.3% were classified as hazardous (medium to very high) drinkers. Using hierarchical regression analysis, we entered the main effects of ACOA status and suspecting mother and/or father of having a “drinking problem” in Step One, and entered the interaction between ACOA status and suspecting mother and/or father of having a “drinking problem” in Step Two. In Step One, only ACOA status (dummy-coded, 0 = non-ACOA, 1 = ACOA) significantly predicted hazardous drinking (β = .146). In Step Two, the effect of ACOA status on hazardous drinking was moderated by suspecting one’s mother (but not one’s father) of alcohol misuse (β = .155), which rendered the main effect non-significant. These results indicate that the effect of ACOA status has a stronger association when one’s mother is suspected of alcoholism. Future research should examine the potential mediating mechanisms through which maternal and paternal alcoholism may have differential effects on young adult children.

Keywords: paternal and maternal alcoholism, alcohol abuse, hazardous drinking, children of alcoholic screening test
The moderating role of leader-member exchange in the organizational justice to job satisfaction and turnover intention relationship

REN, R. (Peking University), WANG, L. (Peking University), KONG, H. (Luxottica Group), YU, Z. (Luxottica Group)

This research examines leader-member exchange (LMX) as a moderator of the relationships between organisational justice, job satisfaction and turnover intention. We hypothesised that group managers would influence the organisational justice feeling in their apartment. Five hundred and thirty-eight employees from the front line participated voluntarily. They were asked to finish the questionnaire independently and seriously, and to return the questionnaire the following day. Measurements included LMX, job satisfaction, organisational justice, and turnover intention. The results showed that the positive relationship between organisational justice and job satisfaction was weaker when the mean on LMX was low. In addition, the negative relationship between organisational justice and turnover intention was weaker for those high in LMX. The findings highlight the important role that leaders play in influencing the relationship between organisational justice to job satisfaction and turnover intention through the patterns of inclusion that they create in their units.

Keywords: leader-member exchange, organisational justice, job satisfaction, turnover intention

The motivations for and barriers to physical activity among overweight women with type 2 diabetes and depression

MOORE, M. (Victoria University), MORRIS, T. (Victoria University)

The aim was to use qualitative methods to explore the motivators, barriers, and mood influences on participation in physical activity (PA) of overweight women with type 2 diabetes and depression. Participants were 11 overweight women (median age of 61 years; IQR = 25) with type 2 diabetes and at least mild depressive symptoms. Following a standard consent process, each woman participated in a semi-structured interview (approximately 30 to 45 minutes in duration) focused on PA motivators, barriers, and mood influences. The interview process continued until theoretical saturation was reached. Inductive Content Analysis was used to analyse data. Nearly half the participants (n = 5) reported a sedentary level of PA. For those who reported some PA, the main modes were incidental/lifestyle (n = 7), and walking (n = 3). Main motivators to PA were socializing with others (9), health benefits (5), enjoyment (4), and doing something different from their daily routine (4). Major barriers to PA included health problems (n = 9), low motivation (n = 9), depression/low mood (n = 7), and weight (n = 5). All participants reported well-being benefits from PA (n = 11), however, the majority of participants (n = 8) indicated that having a low mood resulted in less PA behaviour. The main factors motivating PA participation for these mid-life women related to socializing with others and adding variety to daily routines. These are predictable motives, because isolation (e.g. loss of significant others), and monotonous daily routines (e.g. being retired) are concerns among older people. Given the high risk of health problems associated with being overweight, type 2 diabetes, and depression, it is not surprising that the major barriers to PA participation related to physical (e.g. associated pain, weight) and psychological (e.g. low mood) health, consistent with similar research. Although PA was perceived to have psychological well-being benefits, low mood was a main barrier for PA. Effective, individualized psychological interventions are needed to increase PA behaviour among this population, so that they can attain physical and psychological health benefits.

Keywords: depression, overweight, motivation, mood, type 2 diabetes

The narrative format model for second language learning in migrant pupils

PIRCHIO, S. (Sapienza University of Rome), TAESCHNER, T. (Sapienza University of Rome ), MARCHIONE, C. (Sapienza University of Rome ), ROTILI, C. (Sapienza University of Rome )
This presentation describes the results of an intervention for second language learning, using the Narrative Format Model, among first and second generation migrant children attending Italian primary school. The intervention lasted one school year (2008/2009) and involved first and second grade classes of a school in the province of Brescia, Northern Italy. It was implemented through narrative dramatic activities carried on in Italian, integrated in the general curriculum for migrant and non migrant pupils in an inclusive education setting. Italian language abilities were assessed in children participating in the language intervention and in a control group, in the same school. One hundred and one first and second grade pupils participated in the study, 56 were in the intervention group and 45 were in the control group. Receptive vocabulary, text comprehension and narrative production were assessed in both groups at the beginning (pre-test) and at the end of the language intervention (post-test) in order to assess the effectiveness of the narrative format activities for Italian language learning. As expected, results show a significant improvement of Italian language abilities among the experimental group with regard to complexity of sentence production. Moreover, both groups show improvement in receptive vocabulary and text comprehension. In conclusion, the effectiveness of the narrative format activities for teaching Italian to migrant children has been partially confirmed. It is important to note that the control group is not a “non-intervention” group: teachers in these classes carried on a traditional Italian language teaching activity with Italian and migrant children. This might explain why both groups showed improvements in observed abilities. Moreover, it is worth considering that the Narrative format activities have been positively evaluated by teachers, pupils and the school management, who decided to adopt this psycholinguistic model also in the current school year (2009/2010) in other classes.

Keywords: second language learning, language learning intervention, narrative format activities, psycholinguistic model, migrants

The normative practices of Australian mental health practitioners when assessing risk of violence in offenders

BARBER, D. (Edith Cowan University), DEAR, G. (Edith Cowan University)

This study aimed to: 1) explore the violence risk assessment practices of Australian psychologists and psychiatrists, 2) evaluate local violence risk assessment practices against international standards and, 3) explore the influence of various practitioner variables (e.g. training) and case characteristics (e.g. jurisdiction) on the local practices currently being employed. A combined exploratory-descriptive research design was employed to survey, identify, analyse and describe the violence risk evaluation practices of seventy-five Australian psychologists and psychiatrists with relevant experience. Participants completed an online survey about the type of assessment methods they employed in their most recent violence risk assessment for pre- or post-sentencing matters, the type of information they included in their report, and the way in which they communicated their risk evaluation to the decision-makers. Participants were also asked to provide qualitative explanations for their assessment practices and subsequent interviews with current participants will be undertaken to further explore the factors that influence local violence risk assessment practices. A follow-up study will also be undertaken with key stakeholders to elucidate the implications of the findings from the original study and investigate the needs of consumers of violence risk assessments. Conclusions drawn from the findings of this study and the empirical literature on violence risk assessments address a variety of practice-oriented research questions. The results are expected to contribute to the development of training programs and recognised professional standards and guidelines, which in turn, are anticipated to yield more empirically-based predictions of violence risk, satisfy legal standards and rules, and ultimately result in better risk-related decision-making. Efforts to enhance the provision of valid and reliable violence risk assessments is of particular importance following the introduction of Dangerous Offender legislation in numerous jurisdictions and the increasing reliance by courts and others legal decision-makers on psychological and psychiatric opinion regarding offenders’ risk of violence at the time of sentencing or release from custody.
The Pain of Difference: The experience of shame and embarrassment amongst a sample of gay men living in Australia

BECKER, A. (La Trobe University)

Internalised homophobia has been extensively researched and implicated in the wellbeing of gay men. It has been suggested that shame may be the principle pathogenic factor in internalised homophobia (Allen & Oleson, 1999). Over the last few decades, shame has not received nearly as much research interest as has internalised homophobia. There is clinical evidence to suggest that shame, specifically internalised shame or a shame based identity, is predictive of poorer biopsychosocial outcomes in gay men. Whilst we have seen the ‘depathologising’ of homosexuality and the development of gay-affirmative psychotherapies, there is further need to develop our understanding of the experience of shame, and its correlates, amongst gay men. Qualitative research is being conducted with nine Australian gay men exploring their experiences of shame and embarrassment and how they have been affected by and managed to cope with these feelings within and or without psychotherapy. Preliminary findings and potential implications of this study will be discussed.

Keywords: internalised homophobia, shame

The potential of empathy in building healthier organizations

MORENO-VELAZQUEZ, I. (Rio Piedras Campus, University of Puerto Rico), SÁNCHEZ-CARDONA, I. (University of Puerto Rico ), CUEVAS-TORRES, M. (University of Puerto Rico)

Empathy has been defined as understanding and sharing in another’s emotional state or context (Eisenberg & Strayer, 1987). It originated in Germany as “Eisfühlung” and was initially used by Vischer (1873) in relation to the projection of self in an artistic object. It is believed that was introduced to psychology by Lipps at the beginning of the twentieth century and coined as empathy by Tichner in 1909 as a way of knowing the conscience and understanding the other “in the muscle”. Its development was continued and revitalized by personality theorists in the 1930’s, Rogerian psychotherapists in the 1950’s and the theorists of conditioning in the 1960’s and more recently by social and evolutionary psychologists in explaining altruistic behaviors (Eisenberg & Strayer, 1987). Two traditions has been identified in the study of empathy, one stresses in its emotional components while the other equates it to the accurate perception of others, while a third one emerges from the work of Davis (1966) which suggests that is should be considered as a set of constructs. Empathy has been associated to important individual and organizational variables. The individual variables include: self-esteem, social skills, abilities, interpersonal effectiveness, and helping, customer service orientation and achievement, while the organizational variables include: organizational commitment, work performance and attendance to work, but not related to job involvement. Also empathy in supervisors has been related to higher employee satisfaction and lower levels of depression, anxiety and fatigue of their employees and higher productivity, but also with supervisor’s leniency. More recent research has explored how it can be experienced via the Internet (Preece, J. and Ghozati, K. (2001). We believe that employees have been under-used in different societal settings, but especially in work settings. In this presentation we will explore the relation between empathy and organizational attitudes that have been related in literature to pro-social organizational behavior. We will propose empathy as a variable that not only has the potential to explain positive outcomes in work organizations but the value to be developed so that it may strengthen human relations and develop healthier individual and work environments.

Keywords: empathy, organisational attitudes, human relations, work environment, employee satisfaction

The power of optimism: A road to success?
HO, P. Y. (Chinese University of Hong Kong)

Previous researchers have investigated the benefits of optimism. Yet, most studies only use a comparative approach among control and experimental groups to support the idea that optimism enhances people’s well-being. The current research tries to redefine success as a subjective goal achievement and investigate how optimism has an effect on achieving a self-determined goal. Task performance was measured using Boogle word puzzle among 118 young adults (43 males, 75 females). As hypothesized, dispositional optimism (LOT-R) was positively correlated with successfulness. Variables including proactive attitude, self-efficacy and confidence level were also measured, but no correlation with successfulness was found. Results predicted that optimism has a unique role in determining the individuals’ successfulness. Further research is encouraged to investigate the mechanism for this result.

Keywords: dispositional optimism, well-being, goal achievement, success, self-efficacy

The power of positive action in therapy and leadership

KENNETT, K. (Life ‘Be in It’ Education Pty Ltd)

The aim is to reinforce the importance of responses (actions) as the initiator of behaviour in therapy and leadership and the benefits of the power of positive action; to focus on the fundamental responsibility of psychologists providing therapy to acknowledge expertise in changing behaviour not merely treating symptoms and to re-discover that the order of experience is action followed by feeling and resulting in thinking. The application of the study of human behaviour is fundamentally seeking benefits to improve quality of life. For example, the positive behaviour of the therapist brings about effective improvements in the behaviour of the client and leaders can improve the overall lives of a community or nation. A review was done of leadership in terms of the concept, “Positive Actions elicit Passion and create Visions” © Kennett, 2009, involving application to life, leadership, and therapy and to advances in psychology. Leadership is essential in examining the fundamental differences between psychology and psychiatry as allied professions. The importance of responses (action) is the initiator of all behaviour including effective behavioral changes in clients. Changing behaviour is the prime responsibility of psychologists. A brief review was done of past eminent psychologists and application to psychological therapy and their leadership, embracing the power of positive action in therapy and leadership. Adler reported, “Trust only movement (action). Life happens at all levels of events, not word. Trust movement”. Skinner introduced the concept of operant conditioning. Both Adler and Skinner have been influential as leaders in focusing on competencies for effective behavioral changes resulting in many therapeutic approaches such as, for example, cognitive behavior therapy, rational emotive behavior therapy and holistic psychology. Applied psychologists and clinical psychologists continue to function in a “thinking-feeling-acting” way. “Action has always been the primary and initiating event followed by feelings and consolidated in thinking”. Behaviour (actions), emotion (feelings) and cognition (thinking) are inter-related but the behavior, as Adler and Skinner, has already been identified as the primary event. Applied psychologists need to act based on knowledge and the cumulative structure of past actions. The cycle begins with action that elicits feelings (feelings of the heart) and results in structural thinking (both convergent and divergent). Reference is made to Kouzes and Posner (2008) in Leadership Challenge, namely, concepts of “model the way (action), inspire (feeling) a shared vision (thinking), challenge the process, enable and encourage the heart”. In conclusion: “Grasping the structure of life and leadership involves ongoing responses (action) taken by self and others that support inter-relatedness among practice (action), emotion (feeling) and theory (thinking) in more meaningful ways”. This also applies to the process of therapy and the taking of action by both practitioner and client. “The fatal disconnection between practice (action) and theory (thinking) is still a challenge” Research relies on ‘either/or’ decisions, while life continues to exist in the world of ‘ands’. The structure of our thinking impacts on our actions. However positive thinking without action is
sterile. Constant reliance on incorrect ordering of how behaviour (responses patterns) occurs severely limits effectiveness as therapists and leaders. Therapists and leaders need to focus on the importance of “Positive Actions elicit Passion and create Visions”© Applied psychologists need to ensure research and critical thinking involves application - the need to recognize “time to take ACTION”. Effectiveness of knowledge relies on actions and implementation. Effective behavioral changes only occur through ACTION.

Keywords: positive action, leadership, quality of life, behavior change

The power of written emotional expression on psycho-physiological health

GARGYA, S. (Delhi University), KHOSLA, M. (Delhi University)

The present research examined the effect of written emotional expression on participant’s psychological health–affect [Positive Affect (PA) and Negative Affect (NA)], and cognition [components of the Impact of Event Scale (IES) i.e. intrusions, hyper arousal and avoidance, narrative analysis] and physiological health [Heart-rate (HR), Blood-pressure (systolic SBP) and (diastolic DBP)], and physical health (symptoms, perceived and general health). Ten participants were randomly assigned to each of three conditions- Trauma Condition, Happy Condition and Neutral Condition (n = 30). Each participant wrote for three days consecutively, and a follow up was taken after two months. Pre and post measures of writing were taken on affect using the Positive and Negative Affect Schedule (PANAS), cognition via the Impact of Event Scale revised (IES), and narrative content. Physiological arousal was assessed by recording Heart Rate and Blood Pressure, while physical symptoms and health were assessed using the SMU- health Questionnaire. Findings revealed significant short term affect changes across all the three conditions. The happy condition induced a significant reduction in heart-rate, health problems and symptoms. The trauma condition induced an elevated heart rate, and reduced health problems. The neutral condition also showed significant improvements in health problems. Narratives in the trauma condition had greater usage of negative emotion words while narratives in the happy condition had more positive emotion words. These findings have been discussed in light of cognitive processing and confrontation – inhibition theory to understand the possible mechanism underlying health. All three conditions however showed significant improvements in long term symptoms and health problems. Hence, expressive writing does reap physical health benefits. Therefore it can be concluded that writing is an effective intervention to improve one’s health.

Keywords: psychological health, positive affect, negative affect, physiological health, physical health

The precedence of local features in Attention Deficit Disorder (ADD)

YONGNING, S. (Kyushu University), YUJI, H. (Kyushu University)

The purpose of this study was to examine the weak right hemisphere hypothesis in Attention Deficit Disorder (ADD) by comparing the performance of children with ADD to that of children without ADD on the processing of compound patterns. An ADD group (N = 13) and a paired normal group (N = 13) completed Navon (1977) tasks under three variations of attention procedure. The first was a divided attention procedure in which the target could appear at either the global or local level. The second was a shift attention procedure in which participants were required to shift their attention from a local- oriented task to a global- oriented task or from a local- oriented task to a global-oriented task. The third was a selective attention procedure in which the target always appeared at the global level or the local level. The local interference effect rather than global interference effect was observed in children with ADD regardless of the attention procedure, which was opposite to Navon’s finding of a global interference effect observed in normal individuals. The finding of a local interference effect rather than global interference effect was observed in children with ADD regardless of the attention procedure, which was opposite to Navon’s finding of a global interference effect observed in normal individuals. The finding of a local interference effect in children with ADD suggests that people with ADD process compound patterns quite different from typically developing children, and they process local instead of global information automatically in a very early stage of processing.
The local interference effect confirmed the weak right hemisphere hypothesis in ADD and presented evidence against the DSM-IV criterion’s (APA, 2000) deficit hypotheses of ADD that the inattention symptoms may manifest itself as a failing to give close attention to details. This study also suggests that the Global/Local information interference test may provide more information for diagnosis of ADD and, in regards to training, instead of solely paying attention to training of individual information cognition, the training of grasping global information should be stressed.

Keywords: attention deficit disorder, attention, weak right hemisphere hypothesis, inattention symptoms

The psychic states dynamic of a women’s fencing team during preparation for the main season competition

KOLOSOV, A. (State Scientific Research Institute of Sport), LOZKIN, G. (Institute of Psychology Academy of Pedagogical Science), KOLOSOV, A. (State Scientific Research Institute of Sport)

This research was carried out during preparation for the 2009 European championship, with the Ukrainian female fencing team participation. The methods used included theoretical generalization, the Luscher Colour Test and Friedman ANOVA. During the whole period of preparation, the individual differences of psychic state of sportswomen and the change trajectory of the whole team were analyzed. Such an approach was reasonable for research on organization of interpersonal space inside the team, its regulatory capabilities, and the state of formation of collective subject of activity. The analysis of the psychic state indexes testifies to the presence of increments in predominance of ergotropic balance in sportswomen’s vegetative processes characteristics ($\chi^2 = 10,19; v = 7; n = 4; p = 0,09$). It testifies to increment in activation potential of their psychic sphere. At the same time the current level of sportswomen’s psychic tension came down gradually ($\chi^2 = 6,52; v = 7; n = 4; p = 0,48$), the deviation scope from autogenic norm of psychic state normalized and testifies to increments in the comfort level of the team’s psychic state ($\chi^2 = 13,95; v = 7; n = 4; p = 0,04$), and the mental capacity steadied on the high level ($\chi^2 = 6,93; v = 7; n = 4; p = 0,43$). The frankest changes were registered concerning sportswoman’s psychic state indexes to autogenic norm, and also concerning the coefficient of the vegetative activation. That testifies to increments in the comfort level of psychic state and the psychic activity of the whole team. Positive changes in psychic tension lowering and increments in mental capacity level were specified. Therefore, the positive dynamics in whole of the psychic state of the woman’s fencing team during preparation for 2009 European championship can be specified. In conclusion, the control of a psychic state of sportsmen enables definition of the thresholds for the usual and extraordinary mental activity of the sportsman, his strategy and styles of self-control, their arsenal and efficiency, an opportunity to carry out correctional training actions on expansion and activation of regulatory resource of the athlete which can be constructed through the organization of energo-informational space and results in a sensation of psychological sufficiency of resources to achieve high sports result.

Keywords: sportswomen, psychic state, team change, self-control, psychological resources

The psychological mechanism of Chinese overseas students' collective protests against Western Media

ZHANG, J. (Chinese Academy of Sciences), WANG, E. (Chinese Academy of Sciences), MANDL, H. (Ludwig-Maximilian University of Munich)

Contrary to the image of impassionate bystanders of political issues, in the year 2008 before the Beijing Olympic Games, a large amount of Chinese overseas students protested against some major western media in many western countries. Based on the dual pathway model of collective action (Van Zomeren, Spears, & Leach, 2004), the present study aimed to understand the effect of collective discrimination, political trust of the Chinese government, motivational inference and national identity on two core constructs: group-based anger and group efficacy. One hundred and thirty nine students were surveyed with questions about national identity, collective discrimination and political trust of the Chinese
government. They were then asked to recall a report made by any western media institution about China or Chinese people which impressed them when they were in Germany and to answer questions about their inferences about: the media’s motivation, attitudes of their peers (group emotional and action support), group-based anger and group efficacy, their former participation in these kinds of protests and behavioral intentions for future protests. Structural equation modeling (SEM) was performed using Amos 7.0 to investigate the possible relationships among all variables. The SEM results showed that group-based anger and group efficacy were the most immediate predictors of collective action. Further, group emotional support, collective discrimination and political trust contributed to group-based anger which was partially mediated by motivational inference of the media; on the other hand, political trust of the Chinese government, national identity and group action support contributed to collective efficacy. By confirming the dual pathway model of collective action, the present study further suggested that there would be different predictors of group-based anger and efficacy. Motivational inference could be a major mediator in the emotion-focused coping route, which could partly result from perception of past discrimination; political trust and national identity would provide a basis for legitimacy and external reward which could improve efficacy in the problem-focused coping route. The specific reason of this event and general themes about protest behavior in foreign countries was discussed.

Keywords: media protests, collective discrimination, political trust, motivational inference, national identity

The Queen Bee Syndrome in top positions in the Spanish Government: National and regional

PRIETO, J. M. (Complutense University), GARCÍA-VELASCO, O. (Complutense University)

The Queen Bee Syndrome was identified in 1973 and it entails that women in top positions in organizations appoint men as direct collaborators or team-mates. These women rarely appoint women in their near surroundings. This research verifies whether this exists also in Spain. The complete database of appointments made by the prime minister, ministers in the cabinet, presidents of regional governments and deputy directors appointed by them, has been analyzed first qualitatively and afterwards quantitatively. The total amount of appointments analyzed has been 266 at the national and regional level in the whole country. The prime minister appointed 50% to 50%, whereas the only female regional governor behaved as Queen Bee. Eighty nine percent of appointments made by female ministers favoured men, none were within the Quota 40% to 60%, and 11% of appointments were women. Forty-eight percent of appointments made by female deputy directors in regions were men, 27% kept the 40% to 60% quota, and 13% appointed women. This confirmed the existence of Queen Bee Syndrome effects in top positions of the national and regional governments in the country. A quota system has been enacted by law by the government and the parliament but when top female politicians make decisions they prefer males as top policy makers in their near surroundings. The existence of a Ministry of Equal Employment Opportunities is not enough to change this mentality.

Keywords: queen bee syndrome, equal opportunities, gender distribution in policy makers, gender quotas in organizations

The relation between prior experience and emotional creativity: The role of mindfulness

WENJUAN, Z. (Beijing Normal University), HONG, Z. (Beijing Normal University)

This study explored the relationship between prior experience, mindfulness and emotional creativity. We examined whether prior trauma (such as parents’ divorce or a serious accident) is associated with emotional creativity and the moderate effect of mindfulness. Both quantitative and qualitative data from Assessing Prior Trauma Events, the Mindful Attention Awareness Scale, and Emotional Creativity Triads, were gathered from 312 undergraduate students in Beijing. The results indicate that prior traumatic experience relates positively to emotional creativity. Multiple regression analysis
identified that mindfulness moderates the relationship between prior traumatic experience and emotional creativity after controlling for the effects of personality and emotional intelligence. Qualitative analyses were further made of 40 stories from subjects writing in response to the Emotional Creativity Triads Test. The result demonstrates that subjects with higher mindfulness scores are evaluating prior traumatic events more in a complex manner, and are less likely to reach premature conclusions; they can gain more benefits from overcoming hardships. Early trauma experience is positively associated with emotional creativity. Mindfulness can moderate their relations, and may facilitate subjects who are experiencing trauma events to explore more meaning regarding their prior experiences and appraise these events in a more complicated and mature manner.

Keywords: trauma, mindfulness, emotional creativity, maturity, mindfulness attention awareness scale

The relationship between daily goals and depressed mood

ASGARI, Y. (Deakin University), MILLER, R. J. (Deakin University)

Empirical evidence suggests that setting goals is inversely related to depression. The purpose of this longitudinal study was to examine the relationship between depressed mood changes and small daily goals. In this study, small daily goals have been classified as practical and emotional daily goals. Positive and negative cognition constructs were also examined in relation to the depressed mood. Data were collected from a community sample. A total of 178 adults of both genders (aged 18 to 70) participated in the first phase of this longitudinal study. After an eight week interval, 144 completed the questionnaires again. These questionnaire sets consisted of a demographic questionnaire, in addition to Explanatory Style, Optimism, Negative Thoughts, Hope, Mood and Daily Goals questionnaires. Findings showed that lower levels of emotional goals resulted in significant decrease in positive mood states and increase in depressed mood. This knowledge of individual daily goals is important for an understanding of depressed mood. Furthermore, the predictiveness of positive constructs by depressed mood will be discussed.

Keywords: depression, optimism, individual daily goals, mood

The relationship between interpretation of religion and understanding about gender roles in marriage and the family

ENDUT, N. (Universiti Sains Malaysia), MOHDHASHIM, I. (Universiti Sains Malaysia), AZMAN, A. (Universiti Sains Malaysia)

This study examines group differences (gender, religion and ethnicity) in young adults’ assessments of their level of religiosity and interpretations of related religious views about marital and family relationships and then their views about gender roles in these relationships. It further investigates the links between these sets of constructs. The respondents were 199 young adults who are compulsory participants of two camps of National Service training. They were selected to represent diverse socio-economic backgrounds. Respondents convened in a prepared venue and questionnaires were administered to them within scheduled time. For this study, they were required to answer three sections of questions: background information, a ten-item section on level of religiosity and interpretation of religious views about marriage and the family, and a 28-item section on views about gender roles in marriage and the family. Findings show that there is no difference in male and female respondents’ assessments of their level of religiosity. There are differences between their assessments of level of religiosity based on their religion and ethnic groupings. Malay and Muslim respondents reported higher levels of religiosity compared to other groups. People who reported as more religious also reported more traditional views about gender roles in marriage and the family. Respondents who reported higher religiosity reported higher interpretations of the sanctity of marriage and higher leanings towards a patriarchal interpretation of religion. The study indicates that religion may play a role in how young people interpret gender roles. Youths who describe themselves as religious appear to have more traditional views about gender roles.
Those who demonstrate a patriarchal outlook to interpreting religious teachings tend also to have more traditional views about gender roles. Youths of a particular ethnic group and religion show a higher degree of religiosity than others. These youths also have the tendency to give patriarchal interpretations to religious teachings and to view gender roles in more traditional ways. Taking these implications into account, it is important to further explore the relationship between religiosity and views about gender roles by investigating more elements in religion that may bring about such views.

**Keywords:** religiosity, marital relationships, gender roles, patriarchal interpretations, religion

### The relationship between keen social connectedness and attachment to parents and adults in college students

GHOBARY BONAB, DR. (University of Tehran), MAJID, A. (Medical Sciences University)

The aim of the current study was to investigate the relation between keen social connectedness, attachment to parents, and adults in college students of the University of Tehran. To accomplish the stated goal 120 college students from the School of Psychology and Education were selected by means of random selection from different departments of the school, and the following scales were administered to them: Attachment to Parents Questionnaire (Hazan & Shaver, 1986), Adult Attachment Scale (Collins & Read, 1995) and Questionnaire of Keen Social Connectedness (Ghobary Bonab, 1999). Analysis of data with utilization of multiple regression analysis revealed that the magnitude of keen social connectedness can be predicted from attachment security (i.e. dependability on the partner) to adults. In addition, magnitude of the secure attachment was a significant predictor of keen social connectedness and having a good relationship with parents. In conclusion, the results indicated that quality of attachment is a significant predictor of keen social connectedness.

**Keywords:** quality of attachment, social connectedness, adult attachment scale, attachment

### The relationship between personal and organizational values in an industrial company

Schwartz has determined ten types of personal values including conformity, tradition, benevolence, universalism, self-direction, stimulation, hedonism, achievement, power and security. Organizational values are indeed the supervisor’s ideas and beliefs of how to behave with a subordinate. As long as the organizational values match with employee’s values the employee will be more satisfied and committed to the organization. In addition, they work better and show little desire to leave the organization. The purpose of this research is to investigate the congruency between personal and organizational values. This research was of a correlational kind. Using this method, 269 people responded to two questionnaires: the Schwartz Values Survey (Schwartz, 1996) and Organizational values (a researcher-made questionnaire, 2009). Factor analysis of Organizational values questionnaire showed three factors: Attention to human resources, competition and globalization and Commitment to the organization. The results showed that, there is significant relationship between conformity, tradition, benevolence, universalism with attention to human resources and values, conformity, benevolence with competition and globalization; also the value of conformity, tradition, and power had a significant relationship with the commitment to the organization. According to the results, coordinating personal and organizational values to each other is important in terms of training programs and Strategic Organizational Management. Although, all the Schwartz values seems to be important, some of them are more important.

**Keywords:** personal values, organizational values, employee values, training programs, organisational management
**The relationship between personality and blogging**  
BAKER, J. (Swinburne University of Technology)

Previous research examining the Big Five personality traits found that openness and neuroticism predicted blogging behavior, with female gender moderating the relationship between neuroticism and blogging (Guadagno, Okdie & Eno, 2008). However, the effect of neuroticism was only significant in the second of two trials, and the authors posited that openness may become less related to blog behavior as blogging becomes more mainstream. As blogging has increased significantly from the time of original data collection, and as the effect of neuroticism was intermittent, the present study aimed to replicate this study with a larger sample population. A sample of 583 internet users was recruited from Facebook.com to replicate the initial study by Guadagno et al. The sample was composed of 219 bloggers and 364 non-bloggers, with a mean age of 29.88 years old (SD = 11.30 years), and 60.7% of the participants were female. Personality factors were measured using Saucier’s (1994) Mini Markers. In partial contrast to Guadagno et al.’s study, openness, but not neuroticism, significantly predicted blogging. Also, no gender difference was detected for neuroticism on blogging. No differences in neuroticism were found between bloggers and non-bloggers in this study with an increased sample size, suggesting that the main personality difference lies in openness.

**The relationship between scientific evidence and professional practice in applied psychology: Questioning the APA’s account of evidence-based practice**  
LYND-STEVENSON, R. (Flinders University)

The primary aim of the current proposal is to question the American Psychological Association’s (APA’s) account of evidence-based practice. The APA argues that efficacy research (i.e. experimental research in controlled settings) but not effectiveness research (i.e. non-experimental research in natural settings) is suitable to evaluate causal hypotheses about the relationship between professional interventions and applied outcomes. An analysis was conducted to demonstrate that the traditional paradigm for causal research permeates recent announcements by the APA about the concept of evidence-based practice. The traditional paradigm must be rejected. The unified paradigm for causal research is detailed and indicates that the APA’s account of evidence-based practice must be amended on two accounts. First, the causal conclusions reported in efficacy research are not superior to the causal conclusions reported in effectiveness research. Second, both efficacy and effectiveness research are necessary to evaluate the causal impact of professional interventions. The APA’s account of evidence-based practice must be revised. In particular, the contribution of effectiveness research to evaluate the causal impact of professional interventions is more important than currently acknowledged.

**Keywords:** professional practice, efficacy, effectiveness research, evidence-based practice, experimental versus non-experimental research

**The relationship between stressful life events and social adaption of Chinese teenage students: The role of social problem solving ability as a moderator**  
YANG, Y. (Beijing Normal University), ZOU, H. (Beijing Normal University), CHENG, Y. (Beijing Normal University)

This paper proposed a methodology to illuminate the role of social problem solving ability as a moderator when examining the relationship between stressful life events and social adaption of Chinese teenage students. The hierarchical sampling approach was applied in this study based on the responses from 2,157 Chinese teenage students in junior or senior high school, from Beijing, Shanghai, Harbin, Xi’an, Wuhan, Guangzhou, and Kunming. Questionnaires and surveys were used to collect the data from the sample. Three interesting findings were deduced from the analysis. Firstly, the stressful life events of Chinese teenage
students are embodied by their academic achievements and relationship with their peers, as well as the interrelationship and health condition of their family members. Secondly, the stressful life events of Chinese teenage students are considered as a prediction indicator for their social adaptation condition. Surveys show that those students with more experience of stressful life events possess lower abilities in social adaptation, which can be reflected by loss of confidence, unsuccessful handling of interpersonal relationships, and low efficiency at work, etc. Last, but not the least, the relationship between stressful life events and social adaptation is moderated by social problem solving ability. Individuals with stronger social problem solving ability have lower possibility of pessimistic social adaptation when they are suffering various stressful life events. It was concluded that social problem solving ability plays a vital role in addressing the relationship between stressful life events and the social adaptation of Chinese teenage students.

**Keywords:** stressful life events, social adaptation, problem-solving, moderator, Chinese students

The relationship between the behavior model of Marston and task quotient with employee turnover

The current research is based upon the model of Marston or DISC (consisting of four basic components) and aligning an employee task mixture named Task Quotient (TQ) with Employee Turnover. There are many personality models, and each model uses various interesting personality dimensions to define a person's personality. Marston (1928) developed a personality model referred to as DISC that intended to explain people's emotional response and that measures four dimensions of human personality: Dominance, Influence, Steadiness and Compliance. TQ in this study is defined as the total combination of three tasks, routine (respective), trouble shooting (problem solving) and project (planning). The statistical population was 6400 personnel of a public company and 270 personnel among them were selected randomly. Research instruments were DISC Personality Inventory (Marston, 1928), the TQ questionnaire (Gazzara, 2002) and Turnover opinions (Smitt, Crample & Porter, 1976). Multiple regression analysis was applied to the data. Results show that there are significant relationships between components of Compliance and Steadiness of DISC and Project planning of TQ and also between these two variables and turnover. Thus turnover and displacement are disadvantageous for organizations. Considering influential personality variables in turnover can help human resource managers to identify and select appropriate personnel that fit to work environment.

The relationship between trait anxiety, trait competitive anxiety, riding experience, accident/injury status, and state competitive anxiety for equestrian athletes

HOGG, R. (Charles Sturt University), HODGINS, G. (Charles Sturt University)

This study aimed to develop a deeper understanding of the mechanisms underlying equestrian athletes’ state competitive anxiety levels. It also aimed to explore the relationship between state competitive anxiety and trait anxiety, riding experience, and accident/injury status for equestrian athletes, as these constructs have been linked to state competitive anxiety in broader sport psychology research. One-hundred and fifty-five equestrian athletes who ride competitively completed a questionnaire set distributed locally and online using equine-related businesses and associations. Demographic and information on participants’ riding status was collected, and trait anxiety, trait competitive anxiety, and state competitive anxiety levels were measured. Trait anxiety was found to be significantly related to state competitive somatic ($r = .43, N = 130, p<.01$), and cognitive anxiety ($r = .50, N = 130, p<.01$). Trait competitive anxiety also
demonstrated statistically significant positive relationships with state competitive cognitive ($r = .80, N = 130, p<.01$) and somatic anxiety ($r = .83, N = 130, p<.01$). Trait anxiety and trait competitive anxiety predicted state competitive cognitive anxiety at a statistically significant level $F (5, 124) = 65.23, p<.0005$), and also predicted state competitive somatic anxiety at a statistically significant level $F (5, 124) = 86.20, p<.0005$). Subjective perceptions of accident/injury severity were found to be statistically significantly related to state competitive cognitive ($r = .37, N = 110, p<.01$) and somatic ($r = .33, N = 110, p<.01$) anxiety and to predict state competitive cognitive $F (1, 108) = 17.34, p<.0005$) and somatic anxiety $F (1, 108) = 13.18, p<.0005$) at a statistically significant level. The findings of this study suggest that because of the added dynamic of the horse, as well as other dynamics of equestrian sports, such as the high risk involved, the anxiety experience of equestrian athletes may be unique from that of other sporting populations. In other aspects, however, the results of this study indicate that equestrian athletes are similar to other athletic populations in their state competitive anxiety responses.

**Keywords:** competitive anxiety, trait anxiety, state anxiety, equestrian sports

### The relationship of gender role with mental health and its components in employed women

ALIAKBARI DEHKORDI, M. (Payame Noor university)

In the present study, the relationship of gender role (masculinity and femininity) and mental health was investigated in employed women. For this purpose, a sample consisting of 500 employed women in administrations, organizations and administrative companies of Tehran city were selected randomly. All subjects answered all items of Goldberg’s (1972) General Health Questionnaire (GHO) and Bem’s (1981) Sex Role Inventory (Short Form). To analyze data statistically, Pearson’s correlation coefficient and multivariate regression were used. The results of the research indicated that femininity and masculinity are positively correlated with each other. Femininity also has negative correlations with mental health, anxiety, dysfunction and depression; but has no correlation with somatic signs. Masculinity has negative correlations with mental health and dysfunction; but has no correlations with somatic signs, anxiety and depression. In addition, the results of regression analysis showed that masculinity does not have a significant role in explaining mental health and its components. The results of this research showed that employed women are high in gender role (masculinity-femininity). Also, more study and research must be done about gender role in Iran.

**Keywords:** gender roles, employed women, general health questionnaire, sex role inventory, femininity and masculinity

### The relationship of organizational commitment with effective variables on it

Organizational commitment is a multinational construct that has a specific effect on job and work issues. The current research attempts to examine the relationship of organizational commitment with its 14 predictor variables such as participation in decision making, organizational citizenship behavior, job scope, confidence to supervisor, organizational confidence, job involvement, promotion opportunity, internal motivation, supervisory quality, job alternatives etcetera. Two hundred and seventy two males and females of 4700 employees of a public organization were selected by a random sampling method. Data were analyzed through path analyses and stepwise regression analyses. Stepwise regression results showed that promotion opportunity, job involvement, participation in decision making, pay satisfaction, confidence to supervisor, satisfaction with supervisor and
organizational confidence were most robust predictors of organizational commitment. Results indicate that some subtle variables have great impacts on organizations and their productivity. Thus managers must recognize these variables and their effects on organization. In this trend they can induce or change considerable variables and their effects, variables such as organizational commitment and its predictors that have very important affects on organizational success.

Keywords: organisational commitment, organisational success, organisational management, productivity

The relationship of risk taking propensity, emotional intelligence and entrepreneurial intentions

MANGUNDJAYA, W. (University of Indonesia), DAHLAN, W. (University of Indonesia)

Entrepreneurship is becoming a very relevant instrument in promoting economic growth and development in a country. However, in Indonesia only 0.18 percent from approximately 200 million people are entrepreneurs. It is important for Indonesia that women enter business as well as men, particularly those who are ‘stay-at-home’ wives and mothers who are not officially ‘employed’ who may have more time compared to those who work full-time. This study examined the degree of entrepreneurial intention and the factors that influence it in these women. The objective of the study was to identify the relationship between risk-taking propensity, emotional intelligence and entrepreneurial intentions. The research used a quantitative ex post field study design and correlational methods. To collect the data, this study used the modified Entrepreneurial Intention Questionnaire (EIQ), the Emotional Quotient (EQ) Questionnaire and Risk Taking Propensity Questionnaire which has been recently modified and validated. This research was conducted with stay-at-home wives and mothers (N=128) in Jabodetabek (Jakarta, Bogor, Depok, Tanggerang and Bekasi area). Findings indicated that there was a positive and significant correlation between Risk Taking Propensity and Entrepreneurial Intention \( (r = 0.598, p < .05) \), as well as the positive and significant correlation between EQ and Entrepreneurial Intention \( (r = 0.540, p < .05) \) among stay-at-home wives and mothers. Based on the results, it was concluded that higher risk-taking propensity and Emotional Intelligence is related to higher entrepreneurial intentions of the individual. It was also found that stay-at-home wives and mothers had a medium level of Entrepreneurial Intention. Based on these results, it was concluded that higher risk taking propensity and Emotional Intelligence is related to higher entrepreneurial intentions of the individual. As a result, care and action should be taken to develop the EQ and Risk Taking Propensity of stay-at-home wives and mothers, in order to increase their Entrepreneurial Intention.

Keywords: risk taking, emotional intelligence, entrepreneurship, stay-at-home mothers

The relationships among adult attachment styles, relationship-histories and marital attitudes among Filipino young adults

PARCON, A.M. (University of the Philippines Diliman)

The relationships between adult attachment styles, individuals’ relationship histories and marital attitudes were studied. A survey was distributed among 179 single, Filipino, young adult professionals aged 21-31 years. To measure the Attachment Orientations of the participants, the study used the Experience in Close Relationships-Revised (ECR-R) Adult Attachment Questionnaire by Fraley, Waller and Brennan (2000). Scores were correlated with the participants’ present relationship status, past relationship experience and number of romantic relationships. The researcher also correlated the ECR-R scores with the participants’ perceived marital attitudes. Result showed that the Attachment-Related Anxiety and Avoidance scores were significantly correlated with one’s present relationship status obtaining \( r = -.267 \) and \( r = -.452, p<.01 \) respectively. Anxiety and Avoidance scores were again significantly correlated with past relationships experience, however, Anxiety and past-relationships experience obtained \( r = -.192, p<.05 \) while Avoidance and past-relationship experiences
obtained \( r = -.342, p < .01 \). Further, when correlated with participants' number of romantic relationships, only Avoidance scores was significantly correlated with \( r = -.207, p < .01 \). In terms of perception of marriage, only Avoidance was positively correlated with their perceived age of marriage entry obtaining \( r = .169, p < .01 \) which shows the probability that the more avoidant a person is, the more they will delay their marriage entry. Moreover, a negative correlation was found between perceived satisfaction in marriage and Avoidance with \( r = -.182, p < .01 \). Nevertheless, both Anxiety and Avoidance negatively correlated with the Marital Attitudes Scale with \( r = -.517 \) and \( r = -.492 \) at \( p < .01 \) respectively. Furthermore, both Anxiety and Avoidance scores were negatively correlated with their perception of happiness, agreeableness and confidence in marriage. The findings further validated the ambivalence and fear in entering relationships of highly anxious and avoidant individuals, although it was more salient among avoidant participants as they were less likely to venture into romantic relationships. Moreover, highly anxious and avoidant individuals had negative attitudes towards marriage, although only those who were highly avoidant perceived more dissatisfaction in marriage and would more likely delay their marriage entry. The findings of this research are helpful in terms of relationship, premarital and family counseling.

Keywords: adult attachment, attachment style, relationships, marital attitudes, Filipino

The relationships between gambling severity and implicit attitudes towards gambling

KIM, D. Y. (Chung-Ang University), LEE, J. H. (Chung-Ang University)

The characteristic problems of pathological gamblers are their attitudes towards gambling and their irrational cognitive expectations. Most pathological gamblers believe that gambling will ultimately bring them profit. This kind of positive attitude towards gambling is an important factor which facilitates gambling addiction behaviors to continue or relapse. Irrational beliefs and attitudes for gambling can be explicitly evaluated using self-report scales. However, explicit attitudes which are assessed through self-reports can be manipulated in conscious awareness. Implicit attitudes, on the other hand, are activated automatically and can influence behavior outside the boundaries of consciousness. Thus the aim of this study is to investigate the relationship between problem gambling severity and implicit attitudes towards gambling using the Gambling-Implicit Association Test (G-IAT). Participants will consist of 40 undergraduate students who have gone gambling at least once. Prior to the task, they will be asked to take the Korean Form of the South Oak Gambling Screening (K-SOGS) questionnaire to evaluate gambling severity, and the Gambling Attitudes and Beliefs Scale (GABS) to assess explicit attitudes towards gambling. Participants’ implicit attitudes towards gambling will then be evaluated using the G-IAT. The study is currently in progress. We predict that the K-SOGS will correlate higher levels of implicit attitude for gambling (G-IAT) than levels of explicit attitude for gambling (GABS). For participants with low K-SOGS scores, both implicit and explicit attitudes will predict gambling severity, but for participants with higher K-SOGS scores, implicit attitude will be more predictive of gambling severity than will explicit attitude. The expected results of the present study will suggest that positive implicit attitudes towards gambling are related to gambling severity. As high gambling severity individuals may show differences between implicit and explicit attitudes, we suggest that it may be necessary to assess them both in clinical situations which may in turn increase the predicting effectiveness for gambling severity.

Keywords: gambling attitudes and beliefs scale, implicit association test, pathological gambling, irrational beliefs, implicit attitudes

The road well travelled: The role of past experience in taking another's perspective

GERACE, A. (Flinders University of South Australia), DAY, A. (Deakin University), C, S. (University of South Australia), MOHR, P. (University of South Australia)

The influence of past experience on empathy has rarely been investigated in the psychological
literature. In previous empirical research which has been conducted, empathic outcomes have been largely focused upon, such as interpersonal accuracy and affective responses. The influence of having experienced a similar situation to that of another person on perspective taking, a cognitive empathic process, has been largely ignored. The purpose of this study was to examine whether past experiences make it easier for individuals to take the perspective of another person in a new, but similar situation and the extent to which other perspective-taking strategies, such as switching places with the target or considering common or typical reactions, make the perspective-taking process less effortful. A sample of 152 undergraduate participants was provided with an induction to take the perspective of a vignette protagonist involved in a problematic interpersonal situation (relationship problems, bereavement, work conflict, sexual coercion). Participants then reported their perceived ease in taking the other’s perspective, degree of similar past experience, strategies used to take the other’s perspective, and emotional and cognitive responses toward the protagonist. Results revealed that similar past experience was the strongest predictor of ease in undertaking the perspective-taking task. Moreover, the extent to which similar past experience increased ease of the perspective-taking process was moderated by the extent to which the participant reflected on that past experience. Dispositional empathic tendencies had a limited influence on ease, and neither past experience or ease was found to be a significant influence on empathic emotion. Perceptions of process ease did, however, mediate the relationship between past experience and perceptions of accuracy and confidence in taking the other’s perspective. The important role of past experience in taking another’s perspective is addressed, in particular how this may be used in counselling and helping relationships, and ways in which self-related reflection and insight influence the taking of another's perspective.

Keywords: perspective taking, empathy, counselling practice, self-reflection

The role of aggression and evaluation of emotion regulation on adolescents’ aggressive behavior

MEILIN, G. (Capital Institute of Physical Education), HUI, C. (Chinese Academy of Sciences), JIANXIN, Z. (Chinese Academy of Sciences)

The incidents of juvenile delinquency, especially those involving aggression have risen in recent years. Compared to non-delinquent adolescents, do these aggressive juvenile delinquents demonstrate behavioral and emotional differences? This study investigates the role of implicit aggression and implicit evaluation of emotion regulation in discriminating aggressive juvenile delinquents and test if the roles are gender-specific. Ninety-three aggressive juvenile violent delinquents and 130 age-matched high school students took the Aggression Questionnaire (AQ; Buss, 1992), Emotion Regulation Questionnaire (ERQ; Gross & John, 2003), Implicit Aggression Association Test (self-edited) and Implicit Evaluation of Emotion Regulation Test (Iris, 2006). Logistic hierarchical regressions were conducted on aggressive and non-aggressive behaviors. It was found that implicit aggression has a significant predictive effect. That is to say, the stronger the implicit aggression is, the more likely adolescents are to commit violent crimes. Another interesting finding is that gender regulates the predictive effect of the implicit evaluation of emotion regulation on juvenile delinquency. For females, those who are more controlled in implicit evaluation of emotion regulation tend to be more aggressive than otherwise. However in males, implicit evaluation of emotion regulation could not predict adolescents’ aggressive behaviors even after controlling explicit aggression and explicit evaluation of emotion regulation. This study revealed the predictive effect of implicit aggression and implicit evaluation of emotional regulation on adolescents’ violent crimes and the regulative effect of gender on implicit evaluation of emotional regulation. The possible mechanism behind the finding and the influence this finding has on adolescents’ education are discussed. In conclusion, both implicit and explicit aggression can significantly predict violent crimes. Under the explicit conditions, explicit aggression has a strong predictive effect, yet its predictive power is regulated by explicit evaluation of emotion regulation, that is to say the predictive power is not significant on those who tend to express an explicit evaluation of emotion regulation. When
explicit aggression and explicit evaluation of emotion regulation are controlled, the implicit variables are tested. The research finds the predictive effect of implicit aggression is still significant and the predictive effect of the implicit evaluation of emotion regulation is edge significant, which is regulated by gender.

Keywords: emotion regulation, delinquents, implicit aggression, evaluation

The role of child rearing training skills in reducing mothers’ stress and children’s behavioral problems

FARZADFAR, Z. (Shahid Beheshti University)

The present research examined the efficacy of parenting skills training in preventing stress in a non-clinical sample of mothers, and in reducing behavioral problems among their children. The Parenting Stress Index (PSI; Abidin, 1990) was administered to an original sample of 198 mothers. Fifty-one mothers who scored highest on the PSI were chosen and randomly assigned to two experimental (N = 26) and control (N = 25) groups, and completed the Child Behavioral Checklist (Achenbach, 2001). Quantitative data were analyzed using pre-post test (t test), correlation coefficient, and multiple covariance analyses. Findings showed that after intervention: a) mothers in the experimental group showed lower levels of stress, as compared to mothers in control group, b) children of mothers in the experimental group showed less behavioral problems than children of mothers in the control group. In conclusion, parenting skills training reduces maternal stress and children’s behavioral problems. This procedure may occur because parenting skills directly affect maternal stress reduction and subsequently their children behavioral problems decline. On the other hand parenting skills may empower mothers to manage difficult behaviors, and as a result, maternal stress decreased.

Keywords: parenting skills training, mothers’ stress, children’s behavioral problems, child behavioral checklist

The role of coping in the intergenerational transmission of problem gambling

DOWLING, N. (University of Melbourne), JACKSON, A. (University of Melbourne), GERAGHTY, J. (University of Melbourne), THOMAS, S. (Monash University), FRYDENBERG, E. (University of Melbourne)

There is now substantial evidence that children of problem gamblers are more likely to develop gambling problems themselves than the children of non-problem gamblers. However, little is known about the risk and protective mechanisms associated with the transmission of gambling problems from parents to their offspring. The current study aims to evaluate the role of coping in the intergenerational transmission of problem gambling in a sample of adolescents. The sample consisted of 612 students aged between 12 and 18 years from secondary schools in Victoria. Participants completed self-report measures evaluating parental (paternal, maternal) problem gambling, adolescent problem gambling, and coping (productive coping, non-productive coping, and reference to others). The findings revealed that there was a weak but significant relationship between paternal and adolescent problem gambling but that there was no significant relationship between maternal and adolescent gambling problems. The findings revealed that non-productive coping (avoidance strategies generally associated with an inability to cope) was a mediating mechanism underlying the relationship between paternal and adolescent problem gambling and that productive coping (attempting to solve the problem whilst remaining physically fit and socially connected) served to mitigate the transmission of paternal gambling problems to adolescents. The identification of the role of coping in the intergenerational transmission of gambling problems is important in informing the design of targeted prevention and intervention programs necessary to reduce the transmission of problem gambling from one generation to the next.

Keywords: coping, problem gambling, intergenerational transmission, avoidance, adolescents
The role of dissociation in conceptual and perceptual processing in chronic Posttraumatic Stress Disorder

DORAHY, M. (University of Canterbury), LYTTLE, N. (The Belfast Health and Social Care Trust), HUNTJENS, R. (University of Groningen)

This study explored the role of dissociation in perceptual and conceptual processing of trauma-related material in chronic Post Traumatic Stress Disorder (PTSD). In clinical participants with and without chronic PTSD (N = 50) matched on age and gender and geographic location, a computer presented experimental study investigated perceptual and conceptual priming for trauma-related, general threat, and neutral words in "Troubles"-related trauma survivors in Northern Ireland. Measures of state and trait dissociation, state anxiety and general psychiatric symptoms were also assessed. Evidence of enhanced perceptual priming in PTSD for trauma stimuli was found along with a lack of conceptual priming for such stimuli. State dissociation made a significant contribution to predicting priming for trauma words. The findings show the importance of state dissociation in trauma-related processing and posttraumatic symptoms. Because of its association with perceptual processing, dissociation may be particularly important in the development of intrusive PTSD symptoms, like flashbacks and nightmares.

Keywords: post-traumatic stress disorder, dissociation, perceptual processing, conceptual processing, trauma

The role of emotional intelligence and empathy in adolescent bullying behaviours and peer victimization

STOUGH, C. (Swinburne University), LOMAS, J. (Swinburne University), HANSEN, K. (Swinburne University)

The aim of this study was to examine the role of Emotional Intelligence (EI) and empathy in adolescent bullying behaviours and peer victimisation. The sample consisted of 68 adolescents and eight teachers from a secondary college in southeast Melbourne. Student participants completed a self-report questionnaire which assessed their EI, empathy, social desirability and how frequently they engaged in bullying behaviours and were the target of peer victimisation. Teachers were asked to rate the peer relations of students. Results of the study indicated that EI particularly the dimensions of emotional decision making and emotional management and control, significantly predicted the propensity of adolescents to be subjected to peer victimisation. EI and empathy were also associated with adolescent bullying behaviours. It was concluded that anti-bullying programs in schools could be improved by addressing deficits in EI in adolescents who are at a greater risk of being subjected to peer victimisation.

Keywords: Emotional intelligence, bullying, victimization, adolescence

The role of extracurricular activities in developing students’ self concept

DEWAJANI, S. (Gadjah Mada University)

The study investigated the relationship between extracurricular activities to improve elementary school students’ self concept; types of extracurricular activities which can improve elementary school students’ self concept; and the duration of effective extracurricular activities to improve elementary school students’ self concept. The study used a correlational design to confirm the relationship between extracurricular activities and elementary school students’ self concept, using a sample of 296 students of Jogjakarta province elementary schools. Students’ self concept was measured using the SDQ 1 (adapted from Marsh (1985)), and extracurricular activities were collect by the Student Extracurricular Activities Questionnaire (SEAQ). The result of the study showed that there was a significantly correlation between students’ self concept with their numbers of extracurricular activities involved (r = 10.121; p = 0.01), and that there was no significant correlation between students’ self concept with their duration of performing extracurricular activities in a week (r = 0.889; p = 0.101). Additionally, there were no significant differences between students’ self concept with Arts (F = 0.712; p = 1.09) and Sports.
extracurricular activities ($F = 0.952;\ p = 0.299$). However, there were significant differences between students’ self concept with boyscout (Scout) ($F = 9.297;\ p = 0.03$); Science ($F = 8.228;\ p = 0.04$) and religious ($F = 8.344;\ p = 0.04$) extracurricular activities. In order to improve students’ self concept, as one of the important aspect of children personality development, it is recommended that schools should arrange extracurricular activities for students to train and develop their self concept. This extracurricular activities is the place for students to determine and evaluate themselves. Additionally, schools could arrange extracurricular activities that encourage strong relationships between students and their tutors, such as boy/girl Scout; religious activities and Science activities. Overall, the research found that the duration of each extracurricular activity does not have any impact on the students’ self concept, and therefore it is not to say that the longer the activities the better. The more important aspect is the quality of tutor relationships.

The role of international accessibility law on the psychological outlook and physical functioning of people with disabilities

KUEMMEL, A. (James A Haley VAMC), KUEMMEL, R. (Cincinnati Children's Hospital)

This presentation examines the role that international accessibility laws play in the psychological and physical functioning of People with Disabilities. Given that the wheelchair accessibility of a disabled individual’s environment plays a large role in how People with Disabilities function in different societies, this theory was examined through a literature review and legal research on international accessibility law, then integrated with qualitative data of the presenters’ (one of whom has a physical disability) personal experience of travel to different countries. Analysis of literature and disability legislation revealed that various disability rights laws enacted throughout the world differ not only in their structure and coverage, but also in the way they are enforced and how they impact various societies. As disability is influenced by the societal values and the environment, different societies will have different concepts of disability and how it is protected by law. This will affect the level of access an individual has to accommodation, housing, and opportunities in different societies. In addition to physical functioning, the level of access the law provides impacts psychological variables such as self efficacy, self-esteem, and attitude towards disability. Success of disability laws depends mainly on the actions and attitudes of individuals in society who must enforce it by removing architectural and communication barriers and providing accommodations. Understanding the role that law plays in the psychological and physical functioning of people with disabilities is crucial for psychologists and other rehabilitation professionals aiming to utilize interventions to help patients with disabilities lead more independent and fulfilling lives. This research offers valuable insight into how people in different countries perceive disability and the need for global communication on the topic.

Keywords: disability perception, disability, accessibility laws, rehabilitation

The role of narcissism in social anxiety

WILLIAMS, J. (Swinburne University of Technology), BATES, G. (Swinburne University of Technology)

Recent ethological theories of social anxiety have emphasized that social anxiety is related to perceptions of social rank. While a submissive type of social anxiety (cf. DSM-IV-TR) has been extensively studied, recent cluster analytic studies have identified a variation associated with dominant/aggressive, impulsive and disinhibited behaviours. Viewed through the lens of Personality Psychology, this type shares similarities with narcissistic personality. Therefore, the current study sought to explore the role of narcissism in social anxiety. In response to notices on social anxiety websites, 349 people completed a questionnaire. The questionnaire measured social anxiety (Social Interaction Anxiety Scale), narcissism (Narcissistic Personality Inventory), covert narcissism (Hypersensitive narcissism scale),
narcissistic pathology (Narcissistic Personality Disorder scale), anger (Dimensions of Anger Reactions), Shame (Experience of Shame Scale) and Depression (Depression, Anxiety, Stress Scale). The sample was heterogeneous with 150 participants in North America, 141 in Europe, 40 in Australia/New Zealand, 10 in Asia, and seven in other regions. Ages ranged from 18 to 74. Cluster analysis of the data revealed the presence of five distinct social anxiety clusters. Subsequent multivariate analysis indicated that the groups significantly differed on social anxiety, narcissism and anger. On the basis of group differences in these variables, the groups were labelled: narcissistic social anxiety group (NSA), covert narcissistic social anxiety group (CNSA), angry covert narcissistic social anxiety group (AnCNSA), general social anxiety group (GSA) and low social anxiety group (LSA). In terms of social anxiety, the covert narcissistic groups were more impaired than the other groups. Additionally, all three social anxiety groups with narcissistic characteristics evinced higher scores on measures of depression and shame than the non-narcissistic social anxiety groups. The current results are consistent with Paul Gilbert’s ethological model of social anxiety. Viewed from this perspective, the narcissistic social anxiety groups can be characterised as individuals who have a perception of low social rank (high social anxiety) coupled with a desire for power, control and grandiosity (high narcissism) but feel unable to “challenge” those perceived to be dominant for fear of the interpersonal consequences of such a challenge. More broadly, the current results suggest that social anxiety is a broad and heterogeneous phenomenon, and that re-analysis of social anxiety using alternative theoretical paradigms (such as ethology) yields meaningful distinct variations of the disorder.

Keywords: social anxiety, narcissism, ethology, shame, personality psychology

The role of personality, intelligence, attitudes to education and use of study strategies in academic success in final year secondary and first year tertiary students

WALL, G. (University of Canterbury)

The aim of the current study was to explore the effect of personality, intelligence, perceived value of education, perceived view of school, view of intelligence and use of study strategies on student academic achievement in final year-secondary and first year-tertiary students. Participants were 655 final year tertiary students who completed a questionnaire containing scales measuring the above variables. Study strategies included short and long-term time management, critical thinking, elaboration, rehearsal and peer learning. Participants gave the researcher consent to access their 2008 examination results. In 2009, those students who went on to tertiary study at the University of Canterbury were contacted and asked to complete a similar questionnaire to the one they completed in 2008. Sixty-two students completed the questionnaire and gave consent for the researcher to access their 2009 university results. Multiple regression analyses found that a number of variables significantly predicted academic achievement in final year secondary school, including sex, intelligence, personality (conscientiousness, openness to experience), and use of critical thinking skills. Data analysis of university results is currently being conducted. Correlations will be generated to determine the variation in responses between 2008 and 2009. Multiple regression analysis will be used to determine the relative influence of the variables measured on academic outcomes at a tertiary level. If there are differences in the factors that influence academic success in secondary school compared with a tertiary setting, this has implications for the education and guidance services that should be offered in these settings. Secondary schools may need to consider the support that students require to make a successful transition to tertiary study depending on the relative usefulness of different strategies in the two settings.

Keywords: academic success, secondary students, tertiary students, intelligence, attitudes

The role of regulatory anticipation, regulatory reference, and regulatory focus on health behavior

LUBIS, D. U. (University of Indonesia), TAKWIN, B. (University of Indonesia)
This study examined self-regulation in relation to health related behavior (health behavior), in people of DKI Jakarta. The aim of this study is to understand how people living in DKI Jakarta regulate their self in order to maintain their health behaviors, including the self-regulation principles they use. Using three principles of self-regulation; regulatory anticipation, regulatory reference, and regulatory focus (Higgins, Grant, & Shah, 1999) this study examined the role of those principles on health behavior of people living in DKI Jakarta. Anticipation varied into two types, namely (1) anticipation of pleasure or success in the future, and (2) anticipation of failure or pain in the future. The memory of past experience divided into two, namely (1) recollection of success or pleasure, and (2) memory of failure or pain. Self-regulation strategies varied into (1) regulatory focus promotion and (2) regulatory focus prevention. Health behaviors are divided into health promotion behaviors and health prevention behaviors. A total of 385 citizens of DKI Jakarta (200 males and 185 females) participated in this study as respondents of survey and questionnaire. Each participant responded to questionnaires which measure their regulatory anticipation, regulatory reference, regulatory focus, and health behavior. Data analysis using multiple correlations and multiple regression techniques indicated the role of self-regulation principles on health behavior and preventive regulatory focus and preventive behavior. However no significant relation with regulatory anticipation of pain and preventive behavior was found. This study concludes that self-regulation in order to achieve health is influenced anticipation, memory of past experiences, and self-regulation strategies used.

Keywords: health related behaviours, self-regulation, regulatory anticipation, regulatory reference, regulatory focus

The role of self-efficacy and resiliency as moderating effects between job demand variables and boredom stress

PURBA, D. E. (Universitas Indonesia), MANSOER, W. D. (University of Indonesia), WIDIARTO, P. (Indonesian Ministry of Finance)

Boredom stress as a negative effect of a new public management policy has not been extensively researched in Indonesia, although the impact of this psychological state is pervasive on individual performance in workplaces. Research in the field has shown that job demand variables (quantitative workload and job characteristics) are significant predictors of boredom stress. We assumed that the effect of job demand variables on boredom stress would be moderated positively and negatively by personal resources variables (self-efficacy and resiliency) in the changing work environment, due to a new public management policy in Indonesia. This study employs 213 employees from the regular units of Directorate of General Treasury – Indonesian Ministry of Finance. as participants. Data were analyzed using univariance statistics methods (moderated hierarchical multiple regression). The result shows that workload quantity and task characteristics negatively affect boredom stress. Thus, both variables are significant predictors of boredom stress. Self-efficacy failed to positively moderate the effect of job demands variables on employees’ boredom stress. On the other hand, resiliency shows a negative and significant effect as a moderator variable of the relationship between job demands and boredom stress. Resiliency is more useful and necessary than self-efficacy in dealing with underload conditions at work, to reduce the potential emergence of boredom stress as one of the negative consequences of change in units having the same work characteristics.

Keywords: boredom stress, public management policy, job demands, personal resources, workload

The role of self-efficacy and non productive coping strategies as mediating the relationships between insecure attachment and NSSI (Non-Suicidal Self-Injury)

GIDEONI-COHEN, S. (Monash University), HASKING, P. (Monash University), SABURA ALLEN, J. (Monash University)

Non-suicidal self-injury (NSSI) is a phenomenon on a rise which peaks during adolescence. This study examines the risk factors such as insecure attachment with mother, father and peers, low
self-efficacy and non-productive coping strategies; and their relationship with NSSI in a community sample of young people. The sample included 275 young people (aged 13 – 26), who completed a self-report questionnaire assessing the constructs of interest. Insecure attachment with the mother, insecure attachment with father and peers were found to be related to NSSI. Nevertheless, these relationships were mediated by low self-efficacy and non-productive coping strategies. It may be that low self-efficacy is at least partly a product of the negative internal working models which were established as a result of insecure attachment relationships. Also, it was found that NSSI peaks in early adolescence until mid adolescence. In regard to the peak age and to low self-efficacy which was found to be central as this is the cognitive process which comes previous to the selection of coping strategy, the implications consider the possibility of prevention program to improve self-efficacy perception at the departure from childhood to adolescence.

Keywords: self-injury, self-harm, attachment, self-efficacy, coping strategies

The role of self-perception and third-person-perception concerning intergenerational knowledge transfer

MITTERHOFER, H. (Institute for Communication in the Professional Field and Psychotherapy), STIPPLER, M. (University of Innsbruck), GROPPE, S. (University of Innsbruck)

The demographic change in industrial countries like Austria entails ageing societies (Klein, Lher & Wilbers 2008) and ageing workforces (Frerichs, 1998, Becker/Naegele 1993). Regarding this change, the project “Diversity and Knowledge Management” funded by the Austrian National Bank aims to analyze how intra-company self-perceptions and third-person-perceptions of different generations influence knowledge transfer. Elder workers provide important sources of organizational knowledge (Krenn, 2001). At the same time, they can be seen as rigid (Argyris 2006, Nelson & Winter, 1982). Young workers lack the specific experiences linked to the company’s history (Lave & Wenger, 1993). This may – combined with the different age-related upbringing and imprinting – lead to a more flexible behavior (Sennett, 2008). Conflicts arising from these different working styles manifest in speech by using certain metaphors (Lakoff & Johnson 2007). To analyze the metaphors-in-use by company members concerning self-perception and third-person-perception, interviews with members of all hierarchical levels have been conducted in small and medium enterprises across different sectors. The data was analyzed using atlas.ti. The method included a triangulation of Grounded Theory (Strauss & Corbin 1996) and Qualitative Content Analysis (Mayring 2007), focusing on metaphor-in-use. The analysis of metaphors-in-use shows and explains differences between elder and younger employees in the organizational context. The results help to get an understanding of the organizational culture and, as a consequence, an understanding of enhancing and the constraining factors of knowledge transfer on a linguistic level.

Keywords: ageing workforce, intra-company self-perceptions, organisational culture, intergenerational knowledge transfer, metaphors-in-use

The role of social psychology in alleviating poverty and increasing well-being through women’s empowerment

TAKWIN, B. (University of Indonesia), MARKUM, M. E. (University of Indonesia), PRIMALDHI, A. (University of Indonesia)

The purpose of this study is to construct a model of for alleviating poverty through women’s empowerment by facilitating them to start a small business. Thus empowerment is achieved by successfully increasing family income through small business ventures. This research was conducted over a six-month period using a quasi experimental research design. A total of 100 housewives (age range from 21 to 55 years old) from two poor communities, Depok City and DKI Jakarta, participated in this study. Attrition rate was quite high; only 59 participants completed the whole program (23 people in Depok, 36 people in DKI Jakarta). In order to facilitate the development of individual and group empowerment, participants were first trained to develop individual traits through a series of activities during the intervention program.
Participants participated in activities to increase self-efficacy, self-esteem, trust, cooperation, and need for achievement. These traits were deemed necessary in order for the participants to develop a small scale business venture. Participants were divided into groups where they brainstormed potential business ventures utilizing the resources they had, then designed the product/service which they would provide, and then implemented their business plan. The measure used in this study was a behavioral check-list to record behavioral observation data related to the research variables. Two groups from Depok managed to increase each member’s income by 40% at the end of the program. Almost all indicators of social aspects showed an increase. One indicator which did not show sign of increase was the measure for subjective well-being; participants did not show an increase in general satisfaction with their life, and it was assumed that participants were striving for a better overall condition of their life. Overall, the model shows early indications of successfully facilitating the development of business among women in poor communities. Further refinement of the model is required in future studies.

Keywords: well-being, poverty, women’s careers, self-efficacy, need for achievement

The role of subtitles in the children’s incidental learning

WANG, A. (Beijing Normal University), SHU, H. (Beijing Normal University)

The present study examined the role of subtitles in first and third grade pupils’ incidental learning on a reading alone condition. Participants were 40 first grade and 40 third grade pupils (20 low reading level and 20 high reading level children in each grade according to their Chinese test scores and their Chinese teachers’ evaluating to their reading level). In the experimental design, three factors were participants’ reading level (high and low reading levels), subtitle forms (with pinyin and no-pinyin), and new dense words (high and low dense). The experimental materials were 4 videos, where each grade used 2 of them which included high and low new dense words. Each child watched 2 videos with high and low dense words and pinyin (no-pinyin) subtitles alone. The results showed (1) the first and third grade pupils acquired new words with incidental learning, and acquired more new words in condition of the high new dense words than low new dense words in the task of watching video program with subtitles; (2) first-grade children with the low reading level acquired the same quantity of new words as first-grade children with high reading level in the condition of subtitles with pinyin, but their quantity of new words were significantly lower than the high reading level students in the condition of no-pinyin subtitle; (3) third-grade pupils with high reading level learnt more new words than pupils with a low reading level, but the quantity of new words that third-grade children acquired in the conditions of pinyin subtitle were not different from the condition of no-pinyin subtitles. The findings of the research indicated that incidental learning that made use of subtitles is a favorable method of enlarging children’s vocabulary, specially, for first-year children.

Keywords: incidental learning, reading level, subtitles, dense words, children’s vocabulary

The role of the internet for same-sex attracted youth

OVERTON, N. (RMIT University)

Australian studies have shown that same-sex attracted youth (SSAY) experience higher levels of bullying and victimisation in school settings, and are at a higher risk of substance abuse, mental health issues, self-harm, and suicide. Fear of harassment or rejection from peers and family are one reason many SSAY chose not to disclose their sexual feelings or identity. This can result in feelings of isolation and loneliness, and a lack of visible supports. The internet has unique qualities such as high levels of anonymity and lack of geographical distance that increase opportunities for users to make connections with similar others. The aim of this research is to examine how SSAY across Australia use the internet as a means of finding information, forming and expressing their sexual identity, and forming friendships and a sense of community. What are the characteristics of SSAY who do, and alternatively do not, use the internet to
explore their sexual identity? Quantitative analysis will be employed to explore variables such as age, gender, rural/urban setting, cultural background and sexual identity. Additionally, who discloses their sexual identity, or “comes out” online? Qualitative analysis will then be used to ascertain themes around the function that internet use serves for SSAY. These questions form part of a larger national study and it is expected that approximately 2,000 SSAY people will participate in this study. Data collection is currently being undertaken, and will continue until April 2010.

Keywords: same-sex attracted youth, internet usage

The significance of family support programs for mothers of very-low-birth-weight children: A case study of a mother who had worries about the development of her child

NOI, M. (Seinan Jo Gakuin University)

This case study tried to discuss the significance of family support programs for mothers of very-low-birth-weight children, through a case of a mother who had had serious worries about the development of her child. The case involved a mother who had joined the group of family support programs for children with very-low-birth-weight and their families. She had serious worries about her child’s development and wanted to know the developmental characteristics of very-low-birth-weight children. Family Support Programs: Mother-Child Play Activities and Mother Meetings, were done for two months (13 sessions). Children with very-low-birth-weight at the age of 2 to 3 and their families had joined voluntarily. At the beginning, she saw her child as “my child born with very-low-birth-weight”, and could not approve of child’s characteristics. However, through the intervention with her to recognize the “child’s own developmental characteristics” and the “reasons of the child’s behaviors”, her outlook on “my child” changed to “my child has difficulties to get into the group”, and finally, “my child is developing in her own way”. She also had started to talk more about her child’s behaviors at home. The intervention for her was aimed at noticing the child’s own characteristics, and to understand reasons of child’s behaviors, and mother’s outlook on “my child” has changed. Other mothers’ support was also effective for this case.

Keywords: family support programs, mothers, low birth-weight children, mother-child play activities

The spirit is willing, but the flesh is weak, or rather: The flesh is willing, but the spirit is weak? When automatic associations prevent physical exercise

BLUEMKE, M. (University of Heidelberg), BRAND, R. (University of Potsdam), SCHWEIZER, G. (University of Potsdam), KAHNERT, D. (University of Potsdam), GEBHARDT, J. (University of Potsdam)

Models employed in exercise psychology highlight the role of reflective processes for explaining behavior and behavior change. However, as discussed in the social cognition literature, information-processing models (dual-process models) also consider automatic determinants of behavior. We examined the relevance of automatic processes for predicting physical exercise. Applying a priming task in a quasi-experimental design, we assessed the automatic evaluations of exercise stimuli in physically active sport and exercise majors, physically active non-sport majors, and inactive students (N = 94). Two different affective priming tasks were used: one task applying sport-specific (experiential) positive and negative target words and the other task using target words of generic valence. A second study was run as a conceptual replication (N = 74), using only the sport-specific priming task, but involving a student sample across the complete spectrum of activity and exercise intentions. Results of both studies showed that physically active students responded faster to positive words after exercise primes, while inactive students responded more rapidly to negative words. As a cautious note, findings were obtained only with sport-specific experiential items reflecting negative and positive consequences of exercise. Reaction times of the sport-specific priming task, however, successfully predicted the reported amounts of exercise in regression models. The results illustrate the significance of dual-process models in sports psychology. Specifically, affective states
Abstracts of the 27th International Congress of Applied Psychology

at the automatic level such as automatic evaluations are an important ingredient in exercise behavior, which need to be taken into account when targeting at behavioral changes.

Keywords: automatic associations, physical activity

The state of psychology in Alaska

RICH, G. (University of Alaska Southeast)

This presentation focuses upon psychology in Alaska, which became the 49th of the 50 United States in 1959. With the exception of its largest city, Anchorage - home to about half of the state’s approximately ½ million people - Alaska is largely rural. For instance, there would be sixteen people in New York City if it had the same population density. Alaska is plagued by social problems. Compared against the national average for sex crimes, Alaska ranked 43rd among all states. Since 1976, Alaska has ranked in the worst five states for its rate of reported rape. Substance and alcohol abuse also plague the state. Some polls listed the state as fifth worst in the nation for its assault rate. Alaska ranks among the worst five states for its domestic violence rate, with Alaskan women being killed by a partner at 1.5 times the national average. Alaska’s school dropout rate (8 percent) was double the national average in 2005-2006. Thirty-eight percent of ninth-graders will have no high school diploma in 10 years, according to an Alaskan Commission, which found that Alaska ranks 50th (last), in the number of ninth-graders who will likely have a bachelor’s degree in ten years. Alaska’s suicide rate is consistently one of the highest in the nation. In 2002, Alaska had almost twice the national average of suicides at 10.6 for every 100,000. Other health problems impact the state. For instance, from 2000 to 2007, Alaska had the first- or second-highest nationwide Chlamydia infection rate. There also are severe financial challenges. A poll of the ten most expensive cities in the U.S.A. listed three Alaskan cities: Anchorage, Fairbanks, and Juneau. Alaska leads all states with the highest median credit card debt, based on 2006 information. Finally, the climate greatly impacts the state. In addition to the snow and extreme temperatures, Alaska ranks number one in the U.S.A. for earthquakes.

Against such a backdrop, what is the role and status of psychology in Alaska? This presentation will survey best practices from a positive psychology point of view, including a description of services provided by other helping professionals.

Keywords: Alaska, rural, crime, substance abuse, positive psychology

The structure of attachment mental model in middle childhood

MURAKAMI, T. (University of Tsukuba), SAKURAI, S. (University of Tsukuba)

Given recent evidence for multiple attachment models, we examined the structure of attachment mental models in middle childhood. We aimed to compare three models, that is, the Hierarchy model, Integration model, and Independence model. In examining the structure of mental models, we considered coincidence of mental models for each multiple attachment figure. In the Hierarchy model, the mental model for the first attachment person should strongly influence the mental model for other attachment persons. In the Integration model, mental models for specific persons should be integrated by a general model. In the Independence model, mental models for specific persons should be separated, and independent. Respondents were 541 elementary school students (253 boys and 288 girls). First, we identified attachment figures of the children. Attachment figures were assessed by nomination of three important persons in proximity-seeking function, secure haven function, separation protest function, and secure base function, drawn from Hazan and Zeifman (1994). Second, we measured children’s attachment mental models for each of these attachment figures. Mental models were assessed in two dimensions. One dimension is avoidance of intimacy/other-model and the other dimension is anxiety of abandonment/self model based on Bartholomew and Horowitz (1991). Correlation analysis revealed that the mental models of three persons are modestly related ($r_s = .46$~$.37$ in avoidance dimension, $r_s = .65$~$.61$ in anxiety dimension). The Independence model was not supported. Subsequently, SEM analysis was conducted in...
the other two models. The Integrated model’s fit indices were GFI = .961, AGFI = .940, CFI = .986, RMSEA = .037, BIC = 548.66, chi-square = 180.52, df = 111, p < .01. The Hierarchy model’s fit indices were GFI = .943, AGFI = .916, CFI = .970, RMSEA = .052, BIC = 603.22, chi-square = 259.63, df = 115, p < .01. The Integrated model’s fit index indicated better than the Hierarchy model’s one. Therefore, we concluded that the Integration model provides the best explanation for the structure of attachment mental models in middle childhood.

Keywords: attachment, mental models, middle childhood, attachment model structures

The student behaviour survey: Psychometric properties in an Australian sample

HAMMOND, S. (Australian Catholic University), MURPHY, T. (Australian Catholic University), COVENTRY, N. (Austin Health), NURSEY, J. (Austin Health)

This study examined the psychometric properties of the Student Behaviour Survey (SBS; Lachar, Wingenfeld, Kline & Gruber, 2002), a 102-item teacher report measure of behavioural and emotional problems in children and adolescents. Participants were teachers of primary school children (ages 5 to 11 years) from a regular education (n = 76) and Child Adolescent Mental Health Service (CAMHS) (n = 436) setting. For the regular education group, teachers completed the SBS as part of risk study. For the clinically referred group, teachers completed the SBS at referral to the CAMHS service. The SBS was found to have good internal consistency for both the regular education and the clinical groups. Principal components analysis at the item and scale level yielded 3 components: Externalising difficulties, internalising difficulties and academic resources. Intercorrelations among subscales indicated adequate convergent and discriminant validity. For the regular education group, meaningful significant correlations were obtained between the SBS and the Strengths and Difficulties Scale (SDQ) teacher version demonstrating sound concurrent validity. The clinically referred group differed significantly from the regular education group on all SBS scales, with academic achievement, learning habits, emotional and behavioural problems above the clinical cut-off. The results indicate that the SBS is a reliable and valid scale in the Australian context and is a useful tool for the identification of learning, emotional and behavioural problems among children.

Keywords: student behaviour, behaviour problems, children, adolescence

The study of leadership and new direction for developing entrepreneurs in Thai small and medium sized enterprises

CHONGVISAL, R. (Kasetsart University)

This research comprised of 2 phases. The first phase was designed to study the leadership of Thai small and medium-sized enterprises (SMEs) entrepreneurs and the second phase was to develop new leadership through training course. For the first phase, there were three sample sets. In the first sample set, the data were collected from 30 successful SMEs entrepreneurs by in-depth interview and critical incident technique (CIT). The data were analyzed to generate items of leadership scale for Thai SMEs entrepreneurs. The pilot 120-item leadership scale was tried out on the second sample set consisting of 544 SMEs entrepreneurs. Exploratory factor analysis (EFA) was used to explore the dimensions underlying the leadership scale. Confirmatory factor analysis (CFA) was used as a follow-up to determine the definite number of factors. Six factors resulting from CFA were 1) encouragement of subordinates’ inspirational motivation, 2) consideration and well wishing toward others, 3) morality in business, 4) capability of strategic thinking, 5) encourage social consciousness, and 6) openness. The final 30-item leadership scale was validated with the third sample set composing of 1,064 SMEs entrepreneurs. Exploratory factor analysis (EFA) was used to explore the dimensions underlying the leadership scale. Confirmatory factor analysis (CFA) was used as a follow-up to determine the definite number of factors. Six factors resulting from CFA were 1) encouragement of subordinates’ inspirational motivation, 2) consideration and well wishing toward others, 3) morality in business, 4) capability of strategic thinking, 5) encourage social consciousness, and 6) openness. The final 30-item leadership scale was validated with the third sample set composing of 1,064 SMEs entrepreneurs. The known-group technique was used to test the construct validity using the success of the entrepreneurs as the criterion. The results indicated that the leadership scores of all six factors from the highly successful SMEs entrepreneurs were statistically higher than the scores from the low successful SMEs.
entrepreneurs. In the second phase, new direction for developing leadership of Thai SMEs entrepreneurs was proposed through the training course developed from Phase One. The Training Workshop for Developing SME Entrepreneurs’ Leadership was developed and its quality assessed by the experts. There were three stages in the training course; assessment before training, leadership development by training, and evaluation after training. The course was organized into nine modules. After the training, two meetings were held to monitor and evaluate the progress of leadership development plan, to let them share their experiences with each other, to advise them on how to solve the problems during implementing, and to adapt their plan accordingly.

Keywords: entrepreneurship, critical incident technique, leadership development, leadership training, strategic thinking

The study of psycho-social problems of abused children in Iran, applied psychology preservative processors and some obstacles for prevention

RAHEB, G. (Welfare and Rehabilitation University), EGHLIMA, M. (Welfare and Rehabilitation University)

Child abuse is caused by various factors that create psycho-social problems for children and youth. Children are more vulnerable than others. Everything and every action that jeopardizes a child’s psycho-physical health is child abuse. Any neglect or any action that puts them at risk physically and psychologically is called child abuse. In this study we would like to investigate psycho-social problems of abused children in the family and to recognize the role of psychologists in preventing this phenomenon and also in recognizing some obstacles, such as legislation, which they are facing in Iran. The method of study being used is case studies about children and youth that have been hurt by their parents. The sample is chosen from children being kept in rehabilitation centers or who have visited a clinic. The sample consists of 65 children and the measures are the MMPI, Raven’s Progressive Matrices and Weschler’s test, inquiries of the family’s statuses and psycho-statues. The results indicate that children are more vulnerable than youth. The rate of physical, emotional, and sexual damages are higher. They live in a hard social, economic and familial situation. They suffer from emotional, behavioral, learning, social and personal problems. Psychologist activities with a social approach play a drastic role in preventing child abuse to occur in Iran. However, with this route, there are some challenges concerning cultural, legal and protective problems.

Keywords: childhood abuse, children’s vulnerabilities, familial abuse, child psychology

The study on the behaviors of leaders which influence the trust of employees in the Chinese state-owned telecommunications enterprises

WANG, L. (Beijing Normal University), ZHANG, J. (China Telecom Company), CHEN, M. (Beijing Normal University), CHE, H. (Beijing Normal University)

This paper aims to explore which leader behaviors can influence the trust between a leader and subordinates as perceived by employees in the Chinese State-owned Telecommunications enterprises and to explore any differences by gender and job age. Five leaders and 12 subordinates by Behavioral Event Interview (BEI) method were interviewed. From the interview materials and the literature, a 65-item questionnaire was developed to measure the trust between a leader and subordinates. The questionnaire was tested on 221 participants, including 164 subordinates and 57 leaders. The questionnaire was revised to 50 items based on the data of the first test. After the second test with 220 participants, including 164 subordinates and 56 leaders, the questionnaire showed good reliability and validity. This study showed that the behaviors of leaders, which influence the trust in leadership, were accounted for in a six-factor model, arranged in descending order of importance as follows: ability, integrity and responsibility, job involvement, support and development, acceptance and cooperation, and openness and authority. There was no significant difference between male and female subordinates in the six factors. However, when the leader shows more job involvement, support and
development, acceptance and cooperation, and openness and authority, they can win greater trust of new employees than old ones. In conclusion, the study showed that 1) the behaviors of the leaders that can influence the trust between a leader and subordinates is a six-factor model; 2) the six factors have the same influence on the trust in the gender variable; and 3) there was a significant difference between different job ages in job involvement, support and development, acceptance and cooperation, and openness and authority, therefore we should take different measures to employees of different job ages.

Keywords: leadership, trust

The three “r”s: Psychologists delivering services to regional, rural and remote areas in Australia

DE GRUCHY, D. (Centacare Family Services)

The aim of the study was to showcase what psychologists working in isolated geographic areas within Australia are doing to provide excellent psychological services within the constraints imposed by distance, isolation, multiple relationships, restriction of access to professional development and supervision, working with culturally and linguistically diverse groups, burn out and safety. Work in this area is influenced by costs – time, resources and money – and the lack of suitably qualified staff. Local Australian Psychological Society members wrote of their experiences of the above with a view to outlining the particular challenges and rewards of working within this area as well as the coping strategies they developed to tackle these difficulties. Recommendations are made as to what departments and organisations who service these areas can provide such isolated psychologists to enable them to cope effectively. Evaluation has been undertaken of the various strategies used. This is a constant work-in-progress as the turnover of staff hampers continuity of learning. Some of the strategies used to enable psychologist to work in this isolated region are: collaborative partnerships with other professional bodies, webstreaming, professional development sessions offered in video/DVD format followed by a teleconference, meetings via teleconference, sharing resources and personnel, and sharing the costs of staff, travel, professional development, and resources. Given the unique challenges and rewards of working within this region and the subsequent understandings and coping strategies developed, many psychologists continue to provide excellent psychological services and are willing to share the knowledge gained, and to support other such isolated psychologists to cope effectively.

Keywords: working in rural and remote regions, psychological services

The threat of negative stereotypes in interactions

SHAPIRO, J. (University of California, Los Angeles (UCLA))

The aim of this research was to understand the manifestation of overt and covert forms of discrimination in customer service interactions. Using a customer service paradigm, we measured overt/blatant and covert/interpersonal forms of discrimination expressed by actual customer service agents toward (1) confederate shoppers as their natural average weight size or wearing obesity prostheses and (2) actual shoppers who varied in weight. Overall, the results revealed that when justifications for stereotypes were present in the interactions, actual obese shoppers and confederate obese shoppers faced more interpersonal discrimination than average-weight shoppers. Furthermore, there were negative bottom-line consequences of interpersonal discrimination for organizations (e.g. customer loyalty, purchasing behavior). Overall, this research shows the importance of examining subtle discrimination and offers a mechanism for theory-driven strategies for the reduction of covert forms of discrimination.

Keywords: overt and covert interpersonal discrimination, customer service, discrimination, stereotypes, customer loyalty
The undoing effect of positive emotions on negative emotions in the situation of emotional labor

CAO, Z. L. (Zhejiang University), ZHONG, J. A. (Zhejiang University), DUAN, J. Y. (Suzhou University)

The Broaden-and-Build theory of positive emotions deduces that positive emotions have an undoing effect on negative emotions, i.e. undoing the unusual physiological states invoked by negative emotions. Previous studies focused on the naturally felt positive emotions. While in the service industry, emotional labour requires the employee to display positive emotions to the customers or clients, no matter whether the employee is experiencing negative emotions. The positive emotions displayed are not naturally felt, but demanded by the organization. By exploring the undoing effect of positive emotions in such situation, the present study aims at further understanding of the emotion theory and the health-promoting functions of positive emotions in emotional labour. The 45 college students who participated in the laboratory experiment were randomly assigned to four groups. Group 1, 2, 3 were shown a film clip with sadness content, and then respectively asked to apply surface acting, deep acting, or trying no emotional efforts, to perform emotional labour, i.e. to show positive emotion by smiling. Group 4 was showed a film clip with neutral emotion content, and asked to try no emotional efforts. Two cardiovascular indicators, R-R interval and finger pulse amplitude (FPA), were recorded by polygraph throughout the experiment. The participant’s emotional state was measured before and after the experiment. Results of the emotional state scales showed that the sad film invoked sadness, while the neutral film did not change the emotional state. For Group 3 and 4, the cardiovascular indicators showed that negative emotion actually invoked cardiovascular sequelae, while neutral film did not. For Group 1 and 2, cardiovascular sequelae were also elicited. The recovery of the cardiovascular activity from the abnormal states to the baseline in both two groups was faster than that in Group 3. No significant difference of the recovery time was found between Group 1 and 2. In the situation of emotional labour, those who feel or show positive emotions recover from the cardiovascular sequelae faster than those who do not. The findings support the proposal that the Broaden-and-Build theory serves not only the naturally felt positive emotions, but also the intentionally felt and displayed positive emotions.

Keywords: positive emotion, negative emotion, emotional labour, invoked sadness, cardiovascular sequelae

The validation of the Gallup workplace audit in a South African petrochemical company

BARKHUIZEN, N. (University of Pretoria), BRAND, C. (University of Johannesburg), HAVENGA, W. (University of Johannesburg), STANZ, K. (University of Pretoria)

Around 2002, the term “employee engagement” was used to describe a state of not only being satisfied with the job and workplace, but also giving one’s best effort on a daily basis, and intending to stay (Branham, 2006). Using this definition, consulting firms such as Gallup, Hewitt and others developed employee engagement surveys to help companies measure what percentage of their workforces was truly enthusiastic, dedicated and committed – in other words, engaged. The aim of this research was to determine the validity and reliability of the Gallup Workplace Audit (GWA), as a measurement of work engagement in a South African petrochemical company. A cross-sectional survey research design was used. The Gallup Workplace Audit was administered among a convenience sample \((N = 2588)\) of employees in a South African petrochemical company. Exploratory factor analysis resulted in four factors for the Gallup Workplace Audit. The factors were labeled clarity on required contribution, development opportunities, personal recognition and quality of relationships. All factors showed acceptable internal consistency. In conclusion, the GWA proved to be a valid and reliable measuring instrument of employee engagement. This confirms that an international survey can be utilised effectively to predict work engagement within in the South African work context.
Keywords: work engagement, work context, engagement, Gallup Workplace Audit, relationship quality

The validity of structured behavioral interviews for administrative jobs in China

LI, Y. (Tsinghua University), YU, Y. (Tsinghua University)

This study was conducted to determine the validity of structured behavioral interviews for making predictions of rating of job performance and potential. The validation sample consisted of 122 candidates. The correlations of potential and performance with structured behavioral interview scores were statistically significant and both predictor and criterion measures showed acceptable levels of reliability. The study also provides new evidence on the validity of structured behavioral interviews in administrative jobs in a large China public service organization. The discussion questions the extent to which structured behavioral interviews provide unique or overlapping predictive validity when compared with mental ability tests.

Keywords: structured behavioral interviews, job performance, job potential, predictive ability, mental ability tests

Three, four or five factors? The Occupational Stress Inventory—Revised, reviewed

HICKS, R. (Bond University)

The Occupational Stress Inventory—Revised is in common and growing use in occupational assessment. However, the inventory’s most effective factor structure theoretically, and for practice, is unclear. This paper reports several studies indicating that four or five factors underlie the inventory, rather than three as indicated in the OSI manual. The OSI-R was administered to several groups of Australian employees and students over six different studies. More than 800 respondents in total were involved. Confirmatory factor analyses were conducted over three main groups (examining whether the originally proposed three factor basis or instead, four or five factors, best explained the structure. Analyses to date have shown that a four-factor solution best fits the data, including the data given in the OSI-R manual. This current paper will report further confirmatory factor analyses on three new studies using more extensive samples of employees and students, to examine whether the three-, four- or a five-factor solution can be established. The results will help academics and professionals understand the nature of the OSI-R and its continuing value as a questionnaire linking occupational role stressors, psychological strain and available resources and skills of participants.

Keywords: occupational stress, occupational assessment, confirmatory factor solution

To think or not to think?: Effectiveness of reducing rumination in a Mindfulness Based Cognitive Therapy Group

HUSSAIN, Q. (Psylegal)

The principal aim of this study was to evaluate the effectiveness of a mindfulness based cognitive therapy group in reducing rumination, and the severity of symptoms of stress, anxiety and depression within a clinical population in a private practice setting. The method of evaluation involved pre and post testing of participants who had completed a structured six week group therapy course. The measures utilized were the Depression, Anxiety and Stress Scale (Lovibond & Lovibond, 1995) and the Ruminative Responses Scale (Nolen-Hoeksema, 1991). The results indicated that measures of rumination, stress, depression and anxiety reduced upon conclusion of the six week group therapy course. The conclusion was that mindfulness techniques applied and taught within a structured group context has reasonable effectiveness in reducing rumination and symptoms of depression, anxiety and stress. The implications for running these types of groups in private practice will be discussed.

Keywords: rumination, mindfulness based cognitive therapy, group therapy, depression, anxiety and stress scale, group therapy
Toward a conceptual and operational model of mindfulness in sport: A preliminary qualitative investigation

THIENOT, E. (University of Western Australia /Western Australian Institute of Sport)

In recent years, several conceptualisations of mindfulness have been formulated and tested in mainstream psychology. In the context of sport, mindfulness has also become a focus of interest in terms of promoting performance enhancement, but thus far it has not been conceptually validated. This investigation sought to identify the various perceptions that athletes were aware of during a competition. The study also examined cognitive reactions toward these perceptions to further explore mindfulness in sport. In stage 1, an open-ended questionnaire was completed by 95 athletes from two individual (i.e., swimming, cycling) and two team (i.e., soccer, water polo) sports. Immediately post-competition, participants were asked to report all the thoughts, feelings, and bodily sensations they were aware of (a) immediately before, (b) during, and (c) upon completion of performance. In stage 2, elite athletes from the same four sports were recruited to take part in an in-depth interview, during which they watched a video recording of themselves performing at a high-level competition (e.g., Olympic Games). Using principles associated with self-confrontation interviewing (von Cranach & Harré, 1982), participants were asked to (a) recall all the thoughts, feelings and bodily sensations they were aware of during the event, as well as (b) describe their responses to these perceptions. All data were analysed using inductive content analytic procedures to organize the raw data into interpretable and meaningful themes. Overall, results revealed two levels of analysis. The first level represents what the athletes were aware of. This level is linked to the nature (i.e., cognitions, emotional state, physical sensations) and the content (e.g., task-related, environment-related, self-related) of these perceptions, which are determined by the specificity of the sport-context. The second level represents how the athletes reacted to these internal events from a cognitive point of view and a time-course perspective. This level is illustrated by different cognitive processes that occur in response to the initial perceptions, including processes of mindfulness and attention self-regulation (e.g., present-moment focus, awareness, non-elaborative thinking and acceptance towards internal perceptions, specific focus-strategy). These results can be used to develop an appropriate measurement tool of mindfulness in sport.

Keywords: mindfulness, sport, performance, bodily sensations, focus strategy

Training effectiveness and the use of the training group: An explorative study to investigate this bond

FRASCAROLI, D. (Catholic University, Milan), GOZZOLI, C. (Catholic University of Milan ), SCARATTI, G. (Catholic University of Milan )

The social-productive background is changing (Hatch, 1997; Bauman, 2002) and training and training evaluation are changing as well (Lipari, 2002); they have to deal with even more complex issues and consequently there was a significant evolution in training approach during last few decades. This study arises from an interest to investigate the bond between training effectiveness (Tannenbaum & Yukl; Alvarez et al. 2004) and the use of the training group, proposed with a specific approach (Kaneklin, 1993). Differently from classic literature about training effectiveness, we have adopted this construct to explore a training-path conducted with a psychosocial approach, based on 1) Participative learning (Levy, 2005); 2) Learning focusing on problems and sharing experiences, doing research together on specific objects to support a developing professional identity (Kaneklin & Olivetti Manoukian, 1990; Bion, 1975). This paper presents a training-research program planned by Catholic University (Milan) to approach and support the coaches’ professional identity. Forty youth sector coaches were involved in this year-long educational program. The formative aims were about reflecting together about coaches’ role, experience, efforts and, capabilities. During the program we have proposed different kinds of groups: steady groups (composed of 12 coaches; conducted by an expert trainer and a tutor), small group and plenary moments; they were integrated with individual/groups activities (for example role-playing and theoretical lessons).
The study aims to explore if and how the steady group evolves and how it can support the generation of training outcomes. A qualitative method was used. The content analysis was conducted on specific training moments (five sessions; transcription of 14 hours of training), both on the group dimension and in the trainer function and intervention. The content analysis was conducted with the support of the software ATLAS.ti. The data analysis allowed elaboration of useful indicators (both for group and trainer) to understand the evolution process of the training groups. This study provides an interesting contribution to the understanding of training effectiveness in this training approach and causes new interesting research questions to arise.

Keywords: training evaluation, professional identity, trainer function, trainer intervention

Training of future orientation in educational field at late adolescence

JUWITA, V. (University of Jenderal Achmad Yani)

The aim of this research was to look at the effect of training on the condition of future orientation in educational field on adolescents who were in the third grade of senior high school. This research is categorized as field experimental; the research occurred in a real condition (reality) by manipulating one or more independent variables in as highly controlled condition as possible for the situation (Kerlinger, 1986). The design that was used in this research is a true experimental design which executed a pretest-posttest control group design (Campbell & Stanley, 1966). There are two statistic tests that were used in this research, the U Mann-Whitney test and Wilcoxon test. In this research, Purposive Sampling test was used to attain the research’s subjects. Results of the research show that there is no difference in improvement of condition of future orientation between participants and non-participants of the training, whereas statistic tests from each sub-dimensions show that there is a difference of conditions between participants and non-participants of the training. Those sub-dimensions are plan, internality, probability, and emotion. The results from questionnaire show that there are changes that happened to the participants and those were in cognitive and affective aspects. Training of future orientation has an effect in qualities of the participant’s future orientation. In cognitive aspect, learning level from participants was at least achieved to the application level, where they understood and implemented that understanding into a concrete problem. In the affective aspect, the participants achieved at least a responding learning level or even organization level; they started to show new behaviours as a result from experiential learning,
and simultaneously integrate those new values into their own values.

**Keywords:** future orientation, experiential learning, training

**Training with attitude: The effect of affect**

GEERTSHUIS, S. (University of Auckland), ARASANMI, N. (University of Auckland), COOPER-THOMAS, H. (University of Auckland)

In our preoccupation with training design and the conditions necessary for effective transfer of training the role of trainees’ attitudes and emotions may have been somewhat overlooked. Recent reviews of research on training and transfer call for a greater understanding of the role of affect in training effectiveness. This study aims to assess the relationship between training outcomes and affect and attitudes. All trainees participating in the study were administrators attending courses designed to build skills that personal assistants and executive assistants require. The training concerns communication, problem solving and relationship building and attempts to shift attitudes towards a more accountable and proactive approach to work. Measures were taken one week prior to training and three weeks after training of trainees RBSE and self reported performance. Trainees completed assessments of their proactivity, control appraisal and change orientation, LMX and engagement, prior to and following training. They also completed open ended questions on the changes achieved through training. Regression analyses and thematic analysis indicate that training serves to modify affect and attitudes and that affect moderates the impact of training on self reported performance. This is the first in a series of studies proposed by the authors and the opportunity will be taken to discuss the next steps in the programme of work.

**Keywords:** training, training, training, attitudes, self reported performance

**Trait anxiety and risk decision-making: What are influencing factors?**

JIANG, Y. (Beijing Sport University), ZHAO, H. (Capital Normal University), XIE, J. (Capital Normal University)

This study intends to explore the relationship between anxiety and risk decision-making, in order to provide clinical therapy guidance for anxiety and offer some practical advice for risk decision. Questionnaires and experiments are used to investigate 458 undergraduates (296 for revising a questionnaire, 162 for the revised questionnaire study). The Revised Anxiety Control Questionnaire and Optimism Scale have good psychometric attributes. Controlling depressed mood, we have observed a negative relationship between trait anxiety and risk decision-making. Some factors, such as gender and major field of study, have a significant interaction with trait anxiety on risk decision. Perceived control of anxiety and generalized self-efficacy may mediate the relationship between trait anxiety and risk decision. This study shows the relationship between trait anxiety and risk decision-making is negative. Some factors such as gender, major, perceived control of anxiety and generalized self-efficacy influence the relationship.

**Keywords:** anxiety, risk decision-making, revised anxiety control questionnaire, optimism, self-efficacy

**Transformational dance: The dark side of transformational leadership in professional dance companies**

PYPER, P. (University of Ottawa), LOUGHLIN, C. (Saint Mary's University)

The purpose of this study is to investigate the relationship between leadership characteristics and injuries in professional dance companies. This paper proposes that transformational leadership characteristics of the choreographer would impact the level of affect-based trust, and the number and severity of injuries. It is also hypothesized that an increase in the presence of affect-based trust would increase the number and severity of injuries. Professional dance companies in Montreal were contacted for participation. Sixteen dancers from four companies completed questionnaires that incorporate the Multifactor Leadership
Questionnaire (MLQ), affective and cognitive trust, and questions regarding the number and severity of the injuries they have sustained. In addition to the quantitative analysis, interviews were sought with two dancers from each dance company to get a more in-depth look at the potential causes of injuries and the impact that the injuries have on the dancers’ careers and perspectives towards the dance company and the choreographer. The results demonstrate that the presence of transformational leadership characteristics in choreographers correlates to the development of affect-based trust and the number of new injuries sustained. Idealized Influence (0.825, \( p = 0.000 \)) and Individual Consideration (0.841, \( p = 0.000 \)) were most strongly connected to affect-based trust with Inspirational Motivation (0.586, \( p = 0.022 \)) and Idealized Influence (0.576, \( p = 0.025 \)) most strongly correlated to new injuries. Affect-based trust, in turn, showed significant correlations to new injuries (0.554, \( p = 0.032 \)), in particular for injuries that are mild in severity. Dancers work in pain, on average, over a third of the time (\( M = 35\% \)). This does not seem to be affected by the leadership qualities of the choreographers or by the levels of trust developed between individuals. As brought out in the interviews, this is simply the way it is. However, this does not mean that the leadership qualities of the choreographers do not impact the health of the dancers. This study demonstrates, contrary to the results found in other industries, that when leaders are more transformational, higher levels of affect-based trust are developed and new injuries increase. Awareness of this relationship between leadership, trust and injuries could provide opportunities to reduce new injuries in high performance athletes such as professional dancers.

Keywords: dance, transformational leadership, affect-based trust, injury, leadership

Transiting to college in Hong Kong: Effect of personal attribution, expectation, academic adjustment and discrepancy of expectation-outcome on college Freshmen's psychological well-being

TANG, W. (The Hong Kong Polytechnic University), MAK, W. (The Chinese University of Hong Kong)

College transition is a developmental milestone, and also one of the most stressful events in our lives. The present study aimed at studying the transition process. To examine the underlying factors that may be facilitative of a positive transition, the effects of expectation on adjustment, personal control, perceived adjustment and discrepancy of expectation-outcome on freshmen’s well being were examined in the present study. One hundred and sixty two first year undergraduate students completed self-reported questionnaires twice over the course of their first semester in college. The questionnaire assessed their expectation and controllable attribution in the beginning of the school year, and their perceived adjustment and psychological distress at the beginning of the second semester. Discrepancy between expectation and academic adjustment positively predicted freshmen’s psychological distress. The association between expectation and psychological distress was mediated by perceived adjustment, while the relationship between controllable attribution and perceived adjustment was mediated by expectation. Motivation was not significantly related to academic adjustment. Relative to the social cognitive factors measured in the present study, expectation is the most predictive of academic adjustment and subsequent distress among college freshmen. The intervention could aim at helping freshman to set high but realistic expectations for academic adjustment, which can serve as their goal to pursue in the transition to college.

Keywords: college transition, positive transition, adjustment, perceived control, academic expectations

Transition to university: Development and validation of a questionnaire on the types of the student experience

GILLES, P. (Centre PsyCLE), NICOLAS, C. R. (Université de Provence ), MANGARD, C. (Université de Provence), HADDAB, H. (Université de Provence)

The issue of adaptation to university entrance is the subject of a considerable number of works in the humanities, including psychology. One issue concerns the number and nature of disruptive or facilitative dimensions of this adjustment (see
the questionnaires of Syrik & Baker, 1999 and of Wintre and his colleagues, 2008, 2009). The purpose of this communication is to present a questionnaire whose originality is to translate into psychological concepts the proposal of the sociologist Dubet (1994) that three dimensions are fundamental to predict academic success: the project, integration, and vocation (1994). Participants were 867 high school students who responded to the questionnaire during a visit to the university (576 girls and 288 boys, mean age 17 years). The proposed questionnaire includes 43 items based on models and tools within each field: 15 on project (e.g., “I have a clear idea of the job I want to do”), 17 to integration (e.g., “I get easily make friends”) and 11 for the vocation (e.g., “My studies helped me to better understand the world in which I live”). Each dimension is divided into sub-dimensions (e.g., the project is divided into decision-indecision, need achievement, locus of control, and time perspective). Sensitivity of each item was tested, leading to the deletion of half of them (social desirability bias). Factor analysis (principal components, varimax rotation) of the 22 remaining items reveals three factors explaining about 30 per cent of the variance: school effectiveness, professional project, and perceived competence and self-confidence. The reliabilities (Cronbach’s alpha) are good. These three factors are correlated with values between .13 and .37. The dimensions found are consistent with Dubet’s model (1994), with the model of Syrik and Baker (1999) and with the broader model of Wintre and Bowers (2007). The prolongation of this research is to test predictive validity of our tool, and we’ll present preliminary results obtained from 274 students interviewed at entry into first year university whose results for final examinations session are known.

Keywords: adaptation, factor analysis, university

Trialing a medium-term group for men who have sex with men (MSM) at risk of HIV transmission: What content and process factors facilitate engagement, development and change?

EARLE, M. (The Alfred), RYLATT, D. (The Alfred)

During the past ten to fifteen years, meta-analyses have reported the effectiveness of group interventions for MSM engaging in HIV-risk behaviour (unprotected anal intercourse with multiple partners). However, most studies have not reported intervention detail and the theoretical or evidence base for them, or reported process data. This study aimed to trial a medium-term group informed by Dialectical Behaviour Therapy (DBT, Linehan, 1994) and psychodynamic group process theory, for which outcome and process data were collected. Participants were MSM attending a specialist, sexual risk-reduction clinic because of their sexual risk behaviour. A medium-term group was delivered incorporating skills-training (Mindfulness, Distress Tolerance, Emotion Regulation, Interpersonal Effectiveness) and reflective components, led by male and female Clinical Psychologists. Participants completed a demographic/sexual health/sexual behaviour questionnaire, the Personality Assessment Inventory (PAI, Morey, 2007), the Sexual Compulsivity Scale (SCS, Kalichman & Rompa, 1995) and the Sexual Sensation Seeking Scale (SSSS, Kalichman & Rompa, 1995) at Intake, conclusion and three months. Process data was also collected from participants and facilitators. Outcome data from the group were compared with data from MSM participating in individual therapy. Preliminary data suggested the group intervention was associated with either a decrease or no increase in sexual risk behaviour, general psychopathology and psychosexual symptoms. Process data indicated that participants found both the skills-training and reflective components valuable, with each contributing differently to therapeutic outcomes. Consistent with international data, this group intervention was associated with either a decrease or no increase in sexual risk behaviour among local MSM. Different benefits emerged from the skills-training compared with the reflective group components, suggesting that in this population, maximum therapeutic benefits may derive when attention is paid to both. Some Clinical and Applied Research implications of this work will be discussed.

Keywords: sexual risk behaviour, HIV, dialectical behaviour therapy, sexual sensation seeking scale, group intervention
Tripartite model of depression and anxiety and its association with temperament and character

ZAREAN, M. (University of Social Welfare and Rehabilitation Sciences), MOHAMADKHANI, P. (University of Social Welfare and Rehabilitation Sciences), POURSHAHBAZ, A. (University of Social Welfare and Rehabilitation Sciences)

In recent decades, the Temperament and Character conceptualisation of personality by Cloninger (Svrakic & Cloninger, 2005) has been important role in the explanation of many aspects of individual differences. The present study was carried out to investigate the association of personality factors with basic components of a tripartite model of depression and anxiety including Negative Affect (NA), Positive Affect (PA), and Physiological Hyper Arousal (PHA). In this cross-sectional, descriptive, and correlational study, a sample of 295 undergraduate students (219 girls and 76 boys) from the University of Social Welfare and Rehabilitation Sciences were asked to complete the Temperament and Characteristic Inventory (TCI-125), Positive and Negative Affect Scales (PANAS), Physiological Hyper Arousality from the Inventory of Depression Anxiety Symptoms (IDAS), the Beck Depression Inventory (BDI-II), and the Beck Anxiety Inventory (BAI). Data were analysed using Pearson’s correlation, and multiple regression statistical methods. Findings showed moderate and positive correlations between Temperament (Novelty Seeking, Harm Avoidance) and Negative Affect ($p<.01$), but slightly high and negative correlations between Character (Self-directedness, Cooperativeness) and Negative Affect ($p<.01$). Also, Temperament and Character can predict a meaningful amount of tripartite model components (NA= 43%, PA= 32, & PHA= 20%). These primary findings confirm that Temperament and Character are relevant personality factors that should be enrolled in the dimensional modeling of emotional disorders.

Keywords: depression, anxiety, temperament, character, tripartite model

Truckies as designers: How truck drivers complete design in use

FIDOCK, J. (Defence Science and Technology Organisation), CARROLL, J. (RMIT University)

The aim of this paper is to improve the design of vehicles by taking account of the process through which truck drivers engage in adaptation. A longitudinal comparative evaluation of trucks was undertaken to support an acquisition decision. Fourteen drivers travelled more than 5000 kilometres in each of six different models of trucks. They performed a variety of structured driving tasks on bitumen, dirt and off road. Over a period of 11 weeks the drivers provided their views on the different trucks via surveys, interviews and group discussions, including comparisons with trucks currently in service. Drivers were asked about their views on vehicle ergonomics and performance, as well as any adaptations they had made to vehicles currently in service. Drivers evaluated vehicles poorly when they failed to meet there needs with respect to comfort, usability, and functionality. When given the opportunity, they also made choices to adapt the vehicles to more closely meet there needs. Drivers reported a range of adaptations that can be classified into three types: personalisations, customisations and aberrations. Personalisations involve adjustments to the vehicle related to aesthetics or presentation, such as bumper stickers. Customisations involve the incorporation of additional functionality, such as a Global Positioning System, curtains, and fridges. Aberrations entail employing the vehicle in ways that diverge from the designers’ intentions, such as changing gears without using the clutch. Customisations and aberrations have substantial implications for future design. For example, one of the vehicles had recently incorporated a power supply. However, drivers of an earlier version without a cabin power supply drew power directly from the battery to run music players. The power supply was incorporated to specifically prevent such practices. The role of technology users in completing design has frequently been overlooked. This paper draws out the implications of understanding such adaptations for improving the design of vehicles.

Keywords: vehicle design, truck driver adaptation, vehicle, customisation of a vehicle, technology use
Two case studies of accidents in a large Japanese manufacturing company

FUKUO, H. (Asahi Glass Company Limited)

The purpose of this study is to investigate latent conditions which could cause accidents. According to Reason’s the ‘Swiss Cheese’ Model (1997), organizations include many defensive layers to ensure that accidents do not occur, but each layer often has flaws, or ‘holes’. Usually the ‘holes’ in each layer cancel one another out, but there are some situations in which the holes may line up and a danger is allowed to become an accident by passing through corresponding holes in the layers of defense, barriers and safeguards. The holes can be created by active failure and latent conditions. The former includes errors and violations committed in the front line; for example control room operators, maintenance personnel and the like. Such unsafe acts are likely to have a direct impact on the safety of the system (Reason, 1997). The latter, on the other hand, are spawned in the upper echelons of the organization and within related manufacturing, contracting, regulatory and governmental agencies (Reason, 1997). Active failures usually have immediate effects, whereas latent conditions often defeat the system’s defenses over a long period of time. In this paper, I especially focused on the latent conditions created by the ‘holes’ which could cause accidents and researched those conditions by dealing with two case studies of accidents caused in a large Japanese manufacturing company. Case study 1: Glass tubes for TV’s were being manufactured on an assembly line. When a blockage occurs, workers have to remove the glass tubes from the line using a long tool. However, one worker removed them by hand, because the tool was not in its proper place. It was a clear violation of the rules. When the person had just removed the tubes, a coworker came over to help him and had an accident in which his hand was cut by a passing tube on the line. Case study 2: A worker was assigned to clean up glass shards with a shovel and place them in a box. A nearby hole had been left uncovered, so a line leader roped off the dangerous area to keep others out. However, the shovel had been left within the roped-off area. The worker ignored the safety rope in order to get his shovel but tripped on a cord near the rope and fell over. This worker suffered a broken hand. The accident could have been far more serious if the worker had tripped and fallen into the uncovered hole, which has a drop of six meters. Semi-structured interviews were conducted between August and September 2009. The interviews were held in a meeting room in the company and consisted of two people: the author and the interviewee. The interview time was approximately 80 minutes for both case study 1 and case study 2. The interviews were recorded. Case study 1 was conducted on the basis of interviews with ten people: the victim, a coworker, a maintenance worker, the line leader, a manager, the section chief, a safety officer and three executives. Case study 2 was conducted on the basis of interviews with twelve people: the victim, the victim’s supervisor, a coworker, two line leaders, two managers, the section chief, a safety officer and three executives. Interview questions included Question 1, “Tell me exactly how the accident occurred.” and Question 2, “Why do you think the accident occurred?” Interview data was transcribed and divided into categories using KJ method which was developed by a Japanese ethnologist, Jiro Kawakita. The answers to both question 1 and question 2 were very similar, therefore they were analyzed together. The analysis was conducted by the author and three post graduate students. Case study 1: First I identified four categories for reasons of violation as active failures caused the accident: category 1) “Workers wanted to go home early by finishing their work as soon as possible”; category 2) “Workers found it troublesome to work by the rules”; category 3) “Workers believed a loss of time is incurred when working by the rules”; and category 4) “There have been situations in which the majority of workers have ignored the rules”. Secondly, I found latent conditions which are connected to each of the aforementioned categories: for example “The leader and the manager didn't consider the psychological impact of working on a holiday; employees who had completed their duties gradually left work early”; “The safety at the plant depends too much on individuals being careful to avoid accidents”; “Managers, supervisors and maintenance staff didn’t provide sufficient explanations and training about rules with plant workers”; “Managers did not go to the factory, therefore they could not
comprehend the problem and take appropriate measures”; and “Even though workers try to follow safety procedures and tackle safety matters, it is not reflected in their evaluations. Therefore they tend to prioritize productivity over safety”. Case study 2: First I identified nine categories as latent conditions and then those categories were grouped into four larger categories: category 1) “The line leader didn’t manage the situation effectively”; category 2) “The rope was not appropriate as a safety measure for the uncovered hole”; category 3) “Safety measures had yet to be devised for the uncovered hole which people had realized as dangerous”; and category 4) “In the process of building the factory and facilities, insufficient care was taken with regards to safety”. The results support the view that managers and leaders should seek the opinion of the front line and that they should explain rules and regulations sufficiently to their employees. They need to have better communication with the workers.

### Typical human errors in traffic accidents involving powered two-wheelers

VAN ELSLANDE, P. (Inrets), JAFFARD, M. (Inrets)

Powered two-wheelers (PTW) constitute an increasingly popular form of travel, corresponding to the actual needs and problems of mobility. At the same time, the risk of being killed on a PTW is around 20 times higher per kilometre than in a car, and none of the measures adopted in recent years have managed to bring these rates down significantly. This suggests a more in-depth understanding of the mechanisms behind these accidents and the variables acting on their production is needed. The present study is based on detailed analysis of 384 traffic accidents involving a PTW, which are compared to 1174 other accident configurations. The data were collected on the scene by multidisciplinary teams and covered three components of the road system: drivers, vehicles and infrastructure. Each accident surveyed gave rise to an analytical case analysis, including a reconstruction in time and space of the events leading up to it, designed to corroborate the information gathered. They also gave rise to a cognitive analysis of the “human errors” to which PTW riders and other road users were subject to. Human functional failures of PTW riders differ from those of other road users, demonstrating that certain difficulties are particular to them. Thus, riders tend to commit more errors in prognosis (26.1 % versus 17.1 %), i.e. they are more frequently confronted with situations in which their foresight fails them given the way the situation they encounter actually develops. They also commit more errors in making decisions to undertake certain manoeuvres (11.2% versus 7.3%), notably overtaking, at a time and under conditions where these manoeuvres cannot be undertaken without a certain amount of risk-taking. Lastly, they encounter more failures related to vehicle control (16.3 % versus 12.3 %), notably when they are confronted with difficulties related to the layout of the road or to various external disturbances. The principal explanatory elements for all of these failures are, for endogenous variables, a lack of experience, the choice of an excessive speed and adopting a risky driving style. For exogenous variables, they are most often an atypical, unexpected manoeuvre by another user and infrastructure difficulties. Another important result shows that car drivers involved in an accident with a PTW are not subject to the same patterns of errors as car drivers involved in other types of accidents. They notably have dramatically more perceptive failures (59.9% versus 45.0%) than others. Such a result demonstrates the radical nature of the problem of PTW conspicuity. An accident is a complex process that cannot be summed up by the intervention of a single factor. To achieve operational results, their analysis should not be limited to identifying those “responsible”, but rather should take into account the participation of all actors, which would help in finding solutions for each of them. The results provided are in keeping with the accident research that has marked the major steps in our understanding of motorised two-wheeler insecurity (Hurt et al., 1981; MAIDS, 2004) and, in some ways, constitutes an update by going further into the understanding of the cognitive aspects involved.
Ultimatum game – economic or prosocial behaviour among young people from a developmental perspective

ZALEWSKA, A. (Warsaw School of Social Sciences and Humanities), KRZYWOSZ-RYNKIEWICZ, B. (University of Warmia and Mazury)

The study (supported by Special Grant No. ESF/84/2006) focused on decision-making in the Ultimatum Game. Assuming that these actions can have different underlying mechanisms (economic competition, empathy, reciprocal or inherited altruism, unconditional fairness) the game was carried out in three conditions – “face to face”, in a distance with similar or less similar partner (from the same or other country) – and in three age groups (11, 14, 17). The aim was to examine: (1) if frequency of individualistic, equal and altruistic offers depends on game conditions and age; and (2) whether cooperative behaviour depends on partner’s offer, game conditions and age. Participants were 2046 students at age 11 (682), 14 (708) and 17 (656) from Poland, Spain and the UK. The offered proportion of money was the index of types of offers: 50 percent – equal, above 50 percent – altruistic, and below 50 percent – individualistic. A decision on a given proposal was the index of cooperative behaviour. In all groups equal offers occurred the most often. However, frequency of specific offers depended on game conditions generally and in each age group. In all groups altruistic offers were manifested less often in the “face to face” than distance conditions. Students aged 11 manifested individualistic offers more often, but students aged 14 and 17 manifested equal offers more often in the “face to face” than in distance conditions, and individualistic offers most often towards a distant similar partner. Age influenced frequency of specific offers in each condition and the older students presented the following offers more often; equal offers in the “face to face” condition, individualistic offers towards a distant similar partner, and altruistic offers towards a less similar partner. As regards cooperative behavior, important factors were partner’s offers (equal facilitated it), game conditions (“face to face” enhanced it), and interaction between them. In general, cooperative behaviour and frequency of specific offers did not depend on age of students. Cooperative behaviour was limited by individualistic offers of similar partner or altruistic offers of less similar partner. Age enhanced manifesting specific offers dependent on context - crucial transition occurred between 11-year–old and 14-year-old students, when abstract thinking is developed intensely.

Keywords: decision making, altruism, individualistic, prosocial behaviour, development

Uncontrollability and danger: Toward a common metacognitive component within the emotional disorders

ZAREAN, M. (University of Social Welfare and Rehabilitation Sciences), MOHAMADKHANI, P. (University of Social Welfare and Rehabilitation ), POURSHAHBAZ, A. (University of Social Welfare and Rehabilitation ), BAKHSHIP, A. (Tabriz University)

Most of the emotional disorders had been correlated with metacognitive beliefs (e.g. see Spada, Mohiyyeddini, & Wells, 2008) and it seems that some aspects of metacognition at least have a nonspecific role in emotional disorders. In the present study, we aimed to determine the role of metacognitive factors within the symptomatology of depression and anxiety. A sample of 295 undergraduate students (219 girls and 76 boys) from the University of Social Welfare and Rehabilitation Sciences were asked to complete the Metacognitions Questionnaire (MCQ-30), Positive and Negative Affect Scales (PANAS), Physiological Hyper Arousality from the Inventory of Depression Anxiety Symptoms (IDAS), Beck Depression Inventory (BDI-II), and Beck Anxiety Inventory (BAI). Data were analysed using Pearson’s correlation, and multiple regression statistical methods. Results showed that four metacognitive factors (positive beliefs, uncontrollability and danger, cognitive confidence, and need to control thoughts) were positively associated with negative affect, Physiological hyper arousal, anxiety and depression ($p<.01$); however the fifth factor of metacognition (cognitive self-consciousness) was positively correlated with positive affect ($p<.01$). Surprisingly, the second factor of metacognition (uncontrollability and danger)
predicted noteworthy amount of other variable’s variance, alone (from 24 to 37%). These findings can be primary evidence for the role of metacognitive factors in the recent dimensional modeling of depression and anxiety beyond the influence of affective conceptualisations.

Keywords: uncontrollability, anger, emotional disorders, meta-cognition

Understanding environmental conscience: The benefits of conducting preliminary research by consulting an expert panel and industry liaisons

WILSON, L. (Queensland University of Technology), STRODL, E. (Queensland University of Technology)

In order to achieve meaningful reductions in our ecological footprints, individual citizens will need to dramatically alter their energy consumption and day-to-day habits. Any interventions will need to be evidence based and there will need to be a rapid transfer or communication of information from the point of research, into practice. This research utilises and builds upon the theory of planned behaviour to explore the predictors of environmentally friendly behaviour. In order to ensure that the purpose of the research and the constructs measured would be as theoretically driven and practice relevant as possible, an expert panel and a number of industry and council liaisons were consulted. This is a cross-discipline project, using methods from psychology and public health. Following a qualitative pilot study, we constructed a self-administered mail survey which was distributed to a random sample of 3000 residents of Brisbane and Moreton Bay during October 2009, with follow up continuing until January 2010. An important aspect of the design involved seeking feedback from an expert panel, in relation to the application of theory and real-world relevance of the constructs under investigation. Further, a number of industry and government experts were consulted in order to ensure the relevance of the topics under investigation and to forge pathways for future real world applications. Thus far we have achieved a response rate of 40 per cent (N = 1175) for the initial survey. As a result of the contact with industry and academic experts, we were able to gain additional funding for the research and forge alliances with a number of state and local government representatives who are keen to apply the findings of this research in real world applications. Taking a multi-disciplinary approach to research can have multiple benefits: improving the quality of research, lending credibility to research methods, disseminating knowledge, identifying industry partners and identifying pathways through which research can be translated into practice. It is anticipated that, as a result of this study, a number of important predictors of environmentally friendly behaviour will be identified, including underlying beliefs that can be targeted in interventions. At least three local councils have expressed an interest in making use of the results of this study as part of their community engagement programs.

Understanding mental toughness in Australian tennis

YOUNG, J. (Victoria University)

As the first known study of mental toughness in tennis, this study’s aims were to gain a fuller understanding of mental toughness and, specifically, what mental toughness means to tennis players and how it can be developed, maintained, lost and taught. Eighteen (ten female and eight male) recently retired top world-ranked Australian professional tennis players responded to a questionnaire that was developed to address future directions of mental toughness research proposed by Jones, Hanton and Connaughton (2007). A series of inductive content analyses was conducted to analyse the qualitative data obtained from participants’ responses. These analyses revealed that mental toughness is a most sought-after dynamic attribute that encompasses a range of abilities (e.g. focus, work ethic) to consistently perform well under pressure. Further, mental toughness is thought to be ‘taught’ and/or ‘acquired’ over many years and can be influenced by factors that include injury, changes in a player’s technique, and match results. Examples of mentally tough players were cited (e.g. Monica Seles, Maria Sharipova) and reasons given as to
their selection as outstanding mentally tough competitors. Sport psychologists were identified as significant members of a support team (that also frequently includes a coach, mentor and/or fitness trainer) to guide and equip players to be mentally tough competitors. Indeed, sport psychologists were deemed as vital sources for instilling key values such as perseverance, passion, fun, fair play, giving one’s best and tenacity. In conclusion, this study’s value to the tennis community includes both theoretical and practical benefits from gaining a fuller understanding of what is arguably one of the most important psychological skills in achieving excellence and enjoyment in tennis - mental toughness.

Understanding the outcomes of HRM hybridity in a developing country context: The case of Turkey

YAVUZ, S. (Bahcesehir University)

The present study exploratorily investigated the local employees’ perceptions of appropriate and effective HRM practices at the cross cultural interfaces. The transferability of HRM practices evolved in the industrialized Western cultural context to the developing countries has been questioned very recently (e.g. Aycan et al., 2000). Furthermore, for HRM managers in MNCs operating in these countries, the challenging task of balancing the incompatible demands of being locally responsive (localization) while preserving global integration (globalization) (Horwitz et al., 2002) eventually leads to adoption of hybrid models. Not only the hybridization of HRM but also its outcomes, in terms of their perceived appropriateness and effectiveness, are missing in the literature. Data were collected via self-administered questionnaire from employees working in MNCs in Turkey (n=150). While the appropriateness is conceptualized as the perceived ethicality of that practice, effectiveness is conceptualized in terms of employees’ satisfaction with HRM as well as perceived effectiveness. Questionnaires also included the measures of socio-cultural value dimensions, preferred and actual HRM practices, hybridity of HRM, organizational commitment, turnover intention, and demographics. Data analyses involved scale validation and model testing via structural equation modeling (SEM). Results revealed that employees who are high on fatalism and power distant values preferred more hierarchy-oriented; those who are high on collectivism preferred more group-oriented and those who are high on performance orientation, fatalism and power distant values preferred more formal HRM practices. Furthermore, as an HRM practice was perceived to be more hybrid, it was also perceived as more appropriate (i.e. ethical) and effective. In addition, an exploratory model asserting the mediated relationship between HRM and employee attitudes was tested through SEM. Results revealed that as the discrepancy between preferred and actual HRM decreases, it was perceived more appropriate and effective, which, in turn, lead to higher organizational commitment and lower turnover intention. This study is expected to contribute to the literature by examining perceived outcomes of so-called ‘Western’ cultural influences in the context of HRM in developing countries. It is also expected to contribute practice by providing feedback to HRM practitioners, especially in MNCs, about how to implement HRM in particular cultural contexts to increase their appropriateness and effectiveness. Theoretical and practical contributions of the present study will further be presented.

Keywords: human resources, turkey, employee attitudes, cultural factors

Understanding the processes of intergroup contact and the intercultural sensitivity of university students living in culturally diverse residences

EVERS, U. (University of Wollongong), OADES, L. (University of Wollongong)

Increasing trends in student participation in international courses and study abroad programs have enabled culturally diverse groups of young people to meet and interact. These interactions demonstrate an increasing need to examine the dynamics of student intercultural contact within a multicultural environment. While empirical research has examined the
required conditions for optimal contact between different cultural groups, there is little evidence identifying the underlying processes that determine the outcomes of intercultural contact. The naturalistic observation compared two residential colleges of differing levels of cultural diversity and intercultural contact; a highly cultural diverse residence encouraging intergroup contact and intercultural learning, with a comparatively lower diversity residence emphasizing Australian values. The aim was to observe differences in intercultural sensitivity and to gain an insight into the experiences of Australian and international students living in a multicultural environment. Employing a mixed-methods design, 241 university student residents completed questionnaires and 16 participated in interviews. The residents completed the Intercultural Sensitivity Scale, an adapted version of the Developmental Model of Intercultural Sensitivity, and were asked about the frequency of their intercultural contact. Students living in the high diversity residence reported more intercultural contact than those at the low diversity residence; the Australian students at the high diversity residence scored higher than Australian students at the low diversity residence on measures of intercultural sensitivity. International students reported more frequent intercultural interaction than Australian students. Females scored higher than males on intercultural sensitivity factors including respect for cultural differences and interaction attentiveness. An unanticipated finding revealed that students living in the lower diversity residence for less than 12 months had higher intercultural sensitivity than those that had lived there for 12 months or longer. Qualitative data revealed five main issues pertaining to the underlying processes of student intercultural interactions. These were an initial reluctance toward intercultural contact, opportunity for intercultural interaction, learning about other cultures, stereotypes, and perspective-taking. Quantitative results demonstrate that increased frequency and intensity of intercultural contact lead to higher levels of intercultural sensitivity. In addition, the themes derived from the qualitative analyses form the basis for understanding student experiences within multicultural residences.

Keywords: intercultural contact, intercultural sensitivity, cultural diversity

Unequal perceptions of large-scale organizational change

MAURO, T. (Universidade de Brasilia), NEIVA, E. (Universidade de Brasilia)

The aim of this paper is to present some characteristics associated with the way individuals perceive organizational changes. It is assumed that some individuals have a greater ability to articulate the causes and consequences of events that take place in an organization, even if they don’t directly affect their departments and activities. However, other individuals have a narrower view of macro-organizational aspects and events and only perceive change when it directly affects their work routine. It is proposed that education level, nature of the position and rank are aspects associated with the unequal perceptions of organizational change. Data were collected from 564 employees of three organizations facing strong institutional and market pressures and undergoing large-scale changes. A five point Likert scale (52 items) was developed and validated to collect data. Analysis of variance and the relationship between Mahalanobis distance and frequency distribution were used to analyze data. The results show that respondents with lower levels of education tend to be identified as outliers by the Mahalanobis distance technique. To the extent that the education level increases, respondents show a response pattern more congruent with the reality experienced by the companies. This trend remains constant regardless of the significance level ($p < 0.05; p < 0.01$ and $p < 0.001$). This result was confirmed by the analysis of variance $F(29,4), p < 0.000$. The analysis of variance also showed that employees that perform operational activities with no leading position tend to respond according to the built pattern $F(14,0), p < 0.000$. The organizational change process evaluation methods and program appraisal techniques must consider that individuals perceive large-scale organizational change in a different manner, so as to produce valid data and results.
It is also assumed that to access the prevailing conceptions of what the organization is supposed to do, how it is supposed to do and how it should be judged, it is important the precise identification of the contributions of organizational groups in sharing different ideas, beliefs and values.

**Keywords:** organisational change, organizational rank, change perception, program evaluation

### University place-identity, satisfaction with perceived social support and homesickness: A mediated model of homesickness in first year university students from rural backgrounds

**ELLIS, N. (Curtin University of Technology)**

The aim of the present study was to investigate university place-identity as a mediator of the relationship between satisfaction with perceived social support and homesickness in first-year university students engaged in a rural-to-urban relocation. One hundred and sixty five first year university students who had relocated from rural backgrounds and currently undertaking second semester at Curtin University of Technology in Western Australia completed an online survey comprising the homesickness subscale of the Dundee Relocation Inventory (DRI; Fisher, 1989), Furukawa, Harai, Hirai, Kitamura, and Takahashi’s (1999) amended version of the Social Support Questionnaire (SSQ-6; Sarason, Sarason, Shearin, & Pierce, 1987), and four place-identity items from Hernandez, Hidalgo, Esther Salazar-Laplace and Hess’s (2007) neighbourhood, city and island place-attachment and place-identity measure. Structured equation modeling (SEM) indicated university place-identity fully mediated the relationship between satisfaction with perceived social support and homesickness. Specifically, a one standard deviation increase in satisfaction with social support accounted for a .09 standard deviation increase in homesickness through university place-identity. This result suggests satisfaction with perceived social support reduces homesickness indirectly through place-identity processes. University-based initiatives for the reduction of homesickness in first year students from rural backgrounds are discussed.

**Keywords:** students, place-identity, satisfaction with social support, homesickness, rural-to-urban relocation

### University teachers' effectiveness in relation to their certain background factors: A study

**YADAV, R. S. (Kurukshetra University, Kurukshetra), YADAV, B. S. (University College of Education), DEVI, M. (Kurukshetra University)**

The aim of this research was to study university teachers’ effectiveness in relation to their sex, age group, caste and family, marital status, educational qualification, teaching experience, parental level of education, parental occupation, place of residence and faculty. A Descriptive Survey Method was used. The sample consisted of 168 teachers of different Teaching Department of Kurukshetra University, Kurukshetra (India), selected randomly. The Teachers Effectiveness Scale (Kumar & Mutha, 1982), having sixty nine items, was used and each item consisted of graded series of five self evaluated statements. Teachers had to rate themselves on a five point scale. A t-test was used for data analysis. The study indicated no significant difference in teachers’ effectiveness in relation their sex. Teachers having greater or moderate levels of teaching experience were found to be more effective than those having less teaching experience; teachers having greater and moderate levels of teaching experience did not differ significantly. Parental educational level had no effect on teachers’ effectiveness. Teachers with a parental occupational background of agriculture or job were more effective than teachers having a parental occupation background of business. No significant difference was found in effectiveness of teachers with parental occupational background of agriculture and those with job. No significant difference in teachers’ effectiveness was found in relation to their place of residence. Older and middle aged teachers were more effective than those in the younger age group but there was no significant difference in teachers’ effectiveness of old and middle aged. Teachers with a PhD and Master of Philosophy degree were more effective than postgraduate degree holders. No significant difference was found in teachers’ effectiveness
on the basis of their caste and the faculties they belonged to. The present study had revealed that teaching experience and educational qualification of university teachers have a bearing on teachers’ effectiveness and therefore, age of retirement of teachers should be increased and teachers should be given facilities / opportunities for further studies for their professional development.

Unraveling the complexity of host majority acculturation theories: An investigation into Greek nationals’ beliefs about the role of the state vs. that of the immigrant groups in dealing with the ethno-cultural diversity within the national polity

CHRYSANTHAKI, T. (Imperial College Business School), CHRYSSANTHAKI, T. (Imperial College Business School), LYONS, E. (Queen’s University Belfast)

This paper aims to enrich our understanding of the factors influencing the majority’s conceptions of issues related to the perceived socio-cultural place of immigrant and minority groups within diverse societies. The authors propose that in order to understand better the host nationals’ diverse views on acculturation issues, acculturation attitudes should be theorized and measured as target and context-sensitive responses and also that a distinction should be made based on majority’s beliefs about: 1) what the target groups should do in order to be accepted in the host society (expectations of the immigrants and minorities), and 2) how the state should deal with immigration/minority issues and the level of its interference in domains of private and public values (expectations of the state). Using a sample of 316 Greek nationals, the present cross sectional design survey explores variations in levels of endorsement of host majority’s acculturation attitudes based on target, domain and expectations of immigrant/minority versus the state. As predicted, participants held different acculturative attitudes depending mainly on the life domains and the two sources of expectations. The Greek respondents expected their state to appear more egalitarian and respect the individuality of the ethno-cultural groups whilst promoting policies to ensure that these groups would adopt to some extent the public values. On the contrary, they expected the immigrant groups to marginalise themselves from society by endorsing stronger exclusionist and segregationist attitudes. The current findings support the context specificity argument of host majority acculturation attitudes and highlight the importance of studying the representations that an individual holds about multiculturalism and of its material and symbolic realities referring to the state and its ideologies.

Keywords: acculturation attitudes, ethno-cultural diversity, immigrants

Unwrapping teacher socialization process: An interactionist approach

MA, H. W. (Tianjin Normal University), YUE, G. A. (Nankai University), YAO, Q. (Nankai University)

Although previous research on teacher socialization vividly described what teacher socialization meant, it did not pay enough attention to how teachers could attain adaptation. Using an interactionism approach and integrating three analytical levels (task, group and organization), this research demonstrated the process of teacher socialization by exploring the relations between antecedents, proximal outcomes (contents of socialization) and distal outcomes (job satisfaction, job performance, and organizational commitment). Three hundred and forty-five teachers, from six middle schools in northwest of China, participated in our survey. Antecedents of socialization (including both contextual and personal factors) and proximal outcomes were measured using the Socialization Tactics Questionnaire for Teachers and Socialization Content Questionnaire for Teachers, respectively. Distal outcomes were either obtained from school (job performance) or reported by teachers. Data were analyzed by Structural Equation Model. The results showed that: 1. Organizational tactics have positive influences on distal organizational outcomes not only directly but indirectly through school
understanding, task mastery and school politics; 2. the effects of teachers’ proactive tactics on distal organizational outcomes were fully mediated by proximal organizational outcomes; 3. school understanding partially mediated the relations between support from coworkers and distal organizational outcomes; 4. cooperation from students’ parents had direct positive effect on work performance, and role clarity mediated the relationships between cooperation from students’ parents and distal organizational outcomes. The process of teacher socializations can be explained by learning and the content of teacher socializations serves as an important mediator.

Keywords: teacher socialization, socialization tactics questionnaire, job satisfaction, job performance, organisational commitment

Usability for display of register: The unconscious effect of colors

OHASHI, T. (Miyagi Gakuin Women’s University), SASAKI, H. (Niigata Chuoh Junior College)

The present study investigated whether the typical color of commodity improves the visibility of the touch-panel display or not. Fifty students participated in the experiment. The experiment was controlled by a computer; we devised a search task using a touch-panel display. Twenty-four buttons (6 lines x 4 columns) were presented on the touch-panel display. Each button was colored (red, brown, white, orange, yellow, or green) and labeled with the name of a vegetable. Twenty-four vegetables and their typical/atypical colors were selected from the preliminary investigation. There were two independent variables in the experiment, both of which were varied within participants. The first variable was type of color of the buttons - achromatic, typical or atypical for the vegetables. The second was type of presentation - either color-grouping or random. With color-grouping presentation, the buttons were grouped according to the color. Before the stimulus presentation, the name of the vegetable (target) was presented at the center of the display. The participants were asked to respond to the target position as quickly and accurately as possible by touching the button on the touch-panel display. The main effects of color and presentation and the interaction between color and presentation were significant, indicating that the participants responded more accurately both when the buttons were grouped according to the color and when the buttons had achromatic/atypical color of the vegetable. The main effects of color and presentation were significant and the interaction between color and presentation was significant, indicating that the participants responded faster both when the buttons were grouped according to the color and when the buttons had typical color of the vegetable. The results suggested that the cognitive load was increased by the atypical color presentation and was reduced by that color-grouping presentation.

Keywords: visibility, touch-panel display, cognitive load, color-grouping presentation

Use of the human figure drawing in rain in children’s clinical assessment

SILVA, R. (Santa Cruz do Sul University), SILVA, M. (Santa Cruz do Sul University)

The psychological evaluation with the use of projective instruments allows investigating unconscious aspects. Through the drawings it is feasible to understand the inner world and the mental functioning of the child. The request of the Human Figure Drawing in the Rain (DHF), proposed by Machover (1967), has been frequently used by psychologists in the assessment of personality. This study aims to identify the main performance of children facing the technique of DHF in the rain. Moreover, it is also intended to associate age, sex and school type attended by the children with the form and structure of the figure. This research evaluated quantitatively applying the DHF in rain and the DHF to identify cognitive potential (Weschler, 2003). The sample was composed of 150 children from public and private schools, aged between 5 and 12 years (57% males and 43% females). Information was imputed into a database on SPSS version 11.5 for Windows and analyzed by scanning frequencies of the variables and by the association of measures using the chi-square test. There were significant associations between age, sex and school type which the children attending related with the
figure’s characteristics. Age and sex influence the presence of details in the figure \(p < 0.005\). The children’s sex and the way they structure their body image and the presence of stereotyped figures also were significantly associated \(p < 0.005\). Through this study it is found that the association of some variables with the way the child draws. The rain element represents the external pressures experienced by the child. Male children of school age seem to be experiencing more of such pressures. This was an initial study with which the samples will be enlarged to identify other possible outcomes and associations.

**Keywords:** human figure drawing, children, personality, pressure, mental functioning

**Using a notational system for comparing different theoretical approaches in behavioral medicine**

HERNANDEZ-POZO, R. (UNAM, National Autonomous University of Mexico)

According to Dekker (2008) the field of Behavioral Medicine is witnessing a more elaborated use of theories to further comprehension of empirical findings. However, most of the times the differences among these models are elusive, especially in terms of the methodological consequences for acceptable research to elucidate central assumptions of such models. In this paper, the notational contingency analysis of behavior system proposed by Mechner (2008) is proposed as a methodological tool to compare such models, by means of translating representative exemplars of five theoretical approaches. The notational system consists of six components: actions, agents, two verbs, a modifier and a tag. An exercise of comparing five different theoretical approaches in Behavioral Medicine is presented in detail, in order to unravel subtle assumptions, similarities, levels of complexity and to highlight unclear aspects of these approaches. This paper presents diagrams of the stress and emotional regulation theory (Brown, Katz, Neumann, Maier & Waldstein, 2007), the theory on health behavior, health and disease (Veenhof et al., 2007), the theory on contextual determinants of health behavior (Siegrist, 1996), the social cognitive theory of health behavior (Renner, et al., 2008) and the theory of personality and health (Denollet, et al., 2006). The analysis based on the notational system proposed by Mechner, does not show important differences among three of the selected theoretical approaches. Diagrams brought about by the translation to the symbolic notation are rated from lesser to more elaborated systems. Resulting methodological consequences in their adoption for research in the field are discussed.

**Keywords:** notational system, behavioral medicine, health behaviours, social cognition, personality

**Using a psychometric instrument for driver coaching**

DORN, L. (Cranfield University)

The Driver Risk Index (DRI) is an online self report measure based on the Driver Stress Inventory (DSI) and Driver Coping Questionnaire (DCQ) incorporating additional items and measures specifically aimed at assessing behavioural risks of driving for work. This paper reports on the usefulness of the DRI profile to provide a way of beginning a coaching conversation to build self awareness of driving behaviours, emotions and perceptions that might increase the risk of being involved in a crash at work. Twenty highly trained driving instructors (coaches) attended a three day course at Cranfield University. Expert instruction on driver coaching and how to give DRI feedback was provided. Each of the coaches then approached at least one participant to take part in the study. Forty-five at work drivers completed an online DRI and their feedback profile was sent directly to their coach. Each coaching conversation using the DRI profile as a base from which to explore at work driving behaviour lasted for about 60 minutes and was either taped or written up immediately afterwards. The results showed that virtually all participants agreed with the results of the DRI profile, corroborating the profile feedback and validating its application in this context. A qualitative analysis of the coaching conversations showed that the DRI brought to awareness a whole range of different driver behaviours that were being performed with little conscious awareness of the risk these
behaviours posed. Coaching goals were constructed based on specific ways that each participant could manage their at work road risk to strengthen motivation to address driver behaviour at work. The DRI would seem to be a useful and promising tool in providing feedback in a coaching environment, enabling drivers to better understand how to direct behaviour towards driving in ways that are less stressful and safer. Further research needs to be undertaken to follow-up on the effectiveness of the DRI coaching conversations to manage at work road risk.

Using acceptance commitment therapy principles with injured athletes

MAHONEY, J. (The University of Queensland), HANRAHAN, S. (The University of Queensland)

The purpose of the current study was to investigate the anxieties commonly associated with athletic injury and to evaluate the effectiveness of a specific intervention (Acceptance Commitment Therapy; ACT) in managing such anxieties. Ten anterior cruciate ligament (ACL) injured athletes were allocated to one of two conditions (ACT or imagery) following reconstructive surgery. All participants attended four-weekly one-on-one sessions with a therapist and prior to and following the intervention, completed semi-structured interviews, two questionnaires measuring components of ACT (Acceptance and Action Questionnaire-II; Mindfulness Attention Awareness Scale), and a questionnaire regarding sport injury anxieties (Sport Injury Appraisal Scale). No statistical differences were reported between either of the groups on measures of ACT or anxiety from their pre-test measures. However, injured athletes did report trends indicative of decreased anxiety and qualitative findings suggested individuals felt more capable of managing the hardships of injury recovery and return to sport. It was concluded that ACT is an effect method for supporting injured athletes throughout their recoveries and when returning to sport, but that further considerations have to be made in providing psychological services to this group.

Keywords: sports injury anxieties, acceptance and commitment therapy, mindfulness attention awareness scale, sport injury appraisal scale, sport psychology

Using the Sherman & Funder (2009) method to validate a medical school selection model

MUNRO, D. (University of Newcastle), BORE, M. (University of Newcastle), POWIS, D. (University of Newcastle)

We aimed to validate a battery of personality and ability tests used for medical school selection against a variety of academic, clinical and behavioural measures collected over two years at a collaborating medical school. The pattern of relationships (significant correlations) provided suggestive evidence of validity, but the large number of relationships made clear interpretation difficult using traditional statistical approaches. The paper presents a reinterpretation of the results using the technique proposed by Sherman & Funder (2009), in which the probabilities of obtaining the observed number of statistically significant correlations (or the average size of these correlations) are computed using randomisation tests. Using the routines in the statistical package R, we found patterns of results indicating a partial confirmation of the validity of some predictors.

Keywords: medical school selection, personality and ability tests, validation

Using the theory of planned behaviour and a counterfactual thinking strategy to predict and facilitate upward family communication about mammography

BROWNE, J. (University of Wollongong), CHAN, A. (University of Wollongong)

BreastScreen Australia offers free mammograms to women over the age of 40, and actively recruits women aged 50 to 69 (target women) to attend for screening. However, just 57% of target women in Australia utilise this service, which is substantially lower than the goal participation rate of 70%. This study explored
the viability of using daughter-initiated ('upward') communication within families as a vehicle for the delivery of mammography promotion messages to the mother. Upward communication about mammography was predicted using the Theory of Planned Behaviour (TPB), and a counterfactual thinking (CFT) intervention was piloted that aimed to increase motivation and consequently facilitate upward family communication about mammography. Daughters aged 18 to 39 years ($N = 131$) participated in this two-stage study, and were randomly assigned to either the control or experimental condition. Each participant completed a questionnaire that measured TPB variables in relation to initiating a conversation about mammography with her mother at Stage One. Experimental participants were also exposed to a negative-outcome vignette about a young woman failing to discuss mammography with her mother, and were instructed to record upward counterfactual thoughts in response using the stem “If only...”. Participants reported whether or not they had been successful in initiating a conversation about mammography with their mothers at Stage Two. The TPB model effectively predicted both a participant’s intention to discuss mammography with her mother, and actual performance of this behaviour. The CFT intervention did not increase intention to perform the behaviour, nor did it facilitate behavioural performance. However, many participants (54%) across experimental conditions initiated a conversation about mammography with their mothers at Stage Two. The TPB is an effective framework for predicting upward family communication about mammography, although strategies other than CFT that may be used to supplement the TPB should be explored. Future research should also include behavioural follow-up with mothers.

Keywords: mammography promotion messages, counterfactual theory intervention, family communication, theory of planned behaviour

Validating the 'Franchise E-Factor' model of franchisee satisfaction

NATHAN, G. (Franchise Relationships Institute), LACHEREZ, P. (Franchise Relationships Institute)

Franchising is a 130 billion dollar industry in Australia and there are currently 63,000 franchisees who conduct business under a franchise relationship with 1,100 franchisors. This study sought to validate a franchise relationships model known as the “Franchise E-Factor”, which explains how the relationship between a franchisee and franchisor changes over time. The Franchise E-Factor proposes six distinct stages of the relationship starting with “Glee”, characterized by high levels of optimism and hope, to a low point known as the “Free” stage where the franchisee wants to break free of the confines of the relationship, and ending with the “We” stage which is characterized by an acceptance of the imperfections and interdependencies in the relationship. Using a 58-item franchisee satisfaction questionnaire, the author investigated the attitudes of 5,600 franchisees, rating their overall satisfaction with the franchise relationship over time. These satisfaction ratings were mapped using a locally weighted polynomial regression. The resulting chart validates the Franchise E-Factor model, showing a significant drop in franchisee satisfaction over the first three years to a low point and then a steady rise, with a leveling out of satisfaction at around half of the original “glee” level. The franchise relationship follows a similar path to many interdependent relationships, including marriage, where unrealistic perceptions of the relationship are moderated by the realities of tolerating an imperfect partner and the need to realign expectations. Implications for managing interdependent relationships are discussed.

Keywords: franchising relationships, relationship stages, franchisee satisfaction, interdependent relationships, business management

Variance in reading achievement accounted for by sociocultural and linguistic variables in Mexican American children

Keywords: reading achievement, sociocultural factors, linguistic variables, Mexican American children
CARLSON, R. (The University of Texas Pan American), MEDRANO, H. (The University of Texas Pan American), RODRIGUEZ-ESCOBAR, O. (The University of Texas Pan American), CARLSON, R. (The University of Texas Pan American)

Reading and linguistic theories indicate that individuals read with linguistic expectancy. This would suggest that a portion of reading achievement is accounted for by an individual’s level of oral acquisition of syntactic structures in a language. Empirical studies indicate that socio-cultural variables account for or explain a large portion of academic achievement. There are no studies, however, addressing variance in reading achievement accounted for by socio-cultural and linguistic variables combined or in linear combination in Mexican American children. Three hundred and eighty-four (N = 384) bilingual (Spanish/English) children of Mexican American cultural heritage ranging from six through nine years of age were involved in the study. Four sample cohorts consisting of half males and half females within two months of their midyear (6-4 to 6-8, N = 88; 7-4 to 7-8, N = 100; 8-4 to 8-8, N = 100; 9-4 to 9-8, N = 96) were randomly obtained. The dependent variable was the Comprehensive Test of Basic Skills Reading Achievement subtest in English and the independent variables were family size, family structure, socioeconomic status (SES), acculturation, and oral acquisition of syntactic structures in English. The method of statistical/data analysis was multiple linear regression. Multiple regression coefficients between reading achievement, and socio-cultural and linguistic variables were .76, .72, .63, and .60 for 6, 7, 8, and 9 year old children, respectively. Thus, 36% to 58% of variance in reading is accounted for by socio-cultural and linguistic variables. The standardized regression coefficients, indicating which independent variable and in what amount, however, indicate that at six and seven years of age the preponderance of reading variance is accounted for by oral acquisition of syntax structures and at eight and nine years of age it was socioeconomic status (SES), and acculturation and family size and family structure did not explain any significant portion of variance in reading achievement. These results would suggest that at 6 and 7 years of age linguistic considerations be given to instructional materials, method of teaching, curriculum, and professional development and at 8 and 9 years of age the child’s SES and acculturation should be given consideration.

Keywords: oral acquisition, linguistic variables, school curriculum, socio-economic status

Viparita-Karani Mudra (Yoga Mudra) in the management of stress of irritable bowel syndrome patients

SHUKLA, P. R. (Kayachikitsa, I.M.S., B.H.U.)

Irritable bowel syndrome (IBS) is a gastrointestinal disorder in which most patients report symptoms like cramping, abdominal pain, bloating, constipation, and diarrhea. IBS causes a great deal of discomfort and distress. In the present investigation, the effect of Viparita-Karani Mudra (a Yoga mudra) is seen in the management of stress of irritable bowel syndrome patients. For this, 60 male patients in the age range of 22 to 35 were taken from the Out Patient Department of Kayachikitsa, S.S. Hospital, Banaras Hindu University, Varanasi, India. First, they were rated on stress scale. Then the patients were randomly divided into two groups. In one group, 30 patients were given placebo (Glucose powder in capsule) with regular training of Viparita-Karani Mudra and in the other group, 30 patients received only placebo. After one month, the patients were again rated on the same stress scale. The results indicated that those patients who received the training of Viparita-Karani Mudra show ed the significant decrease in the symptoms of stress than those who had not received the training of Viparita-Karani Mudra. On the basis of the present study it is concluded that Viparita-Karani Mudra relieves stress and improves digestion.

Waste governance and behavioral attributes toward recycling implementation

TETE-ENI, I. E. (University Kebangsaan), AYUB, K. (University Kebangsaan), ENI, D. D. (University of Calabar)
The significance of waste recycling is becoming increasingly important owing to global population increase and technological progress. Implementing a strategy to promote resources recycling under resource shortages is a viable approach to fast industrialization and urbanization. To support policy transformation, reforming the current recyclable resources recycling system is essential. The status of solid waste management in a city is often considered an index for assessing governance. In cities of the developing world, the informal sector plays an important role in recycling and management of solid waste. This paper examines the position of recycling as a tool for planning and reform of solid waste management in developing countries. Our report is from field observations and reviews of relevant legislation, policy documents and reports on solid waste recycling and governance. Recent efforts to visibly improve governance through reform of solid waste recycling are also highlighted. The significant roles of informal recycling were integrated into the framework of reforms in waste recycling and governance. The development in technological trends armed at poverty alleviation, improvement of the quality of life as well as environmental sustainability will be considered. This paper reveals the lapses in recycling strategies and calls for recognition and support of recycling activity and empowerment of people involved within its context.

Keywords: waste recycling strategies, waste management, environmental sustainability, quality of life, global population increase

Wellbeing in volunteer health care workers: A perspective of the motivational pathway of the Job Demands-Resources Model

HUYNH, Y. (University of South Australia), METZER, J. (University of South Australia)

Using the motivational pathway of the Job Demands-Resources (JD-R) model, the aim of this study was to examine the antecedents of engagement and connectedness in a sample of Australian volunteer health care workers. Survey data were collected from 471 volunteer participants and analysed using structural equation modelling (SEM) methods. Three job resources (social support, performance feedback and training) were used to test whether job resources would increase health, volunteer satisfaction and intent to continue through work engagement and connectedness. Results supported the motivational pathway of the JD-R model in volunteer health care workers. Specifically, job resources were positively related to engagement and connectedness. However, only connectedness turned out to be important for explaining the relationship between job resources and the three positive work outcomes. This study offers insight into ways in which the JD-R model (originally developed in the context of paid workers) can be used to understand and improve workplace health and productivity in nonprofit organisations. As the study suggests, the relatively new construct of connectedness, as measured by the revised connectedness scale, may be potentially useful in furthering this understanding.

Keywords: job demands-resources model, volunteer health care workers, work engagement, work connectedness, job resources

What are you drinking? Young people’s knowledge of alcohol "units"

DE VISSE, R. (University of Sussex)

Guidelines for safe alcohol consumption in the United Kingdom and many other countries are commonly presented in terms of "units" of alcohol or "standard drinks". The aim of this study was to examine the accuracy of young people’s knowledge of units and standard drinks, and their use of this information when pouring their own alcoholic drinks. In Study One, a computer-administered questionnaire was completed by 402 secondary students aged 16 to 18. This questionnaire assessed knowledge of definitions of alcohol units and guidelines for safe alcohol consumption and accuracy of estimates of the alcohol content of different alcoholic drinks. In Study Two, 122 university students completed the same computer-administered questionnaire and a task which included pouring their “usual” alcohol drinks and what they believed to be “units” of different alcoholic drinks. Very few participants in either
sample had accurate knowledge of alcohol units. Knowledge of definitions and guidelines was not related to practical knowledge in terms of knowing the alcohol content of different alcoholic drinks or accuracy of pouring alcohol units. Most respondents rated their understanding of alcohol units and guidelines as poor and most wanted more information. The pouring exercise revealed that participants’ “usual” drinks were significantly larger than one “unit” or “standard drink”, and that they overestimated the volume of a “unit” of alcohol. People who poured larger drinks for themselves reported greater alcohol consumption and were higher in sensation seeking and impulsivity. There is a need to improve young people’s knowledge of the alcohol content of various drinks so that they can make better informed choices about their own alcohol consumption. There is some evidence that the drink pouring activity used in this study could be a useful method for increasing knowledge of alcohol units. Inaccurate knowledge of alcohol units also has implications for psychological research which relies on self-reported alcohol consumption. Poor understanding of alcohol units and guidelines also means that young people may be exposed to greater alcohol-related risk than they are aware of.

Keywords: alcohol use, impulsivity, sensation seeking, alcohol outcome expectancies, guidelines for young people

What is the void made of? Australian immigrants draw their experience

LAZAROVA, L.

The aim of this field work study concerns the existing relations between the experience of significant real-life change (immigration, permanent or temporary changed residence) and its reflection in individual psychological realms. It gathers and interprets valuable data, making explicit some of the complex intra-psychic phenomena that mediate the process of transition and acculturation. This qualitative study was repeated biannually. The method included a Questionnaire with instructions and three open questions. The answers were analysed for their content and grouped by frequency; Thematic Content Analysis of the artefacts (directed drawings) was used and Semi-structured interviewing for clarification of pattern overlapping and manifested versus latent content, was used. The participants are from two highly heterogeneous, real-life groups of immigrants (mostly students and overseas qualified professionals). The content analysis shows that although at the deepest psychological level all are in possession of similar emotional drives, the significant individual difference in the narratives and their conceptualisation lies in between. Almost everybody is deeply affected by missing family members and most often this is the Father’s figure. It is a surprise that unexpectedly the Native Food category showed the same range of frequency among the missed elements in the recent life of the studied immigrants. The Mother’s figure syncretises almost inseparably with the themes of food, childhood and other siblings. While at its bottom-line categories’ received results are very similar, further the process goes through ramification and less frequency answers (friends, possessions, natural environment) and unfolds into a vast diversity of highly individualized structures. These data from less-studied psychological issues experienced by immigrants highlight the variability of psychological passages and possible facilitations. The methods used and the related efforts applied from the participating persons contained inbuilt certain integrative ‘healing factors’ which are supposed to elevate their self awareness and unfold their creativity, resilience and imagination.

Keywords: real-life change, creativity, resilience, imagination

What’s going on here? Drug and alcohol abuse, memory loss, and trauma: An individual case study

BUCKBY, B. (James Cook University)

To aim of this session is to further define the efficacy of individual therapy with Indigenous clients; creative therapy responses to the ways in which inherent strengths and resiliencies inform, transform, and are also distorted by distress and dysfunction; intergenerational transmission of trauma; and valid outcome
evaluation. In 2007 an Indigenous woman (R) aged 48 was referred for a cognitive assessment due to short term memory difficulties at work. She had a 20 year history of poly drug and alcohol misuse up to age 36. The assessment showed she was of high average intelligence and had age appropriate memory skills. R also had a lengthy history of traumatic events which included violence, and threats to kill R and her two children, being crushed by a truck with resultant chronic pain (25 years), and fear due to ex-partner’s stalking (20+ years). After assessment she was referred to a specialist service working with similar women. A year later R was re-referred with a diagnosis of PTSD and a lengthy process of trauma therapy began in 2008. R chose individual therapy with a non-Indigenous psychologist to protect her story and confidentiality. Standard evidence based treatment for PTSD was negotiated collaboratively; however, imaginal exposure was too distressing. Principal treatment adaptations included mindfulness exercises particularly those invoking imagery of country, and a systematic reappraisal of R’s life and trauma events. The reappraisal or restorying of R’s life drew on her historically evident strengths and resiliencies. The process also requires greater psychologist self-disclosure to sustain the collaborative therapeutic alliance, and learning from R by asking for help to understand culturally specific meanings. Results included reduced dissociation, improved recognition of onset, and improved self-coping; improved quantity and quality of sleep, and insignificant reduction in depression, anxiety and stress symptoms. Retraumatisation through re-experiencing past events was triggered by frequently removing her grandchildren from family violence. Historical events serve as powerful maintaining risk factors for emotional distress in the present due to intergenerational “transmission” of distress and dysfunction. In this case R’s mother was stolen generation, R’s foster care and other life events, R’s daughter and grandchildren involved in drug and alcohol related family violence. Practice based evidence could potentially provide a foundation for psychological interventions with Indigenous clients.

Keywords: Indigenous clients, trauma, post-traumatic stress disorder, intergenerational transmission, practice based evidence

When Asperger Syndrome runs in the family

LAU, W. Y. P. (University of Queensland), PETERSON, C. (University of Queensland)

This study is based on two theoretical rationales. Firstly, family adaptability and cohesion has been found to be a significant unique variance in explaining psychological well-being of its members. There is a growing body of evidence suggesting that having a child with a disability negatively impacts on family’s adaptability and cohesion. However, to our knowledge, only one study has focussed on families with children with autism spectrum disorders (ASD) and none specifically on the Asperger Syndrome (AS) population. Secondly, although the phenomenon of broader autism phenotype in parents has long been broached, research is still emerging on the implication of parental diagnosis of AS on families of children with AS. Based on these rationales, the purpose of this study is two-fold: 1) to examine the impact of having a child with AS on the family’s adaptability and cohesion; 2) to explore if having a parent also diagnosed with AS will further impact on the family’s adaptability and cohesion. Participants (N = 150) completed a questionnaire which consisted of diagnostic information, and the Family Adaptability and Cohesion Scale (Olson, Bell and Portner, 1982). Subjects were divided into three groups according to diagnosis of AS in the family: one parent plus one child have AS (Group One; N = 40); only child but no parent has AS (Group Two, N = 55); and no child or parent has AS (control, N = 55). Results indicated statistically significant differences (p >.05) between the three groups in family adaptability [F(2, 150) = 11.59, p < .001] and family cohesion [F(2, 150) = 21.57, p < .001]. Post-hoc comparisons found Group One reported significantly lower scores than Group Two in family cohesion (p < .001) but not in family adaptability (p = .842). In comparison to the control group, Group One and Group Two reported significantly lower scores in both family adaptability and family cohesion. These results suggest that 1) having a child with AS significantly impacts on the family’s adaptability and cohesion; 2) parental diagnosis will further decrease family cohesion but not adaptability. These findings give voice to families of children with AS, particularly those having a
parent also diagnosed with AS. Implications for therapeutic intervention for families living with AS in either child and/or parent generations will be drawn. The appropriateness of an ecological approach when working with these families will also be highlighted.

Keywords: family adaptability, family cohesion, children with disabilities, asperger's syndrome, parental diagnosis

When is abusive supervision not related to employee psychological health? The moderating effect of individual power distance orientation

LIN, W. (Peking University), WANG, L. (Peking University), CHEN, S. (Peking University), YANG, Q. (Peking University), KONG, H. (Luxottica Group), YU, Z. (Luxottica Group)

People generally believe that abusive supervision leads to employees’ poor psychological health. However, this relationship is not always true. The fundamental values of power held by employees will have an impact on this relationship. This study examined how individual power distance orientation (defined as the extent to which an individual accepts the unequal distribution of power in institutions and organizations) affects the relationship between abusive supervision and employees' psychological health. In one sample 825 employees from a manufacturing company located in southeastern China rated their power distance orientation, psychological health, and their perceptions of abusive supervision. Results showed that abusive supervision was negatively associated with followers’ psychological health ($r = -.199$, $p < .01$). The relationship between abusive supervision and employees’ mental health was moderated by individuals’ power distance orientation ($\Delta R^2 = .011$, $\beta = .107$, $p < .05$), such that this relationship is statistically significant for followers who were lower in individual power distance orientation ($\beta = -.259$, $p < .01$), but not statistically significant for followers who were higher in individual power distance orientation ($\beta = .085$, $p = .481$). Abusive supervision has been seen as a significant social problem which would ruin followers’ mental health. This study extends previous research by showing that interactive effects of abusive supervision and followers’ power distance orientation help explain psychological health among followers. The findings suggest that focusing on fundamental values held by employees contributed to a better understanding of the impact of leader’s deviant behaviors. In addition, the interaction of leadership and values followers held in relation to mental condition and employee reactions provide an interesting area that needs further exploration in order to enhance our understanding of when and how leaders affect those they lead.

Keywords: abusive supervision, individual power distance orientation, psychological health, employees

When latent inhibition influences creative performance: The moderating effect of epistemic motives on cognitive style

LIOU, S. (National Cheng Kung University), YING FUN, J. (University of Lausanne)

This study examines how epistemic motives moderate the effect of Latent Inhibition (LI) on creative behaviors. Reductions in LI, the capacity to screen from conscious awareness stimuli previously experienced as irrelevant, have been generally associated with the tendency towards creativity. A number of studies suggest the individual differences in LI. This study proposes that the effect of cognitive styles (LI) on creative performance is moderated by need for cognitive closure (NFC). Individuals scoring high on NFC are likely to quickly grasp closure by relying on early cues and the first answer they come across. The need for closure is also said to lead to a very narrow information search and a higher tendency to use cognitive heuristics when it comes to finding a solution to a question. Hence, we hypothesise that higher NFC will enhance the tendency to adopt default cognitive heuristic, thus expanding the difference in creative performance between high and low LI. Two experiments were conducted: one in the laboratory and the other in the field. We used the latent inhibition paradigm (LI; Lubow, 1989) to divide participants into high and low LI group, and manipulate NFC both by situation (time pressure) and by disposition measure (Webster
& Kruglanski, 1994). Creativity was measured by lifetime creative achievements and the Runco Ideational Behavior Scale (RIBS). Results show that low LI individuals are more creative than high LI both in creative achievements and RIBS, and the difference in creative performance between high and low LI is expanded when with higher NFC. This finding supports the proposed moderating function of epistemic motives (NFC) on the tendency to adopt preferred cognitive heuristics (high/low LI) and be more cognitively inflexible. We are also investigating other possible moderating factors (working memory capacity and cultural effect) that may have an impact on the LI-creativity relationship. Implications for potential utility in application of this motivated social cognition research to human factors and design are discussed.

**Keywords:** latent inhibition, creative performance, epistemic motives, cognitive style, heuristics

**Why am I lowering my carbon footprint? Autonomous motivation and sustainable lifestyle change**

COOKE, A. (University of Queensland), FIELDING, K. (University of Queensland)

As a first world nation, the Australian community contributes to the dangerous level of greenhouse gas emissions in the atmosphere by using resources at a much higher level than is environmentally sustainable. To be effective at lowering household carbon footprints from some of the worst in the world towards sustainable levels, it will be essential that the pro-environmental behaviours (PEBs) adopted are generalised across multiple target behaviours, have a large environmental impact, and are maintained. The current research will test a model of motivation for effective PEB developed primarily out of Self-Determination Theory. Through an online questionnaire, the research will explore the relationship between the type of motivation people have for pro-environmental behaviour (i.e. their reasons for adopting PEBs and changing unsustainable habits) and proposed antecedents and consequences of motivation; aspects of the social environment which impact on that motivation, and the level and types of PEB people engage in. Results are pending. However, it is hypothesised that self-determined (autonomous) motivation for pro-environmental behaviour will be related to a wider range (generalisation) and maintenance of pro-environmental behaviour than externally regulated motivation, or amotivation towards environmental problems. Perceived autonomy, competence and relatedness in relation to environmental problems and action are expected to impact on motivation for PEB. The ideal social environment for autonomous motivation is hypothesised to be, and be perceived as, supportive but not controlling, interesting but not over-challenging, and accepting as opposed to rejecting. Results, implications, and plans for further experimental and longitudinal research to test causality of relationships and to identify optimal ways of supporting autonomous PEB adoption will be discussed. It is proposed that a general move towards a positive, holistic approach to environmentalism is necessary, one aspect of which is to make environmental action more satisfying, interesting, and fun, through linking pro-environmental behaviour with the meeting of psychological needs for competence and relatedness, as well as autonomy.

**Keywords:** pro-environmental behaviour, carbon footprint, self-determined motivation, externally regulated motivation, environmental issues

**Why people take more survival actions than damage mitigation actions for hazards: Is cost the key factor?**

MCCLURE, J. (Victoria University of Wellington), FISSCHER, R. (Victoria University of Wellington), SPITTAL, M. (University of Melbourne), CHARLESON, A. (Victoria University of Wellington)

The aim of this research was to show if there is a relation between businesses’ and households’ performance of survival actions and mitigation actions to prepare for earthquakes and their estimate of the cost of those actions. Two studies examined businesses’ and households’ completion of a sample of twelve mitigation and survival actions, their estimate of the costs of those actions in their own case, and their attributions for why they have not carried out the actions. Damage mitigation actions were divided into actions mitigating damage to the
building and actions mitigating damage to contents. Households completed fewer mitigation actions than survival actions, and businesses completed fewer structural mitigation actions than contents damage mitigation actions and survival actions. A logistic regression showed that with households there is a significant relationship between the perceived cost of four of the twelve actions and the probability of carrying out the actions. With companies there is no such relationship. On the measure of attributions for not performing the actions, for both households and businesses, the perceived cost of the actions was only the 4th, 5th or 7th most common attribution. Attributions cited more frequently than costs were: 1. I haven’t thought about it; 2. It’s not a priority, and 3. It would make no difference. There is a relation between performing preparation actions and cost, but it appears that the cost factor is secondary to other factors in explaining what actions people do and do not take to prepare for hazards.

Keywords: hazard preparation, survival actions, damage mitigation, earthquake, cost factors

Work Engagement and the role of psychological climate, value congruence, and social identification

VALENCIA, M. (De La Salle University)

The research tested two models that looked separately at how work engagement is influenced by value congruence and social identification (organisational and work group levels), and psychological climate. Drawing from the Social Categorisation Theory (Turner et al., 1987) and predictions from a Person-Organization (P-O) fit perspective, both models premised that psychological climate mediates the relationship of work engagement with value congruence and social identification. Survey data from 431 employees of various service organisations in the Philippines was analysed using structural equation modeling. Findings supported the mediating role of psychological climate in both models (organisational and workgroup levels). Furthermore, a strong positive relationship was observed for organisational level identification and value congruence. Workgroup level correlation on the other hand was weak. It was also observed that identification had stronger direct effects with psychological climate compared with value congruence. Organisational value congruence also had direct effects on work engagement. It was concluded that organisational level dynamics (compared with the workgroup level) of identification and value congruence are more pivotal in their predictive roles in creating a psychological climate of work engagement. Value congruence serves as a basis for an individual to assess the extent of fit with the organisation but it is not sufficient to drive an employee in ‘going the extra mile’ on behalf of the organisation. Organisational identification is further needed to provide a kind of social ‘glue’ that would bind the perceived aspects of fit between the self and the organisation. The findings were also contextualised in terms of how organisational culture is suggested to be linked to work engagement.

Keywords: work engagement, psychological climate, value congruence, social identification, organisational dynamics

Work engagement on nurses in Surabaya. How nurses manage their emotion at work

CHRISTIAN, F. (University of Surabaya), BATUADJI, K. (University of Surabaya), SUPRIYANTO, A. (Jogjakarta State University)

Nursing is one of three professions that is particularly susceptible to feeling decreased work engagement. The indicators of low work engagement are low levels of energy and mental resilience, and lack of a sense of significance, enthusiasm, inspiration, pride and challenge while working. This paper aimed to test the relationship between emotional labour and work engagement in nurses in three hospitals in Surabaya. The results indicate that there was a positive correlation between ‘surface acting’ and work engagement ($r = 0.518, p = 0.001$) and there was also a positive correlation between ‘deep acting’ and work engagement ($r = 0.593, p = 0.000$). The implications of these findings for health-care workers are discussed.

Work engagement, personal initiative and performance in a sample of Mexican police officers from Preventive Police

LISBONA, A. (Spanish National University for Distance Education ), TREVIN, M. (University of Nuevo León), PALACI, F. J. (Spanish National University for Distance Education )

The main objective will be to discuss the relationships between the concept of self-efficacy and work engagement, personal initiative and performance. Therefore, by reviewing the theoretical models and empirical results that have found relationships between these concepts, we will suggest a model. Research shows that work engagement has a positive relationship with job behavior such as performance and proactive behavior, and that self efficacy is related to personal initiative. Personal initiative, like work engagement, is related to performance too. The sample is composed of 243 police officers from Public Security, also known as Preventive Police, from two police agencies in the metropolitan area of Monterrey, Nuevo Leon, Mexico. The variables analyzed by self-reported questionnaire are self-efficacy, work engagement, personal initiative and subjective individual performance. Maximum likelihood estimation methods of structural equation modeling (SEM) were used to test the five competing models. The fit of two of the five models are appropriated (Model 1: $\chi^2 = 249.668; df = 132; GFI = .897; RMSEA = .061; CFI = .896$ and Model 3: $\chi^2 = 232.424; df = 132; GFI = .903; RMSEA = .056; CFI = .911$). In one model the path between self-efficacy and engagement is not significant ($t = 1.560$), and in the other model the path between personal initiative and performance is not significant ($t = 1.086$). The two models with appropriate fits have all path coefficients being significant ($t > 1.96$). Results confirm that both personal initiative and work engagement can be related to performance. In both models self efficacy predicts personal initiative. Theoretical and practical implications of these results are discussed as well.

Keywords: self-efficacy, work engagement, personal initiative, work performance

Work stress and work-family conflict: Implications for employee satisfaction and health

FIKSENBAUM, L. (York University), GREENGLASS, E. (York University)

Work stress continues to be a problem in most sectors of the workforce, and has many negative consequences for both employees and organizations. Given the current economic climate, examining factors that affect employees’ perceived levels of stress is an important research topic among occupational health researchers. The present study tests a model that examines antecedents of work stress and their effects on various outcomes. These included an outcome at the individual level (i.e., emotional exhaustion, which is often referred to as the prototype of stress), an organizational-level outcome (i.e., job satisfaction), and an overall outcome (i.e., life satisfaction). Data were collected from 214 employees, using a confidential and anonymous questionnaire. Three separate hierarchical regressions were conducted, each incorporating the same set of predictors. The first block included demographic variables (i.e., age, gender, marital status, education) as well as work situation characteristics (i.e., salary, tenure, and number of hours worked per week). Work demands were entered in the second block, and family demands were entered in the third block. The fourth block included work-family conflict, including conflict due to work interfering with family (WIF) and conflict due to family interfering with work (FIW). Perceived organizational support and family and friend support were entered in the final block. With emotional exhaustion, job satisfaction, and life satisfaction as outcomes, the model accounted for 59%, 68%, and 42% of the variance, respectively. Across all models, consistent predictors included perceived organizational support and family support. In both models self efficacy predicts personal initiative. Theoretical and practical implications of these results are discussed as well.
who reported higher levels of work-interfering-with-family conflict were less likely to report being satisfied with life or with work. Further results indicated that both work and family demands contributed to the work-related outcomes of emotional exhaustion and job satisfaction. Demographics differentially predicted to emotional exhaustion and life satisfaction. Family support contributed to overall life satisfaction. Theoretical and empirical implications of the results are discussed.

**Keywords:** work stress, employee stress, work-family conflict

**Work-family conflict and enrichment predicting mental health: Direct, indirect and crossover effects**

HAAR, J. (University of Waikato), BROUGHAM, D. (University of Waikato)

The aim of this research was to test direct and crossover effects of work-family conflict (WFC), family-work conflict (FWC), work-family enrichment (WFE) and family-work enrichment (FEW) towards anxiety and depression and the potential moderating effects of enrichment on conflict (direct and crossover). Structural equation modeling confirmed the unique properties of the dimensions tested with a sample of 266 dual-career couples. Regression analysis was conducted with separate models for male and female outcomes. Predictor blocks of male and female work-family dimensions and interactions were included in all models to also test crossover effects. For males, WFC was positively related to depression, and FWC positively related to both anxiety and depression, while WFE was negatively related to both outcomes. For females, WFC was positively related to anxiety and depression, and FWC positively related to depression, while WFE was negatively related to both outcomes and FWE negatively related to depression. Direct crossover effects were found with female FWC positively influencing male depression, while female WFE negatively influenced male anxiety. Furthermore, male WFE was negatively associated with female anxiety, while male WFC was negatively associated with female anxiety and depression, and male FWC positively associated with female anxiety and depression.

For male outcomes, anxiety was significantly affected by male WFE buffering FWC. For female outcomes, anxiety and depression were significantly affected with female WFE buffering FWC. Furthermore, female WFE and FWE buffered the effects of WFC and FWC respectively. Furthermore, some significant interaction effects were found to crossover to the partner. For male depression, females with high FWE were found to buffer the effects of FWC, leading to lower partner depression but only at low levels of FWC. For female depression, the effects were similar for both significant interaction crossover effects. Male FWE buffered both male WFC and FWC, leading to lower partner depression at low levels of conflict but higher levels of depression at higher levels of conflict. This study supports work-family conflict and enrichment dimensions influencing employees and their partners, and the buffering effect of enrichment on conflict’s influences on mental health. Overall, conflict effects dominated and enrichment had minor direct and crossover effects but strong buffering effects.

**Keywords:** work-family conflict, work-family enrichment, anxiety, depression, dual-career couples

**Working with barriers: A comparison of job seekers with mental health problems with and without additional drug and alcohol problems**

HARRIS, L. (University of Sydney)

Workforce participation for Australians with mental illness remains low, although improved work status reduces symptoms, improves self-efficacy, and improves life satisfaction. Almost half of those with mental illness also have difficulties with substance use, and for these people workforce participation rates are very low (Crompton et al., 2005). The study aimed to understand the additional barriers to employment resulting from drug and alcohol use among people with mental illness. Participants were clients of an employment service provider who had psychiatric disabilities with and without significant drug and alcohol problems identified using the AUDIT and DAST-10. Participants were compared on measures of current psychosocial and cognitive function, symptomatology,
educational history and employment history. There were no significant differences in function or history between the two groups. However, a number of areas of greater unmet needs were identified among the drug and alcohol group using the CANSAS. Since the results do not show any significant differences in function or history between the two groups, there may not be any justification of designing separate interventions for the groups. However, the drug and alcohol user group would need additional emphasis to improve their quality of life by fulfilling their needs related to food, accommodation, mental and physical health and other aspects of everyday life, as higher unmet needs are evident among this group in CANSAS data. As these needs entail a wide range of aspects of life, effective communication and integration among different service sectors are needed to ensure the employment participation of people with co-existing mental illness and drug and alcohol issues as well as their quality of life.

Keywords: workforce participation, mental illness, substance use, self-efficacy, life satisfaction

Workplace ostracism in China: Gender difference on psychological health and job satisfaction

JIANG, J. (Beijing Normal University), XU, Y. (Beijing Normal University)

Accumulating evidence supports the notion that workplace ostracism is a universal experience, but less is known about gender differences in terms of workplace exclusionary behavior. The current study explored the moderating effect of gender on the relation between workplace ostracism and psychological health and job satisfaction. This research tested the applicability of Workplace Ostracism Scale (WOS; Lance et al., 2008) in China and examined the different effects of workplace ostracism on psychological health and job satisfaction in men and women. A Chinese version of the WOS was developed on a sample of 137 persons (57 men and 80 women) and cross validated on a second sample of 300 employees (160 men, 136 women and 4 unknown) from various companies. Internal consistency and confirmatory factor analysis were used to confirm the reliability and construct validity of the WOS. The WOS proved a reliable and valid measure in Chinese workplaces. A moderated hierarchical regression analysis on psychological health and job satisfaction yielded an interaction between ostracism and gender with a significant change in R2. The present study provided a useful measure for Chinese workplace ostracism literature. We also demonstrated that, the effects of ostracism are moderated by gender. At lower levels of perceived ostracism women indicated higher satisfaction and psychological health than men whereas at higher levels women indicated lower satisfaction and psychological health compared to men.

Yoga for children with intellectual disability

NITHYANANDAM, L. (Department of Ageing, Disability and Home Care)

Many studies have highlighted the efficacy of Yoga as a potent tool in bringing out positive changes in the physical and psychological wellbeing of a person. Its application for people with Intellectual Disability (ID) has not been explored enough scientifically. This study is an attempt to answer two questions. First, can Yoga be taught to children with ID and if so how can it be done? The second question is whether Yoga is beneficial for people with ID. Twenty-five special educators were trained in yoga and also in the methodology of how to teach the same to people with intellectual disability. They in turn taught Yoga to 50 children with ID. A before and after evaluation was conducted on measures like number of days the child attended school and changes in his/her Individualized Programme Plan comprising of domains such as motor, self help, language etc., and also changes in individual symptoms that some of the children had as associated conditions. The design was a pre and post quasi experimental design and the experimental group was compared to a control group. The results showed Yoga can be taught to children with ID if a person is trained in Yoga and also in the method of teaching yoga to people with ID. The results also showed significant changes in the health status of the children by
way of improvements in their attendance to school. There were also significant changes in some of the areas in their Individualized Programme Plans (IPP). The study also showed unpredicted results namely changes in many of the associated symptoms that many of the children had. Another set of spurious results were changes in the health status of the special educators as they had to practice Yoga themselves in order to teach the children. Yoga can be taught to children with ID if the educator is trained in the methodology of teaching Yoga to children with ID. Yoga is effective in making positive changes in children with ID.

A comparative analysis of the psychological health status of Chinese undergraduates today

OUYANG, W. (Changsha University of Science & Technology)

Based on multidimensional comparative analysis of the psychological health status of Chinese undergraduates today (e.g., urban and rural, well-off/poverty, boys/girls, sibling/singleton), we will reveal Chinese college students' mental health status and characteristics. 1835 Chinese freshmen are tested with SCL-90 in 2009. The scale was adapted to suit the Windows online computer test designed by us. Each student used a computer. The data was collected by SPSS17.0 and the main statistical analysis was a t-test. The result showed that: I) Generally speaking, the psychological health of the undergraduates is good; II) the psychological health of undergraduates coming from the rural areas is poorer than that of the students coming from the city. Similarly, the same trend was found for female students and undergraduates experiencing poverty. Therefore, we concluded that it is necessary to provide an improved and inclusive education of psychological health in line with college students' mental characteristics, economic status, and individual differences.

A comparative study of anxiety, neuroticism, extraversion and adjustment variables of basketball, hockey and volleyball men players

KHANNA, D. (Panjab University), KUMAR, A. (Ch Devi Lal University), LOHAN, U. (Kurukshetra University)

The purpose of this study was to assess the Anxiety, Neuroticism, extraversion and adjustment levels among the intercollegiate basketball, hockey, and volleyball men players of Kurukshetra University. Anxiety is a complex emotional experience often unconscious in origin, with fear or dread as its most notable characteristic. It is a symptom in various nervous and mental disorders, where the term anxiety state may be used and can be defined operationally as the autonomic response pattern characteristics of an individual organism after a noxious stimulus. Neuroticism is a state characterized by emotional instability, anxiety, low self respect and due to mental disorders. Neuroticism should not be identified with neurosis, since neurotic symptoms may be shown by healthy individuals too. Neuroticism is generally assessed by special scale or personality inventories. Turning outward used primarily in personality theory to refer to the tendency to direct one’s energies outward to be concerned with and qualification from the Physical and social environment. Adjustment consists of psychological process by means of which individual manage to cope with various demands and processes of life. For the study purpose the terms Neuroticism is defined as ‘A neurotic is a person of imbalanced judgment, one whose actions are promoted by emotions rather than by dictates of calm reasoning. Eysenk says that the lack of socialibility must be regarded as an index of neuroticism. Extraversion is defined as ‘The traits of extraversion a sociable lively, active, assertive, sensation seeking, carefree, dominant, urgent and venturesome.’ Adjustment is defined as ‘Adjustment consisting of psychological processes by means of which individual manage to cope with various demands and processes of life.’ The study involved 150 subjects aged 18 to 22 years who were randomly selected, 50 from each of the sports were taken for this study. The questionnaire on Sinha’s anxiety scale by Dr. Durga Nand Sinha, Maudslay personality inventory by S.D. Kapoor and S.S. Jalota and Bells adjustment inventory by S.M. Mohsin variables were administered to find out the various psychological variables on anxiety, Neuroticism, extraversion and adjustment among the different men sports groups. After collecting the data the descriptive statistical techniques were computed i.e. means, standard deviation and t-test were used. On the basis of results of the present study, we can conclude that Basketball players have more anxiety and neuroticism than the players of hockey and volleyball. Basketball players are more extraverts than the players of hockey and volleyball players. Volleyball players are better adjusted in comparison to hockey and basketball players.
A comparison of adaptive change behaviours under three conditions

BOWLES, T. (University of Ballarat)

The Adaptive Change Model (ACM) was developed as an alternative form of the Transtheoretical Model of Change (TTM) to address some of the criticisms of early operationalization. Both models provide a framework for measuring the potentialities of change and to facilitate targeted behavior change in general and clinical settings. The general aim of the research was to explore an alternative model of adaptive change to the Transtheoretical Model of Change (TTM). Specifically, the first aim was to validate the Adaptive Change Model (ACM). This was followed by a comparison of the adaptive functioning of a group beginning career counselling, a group beginning clinical therapy and a non therapy group. The eight factors of the model were validated, and the study comprised of 238 participants. A between groups comparison design was used to compare the respondents. The clinical therapy group was comprised of a similar number of males and females (n = 85) to those receiving career counselling (n = 88) and the non therapy group (n = 65). The findings from the CFA indicated a good fit between the model and data. A comparison of the mean scores of the factors of the ACM showed respondents seeking clinical therapy were lower on self-rating of factors related to adaptive change than a group receiving career counselling and a non therapy group. The ACQ factors correctly predicted the allocation of 79.3% of the clinical and non therapy respondents which confirmed previous research. The relevance of the findings for therapeutic interventions and future research are discussed.

Keywords: adaptive change behaviour, transtheoretical model of change, adaptive change model, career counselling, clinical therapy

A comparison of the problems on time management and self-discipline between morningness and eveningness groups in Japanese college students

SATO, T. (Tohoku Bunka Gakuen University)

Eveningness, a behavioral pattern characterized by a large shift in the sleep patterns, might lead to many kinds of problems in college students, because they have to act, to some degree, in accordance with the timetable of daily work in their colleges. To consider mechanisms that engender shifts in sleep schedules of college students and to devise ways to solve accompanying problems, we must pay attention not only to environmental factors but also to behavioral and psychological factors. In this study, the author focused on the relationship of eveningness to some problems related to time management and self-discipline. A total of 497 students (184 females and 313 males) from two colleges located in the city of Sendai in Japan participated in this study. A self-report questionnaire was administered to all the participants. The questionnaire included items pertaining to night-time sleep and daytime arousal; these items were obtained from the life habit inventory (TMIN-LHI), a Japanese version of the Morningness-Eveningness Questionnaire (MEQ) and the Epworth Sleepiness Scale (ESS). The questionnaire also included items related to certain problems in college-level attention deficit hyperactivity disorder (ADHD), such as inattention, impulsivity, hyperactivity, time management, and self-discipline; these questions were taken from the translated Japanese version of the College-level ADHD Questionnaire (CAQ; Hatayama et al., 1998). On the basis of MEQ scores, the participants were divided into three circadian rhythm types: evening type, intermediate type, and morning type. The results of the CAQ scores revealed that in general, the evening type tended to suffer from more problems related to time management and self-discipline than the other two types. The results of the ANOVA and the post-hoc comparison indicated that the evening type reported significantly higher values on these two scores than the other two groups. These results strongly suggested that eveningness or the delaying of the daily sleep schedule—that is, going to bed late and waking up late—is closely related to the problems related to time management and self-discipline.

**A comparison of United States military members and federal employees’ experiences of discrimination and sexual harassment: The relationship between reporting style and satisfaction with the resolution**

While military and civilian Department of Defense (DoD) workers and federal employees are protected against various forms of discrimination and sexual harassment, these practices still occur. The Defense Equal Opportunity Management Institute Organizational Climate Survey (DEOCS) assesses an organization’s climate associated with military equal opportunity (EO) and civilian equal employment opportunity (EEO) practices. The Federal Equal Opportunity Climate Survey (FEOCS), a modified version of the DEOCS, assesses federal agencies’ organizational climate associated with EEO practices. Both surveys provide an opportunity for members to chronicle experiences of discrimination and sexual harassment, the actions they may have taken following the incident, and their satisfaction with how the issue was resolved. Both the United States (US) military and federal agencies train Equal Opportunity Advisors (EOAs) to aid in the resolution of organizational EO/EEO-related issues (for example, issues related to the experience of discrimination and sexual harassment). Ideally, members experiencing discrimination or sexual harassment will seek to rectify the situation through their EOA, since EOAs are formally trained in complaint resolution and mediation. Moreover, the EOAs’ training should help the offended individual successfully resolve the issue. This study characterizes the relationship between actions taken by the victim after experiencing discrimination or sexual harassment, and their level of satisfaction with issue resolution. This study compares data from over 4,000 (US) military members who completed the DEOCS and data from over 3,000 civilian federal employees who completed the FEOCS, examining demographic variables (for example, race, sex, and age) to gain an accurate depiction of the relationship between specific action taken and satisfaction between the groups. It is sensible to predict that, when victims report discrimination or sexual harassment through their EOA, they will be more satisfied with the issue’s resolution, compared to those who take actions not involving an EOA. In a broad sense, these analyses will represent an attempt to gauge victims’ trust in EOAs, and the EOAs’ effectiveness resolving problems.

**A correlational study on private or public self-consciousness, self monitoring and coping style**

CHI, L. (Beijing Sport University), ZHOU, X. (Beijing Sport University), YE, H. (Beijing Sport University)

This study attempted to investigate the relationship between private and public self-consciousness, self monitoring and coping style. One hundred and ninety six Chinese middle school students (96 male, 100 female) were invited and asked to fill in Private Self-Consciousness Scale and Public Self-Consciousness Scale (Fenigstein, Scheier, & Buss, 1975), Self-Monitoring Scale (Mark Snyder, 1974), and Coping Style Scale (CSS, Xiao, 1994). CSS consist of six subscales: problem solution, self-abuse, help seeking, fantasy, withdrawal, and rationalization. Significant differences exist between male and female students on three coping styles: self-abuse ($F(1,194) = 4.507, p < .05$), withdrawal ($F(1,194) = 5.80, p < .05$), and rationalization ($F(1,194) = 17.00, p < .001$). Significant differences were found between low- and high-private self-consciousness students on two coping styles: problem solution ($F(1,194) = 15.766, p < .001$), self-abuse ($F(1,194) = 4.986, p < .05$), help seeking ($F(1,194) = 4.986, p < .05$), and differences in help seeking tended to be significant ($F(1,194) = 3.879, p=.052$). Significant differences between low- and high-public self-consciousness students only exist on fantasy
coping style \(F(1,194) = 7.061, p < .001\). Between low- and high self-monitoring students, significant differences only existed on problem solution \(F(1,194) = 9.909, p < .01\) and tended to be significant on fantasy \(F(1,194) = 3.872, p = .052\). Significant correlations exist between public self-consciousness and fantasy, private self-consciousness and self-abuse, self-monitoring and help seeking. The conclusions drawn were that female students are more self abusive, withdrawn and rational, high-private self-consciousness students are more self abusive and problem solvers, high-public self-consciousness students use more fantasy, and high self-monitoring students are more problem solvers and help seeking.

Keywords: private self-consciousness, public self-consciousness, self-monitoring, coping styles, students

A criterion of social norm: Appropriateness of judgment as conflict resolution strategies

SHIMIZU, H. (Kwansei Gakuin University)

In this study, we attempted to reveal how people would judge appropriateness of interpersonal behaviors. Shimizu and Kosugi (in print) proposed a hypothesis that people would judge appropriateness of behaviors based on the Pareto principle that people should select the situation in which the benefits for all members are higher than in alternative situations. Also, they predicted that this judgment could vary with social relationship between agents. Kelley and Thibaut (1978) suggested that there were two main types of conflict situation. One is the situation where the selections that maximize the benefit of individuals reduce the benefit of the group (e.g. PD game: PDG). And another is the situation where there are two selections that maximize the benefit of group though it is unfair (e.g. Battle of sex game: BSG). We assumed that people would judge appropriateness of social behavior based on the Pareto principle in order to avoid conflict in both situations. This finding indicates appropriateness judgment as a strategy to resolve conflict situations. In this study, we investigated only individual’s judgment of appropriateness of social behavior. Therefore, we should investigate how people judge appropriateness based on consensual decision making.

Keywords: social norm, conflict resolution, judgement appropriateness, interpersonal factors, consensual decision making

A framework of global competence

TAK, J. (Kwangwoon University), SONG, C. (KAIST), KIM, C.M. (POSCO Research Institute), CHO, E.H. (Kwangwoon University)

This study was intended to identify a variety of global competencies for Korean companies. First, based on literature review and current competency list for major global companies across the world, common global competencies were drawn. In addition, for one of the major global companies in Korea, we conducted semi-structured interviews with executives who had overseas experience, FGI with high performers, and individual interviews with mangers who are working in overseas. A total of 29 individual interviews and three FGIs were conducted. Based on content analysis, a total of 17 global competencies were obtained. Definitions of each of the 17 global competencies were given to 140 high performers who had overseas experience, FGI with high performers, and individual interviews with mangers who are working in overseas. A total of 29 individual interviews and three FGIs were conducted. Based on content analysis, a total of 17 global competencies were obtained. Definitions of each of the 17 global competencies were given to 140 high performers who had overseas experience and asked them to rate the importance of each of the competencies with 5-point Likert scale and also select top five important competencies with a rank order. The results showed that human network and negotiation were shown to
be the most important global competencies and acceptance of different culture, adaptation of different culture, and customer orientation were followed in order. To become global talented employees, relation-related competencies appear to be more important than task-related competencies.

**Keywords:** global competence, Korea, culture, relation-related competencies, task-related competencies

A method to the sadness: Understanding the methods used to commit suicide

OVERHOLSER, J. (Case Western Reserve University), FISHER, L. (Case Western Reserve University), DIETER, L. (Case Western Reserve University)

Death by suicide occurs more often in males than females. It remains unclear as to how strongly these gender differences are influenced by the method used in the suicidal act versus other factors affecting these desperate individuals. The present study explores gender differences in suicidal methods, aiming to identify patterns that could improve our identification and triage of individuals at risk for suicide. The present study examined all cases of suicidal death that occurred in Cuyahoga County Ohio between 1994 – 2008. During the 15 year span, 1,745 males and 477 females committed suicide. Each case was coded for age, race, gender, marital status, method used to commit suicide, and blood alcohol levels at the time of death. All data were collected through the coroner’s office and coded for these demographic factors. Significant gender differences were observed in the method used to commit suicide (c2 (4) = 228.82, p < .001), with males more often using gunshot wound to a vital organ (52.0%), and less often using asphyxiation (23.7%), carbon monoxide (7.3%), or drug overdose (6.8%). In contrast, females relied on a more diverse pattern of methods, including guns (29.8%), overdose (31.4%), asphyxiation (20.9%), and carbon monoxide (7.9%). Significant gender differences were observed in the marital status of the deceased (c2 (3) = 35.94, p < .001). Among individuals who died by gunshot wounds, more females (45.1%) than males (38.3%) were single (c2 (3) = 8.13, p < .05). Likewise, among individuals who died by drug overdose, more females (23.3%) than males (52.9%) were single (c2 (3) = 29.89, p < .001). Additional analyses will explore gender differences in suicidal methods, in relationship to age, race, and blood alcohol levels at the time of death. By examining patterns of suicidal methods, it may be possible to improve our understanding of suicide risk and strengthen efforts at the secondary prevention of suicide. Secondary prevention relies on the accurate assessment and early intervention of high risk groups. The present findings help to refine our understanding of gender differences in suicide risk, and may help to promote different prevention plans for males versus females.

**Keywords:** suicide, gender, method, marital status, Ohio

A preliminary study for adaptability assessment in career counseling: Contribution to the paradigm for career construction

LIMA, M. R. (University of Lisbon), EDUARDA DUARTE, M. (University of Lisbon)

Adaptability is being one of the issues in focus in nowadays and specially in the context of the Life Design International Research Group. Coordinated by Mark Savickas, this Project has been formulating potentially innovative transnational measurements, namely the Career Adapt-Abilities Inventory. The life-design framework for counseling implements the constructivist approach addressing to who aim to help people develop their working lives (Savickas et. al., 2009). The present study aims to assess a measurement of adaptability construct for counseling setting. Supported by the Career Adapt-Abilities Inventory, a counseling version was developed, attending to what concerns adults and young adults during the career counseling. Thus, six items for each of the five adaptability “C’s” were defined: concern, control, curiosity, confidence and commitment. This measurement was answered through email by 43 Psychology graduation students and recently graduated ones. The aim is to investigate if the items are or are not good indicators of adaptability assessment in counseling context. Therefore, reliability and validity analysis with this preliminary version are
provided and data presented. High reliability is illustrated through Cronbach’s Alpha coefficients, with values between 0.72 and 0.82. Further analysis were carried out with the Hierarchical Cluster Analysis (Spearman Coefficient plus Complete Linkage model), the Rank Analysis and the Principal Component Analysis used on the similarity matrix obtained with the coefficient’s LC. The results seem to support a major factor of adaptability and, on the other hand, some of the items need to be eliminated or revised (also corroborated by the Cronbach’s Alpha if item deleted analysis). Given the globalization of career counseling, Life Design research is important since it addresses issues about adaptability and formulates potentially innovative responses (in terms of assessment and intervention) in an international forum. Considering data implications, next steps and research developments are discussed.

Keywords: adaptation, Career Adapt-Abilities Inventory, career counselling, life-design framework, assessment

A project of persuasive communication toward public transportation-oriented-residential choice

TANIGUCHI, A. (University of Tsukuba), FUJII, S. (Kyoto university)

Recently, it has been discussed that development of “compact city” where various types of urban facilities are highly densely would solve various types of traffic and environmental problems. Compact city would be formed if people choose their residential places in city center or near railway stations or bus stops where they do not have to use car. Therefore persuasive communication to induce people’s residential choice in such places where car are not always necessary is a substantially-effective transportation measure to solve various types of urban transportation problems through developing compact city. The objective of this project is to develop a persuasive communication program to induce public-transport-oriented residential choice (PTOR choice) through field experiment. We implemented an experiment that targeted students in university of Tsukuba, Japan, who were about to change their flats. They were randomly assigned into four groups; the first group was a control group, the second group was provided with information brochure about flats that has been commonly used in Tsukuba city, the third group was provided with a brochure that is identical with one for the second group except for a point that information about level of bus service for every flat was added, and the fourth group was provided with a leaflet to motivate PTOR choice in addition to the brochure used for the third group. Residential places were investigated 5 month after the interventions, and we found that no difference of PTOR choice between the control and the second group but significant difference between the control and the third group, and the control and the forth group. It was shown in the result that just information about level of bus service for every flat can induce PTOR choice, and the ratio of PTOR choice in the group with the information was twice as high as the control group. The persuasive message to induce PTOR choice was also found to contribute to increase PTOR choice. These results imply that simple intervention, that is, inclusion of information about level of bus service for every flat can effectively induce PTOR choice, that is necessary for development of compact city, and explicit persuasive message was also effective. Since the cost of these interventions was limited, this can be easily implemented in any universities, any workplaces, and house agent offices. Since PTOR choice would lead less car use, this proposed communicative intervention could be regarded as substantially effective transportation measure.

Keywords: compact city, persuasive communication, transport, communication

A relationship between perceived apathy and mental health among Japanese university students

OSANAI, Y. (Taisho University)

Apathy felt by healthy individuals has been studied from the perspective of depression without empirical research. However, Osanai (2009) coined and classified the term “perceived apathy” to refer to the apathy subjectively felt by healthy individuals. The aim of this study was
Abstracts of the 27th International Congress of Applied Psychology

Electronic Poster Presentations

to find out the relationship between perceived apathy (Domain-General Apathy: DGA and Domain-Specific Apathy: DSA) and mental health (depressive tendency) among healthy university students. Participants were 215 Japanese university students (110 male, 105 female). To measure DGA, "Method of measurement for subjective strength of perceived apathy with single item: MSPS" was used. To measure DSA, the 10 items for the DSA of Japanese university students developed by Osanai (2009) were used. To measure depressive tendencies, “The Depression and Anxiety Mood Scale” developed by Fukui (1997) was used. Results indicated that there was a significant correlation between DGA and depressive tendencies ($r = .516, p < .001$). In addition, there was a significant correlation between the DSA item “self-improvement lectures (such as language schools etc.)” and depressive tendencies ($r = .140, p < .05$). To conclude, DGA was correlated with depressive tendency. However, DSA items were not correlated with depressive tendency. These results suggest that DGA represents a kind of symptom of depression but DSA does not.

A review on research and task in “ibasho”

NAOTO, Y. (Chuo University)

"Ibasho"(existential place) is the word with the physical meaning called "the place where a person is", but “ibasho” comes to be used in a meaning including the psychological condition when I am in the place such as "the place that can be relieved" recently. The study about “ibasho” came to be performed flourishly from 1990's. However, it is the present conditions that various studies are performed because there is not yet the definition of an established “ibasho”. The purpose of this study was to review previous studies on "ibasho" from 1990 and point out the task in the study of “ibasho” for making “ibasho”. In the Scholarly and Academic Information Navigator (CiNii) of the National Institute of Informatics, I searched documents from 1990 to 2008 in keyword called “ibasho” and the object documents were an available article and a book about the “ibasho”. I took 43 studies as an object of this study. Based on the review, the six tasks in the study of “ibasho” were pointed out. The first point is introduction of a viewpoint capturing the individuals has the whole of “ibasho”. The second point is to use the definition to express an actual “ibasho”. The third point is to clarify “ibasho” and its connection with the school refusal. The fourth point is to have to examine in detail about a relationship with another person and “ibasho” and “ibasho” without other people. The fifth point is examination of the making of “ibasho”. The sixth point is to clarify which psychological function of “ibasho” it is got in what kind of “ibasho”. It was suggested that a meaning is really connected for the making of “ibasho” for children because a study is accumulated about these points.

Keywords: ibasho, existential place, children

A study defining HASL life insurance index and analyzing its Influence on insurance intention of consumers

LINZHI, D. (Nankai University), GUIHUA, L. (Nankai University)

The aim of this paper is to explore main cognizing factors which may influence consumer’s insurance purchasing intention, analyze deeply the cognitive level and need types about insurance life of consumers, and study the relation between them. This study utilized The Questionnaire of HASL Life Insurance Index which was designed by ourselves, and investigated 5802 consumers of 12 cities in P.R. China. By exploratory factor analysis, six key factors were found to influence consumer’s purchasing desire, such as Professional Advice Recognition, Industry Impression, Risks Perception, Concerning the Society, Financial Prospect, Relationship between Caring and Insurance, etc. By correlation analysis, there is significant correlation between insurance purchasing intention and six-Cognitive Factors of consumers. By T-test, there is significant difference between high and low of 6-Cognitive Factors about their insurance purchasing intention. By multiple regression analysis, this
A study of community informatization activities building wireless community networks in England and Germany

ISHIMORI, M. (Kyoto Koka Women’s University)

The activity of Wireless Community Networks is one of the grass root informatization activities to bridge the digital divide in local communities, by using wireless LAN techniques. The most significant feature of Wireless Community Networks is that the network is community-owned and community-run by volunteers. The aim of this study is to understand the current state of, and problems in, managing Wireless Community Networks in England and Germany. A case study of five Wireless Community Networks in England and Germany was conducted. Semi-structured interviews were used for the founders or core members of these Wireless Community Networks. Interviews were taped and transcribed. The transcription was analyzed by constant comparative methodology. The case study of five Wireless Community Networks in England and Germany showed that Wireless Community Networks were playing an important role in solving the digital divide issue in local communities, especially in deprived areas. Open-source movement, which is a movement to share the source code and the benefit of free computer software with each other, helped voluntary members of Wireless Community Networks by supplying useful technical information and support. Furthermore Wireless Community Networks can empower people who are suffering from social exclusion by providing them with opportunities to own low cost internet access at their home and sufficient training to make the most use of it. The results of the study suggest that a project of Wireless Community Networks can be carried out with low cost, therefore, it can be also useful for local informatization activities in developing countries.

Keywords: wireless community networks, community, digital divide, informatization, case study

A study of difficult cases for school counselor – focusing on how to work with parents

FURUYA, M. (Yamanasi Prefecture School)

Previously, several case studies about relationships between parental and child change have been reported, however, most of these studies focused mainly on successful cases, not difficult cases. In this research two studies were conducted. The purpose of the first study was to clarify difficulties of school counselors and how to deal with those difficulties. The second study was to explore difficulties of school counselors when they work with parents. Prior to these studies, a questionnaire was sent out to approximately 70 school counselors, to find out whether they have had difficult cases and how they feel about those difficulties. Based on the results of the questionnaire, the first study consisted of semi-structured interviews conducted with 5 participants that have or have had experience as school counselors. In the second study, the semi-structured interviews were conducted with 9 participants. The data of both studies was analyzed by qualitative analysis, using the KJ method originating in Japan. In these studies, a course of how difficulties experienced by school counselors were created was indicated. Several factors

Keywords: insurance purchasing intention, HASL life insurance forecast model, cognition, risk perception, education
were found that might influence the difficulties of the school counselors. Such factors included the motivation in parents or the ability to actually care for the child, a teacher’s lack of energy or the inability to connect with the child because of past experiences, school counselors themselves, and relationships of the people surrounding children with issues. In addition, a new concept, “relationship-connector”, was found. This indicated a function of school counselors as a modifier of relationships and an adjuster of roles for the people surrounding the children. In conclusion, difficulties of school counselors were related to how the relationships of the people surrounding the children were developed. To work effectively as a school counselor, it might be significant to take the role as “relationship-connector”, which not only enhances the relationship between the people surrounding the children with issues, but also establishes partnerships among them. Furthermore, school counselors need more training and appropriate supervision to grow as a profession.

Keywords: school counselors, difficult cases, working with parents, children, relationship-connector

A study of implicit knowledge of creativity in China

CHOE, I.S. (Sungkyunkwan University), PYO, J.M. (Sungkyunkwan University), KIM, Y.H. (Sungkyunkwan University)

This research investigated the implicit knowledge of creativity in China. One hundred and twenty eight Chinese (63 men and 65 women) completed open-ended questionnaires on two questions. The two questions were “what do you think are the characteristics and behaviors of creative people?”, and “who are the most creative people in China?” The results showed that, firstly, Chinese people in general have positive perceptions of the concept of creativity. “Smart” was listed as the most salient characteristic of creativity. This means that intelligence counts most in Chinese implicit knowledge of creativity. The traits of “positivity”, “daring”, “having lot of ideas”, “kind”, “having lots of knowledge” “original”, “weird”, “imaginative”, and “active” made up the ten most cited characteristics. Males and females had almost same implicit knowledge of creativity, but differences were found between generations, with new generations expressing more negative factors. Regarding the second question, artists/entertainers and politicians were nominated as the most creative in the list followed by scientists/inventors, businessmen, writers, and philosophers/educators. Artists/entertainers were nominated mostly by the new generation and politicians were nominated mostly by the older generation. It seems that with the increasing interaction with Western countries via international events such as the Beijing Olympics, Chinese people are naturally exposed to the concept of creativity..

Keywords: creativity, implicit knowledge, creative people, characteristics of creative people, China

A study of the relationship between happiness and creativity among girl high school students in Karaj

REZABAKHSH, H. (Islamic Azad University), YARMOHAMMADI, F. (Islamic Azad University), FARROKHI, N. (Allameh Tabatabai University)

The purpose of this investigation is to determine the correlation between happiness and creativity among girl high-school students in Karaj. The sample in this study consisted of 400 girl, high-school students, who were chosen by a multiple phase cluster random sampling procedure. Two inventories were used: The Oxford Happiness Inventory (Revised Text, 2001) and the Abedi Creativity Inventory (1993). The findings suggest that happiness can predict creativity and its components, both significantly and positively ($p<0.001$). To conclude, the final results confirmed research hypotheses and the effect of happiness on creativity and its components.

Keywords: happiness, creativity, high-school, females

A study on career decision-making strategies among Chinese college students under competition pressures

LI, S.Q. (Tsinghua University)
Nowadays, college students are facing great pressures during their job-search process in China. In a society where the number of job applicants is much higher than the job opportunities, competition is one of the major pressures. We are therefore interested in the strategies that students use to find a job in such conditions, and to better understand the job-searching behaviors among Chinese graduating students. In this ongoing study, based on the framework of stress and coping (Folkman & Lazarus, 1985), we will explore students’ career decision-making strategies under diverse levels of competition pressures in China. Three hundred participants have been recruited from various college levels in Beijing, China, and asked to complete a package of inventories to assess the levels of perceived competition pressures, career decision-making strategies (comprising of rational, intuitive, and dependent factors (Harren, 1979)), as well as demographic variables. First, independent sample-t test and ANOVA will be conducted to examine the differences of perceived competition pressures and career decision-making strategies between gender groups, as well as various major groups. Partial correlation analyses will be conducted to explore the relationship between competition pressures and career decision-making strategies after controlling for gender and major variables. The results and conclusions will be presented at the conference. Moreover, the implications and limitations of the study will be discussed.

Keywords: career, decision making, competition pressures, college students, stress coping

A study on development and effect of rating scale for hospitality

NISHIURA, K. (Miyagi-Gakuin Women’s University), TAYAMA, J. (Nagasaki University)

The purpose of this study was to develop a rating scale for hospitality, and to measure its effect. The term “hospitality” resembles emotional labor including the understandings of emotion. In Japan, three concepts of hospitality are generally defined as “Mekubari”, “Kikubari”, and “Kokorokubari.” Mekubari is to keep a careful watch. Kikubari is to consider other’s feelings. Kokorokubari is to give consideration for other people. Two hundred and seventy nine female subjects, who were women’s university students, participated in a survey questionnaire. The questionnaire consisted of 73 items in a preliminary research stage. After deleting items as a ceiling and floor effect, we conducted a factor analysis. The results of factor analysis showed that 3 factors existed in hospitality. The factors of hospitality were named “cognitive dimension”, “emotional dimension”, and “behavioral dimension.” In addition, we investigated the validity of the rating scale for hospitality in correlation among “Perspective” in multi-dimensional empathy scale, “Emotional Warmth” in emotional empathy scale, and prosocial behavior scale. Three factors were positively correlated with them. Accordingly the validity of our scale was confirmed. Moreover, we developed a screening test of hospitality, which each consisted of 3 items in cognitive, emotional, and behavioral dimensions. We concluded that we could measure differences among individuals for hospitality.

Keywords: hospitality, rating scale, cognitive dimension, emotional dimension, behavioral dimension

A study on the factors influencing mental resilience and social adaptiveness

FUJIWARA, T. (Nagasaki Junshin Catholic University), YOSHITAKE, K. (Nagasaki Junshin Catholic University), YOSHITAKE, Y. (Kyushu University), FUJIWARA, H. (NPO ECO Check Network Japan)

Interpersonal trust in individuals is associated with their social adaptiveness and is said to have an effect on mental health. To deal with negative feelings, mental resilience is also needed. This study examines the relationship between confidence, mental resilience, and stress coping, and clarifies the factors that are closely linked with social adaptiveness. These factors contribute to enhancing mental resilience, which may be particularly beneficial to young adolescents in Japan, who tend to be less adaptive to the environment. A questionnaire survey was conducted among 98 female college students (mean age 20.1) by asking 75 items: confidence scale, mental resilience scale, stress management scale, negative event scale, etc. The mental resilience
was evidently higher in those having higher confidence in oneself and others than those having lower confidence, when analyzed in two separate groups. After reviewing the correlation between confidence and stress coping, those with high confidence could recognize things positively and distract themselves adaptively, while those with low confidence were inclined to avoid confronting the problems. Therefore, to develop confidence in oneself and others strengthens mental resilience. Also, stress management is found to be one of the important deciding factors for adapting oneself to circumstances healthily as well as to keep one’s mental conditions normal.

Keywords: mental resilience, social adaptiveness, adolescents, Japan

A study on the influence of emotionality of temperature on self-esteem in 3 to 5 year old children

WEN, L. (Liaoning Normal University), RILE, H. (Liaoning Normal University)

This research studied the influence of emotionality of temperature on self-esteem in 3 to 5 year old children. The sample consisted of randomly selected 90 children aged from 3 to 5 who come from a normal kindergarten. The research used a questionnaire and the experimental method, using Physical Polytrophic Recording to measure the different physiological dates of different self-esteem. The results indicated that: there is a close relation between 3 to 5 year-old children’s temperament and self-esteem. Emotionality has a significant negative correlation with self-esteem. Significant differences existed in different levels of self-esteem. The regression shows that the emotionality of temperament influences levels of self-esteem.

Keywords: temperament, emotionality, self-esteem, influence

A study on the learning process of psychological assessment techniques

MORITA, M. (Nagoya University), IWAI, S. (Nagoya University)

It is profitable for students who are trained on psychological assessment techniques to begin with their own experience as “testee”. “Testee experience” brings them empathic understanding of the clients’ situation, higher motivation for practice, knowledge of a clinical psychologist on-the-job, and so on (Morita and Nakahara, 2004). The purpose of this study is to demonstrate the significance of “testee experience” from the viewpoint of clinical psychologists who undertake the test for students. The authors have introduced “testee experience” into a practice class of the Rorschach test at the university. 55 certified clinical psychologists have participated as a tester from 1998 to 2004, and 47 testers answered a questionnaire about “testee experience for students”. The questionnaire consisted of the following issues: 1) tester’s age, gender, number of times that he/she has undertaken the Rorschach test on students; 2) What and how students learn through testee experience?; 3) Which is an important aspect of testee experience?; and 4) What was a tester concerned about at test administration? Testers were divided into 2 groups based on their age. Group 1 includes 24 testers under 40 years old, and group 2 includes 23 testers over 40 years old. In group 1, all testers except one had their own testee experience. While in group 2, only one tester had taken the test administrated by an expert. As the results of the comparison between the 2 groups show, more testers in group 1 focused on “how does a non-patient respond to the ink-blot?”, “how properly can the tester administer the test?”, and “how does each student behave toward tester and test situation?”Regardless of age and past experience, majority of testers considered that it is important for students to learn the “inner experience of clients” and “arising process of Rorschach response” form their testee experience. As the results of this study show, the significance of “testee experience” was revealed. Senior clinical psychologists tend to focus on how students understand the inner experience of clients or patients. These results might be important for education and training of psychological assessment techniques in clinical psychology classes.

Keywords: testee experience, training, psychological assessment, Rorschach test
A survey investigating post-incident debriefing and psychological wellbeing in emergency service personnel

PATERSON, H. (University of Sydney), BRYANT, R. (University of New South Wales), KEMP, R. (University of New South Wales), KIRKPATRICK, T. (New South Wales Fire Brigades)

Emergency service workers are commonly exposed to traumatic events that may affect their psychological wellbeing. In an attempt to protect them against PTSD, many personnel are required to attend debriefing sessions following exposure to traumatic events. Critical Incident Stress Debriefing (CISD) is the most common form of post-incident debriefing employed both within Australia and around the world. However, there is little evidence concerning the efficacy of CISD. The aim of this research was to explore current debriefing practices within the NSW Fire Brigades and investigate the knowledge, attitudes and opinions of the employees to these practices. In order to do this we surveyed a stratified sample of firefighters from the NSW Fire Brigades about (a) the prevalence and nature of exposure to traumatic events, (b) levels of stress reactions, (c) coping strategies, and (d) attitudes to current stress management strategies. The results from the survey indicated that firefighters are exposed to a range of stressful situations and that they use a variety of different coping mechanisms to help deal with the stress that they experience. Some firefighters were happy with the current debriefing processes, while others recommended changes, such as varying the debriefing strategy to suit the individual’s specific needs. The results of this survey will inform the development of new post-trauma interventions designed to meet individual needs. Findings from this research have important implications for emergency service organisations throughout the world.

Keywords: debriefing, stress, coping, trauma, interventions

Academic contingency of self-worth and academic achievement in Japanese young adolescents

OHTANI, K. (Osaka University), NAKAYA, M. (Nagoya University)

This study examines how Japanese young adolescents are affected by their academically based self-worth. Academic contingency of self-worth (ACSW) represents the degree to which one stakes one’s self-worth on academic achievement. The past studies on this subject generally focused on the negative effects of pursuing self-worth on academics, yet the researchers have not reached clear conclusions. While Park, Crocker & Kiefer (2007) have demonstrated that ACSW was detrimental in the cases of academic failure in college students, other studies indicated that ACSW played a key role as motivation for academic success in young adolescents (Osborne, 1995). The present study examined ACSW’s effects on academic achievement during one academic semester by conducting 3 successive questionnaire surveys. One hundred and twenty eight junior high school math students participated in the study. The first questionnaire was given to students one week before their mid-term exam and assessed their ACSW, trait self-esteem, pre-test motivation and expectation for the mid-term exam performance. Feedback from the mid-term exam was given to each student, which was then immediately followed by the second questionnaire assessing state self-esteem. The third questionnaire was given one week after the final exam and assessed post-test motivation. Students were divided into 2 groups (success or failure) according to the mid-term results. In the failure group, high ACSW students showed vulnerability as evidenced by a significant drop in state self-esteem. This negative effect was not as significant in low ACSW students in the same group. In addition, ACSW in the failure group did not appear to have a significant effect on post-test motivation as well as the final exam. On the other hand, in the success group, students with high ACSW predicted higher post-test motivation and final exam grade than those with low ACSW. While other studies on the effects of ACSW have shown similar drops in self-esteem for students who experience failure, this study indicates a significant boost in motivation for students who have succeeded academically. Future research should be aimed at identifying the educational
condition on which the effects of ACSW are more beneficial for effective motivation.

Keywords: academic achievement, self-worth, adolescents, academic contingency of self-worth, students

Accommodation motivation moderates group-level dissonance

LEUNG, A.K.Y (Singapore Management University), AU, E. (Singapore Management University), CHIU, C.Y. (Singapore Management University)

Group dissonance describes a state of psychological discomfort that arises from an interpersonal source (e.g., an individual holding a position discrepant from that of the group). Recent research has shown that group-level dissonance reduction may explain conformity in small group settings (Matz & Wood, 2005). The present research shows that the motivation to accommodate may moderate group-level dissonance, such that only accommodation-motivated individuals, probably due to a strong desire to align personal and group opinions, would experience group dissonance. In Study 1, we validated a newly developed individual difference measure of accommodation motivation (AMS) and used a scenario to test the relationship-specificity hypothesis: only micro-accommodation motivation should predict yielding to the influence of a close friend, whereas macro-accommodation predicts yielding to a pressure group in one’s institution. Study 2 showed that accommodation motivation predicted higher likelihood of opinion shift and greater intensity of dissonance discomfort when participants were exposed to disagreeing others in a group discussion setting with low situational demand for conformity (when they needed to discuss only). This research extends previous literature by identifying accommodation motivation as another individual difference moderator of group-level dissonance. The idea that people may willingly accommodate to others’ concerns and preferences challenges the entrenched assumption that accommodation always undermines autonomy.

Keywords: group-level dissonance, accommodation motivation, individual difference measure, opinion shift, dissonance discomfort

Acculturation strategies at educational work

TABERNERO, C. (University of Cordoba), BRIONES, E. (ERCOMER University of Utrech), ARENAS, (University of Seville), CUADRADO, E. (University of Córdoba)

Every day, organizations become more competitive and culturally diverse which necessitates the development of new skills. The present study analysed the role of cultural regulatory and dispositional variables such as self-efficacy, leadership and cultural intelligence, to determine acculturation strategies across four experimental scenarios created with fictitious newspaper articles. Six hundred and thirty eight teachers (120 from Venezuela, 80 from Portugal and 438 from Spain) participated in this study (Mean= 37.20 years old; SD=9.95). 34.2% were males and 65.8% females. Cultural Intelligence consisted of 20 items to assess personal ability to adapt successfully to different cultures (a=.91) in a 5-point Likert scale. Cultural Self-efficacy consisted of 25 items (5-point Likert scale) allocated in 5 factors. Positive and negative affect composed of 20 items with a 5-point Likert scale, 10 items analyzed positive affect (a=.87; e.g., interested) and 10 items analyzed negative affect (a=.86; e.g., sad). Cultural Leadership consisted of 10 items (5-point Likert scale)
scale; a=.80). The results showed interactions between three regulatory variables and ethnocultural origin within an ANOVA. Cultural self-efficacy played a main effect on the acculturation strategies adopted. Teachers from Venezuela, Portugal and Spain show different cultural self-regulatory mechanisms, probably because of their different immigration processes. Teachers in Dual Identity Scenarios feel more identity with acculturation strategy followed by immigrant students, more positive effect, less negative effect, and a more task-oriented leadership than teachers in other scenarios. Cultural self-efficacy, cultural intelligence, positive effect, and cultural leadership, as self-regulatory variables, were shown to be related to how teachers identify the acculturation strategy followed by an immigrant student. This is important, especially in marginal identity situations, where teachers should put into practice their skills to cope with cultural diversity. Since a dual identity is linked with a better psychological and sociocultural adaptation, we consider that empowering self-regulatory variables (cultural intelligence, cultural self-efficacy, cultural leadership, and positive affect of teachers), could influence the adaptation of immigrant students, because they would feel more oriented and supported to develop a dual identity.

Keywords: acculturation strategies, cultural intelligence, leadership, self-efficacy, teachers

Achievement of outcomes is not necessarily prioritized in children’s’ imitation of gestures

MIZUGUCHI, T, (Iwaki Junior College), SUZUKI, H. (Iwaki Junior College), DEGUCHI, T. (Tokyo Gakugei University)

A central idea in the study of imitation behaviors in children is that imitation is goal-directed. That is, in a process of imitation-specific goal selection, achieving an outcome (e.g. push a switch) takes priority over correctly copying the actions (effector or movement path) necessary to achieve that outcome. This study challenges the validity of this theory by directing children to systematically imitate a more complex action model and investigates the factors that affect the occurrence of error responses. 32 children (M: 5 years 11 months; age range: 5 years 2 months to 6 years 10 months) were instructed to imitate an action model that systematically combined three elements: effector (left and/or right hand), movement path (left and/or right side), and object (ear and/or shoulder), so that there were 20 variations of touching the right and/or left hand(s) to the left and/or right ear(s) and/or shoulder(s). Actions and imitation responses were collated by element. Elements that did not match were considered error responses. The K-ABC (Kaufman Assessment Battery for Children) was administered after completion of the imitation tasks to measure hand movement and spatial memory. Friedman test results showed that error responses varied by element ($\chi^2 = 27.32$, $p < .01$) and post hoc comparisons (Wilcoxon test) indicated that there were more errors for movement path than object ($z = -3.02$, $p < .01$) and for object than effector ($z = -2.72$, $p < .01$). Multiple regression analysis showed that error responses were not predicted by the factors of age, hand movement, or spatial memory. To conclude, the data show that the number of error responses varied by element, and the finding that there were less error responses for effector than for object does not support a goal-directed theory of imitation. This corroborates recent studies that state that error response patterns depend on the characteristics of the task to be imitated. The data also indicates that age, hand movement, and spatial memory skills are not closely related to the type of imitation task in this study.

Keywords: imitation behaviours, children, goal setting, task characteristics

Adaptation of job survey among French firefighters

MARIEN, P. (University of Bordeaux), AUVERT, L. (Service Départemental d’Incendie et de Secours de la Gironde), PORRAS, J. (Service Départemental d’Incendie et de Secours de la Gironde.), MICHEL, G. (Université Victor Segalen)

The aims of the current study were: i) to adapt an on the Job Stress Survey assessing the perceived stress among French Firefighters, where the organizational pressure will be considered; and ii) to study the relationship between these components and the symptoms
of three-dimensional BO as envisaged in the Maslach Burnout Inventory. In the current study, 383 firefighters have so far completed the following questionnaires: the "Job Stress Survey" adapted to firefighters (SP-ESP; Marien, Auvert & Michel, 2009) The Maslach Burnout Inventory French version (MBI; Dion & Teissier, 1994). Exploratory Factor Analysis with the method of unweighted least squares (AFE) with promax rotation was allowed to retain 26 items on the 53 original items in the scale frequency and intensity. Among these items, 20 are sub-scale "Organizational Pressure" and 6 "operational work". Each of the scales and subscales has satisfactory internal consistency with Cronbach's alpha ranging from 0.8 to 0.9. Confirmatory factor analysis (CFA) verifies the reliability of the psychometric tool. The correlational analysis of this tool links between perceived stress and symptoms of BO. In addition to presenting satisfactory psychometric qualities, the scale relevant to the job of firefighters can identify the stress factors specific to this work. Thus, through it, understanding the etiology of BO is favored because it respects the environmental constraints. This gives the opportunity to implement prevention programs or intervention respecting both the complexity of the work environment that individual’s perception.

Keywords: job stress survey, firefighters, organizational pressure, work environment

Adolescent male depression: Attachment and the importance of peer support

ZAPRAL, A. (Deakin University), MILLER, R. (Deakin University)

This project examined the influence of perceived peer and parental support on male adolescent wellbeing. It also aimed to investigate a possible age-related effect in the influence of perceived peer support on adolescent depression and two personality factors found to influence depression, namely Certain Self-Identity and Sense of Belonging. It was expected that perceived peer support would have a negative relationship with adolescent depression. Perceived peer support was expected to influence adolescent depression via a positive relationship with the personality factors. Both Certain Self-Identity and Sense of Belonging were expected to have a negative relationship with depression. Participants were 129 year 7 and 130 year 10 male students from a private boys’ school in regional Victoria, Australia. Participants completed an anonymous questionnaire including scales from the Mood and Anxiety Symptoms Questionnaire (Watson & Clark, 1991), to measure anhedonic depression; the Adolescent Personality Instrument (Thomas, 2005), to measure the personality constructs: Certain Self-Identity and Sense of Belonging; the Child and Adolescent Social Support Scale (Malecki, Demaray & Elliott, 2000), to measure perceived support from teachers; and the Parental Bonding Instrument (Parker, Tupling & Brown, 1979), to measure attachment to and support from mothers and fathers. Year 7 and Year 10 data sets were analysed separately via path analysis. One model included Certain Self-Identity in the pathway from support to depression; a second model used Sense of Belonging in the pathway to depression. Results indicate that peer support is more important to wellbeing in younger male adolescents. Contrary to what was expected, mothering exerts a significant effect on both Year 7 and Year 10 male adolescents. Mothering has important influences on Certain Self Identity for male adolescents. Peer support exerted some influence on the personality variables Certain Self Identity and Sense of Belonging, which were negatively correlated with depression. The effects of all risk factors, excluding fathering, were strongest on the younger adolescents. This is in contrast to results found by Jelley (2005) using an all female sample.

Keywords: adolescent male depression, attachment, peer support, parental support, depression

Adolescents’ beliefs about the legitimacy of parental authority and their obedience: The moderating effect of parent-adolescent relationships

LIU, Y.L. (National Chaio-Tung University)

Based on the Domain-Specific Model of Social Cognitive Knowledge, this study investigated the moderating effect of father-child and mother-child relationships on the relationship between
adolescents’ beliefs about the legitimacy of parental authority, their own obligation to obey and their obedience in different social domains. Participants were fifth graders (N=201), seventh graders (N=244), and tenth graders (N=249) from Northwestern area of Taiwan (Total N = 694; Boys, N = 359). They were asked to complete the questionnaires including Parental Authority Questionnaire (Liu, 2009) and Parent-Adolescent Relationship – Father vs. Mother Version (Gongla & Thompson, 1987). Repeated-measures analysis of variance and hierarchal linear regression were used to analyze the data. The results of ANOVA indicated that the younger the adolescents, the more reasonably they believed parents have legitimate authority, and the greater degree of their obedience. There was no gender difference on the beliefs about legitimate authority, although girls were more likely to obey the authority than boys. Adolescents agreed mostly that parents have authority on prudential and conventional issues, but agreed least on friend issues. Moreover, the results of regression analysis indicated that beliefs about the legitimate authority and obligation to obey significantly predicted adolescents’ obedience and explained the major variance of obedience regardless of the domains. Father-child vs. mother-child relationship both predicted adolescents’ obedience in the academic domain; father-child relationship uniquely predicted adolescents’ obedience in the multifaceted domain; mother-child relationships uniquely predicted adolescents’ obedience in moral and conventional domains. There were interaction effects between mother-child relationships and beliefs about the legitimate authority on conventional, moral, prudential, friend and personal domains, and between father-children relationship and academic domains. This study found that adolescent beliefs about legitimate authority and obedience decreased with increasing age. Beliefs about legitimate authority and obligation to obey mainly explained obedience. Adolescents’ relationships with fathers and mothers moderated the relations between beliefs about legitimate authority and their obedience in different domains.

Keywords: adolescents, parental authority, obedience, parent-adolescent relationship, authority

Adult attachment, coping style and job burnout among Chinese maritime rescuers

Li, T. (Peking University), Zhai, J. (Ministry of Transport of the People’s Republic of China), Guo, Y. (Peking University), Deng, S. (Ministry of Transport of the People’s Republic of China)

The aim of this study was to explore effects of adult attachment and coping style on job burnout in Chinese maritime rescuer. Two hundred and eighty maritime rescuers from east China were administered with a series of questionnaires, including Experiences of Close Relationship Inventory (ECR, Brennan, et al., 1998) for measuring adult attachment, Chinese Coping Style Scale (Shi, et al., 2002), and Maslach Burnout Inventory-General Survey (MBI-GS, 1997) for measuring job burnout. The results suggest that attachment avoidance is significantly related to three indices of job burnout, and attachment anxiety has positive correlations only with “emotional exhaustion” and “depersonalization”. With regard to coping style, “denying the problems and mental disengagement” and “avoiding the problems and shifting attention” had negative correlations with three indices of job burnout, while “active coping focused on the problems” were correlated to “depersonalization” and “reduced personal accomplishment”. Attachment avoidance was significantly related to coping style, while attachment anxiety was only related to “denying the problems and mental disengagement” and “avoiding the problems and shifting attention”. Hierarchical regression analysis showed that coping style had a moderate effect between adult attachment and job burnout. Maritime rescuers’ job burnout can be predicted by their attachment orientation and coping style. Furthermore, coping style plays a moderate role between adult attachment and job burnout.

Keywords: adult attachment, coping styles, job burnout, Chinese maritime rescuers, attachment avoidance

Affective and psychophysiological assessment of anti-gay and anti-lesbian bias in a sample of Brazilian citizens

Keywords: adult attachment, coping styles, job burnout, Chinese maritime rescuers, attachment avoidance
LASAITIS, C. (Departamento de Psicobiologia - UNIFESP), RIBEIRO, R.L. (Universidade Federal de São Paulo), BUENO, O.F.A. (Universidade Federal de São Paulo)

The aim of this study was to explore the effects of sex, sexual orientation and declared social distance toward gays and lesbians by the analysis of self-report affective ratings and physiological responses to homosexual and heterosexual visual stimuli. Thirty nine Brazilian young adults [18 males (9 homosexuals/bisexuals); 21 females (11 homosexuals/bisexuals)] were recruited for individual sessions. Each subject viewed a set of 40 standardized pictures [8 depicted heterosexual (HT), 4 gay (G) and 4 lesbian (L) couples]. During the visualization of each picture, physiological measures (skin conductance, peripheral temperature, corrugator and zygomatic electromyography activity) were recorded, and the subjects rated each picture in the dimensions of valence, arousal and dominance. The affective ratings and physiological scores were compared between groups by ANOVA and Kruskal-Wallis tests (level of significance: 5%). G and L stimuli received lower ratings of pleasure than HT from the heterosexual sample, whereas the homosexuals/bisexuals rated all the sexual stimuli as equally pleasing \(F(2,615)=62.15\). Men were more sexually biased against G, whereas women were nonspecific in the ratings of G and L \(F(2,615)=4.78\). L stimuli were rated as highly arousing and elicited greater galvanic responses and zygomatic muscle activity in male heterosexuals compared to homosexuals/bisexuals. Lower ratings of dominance were given by the heterosexuals when viewing G, and homosexuals/bisexuals when viewing HT stimuli, specifically \(F(2,614)=23.04\). The group who declared social distance toward gays and lesbians evaluated more negatively L and G, but also HT stimuli, when compared to non-biased heterosexuals [Kruskal-Wallis H(2,311)=7.48 for valence]. Negative evaluations of L and G stimuli were detected only in the heterosexual sample, and were more negative for heterosexuals who reported a level of social distance toward gays and lesbians. Anti-gay bias was more salient and specific in male heterosexuals, whereas the females tended to show a slight and nonspecific bias toward homosexuality. The positive ratings of L stimuli suggest the eroticization of lesbians by heterosexual men. The dominance dimension showed specificity for sexual orientation and suggests that homophobic attitudes may be associated with low-dominance emotions (e.g. fear), giving support to the defensive nature of homophobia.

Keywords: gay, lesbian, homosexual bias, sexual orientation, homophobia

Airmanship and seamanship: Can one model encompass both professions?

CARRICK, K. (University of Newcastle), BELLMAN, J. (University of Newcastle), PITTMAN, N. (University of Newcastle)

Airmanship and seamanship are frequently used terms within their respective domains yet there appears to be no real consensus on a universal definition, nor any empirical research supporting their usage. This research aims to compare the views of experts in each field with the theoretical model of airmanship developed by Kern (1997). Based on discussion among pilots in the USA, the model’s applicability in an Australian aviation environment and its relevance to seamanship were of interest, along with the experts’ views on the development of exemplary airmanship and seamanship. Twelve Australian experts from the aviation and maritime industries were interviewed, five from the aviation industry, five marine pilots and two marine consultants. Mean years of experience among the aviation experts was 34.1 years, and 33.9 years for the marine experts. The transcripts were analysed on paper and by using NVivo8, extracting themes and concepts raised in discussion, with an initial structure based on the Kern model. The concepts of airmanship and seamanship were found to encompass a much more complex array of skills and attributes than are expressed by existing definitions. Most of the major themes identified by the expert aviators as essential in the understanding of airmanship were also discussed by the mariners as vital aspects of seamanship. These were also aligned with the framework of the Kern model of airmanship (Kern, 1997), with some elaborations and additions. Aviation experts more readily discussed human factors issues than marine
experts, who placed more emphasis on technical skills and mentioned more concepts related to physical aspects of marine activity. Both groups emphasised safety. Experience and appropriate guidance were considered to be the central factors in the development of airmanship or seamanship, however personal predisposition was also seen as necessary to develop to a superior level. While the Kern model supports the basics of good airmanship and seamanship, some elaboration is required for a comprehensive description, and some differentiation between the two terms is needed. Finally, training programs need to incorporate specific human factor components that relate to airmanship and seamanship to facilitate the development of exemplary professionalism.

Keywords: airmanship, seamanship, aviation, maritime, safety

Alcohol, monotonous and urban simulated driving

BERTHELON, C. (INRETS), NACHTERGAËLE, C. (INRETS), HIRT, S. (University of Provence)

Epidemiological studies have shown that alcohol is a major cause of mortal accidents, in particular at night and on weekends, and that the risk of accidents is directly linked to the level of alcohol in the blood. As there is lack of behavioral measures that can be used to define a dangerous threshold for driving after taking licit or illicit drugs, we conducted an alcohol calibration study and simulated different driving scenarios. The objective was to obtain references for impaired behavior in different driving situations. Sixteen participants, aged from 21 to 30 years, took part in the experiment. The participants sat in an interactive driving station (fixed base, 150° W * 49° H), drinking a beverage to obtain 0, 0.3, 0.5, or 0.8g of alcohol per litre of blood (BAC). They were then submitted to monotonous situations where they had to keep a constant speed (110km/h) and a stable position on the lane, and urban situations with scenarios of accidents where they had to drive at 50km/h. The number of collisions and different driving parameters were analyzed as a function of BAC. In monotonous following situations, SDLPs (a variable well known to be sensitive to drugs or fatigue) increased as a function of the degree of blood alcohol concentration, and were significantly higher with 0.8g/l than with a placebo. In urban situations, the number of collisions increased with the level of alcohol but participants’ responses times did not vary from one experimental session to another. Monotonous driving was significantly deteriorated by alcohol but results are not as clear with urban situations. However, participants were trained to the urban scenarios before the experiment in order to avoid any learning effect; urban scenarios were thus not as unexpected as in natural driving. Such results could be very useful to evaluate and quantify the degree of impairment caused by others factors.

Keywords: alcohol, drugs, simulated driving, motor accidents, impaired behavior

An analysis of the interpersonal relationships of bank managers in Bangalore-India

HOSSEINI YAZDI, S.S., HAKAMI, M. (Islamic Azad University)

The main objective in this research is an analysis of the interpersonal relationships of bank managers, and the sub objectives are to study the relationships between various branch managers; between managers and subordinates; and between managers and costumers. In this study, the interpersonal relationships of managers working for a corporation bank were studied in the period of 2008 – 2009 academic year. They were assessed on interpersonal needs. The data was collected through a survey method, and the sample was drawn from the population of bank managers, while other sorts of managers, like business managers, were ignored. The final sample consisted of 21 males and 5 females, with an average age of 34.12 years. 17 participants were married, and 9 were unmarried. The sample’s educational qualifications ranged from a bachelor degree to a master degree. The scores obtained through the Fundamental Interpersonal Relations Orientation Behaviour (FIRO-B) were analyzed. Based on the hypothesis, there is a positive significant correlation between inclusion and affection of bank managers related to their expressed and wanted needs. Therefore, the
managers who express and want affection, also express and want inclusion; but it shows nobody likes to be controlled, while they like to control others a little. Interpersonal orientation of the subjects on all the 3 dimensions revealed a discrepancy between wanted and expressed scores. Very few people have a perfect match between wanted and expressed, based on the direction of the discrepancy (+ / -), that is, wanted score being higher than expressed score and vice versa. Hence, knowledge about the discrepancy between wanted and expressed on each of the dimensions of FIRO-B would help managers in estimating the dynamics of their behavior with customers, and then customer satisfaction.

Keywords: bank managers, interpersonal relationships, interpersonal factors, subordinates, customers

An analysis of viewer evaluations on the images of female Japanese talents in television commercials

OKANO, M. (Bunkyo University), OKANO, M. (Bunkyo University)

Asakawa and Okano (2009) performed text mining on viewers’ free-description answers on their liking or disliking of characters in television commercials, and derived the following four dimensions: (1) external appearances, (2) personality trait, (3) theatrical skills, and (4) age. This research aimed to investigate the reliability of these four dimensions of a character’s “image” and examine which of the four dimensions has the biggest influence on a viewer’s liking or disliking of characters. Two television commercials, each featuring one popular female Japanese talent, were shown to students. They evaluated 24 items related to the characters’ image and the liking or disliking of the talent on 7-point scales. By performing a factor analysis on the acquired data, the following four dimensions were extracted: (1) external appearance, (2) personality trait, (3) maturity, and (4) familiarity. The results of multiple regressions conducted on the four extracted dimensions (independent variable) and the degree to which the participants had a favorable impression of the talent (dependent variable) showed that external appearances, personality trait, and familiarity influenced the degree of favorable impression, and personality trait has the biggest influence on the liking or disliking of the characters. These four dimensions corresponded well with the factors obtained by Asakawa and Okano (2009). Therefore, it seems that these four dimensions are effective for accurately understanding the image of the characters shown in television commercials.

Keywords: television commercials, viewer evaluations, personality traits, appearance, familiarity

An applied investigation of how sport specific physiological demand influences the psychological processes of decision-making in hockey

SPITTLE, M. (Deakin University), EVANS, S. (Victoria University), PAYNE, W. (University of Ballarat)

Research has consistently demonstrated differences in decision making performance of experts and novices, however, in a sport such as hockey, physiological demand might also influence decision-making performance. Previous studies have tended to explore the effect of fatigue or exertion, rather than game-like physiological loads on decision-making and have often used non-sport specific decision-making tasks. This study aimed to determine if physiological demands, created via the Loughborough Intermittent Shuttle Test (LIST), affected decision making performance. A 25 item screen-based decision making test consisting of 5 equivalent test forms was developed with 210 participants (M age =20.45 years, SD = 4.75). The test displayed good discrimination between playing level F(1, 208)= 32.26, η2 = .134, p <.001, good test re-test reliability, and acceptable internal consistency (α = .63). The LIST is a shuttle test that is used to recreate high-intensity intermittent sports, such as soccer and hockey, and requires a repeated walk, sprint, run (85% of VO2 max), and jog (50% of VO2 max) pattern of exercise over 20m for 15 minutes followed by a period of rest. The LIST was completed by 10 hockey players (M age = 24.10 years, SD= 4.04) who performed the decision making test pre exercise and after each of four 15 min exercise periods. Physiological
demands increased across the exercise periods, with a significant effect for heart rate, Wilk’s $\lambda = .01, F(5, 5) = 117.63, p = .001, \eta^2 = .99$, ratings of perceived exertion, Wilk’s $\lambda = .04, F(4, 6) = 36.66, p = .001, \eta^2 = .96$, and blood lactate, Wilk’s $\lambda = .01, F(5, 5) = 105.93, p = .001, \eta^2 = .99$. This increased demand, however, did not appear to influence decision making accuracy, Wilk’s $\lambda = .53, F(4, 6) = 1.31, p = .26, \eta^2 = .46$. The LIST appeared to adequately recreate the physiological demands of a game of hockey, which has practical implications for testing and training in hockey. As the game-like physiological demands did not appear to affect decision making performance, coaches, players, and sport psychologists may not need to specifically train players for decision making under physiological demands.

Keywords: decision making, physiological demands, sport, hockey

An attempt to measure implicit and explicit shyness: Using Implicit Association Test (IAT)

TSUTOTMU, F. (Gakushuin University), TANAKA, C. (Gakushuin University), NOGUCHI, Y. (Gakushuin University), AIKAWA, A.J. (Tokyo Gakugei University)

The previous research has shown the difference between the factor in which participants’ implicit and explicit shyness is predicted (Asendorpf, Banse, & Mücke, 2002). In interpersonal situations, implicit self-concept (estimated from implicit shyness) predicted spontaneous shy behavior, while explicit self-concept (estimated from explicit shyness) predicted controlled shy behavior. The purpose of present research is to examine whether the same result would be reproduced in Japan. Ninety-one college students completed the Trait Shyness Scale (TSS), Extroversion Scale, Social Desirability Scale (SDS; consisting of two factors: self-deception and impression management), and Self-esteem Scale. Fifty college students (those that participated in the Study 1) came to the lab and completed a shyness Implicit Association Test (IAT) and self-esteem IAT. Friends of Study 2a’s participants completed the TSS, Waseda Shyness Scale, Praise-seeking, and Rejection Avoidance Scale. These scales were modified, because the targets of ratings were those that participated in the Study 2a. Through the athletes were relocated to Europe, and others were preparing for their respective transitions; becoming a professional footballer, going to tertiary education while continuing to play football etc. Positive changes such as a deeper self understanding or rational decision making are observed with some of the subjects during this intervention period. In conclusion, since these athletes are training in this special condition which requires intensive training, counseling services by a specialist to ease their daily concerns, and to prepare them for transitions after leaving the academy, seems to be very important. Furthermore, the balanced lifestyle would benefit their athletic performances.

Keywords: athletes, post-modern career counseling theory, transition, lifestyle

An attempt to measure implicit and explicit shyness: Using Implicit Association Test (IAT)
factor analysis, four factors were extracted (interpersonal tension, sociability, praise seeking, and rejection avoidance). The negative correlation was detected between TSS and SDS (self-deception only), as well as between the TSS and Self-esteem Scale. The correlation between implicit and explicit scales (implicit/explicit shyness and implicit/ explicit self-esteem) was positive, but it was not significant ($r_s < .22$, $p_s > .14$). However, there was significant negative correlation between implicit shyness and implicit self-esteem ($r = -.30$, $p < .05$). Using the covariance structure analysis, it was revealed that the correlation between implicit self-concept (estimated from shyness IAT) and explicit self-concept (estimated from TSS) were positive and significant. Also, implicit self-concept predicted others-rated high interpersonal tension. Meanwhile, explicit self-concept predicted others-rated low sociability and low praise seeking. Rejection avoidance was predicted by both implicit and explicit self-concepts. The result of present study was similar to that of Asendorpf et al. (2002). It was revealed that there was significant correlation between implicit shyness and self-esteem scale, which was also seen in the result from the explicit level examination.

Keywords: shyness, self-concept, self-deception, sociability, praise-seeking

An effective intervention for students with traits of pervasive developmental disorders and their parents: Social skills training and psychoeducation

KONISHI, M. (Tokaiagakuin University)

Schools in Japan, in recent years, are giving special attention to the education of students with pervasive developmental disorders. I found that most teachers and parents are embarrassed by the behavior of the students. Then, to improve their uncomfortable mood and social skills, I conducted two programs for junior high school and high school students, and their parents, with the cooperation of the teachers. The first program was a social-skills training for students displaying the traits of pervasive developmental disorders; here, they learnt basic social skills owing to their lack of good communication skills with friends and teachers. I then conducted a psychoeducation program for the parents of these students. In this program, the psychological characteristics of adolescents were discussed and favorable nurturing practices were suggested to the parents. We also discussed the issues faced by these students and how they cope with them. The measures used include the Profile of Mood States (POMS; Douglas M., et al., 1971), Self-esteem scale (Rosenberg, 1965), and Kikuchi’s social Skill Scale (Kikuchi, 1988). The results of these programs showed an improvement in the social skills of the students, and self-esteem of the students, parents and teachers. And consequently, these improvements reduced the tension, depression, anger, fatigue and confusion felt by the students and their parents and teachers. Further, they increased the vigor and self-esteem of all. In conclusion, these programs improved the social skills of the students. Consequently, they led to a higher level of self-esteem, and improved the uncomfortable mood felt by all participants; the students, parents of the students, and teachers.

An international comparative study of the relationship between activities other than school lessons and mathematics achievement: Using an R-based programme for nominal categories model

MURATA, I. (Tokyo Institute of Technology), OKUBO, T. (The National Center for University Entrance Examinations), MUTA, H. (Tokyo Institute of Technology)

The purpose of this study was to clarify the relationship between students’ achievement in Japan and activities other than school lessons using the data of The Trends in International Mathematics and Science Study (TIMSS) 2003. To clarify the feature of Japan, we compare with the East Asian nations that participated in TIMSS2003. The data were achievement and questionnaire items of mathematics in Japan and four countries in East Asia. The four items were the frequency of the activities other than school lessons: watching TV, housework help,
home-work and supplementary lessons of mathematics. The sample was 4,413 students of the eighth school year (799 in Japan, 1002 in Singapore, 836 in South Korea, and 888 in Taiwan). The method of analysis was the Nominal Categories Model (NCM). This model can examine the selection tendency to the scale and the answers in more detail. The Item Category Reaction Function (ICRF) was drawn based on the estimated parameters. The difference between Japan and four other countries is shown as follows. Watching TV: in the subordinate-position of achievement, time tended to be long, and it was longer than the four other countries. Housework help: time tended to be long in high-position students, and the ratio of the student who doesn’t help at all is high regardless of the achievement. This tendency was similar for Hong Kong. Homework: there was no difference between the time length brought by the difference of the achievement. There was a similar tendency for Hong Kong and South Korea. Supplementary lessons of mathematics: tended to be long in high-position students and the items of low frequency were chosen higher than the four other countries. As a result, the differing tendency became clear, with the frequency of the chosen item of the activity corresponding to achievement. The proven realities were the results of supporting the result that had been shown so far. However, this differs from past research in describing the selection ratio corresponding to the scale of achievement, and this suggests it is profitable to settle on the educational curriculum in the future.

**Keywords:** student achievement, Trends in International Mathematics and Science Study (TIMSS), curriculum, mathematics, nominal categories model

### Analyses of personal attitude construct on interpersonal relations in Japan and Malaysia

NAITO, T. (Shinshu University)

A scheme of interpersonal relations, especially the common cultural part of it, is subtle and implicit. In contrast, when we come into contact with a foreigner, we notice cultural differences. But we can hardly find out the total structure. So, we need a technique for assembling information. The aim of this study was to confirm effectiveness of personal attitude construct (PAC) analysis, as a measurement of interpersonal schemes, which contain interpretation of a subject and is suitable for discovery of factors. The subject was a Malaysian international female student at a Japanese university. The first procedure was as follows; i) presented the stimulus sentences about Japanese interpersonal relation for free
association, ii) required to order the cards of association according to importance, iii) instructed to estimate the distance of similarity intuitively, comparing all pairs of cards, iv) Cluster Analysis by Ward was done, and v) asked to describe the image about each cluster. Secondly, the same procedure about Malaysian interpersonal relation was carried out. Results cleared characteristics of Japanese interpersonal relations; i) first cluster was “bonds among fellows and concern for others”, ii) second cluster was “surface interpersonal relation and ambiguous behavior which veil real intention.” On the other hand, clusters of Malaysian interpersonal relations were i) “frank exchange of views, misunderstanding and un Dependable”, ii) “harmonious exchange beyond racial and ethnic backgrounds”, and iii) “endeavor to integrate peoples as Malaysian”. PAC Analyses could reveal the well-known characteristics of Japanese and Malaysian interpersonal relations by a Malaysian international student. We arrive at the conclusion that PAC analysis for single cases is an effective measurement of interpersonal scheme.

**Keywords:** interpersonal relations, schema, attitudes, cultural diversity

**Analysis of individual and collective motivation on prosocial behaviour from a multilevel perspective**

TABERNERO, C. (University of Cordoba), BRIONES, E. (ERCOMER, Utrecht University), ARENAS, A. (University of Seville), CUADRADO, E. (University of Cordoba)

The aim of this research was to understand how individuals, groups and communities perform ProSocial Behaviours (PSBs) to encourage the development of social networks that facilitate coexistence and well-being in more healthy social and environmental contexts. The main objective of this paper was to analyze the role of the motivational factors involved in the development of PSBs. In order to do this, based on a social-cognitive model, we explored the role of individual variables (age, gender, and personal dispositions such as positive orientation towards life, prosocial dispositions, moral disengagement and personal values) and situational variables (social exclusion, share limited resources, uncertainty, culture or previous experiences) on motivational states or self-regulatory mechanisms (self-efficacy, affective states, intrinsic motivation), which facilitate individual and collective PSBs in four current socially relevant settings. We analyzed the social support behaviours towards excluded social groups – three experimental conditions were created across a simulated feedback of personality where participants anticipated exclusion, inclusion or control. Our results show the common and specific motivational determinants of the PSB displayed in each different setting from a multilevel perspective using structural equation modelling. The results show the mediator role of self-efficacy – interpersonal and emotional regulation – and effective states linked with intrinsic motivation to explain PSB. The analytical strategies involved in decision making that provoke prosocial behaviour through the analysis of verbal messages or ruminating thoughts during the decision making process are discussed.

**Keywords:** motivation, pro social behaviour, motivational factors, self-efficacy, decision making

**Analysis of resources and strain at work - The Recovery-Stress-Questionnaire for Work (RESTQ-Work): Versions for screening, organizational and individual recovery-strain-analysis**

JIMENEZ, P. (University of Graz), KALLUS, W. (University of Graz)

To reach a differentiated view of strain, stress and burnout it is very important for work psychologists to have a strong tool to get a real deep insight into the different areas of strain and also see the resources at work. In the line of ISO 10075-3:2002 and some national standards, work psychologists have to get a more exact assessment of these areas of strain. Additionally, it is very important to measure resources and dimensions of stress at the level of organizations and also at the individual level. Looking at the life domain balance means to know about aspects of the working and the private environment. The RESTQ-Work measures strain and recovery and considers different life domains. The questionnaire is now available in various versions and languages. A screening
version that allows a rough judgment of the burnout risk was used in a representative survey \( n = 1458 \) and in further broader online surveys \( n = 750; \ n = 2500 \). The RESTQ-Work consists of the base part which is the Recovery-Stress-Questionnaire (a form with 48 items or a parallel version with 24 items) and a work specific part. The different forms of the RESTQ-Work are designed for different areas of application. The current paper presents the theory and the structure of the RESTQ-Work, the reliability of the dimensions and subtests. The major advantage of the RESTQ-Work is the possibility to use it in employee surveys to get an overview about the recovery and strain balance and on the other hand to use it for individual assessments too. Especially for individuals it proved to be a very good way to use the results for an interview with the person and to derive interventions together with the assessed person.

### Animal psychology as a legitimate and viable field

**ENGLAND, M.**

The aim of this study was to explain and expound upon the application of human psychology to other animals. Animals may be perceived as beings with minds and related emotions. With such an approach, a field of animal psychology takes its place with that of the much studied human psychology. This paper explores such an approach and draws upon published research in doing so. By establishing that the study of animal psychology is just as legitimate a study as that of human psychology, its viability may be explored. The study of animal psychology may enrich the well being of animals, including humans.

**Keywords:** animal psychology, animals

### Application of natural language in fire spread display

**GE, Y.** (Chinese Academy of Sciences), **SUN, X.** (Chinese Academy of Sciences)

How to express fire spread efficiently and effectively to firefighters is an important issue. The present study aimed to investigate how to present the fire alarm information, focusing on whether natural language alarm presentation was better than the alarm list presentation. Objective method and subjective evaluation were used to compare the differences among four forms of fire alarm information, including traditional alarm list, integrated alarm list, natural language, and natural language with spatial information. 12 firefighters were asked to read and listen to these fire alarm information, and then to choose the correct scenario matched with each expression from four scenario simulations. Six dependent variables were recorded for analysis, including percentage of correct responses, response time, description viewing time, simulation viewing time, switch times between description and simulation, and subjective ranking data. The results revealed that natural language was better than alarm list, and the effect was more robust when natural language added spatial information. The traditional alarm list was more accurate than other forms, but it costs more time to read and comprehend. For emergency scenes such as fire fighting, one which costs little time and brings about higher performance will be chosen as the formal description of the real product to improve the quality of it. From these results, we concluded that natural language with spatial information will be recommended for the expression used in future fire alarm systems.

**Keywords:** fire alarm information, firefighters, natural language, alarm list

### Applying oral tactile imprinting theory to practice

**MOBBS, E.** (Perinatal and Infant Mental Health Service)

Breastfeeding relies on a number of psychological factors, yet generally, breastfeeding is not regarded as being within the scope of a practicing psychologist. What are the practical applications of applying the oral tactile imprinting theory to practice? By a literature search, those clinical outcomes advantaged by good latching by the newborn on the nipple are recorded. Those books recommended by the
International Lactation Consultant Association (ILCA), Australian Lactation Consultants Association (ALCA) and the Australian Breastfeeding Association (ABA) were used to record the advantages of achieving a good oral latch by the newborn on the mother. The results were collected under the categories of (1) mother based (2) infant based and (3) socially based. Results included: (1) the maintenance of the mother’s hormonal status, general health and psychological wellbeing; (2) the infant’s hormonal status in relation to the infant’s emotional state and improved morbidity and mortality; (3) the direct and indirect monetary cost saving to the social system. To conclude, psychologists have a part to play in the promotion of the wellbeing of both mother and baby. Education in the process of lactation would be advantageous to psychologists in their clinical management of the mother and baby in the perinatal period, especially in the fundamental process of oral tactile imprinting.

**Keywords:** breast-feeding, oral tactile imprinting theory

**Are stress responses (physical and psychological problems) attributable to stressors?**

HAYASHI, K. (Shiraume Gakuen College), NANAE, O. (Shiraume Gakuen University), YAGI, T. (Chuo Gakuen University)

According to the Lazarus and Folkman model, many stress studies using questionnaires have been carried out to demonstrate relationships among stressors, stress coping and stress responses. The present study examined the relationship between personality traits and stress responses. University students in the Tokyo metropolitan area (N=95) completed the Stress Response Scale (SRS) and Minnesota Multiphasic Personality Inventory (MMPI) in 2008. SRS is one of the Stress Self-Rating Scales (SSRS) and consists of 4 subscales (Emotional Response, Cognitive Behavioral Response, Physical Fatigue and Activation of Autonomic Nervous System). The participants were classified into high score group (HS group) and low score group (LS group) with Stress Response Scale. An ANOVA and t-test indicated that the HS group had significantly higher scores on 7 MMPI subscales (Hypochondriasis Scale, Depression Scale, Psychopathic Deviate Scale, Paranoia Scale, Psychasthenia Scale, Schizophrenia Scale and Social Introversion Scale) than the LS group except for 3 MMPI subscales (Hysteria Scale, Masculinity-Femininity Scale and Hypomania Scale). The results of this study suggest that physical and psychological problems (stress responses) are not always attributable to stressors. In Lazarus’ model, evaluation and coping are thought of as major intermediate variables. However, we found that there is a close relationship between stress responses and personality traits, so when we examine the process from stressors to stress responses, we have to evaluate personality factors (there were not enough participants in the current study). We should continue these surveys to identify various characteristics that affect higher stress responses.

**Keywords:** stress responses, personality traits, stressors, stress coping, university students

**Assessing the effect of safety training through a human-error-experience program**

USUI, S. (Osaka University), WADA, K. (Safety Research Institute, West Japan Railway Company)

Usui et al.(2007) developed a software program to prepare cognitive tasks on a personal computer that induce human errors so subjects can experience human errors while performing such tasks (referred to as “the error-experience program”). The purpose of this study is to implement safety training using the error-experience program and examine the effect of that training. The human-error-experience program contains two menus, the biased-attention menu (a menu through which subjects experience an oversight caused by a distraction) and the violation menu (a menu through which subjects experience the temptation of omitting checks when repeated checks are required). Participants were divided into two groups; one group experienced the biased-attention menu (biased-attention group) and the other group experienced the violation menu (violation group). After experiencing the program, participants were divided into groups of four to five members each. The groups then discussed
whether they had ever experienced such accidents and near-misses that occurred due to factors similar to those in the experience menu and described such accidents and near-misses if any. Twenty-five firemen participated in the program. The participants answered the Risk Propensity Questionnaire (RPQ), a questionnaire to assess risk-taking trends, before receiving the safety training and answered the same questionnaire after receiving the safety training. The average scores on the RPQ were compared before and after the safety training. The scores of all program participants changed significantly in the direction of enhanced safety. The average scores were then analyzed by dividing them into those of the biased-attention groups and those of the violation group. The scores for the violation group were found to have changed significantly in the direction of enhanced safety. The participants’ safety attitude improved, verifying the effectiveness of safety training using the error-experience program. The effect of safety training was especially remarkable in the group that experienced the violation menu. In future work, we will analyze factors in the RPQ and examine the sustainability of the effect of safety training.

Keywords: error-experience program, safety

Assessing the function of a standards discrepancy in the relationship between fear of positive evaluation and social anxiety

CASHMAN, E. (Macquarie University)

The present study sought to examine whether a standards discrepancy mediates the relationship between fear of positive evaluation and experimentally induced social anxiety. In addition, the study experimentally tested whether the administration of bogus feedback (i.e., positive or neutral) would moderate the relationship between standards discrepancy and induced social anxiety. First year psychology students (81 female, 19 male) completed measures of social anxiety and depression. They then completed a 5 minute impromptu speech task which they were informed would be recorded and later viewed by university psychologists and compared to their second speech in front of the same audience. The experimenter then administered randomly assigned feedback to participants on their speech performance to examine its effect on state social anxiety and ratings of standards for an anticipated second speech. Results did not support the mediation hypothesis, however, fear of positive evaluation and standards discrepancy were significant unique predictors of state social anxiety. The moderation hypothesis was also not supported as the interaction between feedback condition and standards discrepancy did not predict state social anxiety. The current study revealed that fear of positive evaluation was able to predict state social anxiety in a realistic social evaluative situation. Considering the above findings and previous literature, there is a need for future studies to examine the mediational role of standards discrepancy in a clinical sample of socially anxious individuals. Implications of the present findings extend to both future models of social anxiety and its treatment, in that positive evaluations and successful social situations do not necessarily revise the inherent negative cognitions of socially anxious individuals in regards to their social ability and can increase the intensity of their socially anxious fears.

Keywords: standards discrepancy, positive evaluation, social anxiety

Associations between different types of physical activity and depressive symptoms in Taiwanese older adults

KU, P-W. (National Changhua University of Education), CHEN, L-J. (National Taiwan Sport University), SUN, W-J. (Hunei Health Station)

Less attention has been paid to explore the association of non leisure-time physical activities (NLTPA), including domestic and work-related physical activities, with depression. The study was designed to elucidate a) whether leisure-time physical activity (LTPA) and NLTPA are independently associated with depressive symptoms; and b) the relation of specific components of physical activity (frequency, duration and intensity) and depressive symptoms in later life. A total of 2727 persons (65+ years) participating in the 2005 Taiwan National Health Interview Survey were studied.
This study used a multi-stage stratified systematic sampling design with a nationally representative sample. Depressive symptoms were measured by the CESD-10 (Center for Epidemiological Studies Depression Scale-10). Participants scoring 10 or higher were classified as having depressive symptoms. Information on names, frequency and durations for each type of LTPA and NLTPA during the past 2-week period was self-reported. Metabolic equivalent intensity levels for each activity were assigned (31 identified LTPA, 10 identified NLTPA). Energy expenditure of each activity per week was calculated by: activity intensity code (kcal/min) x frequency x duration for each time (min)/2. The energy expenditure values were then added up into total weekly amount of energy expenditure for both LTPA and NLTPA. After adjusting for socio-demographic variables (gender, age, educational level, marital status, income), lifestyle behaviors (smoking and drinking) and health status (cardiovascular diseases, stroke, diabetes, body mass index, physical functioning), multivariate logistic regression models for predicting depressive symptoms were undertaken to compute adjusted odds ratios (AOR) for LTPA and NLTPA. Given that LTPA ($p < 0.001$) rather than NLTPA ($p = 0.69$) was associated with depressive symptoms, AORs for the three components of LTPA were calculated. Results showed that individuals expending less energy in LTPA had higher risk of depressive symptoms (0 kcal/week: AOR = 2.14, 95%CI: 1.26-3.63; 1-999 kcal/week: AOR=1.51, 95%CI: 0.88-2.61, reference 2000+ kcal/week). The benefit of risk reduction among the three components of LTPA energy amount was only observed in intensity ($p = 0.03$) (no change in breath: AOR = 0.41, 95%CI: 0.21-0.79; slightly fast: AOR=0.50, 95%CI: 0.24-1.03, reference fast or very fast). To conclude, LTPA, especially activities of light to moderate, is associated with reduced risk of depressive symptoms in older adults.

Keywords: depression, older people, physical activity

Awareness of environmental problems among Japanese youths and effective persuasion

We tried to find the level of awareness of environmental problems among youths, and make clear effective persuasion of the need for energy saving. 97 female college students were questionnaired, asking about energy saving, their personality, and their parents’ attitude towards energy saving. They also read two writings in two groups; one story is written with one-sided views of only the good things about energy saving, and the other is written with both good and bad views. Then, we measured the effects. 93% of the students were highly concerned about environmental problems, and the action they put into practice the most, is reducing trash. Also, as for the terms about the environment, they know global warming and photovoltaic generation well, but have little recognition of the term low carbon society. Terms that are usually heard through the media are well known. As to persuasion, the story with both sides was more persuasive. Parents’ or their personality have no influence on the result. In order to increase awareness of environmental problems among youths, public information and education are important. Furthermore, in explaining the need for energy saving, persuasion shown with both good and bad sides is effective.

Banning smoking in Victoria’s licensed premises: An evaluation of a campaign to prevent butt littering behaviour

SPEHR, K. (Community Change), CURNOW, R. (Community Change)

The aim of this study was to assess the effects of a cigarette butt litter prevention campaign on butt littering behaviour, following the introduction of new legislation to ban smoking in Victorian licensed premises. Using behavioural observation, 2,444 records of butt disposal behaviour were collected at 64 outdoor public place smoking locations at licensed premises in
Melbourne. A systematic assessment was conducted of factors known to influence disposal behaviour such as the amount of litter on the ground, presence of appropriate butt ‘binrastructure’ and venue infrastructure designed to provide a comfortable environment for smokers. Six hundred and ninety eight venue patrons were surveyed to determine their level of support for the campaign. Data was collected from the month prior to the introduction of the campaign, during the campaign and at 5 month follow up. As a proportion of total butt disposals (binning and littering), littering accounted for 58% of total disposals one month prior to the campaign. Significant reductions in littering were evident (33%) during the campaign peak period; this remained largely sustained at follow up (37%). When venues were categorized by the rate of adoption of the innovation (Rogers, 1995), ‘straggler’ venues (where improvements were slow to arrive) showed the highest littering rates at all stages of the evaluation, with lowest rates evident for ‘innovator’ venues (where improvements took place very early). ‘Straggler’ venues however showed the largest percentage improvement in littering behaviour from pre campaign to follow up. Litterers tended to be further from bins than binners with ‘innovator’ venues relying more on ashtrays than the installation of permanent butt bins; the distribution of ‘personal’ ashtrays as campaign giveaways was ineffective with very few instances of use observed. Support for the campaign was strong and increased further during the campaign but was not sustained at follow up. Acknowledgement of early success in adaptation to change was recommended to facilitate sustained gains in the reduction of littering behaviour seen as a result of the campaign. Programs need to continue long enough to bring ‘straggler’ venues on board and provide tailored support to facilitate change. Early identification of adopter categories and tailoring promotions and support to suit specific indicators of venue readiness for change is likely to lead to sustained improvements.

Keywords: smoking, smoking, butt litter prevention campaign, butt littering behaviour, licensed premises

Being flooded: A qualitative study of the experiences of people affected by the Mackay 2008 flood

DIXON, K. (Queensland University of Technology), SCHOCHET, I. (Queensland University of Technology), SHAKESPEARE-FINCH, J. (Queensland University of Technology)

The aim of this qualitative study was to explore what it was like to live through the Mackay flood and its aftermath. In particular, it focussed on what affected people found particularly stressful during the flood and its aftermath, what factors helped them cope, and the long-term impact on their psychological well-being. Results will inform the next study which will be a larger scale quantitative investigation. Semi-structured interviews were conducted with Mackay residents who had experienced water damage to their home or possessions on February 15, 2008 (N = 18). The interviews were conducted twenty months after the flood. Participants were asked what happened during the flood and the months that followed, what they found to be particularly stressful and what factors helped them cope. They were also asked about the helpfulness or otherwise of the disaster management and community recovery response. Interview data were subjected to thematic analysis. Results suggest both positive and negative impacts on well-being that were attributable to the flood (for example, health problems, exacerbation of existing mental health issues, restored faith in “community spirit” and increased self-efficacy). For example, one woman declared, “I’ve survived this, now I feel like I can cope with anything.” Themes concerning the factors influencing adjustment include the helpfulness or otherwise of insurance companies, support network strength, and feeling helpless compared to having some knowledge of what to do as the flood waters rose. For example, one participant commented “There was no-one to tell us what to do” and another said, “I rang 000 and they said, police, fire or ambulance and I said SES, to which they said no, police, fire or ambulance”. This study used qualitative methods to explore the long-term psychological impact of the Mackay flood. Themes concerning stressors and coping strategies are discussed and detail of how these themes will inform future research are outlined. Some themes suggest implications for
policy and training in insurance companies and public education regarding what steps to follow in the case of flood.

Keywords: flood, psychological well-being, natural disasters, community recovery response, self-efficacy

Beyond the pain: Exploring the psychosocial meaning of injury and illness

ANDERSEN, M. (Victoria University), WILLIAMS, D. (Victoria University)

A life history case-study approach was used to explore the meanings of injury and illness experiences from the perspective of a junior football player, and a senior coach (Rick and Ben). Rick and Ben were both interviewed twice each, and each conversation was recorded and then transcribed verbatim. Various excerpts were taken from each participant’s story, and the selected portions were then interpreted using an Eriksonian (Erikson, 1985) framework. Rick had strong desires to become a professional footballer at the end of his junior career, and through achieving selection to a state team his dreams were beginning to be realized and he was gaining a sense of industry. Rick’s experiences with multiple injuries led him to develop a sense of inferiority as he was unable to demonstrate competence on the field. The timing of Rick’s injuries prevented him from playing much football in his final year of juniors, and so he was not able to be drafted to the professional ranks. Rick’s subsequent struggles in the senior system provided some challenges relating to his sense of identity. Ben was a senior level basketball coach who experienced a severe heart attack, and thus was unable to continue coaching temporarily. Ben saw coaching as an opportunity to pass on knowledge to future generations of players, and felt a great deal of satisfaction in seeing former athletes develop into high-achieving adults. Ben had developed a sense of generativity through desiring to pass on knowledge, but his experience with illness also resulted in issues of intimacy and isolation. Erikson’s psychosocial stages of development, rarely used is sport psychology research, were useful in understanding the athlete’s and the coach’s life histories. Further research into the relationship between psychosocial development, and enforced absence from sport, could provide greater insights for helping not only injured athletes but also coaches.

Keywords: Erikson’s psychosocial stages of development, case study, Injury, Illness, football

Biofeedback training using indicators for relaxation and alertness from an EEG signal

LUO, F. (Chinese Academy of Sciences), LUO, J. (Chinese Academy of Sciences), WU, Y.B.

The aim of this study was to develop a series of new indicators for the biofeedback treatment of psychological and psychosomatic disorders. We recorded single-channel EEG using two frontal electrodes, and developed a series of indicators using wavelet analysis for varies dimensions of conscious states such as concentration, alertness, awareness, relaxation, etc. The indicators for alert relaxation, i_35 and i_22, were selected as indices for biofeedback training. This was applied in experimental treatments such as post earthquake recovering, grouped relaxation training, and problem solving. i_35 and i_22 were found to be significantly correlated with mental relaxation and mindfulness, respectively. We have also identified several indices that may reflect anxiety. Biofeedback training based on the real time analysis of these indices, especially the i35, could result in better self-awareness and psychological health condition. Our results indicate that EEG parameter-based biofeedback training may be useful for mental health management.

Keywords: biofeedback training, EEG, psychological disorders, psychosomatic disorders

Blessed are the peacemakers: SmartAid’s expansion of the personality-focused performance requirements

ATKINS, S. (Otago Polytechnic), HALBERSTADT, J. (University of Otago), FOSTER-THOMPSON, L. (North Carolina State University)
This paper describes early steps in research programmes intended to infuse relevant industrial psychology principles into “online volunteerism” (see Foster-Thompson & Atkins, in press; Carr & O’Driscoll, 2008). This present phase of research builds upon prior expansions (Atkins, Carr, Fletcher, & McKay, 2006) of Raymark, Schmitt, and Guion’s (1997) Personality-focused Performance Requirements Form (PPRF) via new data sets supporting exploratory factor analyses (EFA). One hundred and seventy five psychology students, cogitating on jobs highly familiar to them, completed an expanded form of the PPRF. They did this while focusing on one job, preferably one not common for students. This expanded PPRF (Atkins, et al., 2006, May) added items capturing 16 classic lower-order factors in Cattell’s 16PF (Conn & Rieke, 1994). Expansion was necessary, as Raymark’s PPRF had fewer lower-order factors, despite covering the Big 5 higher-order factors. A prior panel trimmed this to roughly 5 items per 16PF trait. Anticipating correlated latent attributes, EFA was pursued via principal axis factoring allowing oblique rotations. Scree plots suggested potentially efficient dimension reductions at 5, 10, 17, and 19 factors. Breaks largely evinced with reasonably interpretable results and simple structure. The Big 5 taxonomy was generally supported, as was Cattell’s classic16PF arrangement (albeit Cattell’s surgency factor appears clouded by the social boldness factor here; likewise his shrewd/privateness factor by the oppositional/suspiciousness factor). Of course, given the sample size, only the Big 5’s replication is noteworthy in the omnibus EFA. Of special interest to aid applications, however, in our new results – there appears to be, within our modified form of the Raymark, et al., PPRF instrument, a factor related to “peacemaker” (i.e., “consensus-seeking mediator”), an important talent contributing to social capital. This may be surfacing in our sample since today’s students (i.e., Millenials) apparently have greater interests in social capital and community volunteerism. Because Cattell’s factor “A” is also associated with providing tender heartedness, while Cattell’s factor “E” is negatively correlated with submissive docile behaviour, the “A” and “E” items were run in a separate EFA with the items manifesting our new peacemaker factor. Several features of the subsequent results support these latter item sets as capturing three distinct, but logically related, factors. Thus, this paper describes our plan for developing (e.g., CFA) and applying these and other 16PF factors in calculating fit between “aid project” requirements and volunteers (while also optimizing Belbinesque online “aid team” fit).

Keywords: Personality-focused performance requirements form (PPRF), SmartAid, peacemaker, social capital, volunteerism

Body image, eating behaviours and weight management in DanceSport competitors

KYAN, N. (Victoria University), SPEED, H. (Victoria University)

The research explored physical self-perceptions (e.g. body image dissatisfaction, perceived physical attractiveness and physical self worth) and patterns of eating and weight control behaviours of male and female ballroom dancers competing at the elite levels of DanceSport. Phase 1: Questionnaire packages, comprising the Eating Attitudes Test (EAT-26), the Eating Disorder Inventory (EDI-2); the Physical Self-Description Questionnaire (PSDQ) and a brief demographic questionnaire (designed specifically for this study) were distributed to male and female DanceSport competitors currently competing in Australia. Subscale scores were calculated for the EAT-26, EDI-2 and PSDQ. Demographic data were analyzed using summary statistics. Appropriate t tests and MANOVAs were undertaken to compare male and female dancers. Phase 2: On the basis of participant responses in the questionnaires, 8 dancers were invited to participate in follow-up semi-structured interviews to explore in greater detail their eating and weight management behaviours and to examine the influence of the competitive DanceSport environment on dancers’ physical self-perceptions and related behaviours. Four of the invited dancers were identified as having a healthy body image and approach to weight management, whereas the other four participants indicated a moderate-high level of body dissatisfaction and engaged in disordered eating and/or other weight management behaviours. Tape-recorded
interviews were transcribed and content analysed independently by both members of the research team. The coded data was then collated to identify common themes within and across the two groups of participants. Where possible, male and female data were analysed separately. A preliminary analysis of the data showed similarities and differences between male and female DanceSport competitors as well as between this population and other dance-related groups (e.g., ballet, cheerleaders). The data also highlighted several areas of influence of the competitive DanceSport environment on dancers’ body image and the ways in which the dancers cope with the physical and aesthetic demands of the sport. These results are discussed in terms of past research and DanceSport cultural contexts. The results are also considered in light of research undertaken with athletes from aesthetic sports, such as diving and gymnastics. A full analysis of the data is currently underway and is expected to support the pattern of results revealed by the preliminary analyses. Further conclusions will be made regarding the implications of these findings for the health and wellbeing of the greater DanceSport community.

Keywords: body image, eating behaviours, weight management, physical self-perceptions, dance

Brazilian personality factor questionnaire: Development and validity evidence

NUNES, C. (Federal University of Santa Catarina), NUNES, M. (Federal University of Rio Grande do Sul), HUTZ, C. (Federal University of Rio Grande do Sul)

The aim of this presentation is to discuss the development and validation studies of the Brazilian Personality Factor Questionnaire (BPFQ), which was created to assess personality traits based on Five Factor Model (FFM). The BPFQ was developed considering Brazilian common language expressions of the five personality domains. Different sources were used to construct the scale: specialized literature regarding the FFM, a Brazilian study that identified personality markers as did Goldberg, other personality scales that assess the same domains, the DSM-IV and the International Personality Item Pool. Validity studies of BPFQ were conducted with 6,599 subjects, from 11 different Brazilian states. Their mean age was 22.5 years (SD = 7) and 62.4% female. The BPFQ has 126 items that describe the way people feel, think, and behave. The BPFQ had its internal structure analyzed with exploratory factor analysis and five factors were extracted in agreement with the content of the FFM. Cronbach Alphas were .90, .84, .84, .82, and .70 for Neuroticism, Extraversion, Agreeableness, Conscientiousness, and Openness, respectively. Another factor analysis conducted to assess factor facets showed four facets for Neuroticism and Extraversion and three facets for Agreeableness, Conscientiousness, and Openness. Several validity studies were conducted. Their results showed correlations between Neuroticism and its correspondent factor at the Eysenck Personality Questionnaire ($r = .80; p < 0.001$) and the Beck Depression Inventory ($r = .66; p < 0.001$), and between Agreeableness and Anti-social personality disorder symptoms ($r = -.59; p < 0.001$). Another study correlated the BPFQ with the NEO-PI-R (Brazilian version) and its results showed several significant correlations between the correspondent personality factors, ranging from .65 (Openness) to .82 (Agreeableness). The studies conducted with BPFQ indicate its usefulness at health care context, vocational guidance, clinical treatment of chemical dependents, and research in several fields. In general, these findings were in accordance with most theoretical expectations and with findings in the literature, and they indicated positive validity evidence for the questionnaire.

Keywords: personality factors, big five model of personality, personality markers, Beck Depression Inventory

Building a new role for educational psychologists through guided participation of students of psychology into “communities of work learning”

ERASUSQUIN, C. (Facultad de Psicologia Universidad de Buenos Aires), LABANDAL, L.G. (Facultad de Psicología Universidad de Buenos Aires)

The aim of this study was to analyse mental models and activity systems through educative
experiences that “cross boundaries” between the “academic world” of university and the “real world” of work. “Psychologists in modeling” learn to work with different professionals in educational contexts through actual societal practice. The framework for this research is the “contextualized shift” in psycho-educational agents (Pintrich), “mental models” and cognitive change in educational contexts (Rodrigo), cultural-historical “activity theory” (Engestrom), and the Vigotskian concept of Zone of Proximal Development, to understand the process of “professionals modeling” as well as the process of developing minds through schooling. Three experiences of apprenticeship narrated by different groups of students of psychology in educational contexts were analysed. The first was of applied psychology in education, in institutions with special educational needs schooling; the second was of research in education, to investigate “integration” in mainstream inclusive school and TICs in special education; and the last was of teaching psychology, in secondary school or university courses. The methodology used was descriptive ethnography with quantitative and qualitative data. Questionnaires about situation-problems from psychologists’ intervention perspective in education were given to 200 subjects at the beginning and end of their apprenticeship. A multidimensional matrix of analysis of psychologists’ professionalism was applied to examine the shifts happening between pre-test and post-test in students’ mental models, and differences related to contexts and roles appropriate in advanced students of undergraduate courses of psychology at the same Argentinean university during 2008. Professional knowledge and competence is co-constructed in the contexts of work and study. The historical role of educational psychologists related to segregated schooling and IQ assessment is changing towards a “contextualized shift”, however changes are different for different roles appropriation and for different model dimensions, with strong tension between “clinical models” in psychologists formation (one matrix of development and focus on individual de-contextualized mind) and the need for new perspectives in inclusive education. In conclusion, we learn to work while working, although we do not know at the beginning how to do it. Those who learn have a chance to build a way to do something with others. While they are learning they choose one from many ways, likely different to the tutors’ way, including one that isn’t yet there.

Keywords: educational psychology, guided participation, community, psychology students, real world

Building explicit and implicit trust toward a new leader in the Chinese context

SHI, X. (Ajou University), KIM, M. (Ajou University), KIM, D-Y. (Ajou University)

Research on South Koreans showed that reading about a new leader’s trustworthiness could form explicit (conscious evaluation of trust) and implicit (non-conscious associations between a leader and trust) trust (Kim, Shi, & Kim, 2009). While Chinese may also rely on information to form explicit trust, they may form implicit trust through merely knowing someone is a leader, since there is a prevalent stereotype which associates the position of leaders with trustworthy characteristics. Therefore, merely revealing a person to be a leader may be sufficient to form implicit trust. Studies 1 and 2 replicated Kim et al.’s (2009) design. Study 1 investigated the effect of reading about a new leader’s trustworthiness on explicit and implicit trust. Study 2 was a replication of study 1, but examined the effect of positive or negative rumors before exposure to information. In study 1, 63 participants read a short profile about a fictional leader and completed pre-test measures (affect and cognition based explicit trust measures and an implicit association test (IAT)-based implicit trust measure). Participants were then randomly assigned to either the information group, where participants read information about the leader’s trustworthiness, or to a control group. At post-test, participants completed identical measures of trust as in the pre-test. In study 2, 120 participants read positive or negative rumors about a new leader then completed the same procedures as study 1. In both studies, a one-sample t-test on Pre-test measures showed higher than neutral affect, cognition, and implicit trust across all conditions. Also, in both studies, analyses revealed the
information group showed significantly increased explicit trust toward the leader compared to the control group, but there was no difference in implicit trust. In study 2, positive rumors resulted in significantly higher affect and cognition based trust than negative rumors at pre-test, but there was no difference in implicit trust. Reading about a new leader’s trustworthiness was effective in increasing explicit trust, but did not affect implicit trust, which already existed at pre-test. In addition, rumors influenced explicit but not implicit trust. Despite being both east-Asian, Chinese and South Koreans differed substantially in the pattern of trust formation.

Keywords: leadership, explicit trust, implicit trust, rumors, Chinese

Calling at work, perceived organizational support and work engagement on nurses

CHRISTIAN, F. (University of Surabaya), BATUADJI, K. (University of Surabaya)

This paper investigates the topic of the meaning of work, especially a calling to work, on nurses. Nurses with a calling orientation to work, rather than for financial rewards or for advancement, find fulfillment in doing the work. In callings, the work is an end in itself, as opposed to a means to some other end, and is usually associated with the belief that the work contributes to the greater good and makes the world a better place. This research found that nurses who have higher scores in calling orientation at work and perceive that they have higher support from an organization will show high engagement with their work. The participants are nurses from two middle-class hospitals in Surabaya, Indonesia (N=100). The implications of these findings for health-care workers will be discussed.

Keywords: meaning of work, calling orientation, perceived organisational support, work engagement, nurses

Can personality characteristics predict tendency to addiction?

NIKPOUR, G. A. (Applied and Science University of Behzisti), HOMAYOUNI, A. (Islamic Azad University)

The aim of this research is to test this question of whether there are there specific personality characteristics that lead to addiction. The method of this research is causative-comparative (ex post facto). One hundred and fifty three addicted people and 153 non-addicted people were randomly selected and MoKioly’s Characterology Inventory (MCI) was administered on them. The inventory assesses personality based on eight characteristics: sanguine, indifferent, nervous, indolent, indignant, passionate, sentimentee, amorphous. Findings showed addicted people are much more indifferent, sanguine and passionate than non-addicted people. In conclusion, in regard to people with these characteristics are much more at risk, they should be trained with special plans and be cared so that the tendency to addiction in them decreases or is controlled.

Keywords: Personality characteristics, Addiction, Tendency to addiction, MoKioly’s Characterology Inventory (MCI)

Carer-child relationships in permanent care programs

HAMMOND, S. (Australian Catholic University), ALEXANDRIS, M. (Australian Catholic University), MCKAY, M. (Australian Catholic University)

Over the past 20 years, there has been a steady increase in permanent care placements in Australia, however, relatively little research has been conducted on how to best support this growing population. The aim of this study was to examine carer and child variables in permanent care carer-child relationships. Participants were 46 permanent carers of at least one child aged between 3-12 years. Carers were recruited from metropolitan and rural permanent care agencies. Participants completed a questionnaire booklet on empathy, parenting styles, the relationship with their child, and on child variables including emotional and behavioral difficulties, temperament, and resilience. Thirteen carers also participated in a qualitative interview. Carer variables were less important in predicting carer-child relationships than child variables, especially emotional and behavioral difficulties. Most children had significant difficulties. Qualitative data were consistent with quantitative findings, showing
that it was the child’s troubling behaviors which were the most taxing on the development of positive carer-child relationships. Where carers perceived improvements in their children’s behaviors or could recognize positive aspects in their children and their relationships with them, this seemed to support carer-child relationships. Given the extent of emotional and behavioral difficulties among children in permanent care, effective management of these challenges by carers may be an important consideration in the development of positive carer-child relationships.

**Keywords:** relationships, behaviour, permanent care placements, caregivers, Australia

**Causal analysis utilizing structural equation modeling based on third-order moment structures**

**HATTORI, T. (University of Tsukuba)**

Structural Equation Modeling (SEM) is a powerful multivariate analysis technique that incorporates many of the techniques of traditional statistical analysis (e.g., regression analysis, causal modeling, confirmatory factor analysis, correlation structure models) as special cases. The serious problems with using traditional SEM relate to model under-identification and the existence of equivalent models. In contrast to traditional SEM plagued by such problems, non-normal SEM (nnSEM) utilizing higher order (e.g. third and fourth) moment structures has the potential to overcome these problems. We develop computer programs for the nnSEM approach that incorporate the asymptotically distribution free (ADF) estimation method. Analyzing several sets of real-life data with the programs, it is shown that the nnSEM utilizing third-order moment structures can estimate the parameters of structural models, which could not be identified by traditional SEM. The relative fits of equivalent models are also examined. Finally, based on simulation studies, we present the necessary sample sizes in order to detect significant path coefficients in full path models with two or three observed variables and those with three latent variables with two observed variables each.

**Keywords:** structural equation modeling, multivariate analysis, statistical analysis

**Change of career awareness and adjustment in Japanese adolescents**

**NIIMI, N. (Hiroshima University), MAEDA, K. (Hiroshima University)**

Preparing for an adult career is an important career developmental task of adolescence. Hypothetically, career development is positively related to adjustment, which incorporates multi-dimensional constructs. Although a number of studies have demonstrated that career development in adolescents is positively related to various indicators of adjustment, the types of adjustment that are effective in changing the levels of career development have not been clarified. Therefore, these variables were investigated in Japanese adolescents. Japanese high school students (n = 510) participated in this study. They completed the Career Awareness Scale and the Adjustment Questionnaire at Times 1 and 2, 12 months after Time 1. The Career Awareness Scale was used to assess the level of adolescents’ career development and the Adjustment Questionnaire was used to measure five areas of adjustment that included self-acceptance, school adjustment, family adjustment, friendships, and academic achievement. Cross-sectional relationships between career awareness and the five areas of adjustment were examined at Times 1 and 2 respectively. Results indicated that similar to previous studies, the career awareness score was positively related to the five adjustment scores. Participants were then divided into one of four groups based on the career awareness scores at Times 1 and 2 (high-high, high-low, low-high, and low-low groups). In this study, we focused mainly on low-high and low-low groups. Five analyses of co-variance were conducted to examine differences between students who increased career awareness score (low-high group) and those who maintained low career awareness score (low-low group) on the five areas of adjustment scores at Time 2, while controlling for each score at Time 1. The main effects of the group were significant for school adjustment and academic achievement scores. Post hoc analyses for these two adjustment scores indicated that the low-
high group had significantly higher scores than the low-low group. These results suggest that school adjustment and academic achievement have a strong influence on the career development process of adolescents.

Change of emotions and cognition before a deadline on an academic task

KOHAMA, S. (University of Tsukuba)

The aim of present study is to investigate the change of emotions and cognition when a student doesn’t engage in an academic task. Delaying what should have been done is viewed as academic procrastination. Many studies have investigated academic procrastination to the extent of dispositional phenomena, and revealed positive relation between academic procrastination and psychological illness (e.g. Solomon & Rothblum, 1984). Despite procrastination being negatively related to psychological illness on one occasion (Tice & Baumeister, 1997), few have investigated academic procrastination from a situational view. Thus, this study investigates situational change of emotions and cognition which take place in academic procrastination. Fear of failure and positive emotion were investigated as emotional factors, and optimistic thinking was investigated as a cognitive factor. Participants were 94 undergraduate students attending psychology classes in a Japanese university. The participants were asked to rate questionnaire three points at a time; seven days, three days, and one day before a deadline. Between 18:00-20:00 on the research day, e-mails were sent to participants’ cellular phones. Participants were then asked to rate a web-based questionnaire. At the beginning of the questionnaire participants were told to recall why they didn’t engage in the academic task on that day. Three variables (fear of failure, positive emotions and optimistic thinking) were measured by 4 items. Items were rated with a 5-point Likert scale. To compare emotional and cognitive factors with each point of time, one factor within-subjects ANOVA were conducted. Fear of failure at three days before deadline ($M=2.31$) was significantly higher than that one day before deadline ($M=2.61$) ($F(2,93)=4.34$, $p<.05$). Optimistic thinking at seven days before deadline ($M=3.24$) and at three days before deadline ($M=3.10$) was significantly higher than that at one day before deadline ($M=2.46$) ($F(2,93)=16.72$, $p<.001$). There were no significant differences on positive emotion ($F(2,93)=2.00$, n.s.). The mean score of positive emotion was 2.78 (seven days before), and 2.89 (three days before), 2.67 (one day before). Investigations revealed that students who did not engage in the academic task felt negative emotions and pessimistic thoughts near the deadline. These findings imply that the relationship between procrastination and psychological illness strengthens near a deadline.

Keywords: emotions, cognition, deadline, academic procrastination, fear of failure

Changes of mental health during unemployment: A longitudinal study

TAK, J. (Kwangwoon University)

This study was intended to examine changes in mental health variables among unemployed adults using a longitudinal study. First, the survey was administered to unemployed adults within two months after unemployment using an online survey method. A total of 1,530 people responded to the survey. Second, the survey was administered to the same individuals six months after the first survey. Only 706 individuals responded to the online survey. Among them, 443 people successfully got a job. Finally, the survey was administered to those 706 people six months after the second survey. This time 483 individuals responded to the survey. Respondents were classified into four groups based on status of employment at three different times: Group 1 represents unemployment-reemployment-reemployment across the three different periods, Group 2 represents unemployment-reemployment-unemployment, Group 3 represents unemployment-unemployment-reemployment, and Group 4 represents unemployment-unemployment-unemployment. Mental health variables such as GHQ, anxiety, depression, and psychosomatic were measured to examine how
these variables change depending on the status of unemployment across the three different periods. Results showed that mental health becomes worse after unemployment, but it gets better after reemployment. Mental health appears not to get worse continuously. Future study needs to be conducted using a longer interval during unemployment to confirm these results.

Keywords: mental health, unemployment, longitudinal study

Children’s emotion regulation and socialization in preschool

HIRABAYASHI, H. (Tokyo Woman's Christian University)

Emotion regulation is an element in emotional competency (Denham et al., 2006). In early childhood, children express negative emotions at first, and then they will be able to regulate their negative emotions gradually. In preschool, the teacher plays an important role in the development and socialization of emotion regulation. The first purpose of this study was to examine the frequency and the context of children’s negative emotions (e.g. sad, anger) in preschool. The second purpose of this study was to examine the teacher’s strategies of regulation for children’s negative emotions. Three year-old children and the teacher were observed in a preschool where the frequency and the context of children’s negative emotions were recorded. The teacher’s strategies of regulation for children’s negative emotions were also recorded. 103 episodes were observed, 31 sad episodes, 62 anger episodes, six sad/anger mixed episodes, and four others. Boys expressed negative emotions more than girls. In sad episodes, interpersonal conflict occurred as body aggression, and children expressed sadness and crying. In anger episodes, interpersonal conflict occurred as a scramble for a single toy. The teacher’s strategies of regulation for children’s negative emotions were various. In sad episodes, the teacher used several strategies like comfort, stroking, and asking for the reason of the sadness. In anger episodes, the teacher used several strategies like stopping the aggressive behavior, prohibition, asking for the reason of the anger, and explanation of the other child’s intention. It was found that three year-old children often expressed negative emotions in preschool, because of interpersonal conflict. The teacher used various strategies of regulation for children’s negative emotions. The teacher coached children how to deal with their negative emotions and socialized children’s emotions.

Clients’ and their treating clinicians’ perspectives regarding deliberate self-harming behaviours

GOVINDAN, A. (Deakin University), MILDRED, H. (Deakin University)

Deliberate self-harm (DSH) is a significant health problem in the Western World, and a risk factor for completed suicide. The aim of the current study was to identify the reasons for, and risk factors associated with Deliberate Self-Harm both from the perspective of people who significantly self-harm, as well as their treatment of mental health clinicians. A qualitative methodology was used to explore the causes, motives and factors associated with deliberate self-harm from these two groups of experts. Focus groups were conducted both with clients with a history of DSH, and mental health clinicians who were treating them in an acute mental health setting. The researcher conducted the focus groups with a consumer consultant for the mental health service and extensively documented responses from participants. Repeated reading and analysis of the recorded data was used to extract common and divergent themes from the material. A number of similar themes emerged within both the clients’ and clinicians’ perspectives of the reasons for DSH, which included affect regulation, communication and self-hatred. Clients and clinicians both viewed DSH as sometimes being an effort to manipulate...
or obtain care from others, whereas clients did not feel this was an accurate explanation. Their perspective was that clinicians are often absorbed by the risk and the effect that the DSH has on them (clinicians) and the busy health service that they minimise client distress which clients stated very strongly is the predominant motivator for them harming themselves. In conclusion, there was significant agreement regarding some of the reasons for and associated factors of DSH; however clinicians and clients regarded the predominant motivating factors differently. This discrepancy may well hinder the relationship between clients and clinicians which in turn may affect the relevance and efficacy of the care they offer.

Keywords: deliberate self-harm, suicide, risk factors, motives, distress

Cognitive, psychomotor and personality predictors of self-reported driving behavior

AUSTERS, I. (University of Latvia), PEREPYOLKINA, V. (Riga Teacher Training and Educational Management Academy), VOITA, D. (Riga Teacher Training and Educational Management Academy)

In previous studies the predictive relevance of various driving-related abilities and personality traits mostly has been studied in isolation. The aim of the present study was to investigate the usefulness of combining various driving-related abilities and personality traits in predicting self-reported driving behavior, i.e. traffic violations, and errors. A total of 116 (52 females and 64 males) lay drivers, aged between 20 and 57 years (M = 33 years) participated in this study on an unpaid voluntary basis. Most of the participants (68.10%) were accident-free drivers, and only 12.9% had been engaged in two or more traffic collisions during the last three years. The respondents completed a test battery made up from the six computerized measures derived from Vienna Test System (Schuhfried, Austria) measuring decision speed and physical motor speed, perceptual speed, selective attention, eye-hand coordination ability and reactive stress-tolerance, and a subjectively accepted level of risk in traffic situations. Four subscales of NEO-PI-R (McCrae & Costa, 1992) were used to measure driving-related personality traits of excitement-seeking, impulsiveness, dutifulness and discipline. Driver Behavior Questionnaire (DBQ, Reason et al., 1990; Austers & Renge, 2007) was used as a self-reported measure of traffic violations and errors. The incremental validity of mentioned potential predictor variables was investigated by means of a hierarchical regression analyses. The results of the hierarchical regression analyses revealed that excitement seeking and being male predicted DBQ traffic violation score, whereas DBQ errors were predicted only by discipline personality trait. The findings of this research confronts the usefulness of the implications of cognitive and psychomotor abilities measures for driver assessment, at least in the assessment of relatively young, healthy and ‘successful’ drivers, who are not the representatives of the ‘problematic driver group’. These conclusions should be carefully examined in future research investigating the predictive power of the analysed predictors in different age groups and in the group of traffic offenders.

Keywords: driving skills, personality traits, driving behaviour, excitement seeking, gender

Collaborative evaluation of a school based water conservation program

CURNOW, R. (Community Change), CURNOW, K. (Community Change)

A school-based water saving education program, provided by cooperation between government owned water businesses, used a specially designed Behaviour Change Framework to target behaviour related to water saving objectives, including proposed improvements in the knowledge, attitudes and behaviour of both students and teachers. The evaluation program consisted of questionnaires distributed by trained teachers and program support officers who issued and collected surveys pre and post program participation. The program was conducted from 2006-2009 and included ongoing consultations with a diverse range of program stakeholders to enable continuous refinement of the program and its evaluation. In total 1,905 primary, 513 secondary, 73 special school and 109 teachers participated in the evaluation. Sound benchmarks have been set for knowledge levels and attitudes to saving water;
however attempts to assess behaviour change have been problematic due to reliance on measures of self report. Significant improvements were found in: 1) knowledge of the causes of water shortage including climate change; 2) knowledge of water use and saving methods in school and at home; and 3) primary and special school students undertaking more water saving actions than secondary students and teachers. Attitudes about the importance of saving water were high pre-program and remained high at follow up. School based behaviour change programs can effectively improve knowledge about water shortage and methods for saving water. Consultations in the evaluation process were critical to its success and usefulness of outcomes for ongoing program improvement. Further refinements to evaluation issues need to continue in order to improve the methodology and verify self report behavioural data from teachers and students and to engage the full range of stakeholders.

Keywords: attitudes, behaviour change, water conservation, schools

Communicating change in educational organization

NORHAFEAZH YUSOF, N. (UUM), HASHIM, R.A (Educational Studies, CAS, UUM), ABDULLAH, S.S (Educational Studies, CAS, UUM), RAHIM, F.A (Educational Studies, CAS, UUM), WAN ZALINA, W.Z (Educational Studies, CAS, UUM), NORDIN, H. (Educational Studies, CAS, UUM)

The objective of this study was to investigate the experiences of communicating change i.e., introducing a new method into the educational setting. The methods used are observations and interviews. Data were analyzed using Five Key Change Sentiments suggested by Armenakis and colleagues (2007). The findings suggest that strong belief in Project Based Learning (PBL) effectiveness, principals’ supports and parents’ blessing are eminent factors which support change in the organizations. Future research in the Malaysian setting needs to be aware of the high resentment of change among teachers due to immense pressure of exam-oriented culture in the nation.

Keywords: change, educational institutions, Project Based Learning, exam-oriented culture

Community counseling model viewpoint: A study of the status and difficulties of the Suicide Attempters Crisis Intervention Service in Taiwan

CHING-TENG, Y. (Nanhua University), JIN-LIN, Y. (Nanhua University)

The most basic goal of public health is to prevent the occurrence of disease, preventing the disease from causing pain, inhibiting function and disabling. The community counseling model also emphasizes that prevention is important. This study shows that the 40%-60% of suicide deaths have never made prior attempts at suicide. The community counseling model advocates the provision of a case service that reaches out to the high crisis group as a practical strategy to prevent suicide. The aim of this research is to evaluate the suicide attempters’ crisis intervention service status in Taiwan, and discuss related difficulties. The main research method of this study is purposive sampling. The study used purposive sampling method, tracking services for three months by using the records of cases which were further supplemented by counselors’ understanding of the situation studied. In addition, the use of these services before and after the given case (measured by the Beck Hopelessness Scale) was also measured, providing a total of 20 cases before and after the test and follow-up. The results showed that women attempted suicide cases were approximately double that of men in, especially for individuals aged 30-39 years old. In relation mental problems, the case study revealed that 62% suffered from depression or bipolar disorder, in line with trends found abroad. Personality disorders account for 19%, and those with no disturbed mental disorders accounted for 19%. The results show that over 85% of cases suicide occurred within three months of the crisis situations. The Beck Hopelessness Scale was used for case screening before and after the crisis, crisis cases referred by the high drop crisis or no crisis low was 76.9%, \( t = 3.412, p < .002 \), where moderate a crisis situations were 25%. The intervention was found to improve cases in the suicide crisis. In addition, another study has found that the case of
depression and bipolar reoccur again after a suicide intervention in crisis situations more so than schizophrenia and personality disorder cases. Studies have shown that timely and intensive intervention against suicide attempts can effectively reduce the suicide crisis, but can also be a helpful suicide prevention strategy. To better manage suicide prevention, there is a need to meet legal policy, and a need for improved professional human resources. The evaluation of this program expects to provide practical guidelines for future reference, from a prevention and mental health viewpoint. At present, this research found that: (1) Taiwan focused on medical services but not on a community model service; (2) the suicide preventive service uses “hotlines” and public education primarily, however these remain to be not readily accepted as suicide crisis intervention services; and (3) this trend is closely associated with the development of local mental health policies and resource allocation.

Community identity and perceived legitimacy for managers of commons: A study on social governance in Japan

NONAMI, H. (Kwansei-Gakuin University), KATO, J. (University of the Ryukyus), NAKAYACHI, K. (Doshisha University)

Consistency among the evaluations of actors who have the right to decide on public policies that affect the interests of diverse people is an important premise for social governance. Confusion is particularly likely in decisions on who are legitimate managers of common resources, because many actors with a wide range of interests and beliefs participate in managing the resources. In the present research, legitimacy is defined as the approvability of the rights of others and the self to participate in the management of common resources, and a distinction is made between perceived legitimacy and institutional legitimacy. The former, based on individuals’ subjective estimation, is assumed to be affected by various determinants like trust, whereas the latter is legitimized by legal assurances. Actors who are viewed by community members as holding a higher community identity are expected to consider the public interests of the community on the whole more seriously. Such an actor is hypothesized to receive approval for perceived legitimacy as a manager of common resources. A questionnaire survey was conducted with about 500 residents in a community wherein the coastal sea area has been utilized as a sightseeing and fishery resource. Three kinds of actors, local civil servants, members of a fishermen’s union, and other general residents of the community took part in decisions on policies for the management of sea resources as commons. Their perceived legitimacy and prediction of other actors’ community identity, trust in those actors, expectations for them to place priority on public interests, and other factors were measured on 5-point scales. The results showed that certain kinds of factors, including community identity, determined the perceived legitimacy of rights of the 3 respective actors to manage the sea resources. The prediction of others’ community identity among various actors is thought to be important in determining their perceived legitimacy to decide policies on managing common resources. These findings showed several determinants of perceived legitimacy for governance systems for the appropriate preservation of commons. Distinctions between perceived and institutional legitimacies and the effects of community identity on perceived legitimacy are discussed theoretically and practically.

Comparative appraisal of motivational objects as the work motivation diagnostics instrument

STRIZHOVA, E. (State University), GUSEV, A. (Moscow State University)

The aim of this study was the elaboration and standardization of a new method, which could help to evaluate and forecast work motivation. The main purposes for elaboration were practice necessity and operational validity increasing. This research used an in-group design and consisted of 3 stages: elaboration, approbation, standardization. Participants were instructed to
Abstracts of the 27th International Congress of Applied Psychology

Electronic Poster Presentations

compare 15 motivational objects (J. Nuttin) with each other using 3 graphical two-dimensional spaces. They did it step by step putting motivational objects markers in the frame of axis. Generalized R.A. Emmons's scales of personal striving assessment were used as the axes. Elaboration results were 15 motivational objects and 6 generalized R.A. Emmons's scales of personal striving assessment, organized in 3 two-dimensional spaces. Approximation results were 47 regression equations where depended variables were 47 widely used motivational scales, independent - Euclidian distances between motivational objects. As such, the standardization of the method is proceeding.

Comparison between combine EMDR and drug with drug only in reduction symptoms and severity of obsessive compulsive disorder

ABYAR HOSSEINI, A. (Islamic Azad University), VAZIRY, S. (Islamic Azad University - Rood-e hen Branch), LOFTI, F. (Islamic Azad University - Rood-e hen Branch)

This study was a comparison between the effects of combine eye movement desensitization and reprocessing (EMDR) and drug, with drug only, in the reduction of symptoms and severity obsessive compulsive disorder. Thirty patients that were assessed as suffering OCD by a psychiatrist were divided in two groups randomly (experimental and control groups). All subjects have been tested by Maudsley obsessive compulsive inventory (MOCI) and Yale-Brown obsessive-compulsive scale (Y-BOCS). The experimental group learned EMDR and across 8 weeks, when they experienced disturb thought, used EMDR without compulsive behavior. During the 8 weeks, the control group just used drugs. Results showed a significant reduction of symptoms and severity of OCD in both groups but in the experimental group, the reduction was more effective and significant. Thus, to conclude, although EMDR has been used for PTSD symptom reduction, the present study revealed that this technique is also effective for the reduction of symptoms and the severity of OCD.

Comparison of athletes' study strategies between special sport event groups and general groups

CHU, Y. (Beijing Sport University)

The purpose of this study is to explore the differences of learning strategy between the same sport event athletes and general athletes, as well as to explore the differences of learning strategy between the different sport event athletes and general athletes. A cross-sectional design was used. We adopted the Secondary School Student Study Strategy Questionnaire to collect data. The questionnaire consisted of 56 items and three dimensions. The internal reliability was satisfied. We recruited 140 participants for the study. The results showed: (1) There are significant differences in cognitive strategy and goal management strategy among different level athletes in the same event-group; (2) Significant differences are found in three dimensions of the study strategy among different event-group athletes. It was concluded: (1) The cognitive strategy is different among different levels of the athletes; (2) The learning strategy is different among different athletes.

Keywords: learning strategies, sport, athletes, cognitive strategy

Comparison of classical test theory and item response theory in developing knowledge tests for Croatian national assessment

The aim of this paper is to compare Classical Test Theory (CCT) and Item Response Theory (IRT) and to show benefits of using IRT approach in knowledge-test development. In the international project which aimed to develop instruments for Croatian national assessment,
Mathematics and Croatian language tests were pretested. The samples consisted of 1100 gymnasium students. After the pre-test, CTT and IRT parameters were calculated. In analysis of results we used TiaPlus software (Heuvelmans, 2008) for CTT and OPLM software (Verhelst, Glas & Verstralen, 1995) for IRT analysis. OPLM is a model where difficulty parameters are estimated and discrimination indices are imputed as known constants, which is an extension of the Rasch model. Two types of item statistics were compared: item difficulty parameter \( b \) from IRT model with CTT item difficulty \( p \) value and IRT item discrimination parameter \( a \) with CTT item discrimination index. Choice of the main-test material was done according to the results of psychometric analysis. Pearson correlation indicated that there were considerable similarities between the item statistics obtained through CTT and IRT. Information functions calculated in OPLM were helpful when deciding which of the items with similar CTT parameters were better. Results of CTT and IRT analysis were dominantly consistent. IRT parameters were especially useful for detecting some differences between items that had very similar CTT parameters. When developing knowledge tests it is strongly recommended to use both test theory approaches.

Keywords: Classical Test Theory, Item Response Theory, national assessment, knowledge tests

Comparison of sport orientation on athlete teachers in all of the Iran

NIAZI, M. (Jiroft University)

Athletes, who participate in activities and athletic competitions, have different motives and possibly different sport orientations. So the purpose of this study is to perform a comparative study on sport orientation of athlete teachers in all of Iran. For this purpose 213 athlete teachers (113 males & 100 females) were selected as subjects. Individual characteristics such as gender; sport field (individual or team); and recorded medals were questioned in the beginning. Then to measure sport orientation, Gill’s Standard Sport Orientation Questionnaire-1988 (SOQ) was used in order to measure this phenomenon in three aspects of: competitiveness; winning; and goal orientations. After translation of the original questionnaire and consulting with eight physical education (PE) and social science faculty members, it was used in two pilot studies, and its reliability was estimated through the method of Cronbach Alpha Coefficient \( r = 0.88 \). The data were analyzed by using \( r \) (Ataş coefficient of correlation), chi-square and an ANOVA test, at the level of \( p \leq 0.05 \). The results of this study indicated the following matters; the priorities of sport orientation of athlete students were accordingly, 1. Goal setting; 2. Competitiveness; 3. Winning Orientation. However, there was no significant difference in the priority of sport orientation among athlete teachers with regard to; gender, sport field (team or individual), and recorded medals. For a more careful comparison and further recognition of sport orientation, more investigations among different levels of athletes are required.

Keywords: sport, competitiveness, winning, goal setting

Compensatory self-enhancement as a solution of the multiple audience problem

KASAGI, Y. (Osaka University), DAIBO, I. (Osaka University)

The multiple audience problem (e.g., Fleming, 1994) is the difficult self-presentation situation in which someone is faced with two or more “audiences”, simultaneously wanting each audience to form or preserve a different impression of him/her. Generally, people are often confronted with this problem, but they can’t resolve it effectively. According to Kasagi and Daibo (2009), participants who confronted the multiple audience problem showed compensatory self-enhancement; if the audience has formed an unfavorable impression of them, people will try to counteract that impression by presenting new and highly favorable information about themselves, which may compensate for the bad image. But, the effectiveness of the compensatory self-enhancement as a solution of the multiple audience problem has not been explained. So, this study examined the effect of compensatory
self-enhancement on the multiple audience problem. Participants were randomly assigned to the multiple audience condition or the control condition. Also, they were randomly assigned to the compensatory self-enhancement possible condition or impossible condition. Then, they spoke in front of the video camera to impress others who would watch this video. After the participants spoke in front of the video camera for 3 sessions, participants completed the state self-esteem scale. As we predicted, the results revealed that participants in the multiple audience condition/ the compensatory self-enhancement impossible condition reported the lowest state self-esteem scores than any other condition. Thus, when we can’t do the compensatory self-enhancement, our state self-esteem would decline. So, the effectiveness of compensatory self-enhancement as solution to the multiple audience problem was demonstrated.

Keywords: self-enhancement, multiple audience problem, self-esteem

Competence makes a difference: Examining the interactive effects of social contexts, gender, and relative status on our liking towards a cold person

CHEN, C-A. (Chung Yuan Christian University), LIN, W-Y. (Chung Yuan Christian University), WANG, J-W. (Fo Guang University), LIN, H-Y. (Fo Guang University), LIN, H-T. (Fo Guang University), CHEN, C-A. (Chung Yuan Christian University)

Warmth and competence are the centralities underlying our person perceptions and interpretations of other’s behavior. From an evolutionary perspective, intention is evidently able to alter our perception judgment of others, either foes or friends. This study investigated whether competence level would interact with such interpersonal relation factors such as status and competition, in influencing people’s liking towards one who was perceived coldly. A sample of 655 participants (M =25.2yrs, SD =9.0), recruited from company, university, and church groups, partook in this research with two experiments. Participants were, on each sample basis, randomly presented with one of four versions of vignettes, used to illicit their liking opinions towards the target person according to a seven point scale. Protagonists characterized by a low warmth trait, were manipulated throughout the vignettes. Experiment 1 used a troupe vignette with a 2 (same vs. superior relative status)× 2 (gender)×2 (high vs. low competence) factorial design, whereas experiment 2 was based on a 3×2×2 factorial design, replacing only the gender variable with three vignettes varying in the characteristic of task orientations, but corresponding to each sample group’s social context. In experiment 1, high-competent (HC) targets were rated significantly more likeable than their low-competent (LC) counterparts across both genders by all, but the church group, for the female targets, regardless of the relative status imagined by the perceivers. Higher likeness score was found awarded towards the HC target person when judged from the superior- (M =4.8) than the same-status positions (M =3.6). This result was replicated in experiment 2, with an average score of 4.6 for the former and 3.7 for the latter. Also, a significant vignette, competence and group main effect appeared as expected. The results show exactly the same pattern in either of the status relations. All participants, except the church respondents in the church story, consistently reported liking others with HC more than LC. Competence’s η values fell between .118 and .286. To conclude, Taiwan is generally identified culturally as a collectivistic society, thus, one lacking in warmth is particularly unflattering in interpersonal interactions. It is nonetheless demonstrated that HC, in ecologically relevant and irrelevant social contexts, has an enhancement effect on liking perceptions in this study.

Keywords: warmth, competence, perceptions, interpersonal factors

Computing common effect sizes and their asymptotic sampling variances for meta-analysis in structural equation models

CHEUNG, M. (National University of Singapore)

Structural equation modeling (SEM) has been proposed as an alternative approach to conduct meta-analysis. Univariate and multivariate meta-analyses can be conducted within the SEM
framework. One limitation, however, is that effect sizes and their approximate standard errors have to be estimated outside the SEM framework. This study further extends the SEM approach to compute common effect sizes and their standard errors. It shows that SEM can be used as an integrated approach to estimate effect sizes and to conduct meta-analysis. This makes the current SEM approach more appealing to meta-analysts. Several Monte Carlo computer simulations were conducted to evaluate the accuracy in estimating the effect sizes and their standard errors. These effect sizes included (1) raw mean difference and standardized mean difference for independent groups; (2) standardized mean difference of repeated measures; (3) proportion and logit; (4) log of odds ratio; and (5) log of risk ratio. The relative percentage bias of the parameter estimates and their standard errors was used to evaluate the empirical performance. The relative percentage bias of the parameter estimates and the standard errors was reasonably small. Results indicate that the SEM approach is accurate in estimating the effect sizes and their standard errors. This study shows that SEM can be a useful framework in estimating effect sizes and their standard errors. SEM can be used as a favorable approach to conduct meta-analysis.

Keywords: structural equation modeling, meta-analysis, effect size, standard error

Construction and co-construction of knowledge in scientific inquiries

HORNG, (National Chiao Tung University), LIN, T-J. (University of Illinois-Urbana-Champaign)

The purpose of the study was to explore the knowledge construction processes in scientific inquiry. We predicted that knowledge construction in science is an act that involves extensive and creative conceptual combinations. Conceptual combination refers to creation of a meaning that links two, or more than two, concepts together. How conceptual combination occurs to produce the scientific breakthroughs was the target of the study. Twenty scholars (professors, and research and development (R&D) workers) in science or technology were interviewed. They were asked to use one of their studies as a case to explain how the research idea emerged, how the study was performed, how they conquered difficulties in the research process, and how they evaluated achievements of the study. The content of their reports was analyzed to extract variables facilitating or hindering their creative processes. Qualitative analysis of data revealed that conceptual combinations occurred at every stage of scientific knowledge construction. Scientific investigation involves three distinctive tasks: mapping a conceptual structure to the observed data structure to extract a research problem, importing an explanatory knowledge structure to account for the discrepancies between the current knowledge and observed anomalies; and mapping or creating a logical-mathematical structure as a guide to gather evidences to test hypotheses. At every step of the inquiry, importing knowledge from other researchers is the key to obtain ideas for conceptual combination that eventually led to emergency of new knowledge. Scientific inquirers share a common feature: seeking and applying a knowledge structure onto another knowledge structure with an aim to create a new knowledge structure. Knowledge necessary for scientific breakthroughs is distributed among scholars. Although the emergence of a new knowledge structure comes from the working of an individual mind, its antecedent condition is importing knowledge from other scientists. Thus, scientific knowledge is co-constructed, rather than constructed solely by individual scientist.

Keywords: knowledge construction, scientific inquiry, science

Construction and standardization of dormitory adjustment questionnaire (DAQ)

MANSOUR, L. (Univeristy of Shahid Beheshti), MOLLA-SHARIFI, S. (University of Shahid Beheshti), VAKHSHOUR, H., ETEMAD, S. (University of Western Australia)

The aim of this research was based on making a specific psychometric tool for evaluating the dormitory adjustment of university students in Tehran, Iran. Two major aspects of the questionnaire, its reliability and validation, were evaluated through this study. The statistical
population of the research comprised of dormitory students from Tehran's universities. For this purpose 929 females and males, with consideration of their ratio, were randomly selected by a multi-steps method from Allameh Tabatabaie, Shahid Beheshti and Tehran Universities. Regarding the theoretical bases and principles of questionnaire construction, the dormitory adjustment questionnaire (DAQ) was designed and carried out passing three steps. The information gathered from the final examination was analyzed by statistical psychometric methods. The reliability of the questionnaire was evaluated using the inner consistency ($\alpha = 0.88$) and retest methods ($r = 0.77$). Factor analysis was used for validation. The results showed that the extracted factors explained 51% of questionnaire variances. The scores were standardized separately for both males and females (T and Z scores). A novel questionnaire for the evaluation of dormitory adjustment of university students was designed and standardized.

Construction of IRT scales for the Five-Factor personality scale in Japan and examination of the short-form of the scale

TANI, I. (Hamamastu University School of Medicine), NAMIKAWA, T. (Nagoya University), WAKITA, T. (Kansai University), KUMAGAI, R. (Niigata University), NAKANE, A. (NTT Cyber Solutions Laboratories), NOGUCHI, H. (Nagoya University)

In Japan, personality scales based on the Five-Factor model, especially the Big-Five scales using personality trait adjectives are common (Wada, 1996), and have been often used in many studies. A short-form of the Big-Five scale was constructed. To avoid changes in the capacity dimension caused by the decrease in the number of items, item selection was conducted after Item Response Theory (IRT) scales were constructed for all the items. Then, the reliability and validity of the short-form of the Big-Five scale were examined. Data was collected from participants ($n = 3612$). A Generalized Partial Credit Model was applied to the IRT model, and items were selected using the Slope and Location parameters for each item. Reliability of the short-form was assessed using Cronbach’s alpha, while its validity was determined using correlation coefficients. Cronbach’s alpha showed that the short-form as well as the five sub-scales had sufficient reliability as a personality test. Moreover, considerably high correlation coefficients were obtained for all the sub scales. It was confirmed the short-form functioned sufficiently. It is suggested that further examination of its validity should be conducted.

Keywords: big five model of personality, reliability, validity, Japan

Consumer-based brand equity: Comparisons among convenience goods and shopping goods

LEE, Y-H. (National Taiwan University of Science and Technology), HSIEH, C-L. (Hsing-Wu College), CHEN, S-L. (Tamkang University), LEE, Y-H. (National Taiwan University of Science and Technology)

Private label, also store brand, is the brand which retailers are responsible for promoting, shelf placing, pricing, and positioning its own brand in the product space. In view of the differences between globalised and localised images, this research groups the private labels (PL) into two categories, that is, the international PL (IPL; e.g. American Costco and British Tesco), and the local PL (LPL; Taiwanese RT-Mart). The research purpose is to realize the consumers’ different perceptions toward convenience goods and shopping goods on international private labels and local private labels. This research investigated the consumer perceptions towards convenience goods and shopping goods on product quality, price, brand leadership and brand personality based on international private labels and local private labels. The data was collected outside the entrances of the main rail station of Taipei, Taiwan. A systematic sampling was adopted and 254 questionnaires were eventually collected. The findings revealed that the consumers in Taiwan perceive that hypermarkets, including international hypermarkets and local hypermarkets, produce
better convenience goods than shopping goods that have high quality and deliver more value. For price, brand leadership and brand personality, on the whole, international private labels and local private labels were not perceived significantly differently. There is little research distinguishing international private label and local private label from private labels. Our findings indicate that consumers have different perceptions of these two brand types. This calls for marketers to exploit the opportunities in these segments. Finally, implications for leisure practice and further research are discussed.

Keywords: international private label (IPL), local private label (LPL), consumer perceptions, Taiwan

Contextual barriers and career choice goals in Greek mid-adolescents

KATSIKIS, D. (Aristotle University of Thessaloniki), SYNGOLLITOU, E. (Aristotle University of Thessaloniki)

The purpose of this study was the investigation of basic psychological predictors of career choice goals in mid-adolescents according to the Social Cognitive Career Theory (SCCT; Lent, Brown, & Hackett, 1994, 1996, 1998, 2000). The first goal of this study was the investigation of possible relationships between Career Contextual Barriers and Career Choice Goals. Further, we intended to investigate the moderating role of Contextual Barriers between Interests and Career Choice Goals. Finally we investigated the moderating role of Contextual Barriers between other SCCT variables (Self-Efficacy, Outcome Expectations) and Career Choice Goals. The sample consisted of 500 10th-grade Greek students from a representative area of Thessaloniki, Greece. Measures included the “My Perceptions of Barriers” Questionnaire (McWhirter, 2000: see revised version of Gibbons, 2005), the Self-Efficacy Measure (Gore & Leuwerke, 2000), the Outcome Expectations Measure (Gore & Leuwerke, 2000), the Vocational Interests Measure (Gore & Leuwerke, 2000) and the Choice Goals Measure (Gore & Leuwerke, 2000). Results are discussed in relation to the design and the implementation of a career counseling program, which focuses on coping with career barriers and setting career choice goals in adolescents who are at risk of choice failure. Conclusions include the practical implications of the SCCT model in Greek adolescents.

Keywords: contextual barriers, career choice, Greek, psychological predictors, career counselling

Contingent employment as invisible diversity and its influence on work attitudes

SMALL, C. (DEOMI/Florida Institute of Technology), STEINHAUSER, E. (Defense Equal Opportunity Management Institute), CREPEAU, L. (DEOMI)

For organizations to remain competitive in a global market, factors including diversity within organizations and the use of alternative employment arrangements have become critical dynamics. There are two common types of diversity: visible diversity (characterized by surface traits including age, gender, and race), and invisible diversity (characterized by diversity in thought, values, and experiences). This study examined one type of invisible diversity, namely contingent employee status. Contingent employees are typically employed part-time, seasonally, via contract, or on a temporary basis. These individuals often work in the same environment, carry out comparable job tasks, and serve the same goals of the organization as traditional full-time employees. Unfortunately, research in the area of contingent employment has been scarce, due to the short term and/or transitory nature of their employment. Contingent employees seldom receive the same indoctrination and/or socialization as traditional employees. Based on a social identity approach, contingent employees may experience out-group dynamics that can influence work attitudes differently than traditional employees. This study examined attitudinal differences between traditional and contingent employees, utilizing a unique sample of over 900 personnel assigned to a major U.S. Navy seagoing command with over 30 ships. The sample included traditional employees, as well as individuals who worked within, but were not directly employed by, the organization (contingent employees). These two types of personnel work in the same physical environment, share the same goals, and conduct
comparable tasks. After controlling for rank and common method variance, the results suggest that, compared to contingent employees, traditional employees harbor greater organizational trust ($F(1,817) = 4.87, p < .05$) and perceive greater leadership cohesion ($F(1,205) = 2.14, p < .01$). No between-group difference was found for level of job satisfaction. The results of this study can help guide on-boarding and socialization processes that form the initial social bases from which attitudes are developed. Understanding the interpersonal dynamics that occur—based on employment type—can help inform research and practice about how invisible diversity can powerfully influence the job attitudes of organizations’ employees.

Keywords: visible diversity, diversity, employment, job satisfaction, work attitudes

Contributing factors to rail incidents and accidents

READ, G. (Monash University), LENNE, M. (Monash University Accident Research Centre), MOSS, S. (Monash University)

The study was undertaken to determine the human errors and violations, as well as the local and organisational factors involved in rail accidents in Australia over a ten year period. The focus of the study was the associations between factors and determining the relevance of some human performance concepts to different error types in an applied setting. The Contributing Factors Framework (CFF), a tool developed for the analysis of rail accidents and incidents, and based on James Reason’s model of organisational accidents, was used to gather aggregate data about the factors that have contributed to a sample of investigation reports. In addition to applying the CFF, a more detailed categorisation of errors was utilised. Ninety-six investigation reports into Australian accidents and incidents occurring between 1999 and 2008 were analysed. Each report was coded independently by two experienced coders. Task demand factors were significantly more often associated with skill-based errors, knowledge and training deficiencies were significantly associated with mistakes, and violations significantly linked to social environmental factors. Furthermore, the organisational factors of risk management, functionality of equipment, and adequacy of procedures were found to be key contributors within this sample. The results of this study provide information about what factors may influence individuals to make errors or commit violations; a finding that may be applicable across industries and contexts. Further, systemic issues relating to accident causation generally have been identified for remediation. Finally, the CFF has been shown to provide a useful methodology for the collection of data associated with rail incidents and accidents in Australia.

Keywords: rail incidents, organisational accidents, human errors, organisational factors, Contributing Factors Framework

Coordination between departments in organizations: Examining individual and departmental characteristics

YANAGIZAWA, S. (Nakamura Gakuen University), TUTUMI, U. (Hitachi Institute of Management Development)

An organization is constructed from departments with different job characteristics. Conflicts between the departments are caused because they often have different interests. To achieve organizational goals, it is crucial to resolve conflicts and to coordinate between groups and teams. The object of this study was to examine individual and departmental characteristics influencing coordination and communication between departments in an organization. The target organization was a Japanese building maintenance company. Before the main research, a preliminary interview was conducted to explore job contents and the relationship between departments. Based on the result of the interview, the main research was implemented as follows. Two hundred and seven employees belonging to seven departments answered the questionnaire about their department and individual characteristics. Questions about individual characteristics asked about understanding organizational goals, individual empowerment and communication with members in other departments. Questions about their departments asked about leadership of managers in their department, group empowerment and coordination with other
departments. To examine individual and departmental characteristics, and leadership influence on coordination between departments, hierarchical multiple regression analysis was conducted. Understanding organizational goals and individual empowerment was significantly related to communication with members in other departments. Employees who understood company policies and were empowered actively communicated with members in other departments. As for department characteristics, leadership of managers and group empowerment was related to coordination with other departments. Leadership encouraging cooperation with other departments and high group empowerment was associated with high coordination. The results of this study suggest that one factor promoting the coordination might be that employees are interested in organizational goals, and not only their own task goals. Awareness of superordinate goals above individual goals may lead to coordinating behavior with other departments. This study also showed that individual empowerment and group empowerment have important roles in coordination and communication between departments in an organization. Empowerment may be derived from productive activities by employees, as suggested by previous research. Furthermore, results also suggest that leaders have influence on members’ coordinating behaviors with other departments.

**Correlates of eating disorder, anger and depression among working women**

**SUDHAKARAN, M.V. (Tamil Nadu Open University)**

In a developing country like India, in addition to a dual career, women in the information technology (IT) industry have to work under various shifts, which induce specific traumatic and unpleasant situations which may lead to loss of job, illness, bereavement and marital disharmony or divorce, which will be the leading cause of the global disease burden. As per the literature and societal mapping, it can be observed that stress at work for the working women is the result of working style, inadequate food consumption, perceived anger and depression. It was aimed to study the interactive phenomenon of shift work, eating disorders, anger and depression among the working women and to compare them with their male counterparts. A purposive sampling technique was adopted in the study comprising of 80 employees, all below 30 years of age. Employees who are working in business process outsourcing (BPO) and employees who are working in other organizations were selected for the study. Out of the 80 employees, 40 were from call centers and 40 from other organizations (i.e. 20 of them males, and females, for each group). The data were collected through the questionnaire package comprising the state trait anger expression inventory (STAXI), Beck Depression Inventory and Eating disorder Inventory. An SPSS package was used for analysis. The results show that women in BPOs do have eating disorders and experience more anger and depression than their counterparts. Women employees working night shifts do experience more depression and anxiety than male employees. To conclude, night shift induces eating disorders, which in turn significantly influences both depression and anxiety.

**Keywords:** night shift, gender, eating disorders, depression, anxiety

**Counterfactual thinking improves TTCT performance**

**LIAO, J. (Tsinghua University), WANG, L. (Peking University), PENG, K. (University of California)**

Counterfactuals are thoughts of what might have been. Previous research has indicated that counterfactual thinking has a preparatory function. This function plays a role in behavior regulation and performance improvement. The purpose of this study was to explore the impact of counterfactual thinking on creative thinking, in order to clarify the contribution of prepared function of counterfactual thinking for creative thinking. One hundred and four University of Peking University students completed this study and were paid 10 ¥ for their participation. Participants were asked to finish a sequential
priming paradigm called the sentence completion method in order to prime counterfactual thinking, and then completed the Torrance Test of Creative Thinking (TTCT) (Torrance, 1965, 1984) to measure creative thinking. ANOVA results showed that counterfactual thoughts helped participants to complete the TTCT. Counterfactual thinking had different effects on the three dimensions of creative thinking, namely originality, $F(2, 102) = 3.48, p < .05$; fluency, $F(2, 102) = 8.02, p < .001$, and flexibility, $F(2, 102) = 4.12, p < .05$. The priming effect depended on test type (Unusual Usage Test and Figure Structural Test) in the TTCT. Counterfactual thinking improved TTCT performance in originality, fluency, and flexibility dimensions in Unusual Usage Test, which is linguistic, and only improved TTCT performance in the originality dimension ($F = 4.02, p < .05$) in the Figure Structural Test, which is geometric. We conclude that counterfactual thoughts not only reconstruct the past but also influence the future by affecting performance on new tasks.

**Keywords:** counterfactual thinking, TTCT, behavior regulation, performance improvement, creativity

**Counterstrike strikes back? How Shooter players are perceived**

KNEER, J. (Cologne University), BENTE, G. (Cologne University)

In Germany, violent digital games are discussed to be strictly censored. Motivation for censorship strives by school shootings in Erfurt and in Emsdetten. Both assailants had spent much of their time playing violent digital games, particularly first-person shooter games like "Counter Strike" or "Wolfenstein". This observation fuelled an intense public debate about the effects of violent digital games on aggression. Since the recent school shooting in Winnenden in March 2009, where 15 people and the assailant died, this debate was extended. The relationship between school shootings and violent digital game playing, particularly shooter playing, seems to be obvious. Therefore, the question arises of whether this relationship only exists between aggression and the games or if even the shooter players are associated with higher aggression. Our two studies are concerned with person perception, particularly how shooter players are perceived. Study 1 investigated differences between computer players and nonplayers concerning judgements ($N = 66$). Players’ and nonplayers’ person judgements were recorded after reading a description about a person who regularly played either car racing or shooter games. The only effect found was for nonplayers. They associate shooter games with aggression and therefore perceived the shooter player as more aggressive than any other condition. In study 2 we focussed on nonplayers’ person perception ($N = 60$): Participants watched a 4 minutes video tape showing a person playing a computer game. Afterwards they described the gamer in their own words. We found differences in person perception concerning information about what computer game exactly, the person had played. To conclude, violent digital games seem to influence the perception of shooter gamers resulting in an aggression bias. This bias in person perception might be due to the cognitive association between shooter gamers and aggression frequently strengthened by the relationship between school shootings and violent digital game playing.

**Creativity in the work place: The role of leadership style, morale, and regulatory focus**

WILSON-EVERED, E. (Relationships Australia), BRANTON, K. (Monash University), COLEMAN, G. (Monash University)

Given the ongoing requirement to remain competitive, both public and private organisations face ever increasing challenges for continuous improvement in their business practices (Dunphy, Griffiths, & Benn, 2007). In times of scarce resources and high competition, leveraging creative talent provides competitive advantage. Theoretically, leadership style exerts an enhancing effect on creativity directly, as well as on morale which, in turn, also affects creativity (Hirst & Mann, 2004; Thompson, 2003; Wilson-Evered, Dall, & Neale, 2001). Specifically, this study hypothesised that stable and
innovative leadership styles are associated with creativity. We expected that morale would mediate the relationship between stable leadership and creativity (hypothesis 2a) and also the relationship between innovative leadership and creativity (hypothesis 2b). In addition, regulatory focus was expected to moderate the relationship between leadership style and creativity: where a high degree of regulatory fit between leadership style and regulatory focus is present, increased creativity should result. Specifically, a prevention regulatory focus was hypothesised to moderate the relationship between a stable leadership style and creativity, with the relationship stronger at higher levels of regulatory fit between prevention focus and stable leadership (hypothesis 3). Similarly, a promotion regulatory focus is hypothesised to moderate the relationship between an innovative leadership style and creativity, with the relationship stronger at higher levels of promotion focus (hypothesis 4).

Keywords: creativity, leadership style, regulatory focus, stable leadership, innovative leadership

Critical incident stress among Japanese journalists (1): Job-related traumatic event and mental health

HATANAKA, M. (Meijo University), MATSUI, Y. (University of Tsukuba), ANDO, K. (Toyo University), INOUE, K. (Yokohama National University), FUKUOKA, Y. (Kawasaki University of Medical Welfare), YUKI, H. (Toyo University), ITAMURA, H. (Kansai University)

The effect of traumatic incidents at work on disaster workers, such as firefighters and policemen, has been demonstrated in previous works (e.g. McFarlane, 1988; Nurmi, 1999). More recently it has been noticed that journalists who are exposed to traumatic emergency situations may be at risk of mental health problems. Several previous studies in other countries have reported that journalists suffer from traumatic stress (McMahon, 2001; Pyevich, Newman, & Daleiden, 2003). Therefore, job-related traumatic stress experienced by journalists in Japan and factors contributing to them were investigated. In Study 1, questionnaires were administered to 149 broadcasting journalists in managerial position and 211 broadcasting journalists in non-managerial positions, such as reporters and camera operators. In Study 2, questionnaires were administered to 102 newspaper journalists in managerial position and 291 newspaper journalists in non-managerial positions. The questionnaires included items concerning the most traumatic event experienced at work, Japanese-language version of the Impact of Event Scale Revised (IES-R), the 12-item Japanese version of the General Health Questionnaire (GHQ-12), and scales designed to measure predictors of current posttraumatic stress symptoms, such as stress reactions during coverage, workplace issues and social support. The results showed that 80-90% of the respondents in both Studies 1 and 2 have had at least one traumatic experience during the course of their coverage. Of these, 8% met the IES-R criteria for potential post-traumatic stress disorder (PTSD). Journalists in non-managerial positions, especially newspaper journalists exhibited a higher IES-R score than journalists in managerial positions. The level of mental health measured by GHQ-12 in all the respondents, indicated that 40-50% of journalists in non-managerial positions met the criteria (>4) for unhealthy status, compared with 25% of journalists in managerial positions. Moreover, post-traumatic stress reactions at the time of the survey were strongly related to symptoms of stress experienced on-site, or relatively early in the course of the stressful assignment. These findings suggest the need for implementing a program for reducing stress induced by critical incidents in Japanese journalists, especially journalists in non-managerial positions.

MATSUI, Y. (University of Tsukuba), YUKI, H. (Toyo University), FUKUOKA, Y. (Kawasaki University of Medical Welfare), ANDO, K. (Toyo University), INOUE, K. (Yokohama National University), HATANAKA, M. (Meijo University), ITAMURA, H. (Kansai University)
Studies have been conducted on critical incident stress suffered by disaster relief workers such as firefighters. However, only few studies (Matsui, et al., 2006) have been conducted in Japan regarding stress experienced by journalists covering disasters. A questionnaire survey was conducted to Japanese journalists to investigate their opinion about the critical incident stress care system in the organization they belonged to. A mail questionnaire survey was conducted to journalists and photographers (non-managerial workers) and their superiors (managerial workers) from broadcast stations and newspapers. The number of valid responses of managers was 149 (recovery rate of 42.0%) and of workers was 211 (29.4%) for broadcast stations. For newspapers, the number of valid responses of managers was 102 (57.3%) and of workers was 291 (30.8%). From 18.9% of newspapers workers to 40.3% of managers of broadcast stations affirmed the existence of critical stress care system in their organization. Nevertheless, the stress care system mostly consisted of labor safety and hygiene such as establishment of a clinic in the office with an occupational health physician (response from 81.4% of managers of broadcast stations.) However, only few (2-6% of) broadcast workers (n=4), responded that they have used such clinics. The most common reason given for not having used the clinics was the lack of stress (90.4% of broadcast station managers, while the rate of this response was 52.3% among non-managerial newspaper workers. The latter also responded "too busy to visit the clinics" 40.9% and "feeling reluctant to visit the clinics" 27.3%. There were only few responses stating that the present stress care system was "adequate" 3-6% whereas more than 50% considered that the whole organization should deal with the problems and raise the consciousness of the managers. Over 30% of the respondents stated that they would think of a way to keep in secret to managers and colleagues that they sought help. Although most journalists recognized the importance of organizational services specializing in critical incident stress, they are not available yet.

Keywords: critical incident stress, Japan, journalists, occupational health

Critical incident stress among Japanese journalists (3): Differences in managers’ and workers' perceptions on dealing with daily job stress

FUKUOKA, Y. (Kawasaki University of Medical Welfare), INOUE, K. (Yokohama National University), MATSUI, Y. (University of Tsukuba), ANDO, K. (Toyo University), HATANAKA, M. (Meijo University), YUKI, H. (Toyo University), ITAMURA, H. (Kansai University)

Studies on critical incident stress in Japanese journalists have just started. Preliminary interviews indicated the role of the supervisor was important in dealing with critical incident stress, and that there were close relationships between critical incident stress and daily job stress (Matsui, et al., 2006). A questionnaire survey was conducted with managerial and non-managerial journalists working for newspapers and broadcast stations to investigate how managers deal with workers’ job stress. A mailed questionnaire survey was conducted with journalists in non-managerial positions, such as reporters and camera operators and their supervisors (journalists in managerial positions) of selected broadcast stations and newspapers in Japan. In broadcast stations, the number of valid responses was 149 (recovery rate 42.0%) from managers and 211 (29.4%) from workers. In newspaper companies, the number of valid responses was 102 (57.3%) from managers and 291 (30.8%) from workers. The questionnaire inquired about the communication between managers and workers and among colleagues, sensitivity of consideration given to the workers’ stress by managers, and the workers’ recognition of the managers’ consideration. Generally, responses of the managers were optimistic and positive, whereas the workers’ perceptions were different. For example, in the survey at newspaper companies, 67.8% of managers responded that the office had an atmosphere in which supervisors and workers could talk freely, whereas only 37.5% of workers thought so. Moreover, 43.2% of managers responded that they tried to reduce the job load with consideration to workers’ stress, whereas only 18.4% of workers were aware of such consideration. Furthermore, 73.1% of managers responded that they tried to listen to workers and understand their feelings, whereas workers...
who were aware of such efforts were only 28.0%. Results suggested that there was a noticeable difference between the perspective of managers and workers when dealing with job stress. This difference might prevent countermeasures for critical incident stress from being introduced into the workplace. If appropriate social support is not given on a daily basis, it might be impossible to provide effective support in situations of critical incident stress, which could result in workplace problems.

**Cross-country differences in traffic risk judgement – Norway and Ghana compared**

NORDFJERN, T. (Drug and Alcohol Treatment in Central Norway), RUNDMO, T. (Norwegian University of Science and Technology)

This study aimed to investigate differences in traffic risk judgement in a Norwegian and Ghanaian sample. This was carried out while controlling for relevant background variables, such as gender, age and levels of educational achievement. In order to obtain the core aim of the study, a self-completion questionnaire was devised and distributed to a representative sample of the Norwegian population (n=247) and to a stratified sample in Accra and Cape-Coast in Ghana (n=299). The results showed that Ghanaians judged traffic risks to be larger compared to Norwegians. Gender, age and levels of educational achievement contributed less to risk perception than country. The results indicate that the traffic environment is more hazardous in African countries with fewer regulations concerning speeding and other risk behaviours. The differences may also partly be related to differences in road and vehicles standards.

Keywords: Traffic risk, Traffic risk, Norway, Ghana, Risk perception

**Cross-sectional study of developmental changes in the Five-Factor personality model in Japan**

NAMIKAWA, T. (Nagoya University), TANI, I. (Hamamatsu University School of Medicine), KUMAGAI, R. (Niigata University), NAKANE, A.J. (NTT Cyber Solutions Laboratories), WAKITA, T. (Kansai University), NOGUCHI, H. (Nagoya University)

Big-Five scale of Personality has become the most commonly used personality scale in Japan. However, there are only a few studies on the development of the five-factor personality, which are based on large-scale data sets. Therefore, we conducted such a study using a cross sectional design. First, we evaluated the stability of the scale’s factor structure across developmental stages. Then we examined developmental changes in the mean score for each sub scale of the scale. We used both the Japanese version of the adjective check list (Big-five scale) constructed by Wada (1996) and the short-form of the same scale developed by Tani et al. (2009). Finally, we examined the validity of the short-form of the scale. Participants (n=3612, aged between 15 and 83 years) completed the Big-five scale. Stability of the factor structure was examined using multiple population analysis in the SEM. Developmental changes and gender differences were examined by estimated scale values in the IRT model for the participants. Results indicated the stability of the five-factor structure across age and gender. (1) Extroversion: There was no significant mean difference in age. The mean score for women was significantly higher than that of men. (2) Neuroticism: The mean score decreased with age. Moreover, the mean for women was higher than that for men. (3) Agreeableness and Conscientiousness: The mean scores increased with age and the mean for women was higher than that for men. (4) Openness to experience: There was no significant mean difference between age and the mean for men, which was significantly higher than that for women. The results for the short form and the original versions of the scale were nearly identical. The results of this study corroborated the findings of other studies, confirming the cross-cultural consistency of the five-factor structures. Moreover, the short-form of the scale had sufficient criterion-related validity.

Keywords: big five model of personality, validity, gender differences, age differences
CSR, authentic leadership employees’ mental health and life satisfaction in Polish and French enterprises

GRAZYNA, B. (University of Economics)

The author’s subject of interest is the practical realisation of Corporate Social Responsibility (CSR) in the employment sphere in the aspect of employees’ authentic leadership, mental health, and life satisfaction, in Polish and French enterprises. The aim of research which was carried out, was finding the answer to the following question: is there any relation between a level of CSR activities in the recruitment sphere in selected enterprises in Poland and France, and a level of the authentic leadership and employees’ welfare (a level of professional burnout and health conditions – a subjective evaluation and a level of job satisfaction)? In order to verify such a research problem, 164 employees of 18 Polish medium enterprises and 84 employees of 4 French enterprises were investigated. Research tools were: the CSR activities in recruitment sphere Questionnaire (specially constructed and validated), Authentic Leadership Questionnaire (ALQ), Maslach Burnout Inventory – Human Services Survey (MBI-HSS), 12-item General Health Questionnaire (GHQ-12) and also the Satisfaction with Life Scale (SWLS) by Diener, Emmons and Larson in its adapted form. Research was carried out between 2008 and 2009. Obtained research results indicated that both in Polish and French enterprises, there is a correlation between a level of CSR practical realisation, and a level of the authentic leadership and employees’ welfare (a level of professional burnout in the emotional exhaustion aspect). It means there is a necessity to promote the CSR idea, despite differences between the countries.

Keywords: corporate social responsibility, Poland, France, authentic leadership, employee welfare

Cultural basis of cooperation: Comparing the achievement of Turkemen and non-Turkemen Iranian students using cooperative learning method

HAMEEDY, M.A. (Alzahra University), ESMA’EELEE, Z. (Alzahra University)

The aim of the research conducted within a social constructivist framework was to show that using different methods of learning and teaching can be beneficial only when the socio-cultural prerequisites are in place. To use cooperative learning method of instruction can be effective only if the students already have a positive attitude towards cooperation. Such an attitude is more likely to exist if the learners’ cultural background indicates an emphasis on cooperation. Turkemens, one of the cultural groupings in Iran, are assumed to have more of such a background than the other groupings. Two groups of participants were questioned, observed, and tested in a regular class room setting wherein the subject of English Language was taught using the cooperative learning method. The participants were all 30 students of a 7th grade class selected from among all such classes in the city of Gonbad, where the majority of the population is Turkemen, using a cluster sampling method they were subdivided into small working groups. The three measures used initially, through out, and at the end of, the course were an attitude scale, an observation list, and an achievement test, all with acceptable reliability. The collected data were analyzed using both parametric and non-parametric tests. The initial comparisons of the two groups of students revealed their lack of difference in academic standing (i.e. graded point average (GPA)) and a significant positive difference in attitude towards cooperation for the Turkemen students ($t=4.445$, $df=28$, $α=0.05$). Comparison of the observational data on two groups revealed that the Turkemen subgroups engaged in significantly more cooperative behaviors during the learning sessions ($Ψ^2=12.078$, $α=0.05$). The two groups’ test scores indicating students’ achievement in the course taught, also showed a significant superiority for the Turkemen students ($t = 2.247$, $df = 28$, $α=0.05$). In conclusion, attempts have been made in Iran to introduce cooperative learning as a way of helping to improve the quality of education. However, what in these attempts has seemingly been overlooked is the cultural pre-requisites of effective use of this method, i.e. a positive attitude towards cooperation. Given the findings of this research, and the fact that attitudes are learned, it seems necessary that any attempt at using the cooperative learning method needs to be preceded by efforts aimed at improving
students’ attitudes toward cooperation if the teaching method is to be fully effective.

**Keywords:** cooperative learning method of instruction, sociocultural factors, attitudes, cooperation, Turkemens

**Cultural pathways to internalization: The example of Turkish children**

CEBIOGLU, S. (Koc University), SEN, H. (Koc University), IREM, M. (Koc University), CORAPCI, F. (Bogazici University), AKSAN, N. (Koc University), YAGMURLU, B. (Koc University)

This study aimed to examine internalization of maternal rules in Turkish preschool children. Research with United States (US) samples point to committed compliance, reflecting child’s wholehearted eagerness to maternal agenda, as the precursor of internalization (Kochanska & Aksan, 1995). Furthermore, committed compliance appears to be associated with child’s increased positive affect during mother-child interactions (Lay et al., 1989; Parpal and Maccoby, 1985; Kochanska et al., 2005). The causal chain that emerges from this literature suggests that child’s positive affect experienced during dyadic relationship with the parent increases committed compliance which in turn fosters internalization. The aim of the study was to examine the applicability of this process to socialization in the relatively more collectivistic setting of Turkey. 118 children (68 boys) between 3 and 6 years old and their mothers participated in this study. The laboratory consisted of a naturally furnished room videotaped through a one-way mirror. Child positive affect, child negative affect and child compliance to mother during prohibition context were observed through typical mother-child interactions. Children’s internalization of maternal rules was observed through a resistance to temptation task involving prohibited toys (Kochanska & Aksan, 1995). Videotaped interactions were coded by independent teams and kappa scores revealed adequate reliability. Committed compliance was positively associated with internalization ($r = .65$, $p < .01$) whereas situational compliance was negatively associated with it ($r = -.49$, $p < .01$). However, positive affect was unrelated to child committed compliance though negative affect was negatively associated with it ($r = -.41$, $p < .01$). Regression analyses which tested the suggested causal chain revealed that committed compliance fully mediated the relation between negative affect and internalization while controlling for the effects of situational compliance. Specifically, declines in child’s negative affect rather than increases in positive affect were associated with greater committed compliance which in turn predicted children’s increased internalization. Results indicate an important source of cultural variation in the socialization processes. The findings suggest that unlike the US case, the factor that motivates the child to embrace parental agenda is not so much the opportunities the relationship provides to experience positive affect but rather respite from negative affect.

**Keywords:** internalization, maternal rules, affect, Turkey, preschoolers

**Decision making process in work-personal life dilemmas: The case of expatriate post-doctoral researchers**

GONZALEZ MORALES, M.G. (University of Guelph), TETRICK, L. (George Mason University)

The aim of the present research was to study the decision making process when people face work-life dilemmas that can lead to work-life conflict. From the decision process theory, work-family conflict is a process. More specifically, it is an intermediate result of decisions made in the course of time (Poelmans, 2005). Young Spaniards who have recently obtained their PhD degree are frequently confronted with the decision of moving to a foreign country to continue their professional career as researchers. The specific purpose of this research project was to conduct a qualitative study of the decision making process of voluntary expatriates and their partners, and the possible relationship of this process with work-family/life balance, life adaptation and job, marital and life satisfaction. The sample is composed by 20 Spanish post-doctoral researchers who were given a grant to work in the USA at least for one year. The participants completed an online survey and were invited to participate in a personal interview by telephone. A correlational analyses of the demographic data
was developed – professional data, relationship and family data and simple specific questions on the decision making process related to applying for the grant and moving with their family or partner. These analyses showed that job, marital and life satisfaction and the implication of the partner on the decision making are related. The content analysis of the interviews shows different motives and processes depending on the specific case of the person. In general, the motives are focused on career and personal life as independent areas that can be damaged by decisions in the other. The qualitative analyses of this data suggest that this type of decision does not only affect the couple but also other relationships like friends and relatives. At this stage of their lives, decisions about applying for post-doctoral scholarships in foreign countries pose a dilemma in their personal lives and their partners' lives.

Detection of driver cognitive distraction based on driving performance

YU, L. (Chinese Academic of Sciences)

The aim of this paper is to develop a classification algorithm based on driving performance which can detect driver cognitive distraction. A modified Hidden Markov Model (HHM) was applied. Data were collected in a simulator experiment in which participants fulfilled a driving task with and without secondary tasks, respectively. Driving performance data were collected which included speed, steering wheel angle, degree of acceleration, degree of braking, etc. The results show that the HMM models were able to detect driver distraction with an average accuracy of more than 80%. Driver cognitive distraction can be detected by monitoring of driving performance. This result has potential applications in design of adaptive in-vehicle systems and evaluation of driver distraction.

Keywords: driving performance, driver cognitive distraction, classification algorithm, Hidden Markov Model, in-vehicle systems

Determining the relationships of age, occupational type, and educational level with sense of affective attachment to spouse in men: Attitudinal study

REZAEI DEHNAVI, S. (University of Isfahan), SHAHGHOLE GAHFAROKHI, S. (Payame Noor University of Fereidoonshahr)

The purpose of this study was to determine the relationship between age, occupation, and educational level of spouse in predicting affective attachment in men living in Shahrekord (the city in Iran).130 married men participated in this study and completed a questionnaire assessing their sense of affective attachment with regards to the perspective of the men. This questionnaire was developed and validated by the researchers. The data was analyzed through MANOVA. The results indicate that only the level of education has a significant relationship with a sense of affective attachment in men. Men with higher education levels have higher senses of affective attachment. This result is debated with regard to special cultural issues in Shahrekord.

Keywords: age, occupation, education, affective attachment, married men

Development and assessment of a course program to improve mothers' child care happiness

YOSHIKO, S. (Nagano College of Nursing), SEKIMIZU, S. (Tohoku Women's College), ENDO, T. (Kyoto Tachibana University), HIROSE, A. (Nagano College of Nursing), MIYAZAEIA, M. (Nagano College of Nursing), AKAHANE, H. (Nagano College of Nursing)

A six-session program was developed over three months, each session lasting two hours, for mothers of infants in order to increase the level of happiness in raising their children. We conducted this program twice with nine and ten mothers per group, respectively. A total of 19 mothers participated in the program. Differences in psychological indicators (i.e., psychological scales) such as feelings of happiness and stress in raising children, and physiological indicators (i.e., autonomic nervous activity, brain waves, salivary chromogranin) such as levels of relaxation and stress were
evaluated. These indicators were assessed before, immediately after, and one month after their participation in the course program. Similar evaluations were made on a control group of 16 mothers who did not participate in the program. Contents of the program for enhancing feelings of happiness in raising children consisted of developing relationships by talking with others about oneself, reflecting on one’s feelings towards one’s children, valuing happy moments in raising children, recognizing each other’s hard work, affirming oneself and gaining self-confidence, making a life plan, and having others listen to one’s issues. In addition, each session incorporated deep abdominal breathing and facial stretching exercises for smiling. The effectiveness of the program was revealed by the psychological and physiological effects observed. Our future task is to develop a course program that is even more effective than the one described here.

**Keywords:** mothers, infants, child care happiness, raising children

**Development and validation of Tehran Multidimensional Perfectionism Scale**

BESHARAT, M.A. (University of Tehran)

This paper presents an account of the development, reliability, and validity of the Tehran Multidimensional Perfectionism Scale. Five hundred students from the University of Tehran (300 females, 200 males) were included in this study. All participants were asked to complete Tehran Multidimensional Perfectionism Scale (TMPS), the Inventory of Interpersonal Problems (IIP), the Mental Health Inventory (MHI), and Neuroticism and Extraversion subscales of the NEOPI-R. Test-retest reliability and internal consistency of the IIP were evidenced at satisfactory levels. Concurrent validity of the TMPS was calculated according to correlation coefficients between the scores on the TMPS and scores of the IIP, MHI, and NEOPI-R. All correlations were statistically significant. It was concluded that the TMPS is a reliable and valid scale to measure multidimensional perfectionism in Iranian populations.

**Keywords:** Tehran Multidimensional Perfectionism Scale, validity, reliability, Iran

**Development of a safety culture assessment tool (SCAT) in a Japanese company**

Importance is being increasingly given to building a safety culture against a background of increasing numbers of serious industrial accidents in Japan. The purpose of this study is to develop and demonstrate a concrete way of building a safety culture in an organization. In this study, the constructs of a safety culture were first defined based on existing knowledge. An attempt was then made to develop a Safety Culture Assessment Tool (SCAT) with two dimensional criteria, a three-layered cross-assessment between ‘administrator’, ‘manager’ and ‘operator’, and a sharedness assessment between the three layers, set against ten areas such as ‘Safety Statement’, ‘Safety and Productivity’ and ‘Rules and Documentation’. The SCAT was tested in 38 companies. After extracting a set of data necessary for standardization, a comparison was made before and after the installation of the safety culture education program in one company. In the safety culture education program PDCA cycle we are offering, the planning of a measure is conducted after the extraction of data and explaining the risks for employees. Additionally, not only the administrator and the managers but also the operator who is to execute the measure participate in the planning stage and suggest a feasible plan for execution on the actual site. The cycle also requires clearly planned 4W1H – When, Where, Who, What and How – on all participants. Further to the above, a process to confirm smooth execution without any new problems occurring, was run three times, establishing the ‘Check’ and ‘Action’ phases. As a result, an improvement was confirmed after the installation of the program. The validity of the safety culture education PDCA program was
confirmed by the study. It is expected to be applied in an increased number of companies in order to further establish the program.

Development of reaction-evaluation measures of training programs: A reinterpretation of Kirkpatrick’s model

HONG, G.H. (Ajou University), KANG, B. (Ajou University), KIM, D-Y. (Ajou University)

In borrowing concepts from Kirkpatrick’s (1959/1960, 1994) 4-level model (reaction, learning, behavior, and result) to evaluate human resource development training programs, previous research resulted in the development of many measures. However, those measures faced limitations as different levels were assessed either at individual or organizational levels, creating unit of analysis issues, and also, the operationalization of behavior/result levels were problematic. To overcome the limitations, we reinterpret Kirkpatrick’s 4-level model (1959/1960, 1994) and developed new measures of learning, behavior, and result levels as well as including a measure of the reaction level (Warr, Allan, & Birdi, 1999) to evaluate training programs. These measures, comprising of reaction (emotional reaction, perceived usefulness, perceived difficulty), learning (objective evaluation), behavior (transfer motivation, possibility of transfer), and result (expectation of results) were used to examine a 7-factor model proposed in this study. Two samples were investigated in the study to examine the psychometric qualities of the measures (e.g., reliability and validity). The first sample (N=256) was drawn from an action learning training program that lasted for three days, and the second sample (N=148) was from a leadership training program that lasted for three days. For both samples, the measures were administered at the end of each training program. Measures of self-efficacy, locus of control, and openness to experience were additionally administered only for the second sample prior to the leadership training program to examine convergent validity of the measures. While the training context of the two samples were different, both showed significant and similar results. Our measures in both samples showed acceptable reliabilities (Cronbach’s α=.56-.96) and replicated a theoretically expected 7-factor model through exploratory factor analysis (EFA) and confirmatory factor analysis (CFA). Moreover, our measures were correlated with self-efficacy, locus of control, and openness to experience in the second sample, demonstrating convergent validities of the new measures. In general, evaluating the effectiveness of training programs has been limited with regard to the reaction and learning levels. However, the measures developed in this study can provide multi-faceted evaluation of programs and we hope that such developments will lead to the development of effective training programs.

Keywords: Kirkpatrick’s 4-level model, measurement, training programs, reliability, validity

Development of the Measure of Absorption in Sport Contexts (MASC)

KOEHN, S. (Central Queensland University), MORRIS, T. (Victoria University), WATT, A. P. (Victoria University)

Absorption is a positive state of heightened concentration and involvement in the task at hand (Roche & McConkey, 1990). The development of a measure of absorption in sport is important for examining the connection to other sport-related constructs, such as imagery and flow. Tellegen and Atkinson (1974) developed and validated the Tellegen Absorption Scale (TAS) as a self-report measure to assess absorption in everyday life. The MASC items were derived from the original TAS and transferred to sport situations, that is, we modified the original items from an everyday context into a sport-specific context. This study aims to examine the psychometric properties of the MASC. The sample in this study consisted of 319 physical education students (mean age 20.7 years; SD = 3.74) who were involved in range of individual and team sports. On average, participants had been participating in the various activities for 9.7 years (SD = 4.83) on a recreational (n = 66), club (n = 168), state (n = 62), or national (n = 23) level. After ethics was approved, participants completed the MASC in
Melbourne, Australia. Cronbach’s alpha coefficients showed acceptable scores for most of the MASC subscales. Internal consistency ranged between .71 and .80. Convergent validity was supported with item loadings of .45 and higher for the six factors. Inter-factor correlations ranged between .46 and .85 ($M = .64$). The measurement model showed a significant $p$ value, but acceptable fit values for the Comparative Fit Index (.92) and Tucker-Lewis Index (.91), the standardized root-mean-square residuals (.05), and root-mean-square error of approximation (.05). Convergent and construct validity has been found acceptable for all six factors, and the overall measurement model revealed acceptable fit. As a limitation of the study, a homogenous sample was used and the results need to be cross-validated with a second sample. In addition, future studies need to test possible model misspecifications that were evident in the significant $p$ value. External validity of the MASC also should be assessed, examining links with sport constructs that should be theoretically linked to absorption, including imagery, hypnotic susceptibility, and flow.

**Keywords:** absorption, flow, sport-related constructs, imagery, hypnotic susceptibility

### Development of the Victimization and Bullying Inventory: A post-school measure

GOLDSMID, S. (University of Sydney), HOWIE, P. (University of Sydney)

The aim of this study was to develop a new self-report instrument, the Victimization and Bullying Inventory (VBI), for the measurement of victimization and bullying behaviour in early post-school aged populations. No published measure could be identified that was specifically designed to measure victimization and bullying in this population. The initial pool of 36 behaviours was drawn from school and adult measures with some new items written specifically for the post-school aged population. All behaviours were presented once from the victim perspective and once from the bully perspective. Participants were asked to indicate how frequently they had been bullied/bullied others by each of the 36 behaviours, in the preceding six months, on a five-point scale (from 0 = Never to 4 = Almost Always). Data from a sample of over 300 first year psychology students was used to test and refine the psychometric properties of the instrument. Several items were removed from the initial version of the VBI due to floor or ceiling effects. Results indicated that the resulting victimization and bullying scales were reliable, for both males and females. Prevalence data of endorsement of individual items indicated that substantial numbers of individuals had been involved in some form of bullying behaviour, with experience of both bullying and being victimized not uncommon. Principal Components Analysis identified a 3-factor and 4-factor structure as underlying the victimization and bullying scales, respectively. The three victimization factors were characterized as Social (Relational), Physical, and ‘Teased and Taken’. The four bullying factors were characterized as Manipulation of Property and Person, Physical Intimidation, Verbal and Social (Relational). A factor structure notably different to that observed in school-aged studies suggests possible maturational differences in social networks and/or support for Bjorkqvist’s theory that as individual social skills evolve, so does the nature and sophistication of bullying behaviour. Differences in the factor structures of post-school victimization and bullying may suggest that the population is being victimized by different behaviours to those employed to bully others, possibly due to victimization by non-peers. In sum, the new measure should be a useful instrument for examination of the nature and prevalence of victimization and bullying in early post-school aged populations, an under-researched population, and for the study of the stability of victimization and bullying behaviour beyond the school years.

**Keywords:** victimization, bullying, self-report inventory, post-school, Bjorkqvist’s theory
Developmental consultation and educational support for harmful effects by prophylactic BCG vaccination in an infant with profound disabilities

TANAKA, S. (Kyoto University)

Approximately 4,000 infants and children have suffered from mental and physical damage due to the harmful effects of a vaccine in Japan, 60 years after World War II. They display many kinds of mental problems and need not only medical treatment but also psychological care. First, we tried to correctly perceive the reality of mental and physical retardation and the recovery processes of the inoculation damage. Second, we carried out new approaches for impaired infants, which we based on developmental consultation and guidance, bringing up interpenetrative relationships between their self-recognition and social communications. We longitudinally observed an infant from 1 year and 11 months of age to investigate the psychological effects of prophylactic inoculation with BCG vaccine and to evaluate properties of our educational methods for mental retardation. Two normal infants were controlled for the equivalent period. We carried out the G-band staining of the chromosome with blood lymphocytes. Head MRI and EEG were repeatedly recorded for physiological and psychological assessment. Moreover, we observed behavioural features in daily life and evaluated the developmental properties with the Kyoto Scale of Psychological Development. The infant’s chromosomal karyotype was 46XX/47XX, ti(12+) due to Paillister-Killian syndrome. She had mental and motor retardation, and magnetic resonance studies of the whole brain revealed an atrophic cerebrum, aplasia of the brain stem, and expansion of the lateral ventricle. After BCG inoculation at the age of 5 months she experienced hyperthermia and ictus epilepticus. Furthermore, she showed more severe mental retardation, deafness, and amblyopia after epilepsy. However, she did gradually recover perceptual and verbal functions with support of her development of self recognition and expression. These results indicate that the BCG vaccination may have more harmful effects in infants and children when they have a high rate of chromosomal mutation and an anamnesis of epilepsy. The results also suggest that the infant has potential abilities of recovery despite severe disorders and could educate her development by these approaches.

Diagnostic evaluation of a suicide prevention program among Mexican adolescents

PINTO LORÍA, M. (Universidad Autónoma de Yucatán), FLORES GALAZ, M.M. (Universidad Autónoma de Yucatán), GÓNGORA CORONADO, E. (Universidad Autónoma de Yucatán), BRAVO HERNÁNDEZ, A.J. (Fe y Alegría), MENA MAY, G.B. (Universidad Autónoma de Yucatán), XOOL MONTERO, M.A. (Universidad Autónoma de Yucatán)

To assess the effects of a program of life skills and competencies for life (WHO/PAHO) in three groups of adolescents who received training workshops to prevent suicidal behavior. A quasi experimental field study was conducted, involving three groups of students chosen randomly from the first grade of a public secondary school in the State of Yucatán, Mexico. Each group filled out a pretest, implemented a workshop to develop one of the three life skills selected (coping with emotions, assertive communication and conflict management), and finally filled out a post test. The duration of each workshop was 20 hours. The results obtained by test Student T showed statistically significant differences. Regarding assertiveness, assertive behaviors and acceptance of this style of communication increased; also noted is the increase in positive styles to address conflict. Regarding coping with emotions, self-knowledge of emotional responses increased, as did the awareness of the effect of the emotions in the body, and also, ways to react using breathing and healthy cognitions. In general, the study underpins the importance of promoting among the adolescent population life skills and competencies for life in accordance with the WHO/PAHO proposal (1993; 2001; 2003) to strengthen the protective factors in this stage of life and prevent the occurrence of risk factors as suicidal behavior.
Diagnostic test validation with mixed groups

JEWSBURY, P. (University of Melbourne), BOWDEN, S. (University of Melbourne)

The standard method to validate diagnostic tests requires the construction of two pure groups: participants with the condition of interest, and participants without the condition of interest. The aim is to evaluate the tenability of diagnostic test validation with mixed groups: groups which include both participants with and without the condition. Special emphasis is given to the statistical model “mixed group validation” (MGV) proposed by Dawes & Meehl (1966). MGV was comprehensively described using standard statistical theory to specify the standard error and the effect of assumption violation. MGV’s effectiveness in recovering true validity coefficients in real data was tested by reinterpreting published validation studies as mixed group designs. The assumptions of MGV were considered in greater detail in qualitative and quantitative analyses. MGV effectiveness was tested again in conditions specifically chosen to satisfy the assumptions of MGV. Finally, the mathematical structure of MGV was compared to other models to look for similarities and to find other models suitable for diagnostic test validation with mixed groups. The standard error and effect of assumption violation of MGV was specified. MGV failed to recover the true validity coefficients in real data without bias. The assumptions of MGV were found to be strong, not satisfied in published MGV studies, and that MGV is not robust to assumption violation. It was found that MGV assumptions can be practically satisfied, but only for special cases. In the test of MGV with specially chosen conditions, MGV performed well. MGV was shown to be related to latent class models and mathematically identical to ecological regression. Other models that can be co-opted for diagnostic test validation with mixed groups are reviewed. All these models also have strong assumptions that can only be satisfied in special cases. Diagnostic test validation with mixed groups is tenable but all models involve strong assumptions. No model reviewed is robust to assumption violation, so the assumptions require justification before the results can be meaningfully interpreted.

Differences in driving behaviours between elderly drivers and middle-aged drivers at intersections

RENGE, N. (Osaka University), TADA, M. (Advanced Telecommunications Research Institute International), RENGE, K. (Tezukayama University), USUI, S. (Osaka University)

Previous research had shown that elderly drivers rate their own driving behaviours higher than their actual behaviours. The objective of the present study was to compare driving behaviours of elderly and middle-aged drivers at intersections where many accidents are caused by elderly drivers. Questionnaire surveys and field experiments were conducted for 20 elderly drivers (M = 68.35, SD = 4.02) and 20 middle-aged drivers (M = 40.60, SD = 8.80). All participants answered questionnaires about self-reported driving behaviours, and then their actual driving behaviours were measured on a course in a residential area. Two cars with video cameras, drive recorders and wireless 3D-gyro sensors attached to the drivers were used for the field experiments. Driving performance was measured for turning right at non-signalled intersections and going straight at intersections with stop signs. As behavioural measures, driving speeds, speed changes during acceleration and deceleration and visual search behaviour for right and left directions were used. First, no significant difference was observed between the self-reported driving behaviours of elderly and middle-aged drivers. Second, elderly drivers drove at lower speeds before the non-signalled intersections and going straight at intersections with stop signs. As behavioural measures, driving speeds, speed changes during acceleration and deceleration and visual search behaviour for right and left directions were used. First, no significant difference was observed between the self-reported driving behaviours of elderly and middle-aged drivers. Second, elderly drivers drove at lower speeds before the non-signalled intersections than middle-aged drivers; however, at the lowest speed, at 30 metres before intersections and just on the intersections, no significant difference was observed. When turning right, elderly drivers performed better with respect to visual searching angle, timing and frequency for right direction, whereas they performed poorly with respect to the visual searching time for left
Direction. At intersections with a stop sign, elderly drivers reduced their speed more near the intersections than middle-aged drivers. Although there was no difference in driver speeds before the intersections, the lowest speed of the elderly drivers on the intersections was significantly higher than that of the middle-aged drivers. Finally, some relationships between the self-reported driving behaviours and actual driving performances were found. Elderly drivers tended to search their own driving lanes sufficiently but opposite ones insufficiently, which can contribute to accident risk at non-signalled intersections. Furthermore, it was also noted that they could not sufficiently reduce their speed on intersections with a stop signal, creating higher risk of accidents.

Keywords: driving behaviour, elderly drivers, middle-aged drivers, intersections, accidents

Differences in risk perception among nurses based on experience

ADACHI, Y. (Osaka University), USUI, S. (Osaka University)

We examined whether nurses who had worked for less than a year, two to five years, and over 15 years differ in (A) risk evaluation, (B) hazard perception (C) choice of avoiding hazards in nursing. Forty-nine nurses participated in this study. All of them were Japanese. They were divided into three groups based on length of time working as a nurse: the one-year group (N = 23), the two-to-five-year group (N = 12), and the over 15-year group (N = 14). A picture of nursing activity was displayed for 25 sec. After the picture disappeared, participants answered three questions with a questionnaire. The first question related to (A) risk evaluation. Participants evaluated how risky the picture was (extremely risky (5), not at all risky (1)). The second question related to (B) hazard perception. One picture had three hazards; three hazards and one dummy were listed in the questionnaire. Participants responded with “I found one” or “I didn’t find one.” The third question related to (C) choice of avoiding hazards. There were three choices: behave safely to avoid hazards (3), keep things as they are, or take more risk (1). There were 16 scenes. We conducted this study in a group. One-way analysis of variance (ANOVA) was performed to check experience differences separately. No experience differences were found in A or B (raw score, d’, β) scores. C scores were in the following order: the two-to-five-year group was less than the 15-year group which was less than the one-year group. A high score means more safety. Multiple comparisons confirmed a significant difference between the two-to-five-year group and the one-year group (p < .05). The lack of significant differences in A scores and B scores, d’ and β suggested that experience made no difference to risk evaluation and hazard perception. A significant difference in C suggested that the two-to-five-year group’s choice of avoiding hazards was more risky. This result is consistent with a previous study (Usui, Wada, Aoki, Tachikake, 2005) that suggested that nurses with two to five years of experience had lower safety awareness.

Keywords: risk evaluation, hazard perception, nursing, experience

Differential effects of chronic paroxetine in adult and adolescent rats: A behavioural, neurochemical and proteomic analysis

KARANGES, E. (University of Sydney), LI, K.M. (University of Sydney), MOTBEY, C. (University of Sydney), SARKER, R. (University of Sydney), KASHEM, M.A. (University of Sydney), CALLAGHAN, P.D. (University of Sydney), MCGREGOR, I. (University of Sydney)

Use of selective serotonin reuptake inhibitors (SSRIs) in adolescent depression has recently been scrutinised following reports of minimal efficacy and increased risk of suicidal ideation/behaviour associated with children and teenagers given these drugs. This study examined the behavioural and neurochemical effects of chronic paroxetine treatment in adult and adolescent rats in order to identify differential brain changes potentially underlying these age-specific effects. Adolescent and adult male Wistar rats were treated with paroxetine in their drinking water for 22 days, during which time they were assessed for depression- and anxiety-like behaviours on the emergence test, elevated plus maze, social interaction test, novelty-induced hypophagia test and forced
Swim test. Subsequent ex vivo analyses investigated changes in the serotonin (5-HT) and dopamine systems using high-performance liquid chromatography (HPLC) and quantitative autoradiography. Serum paroxetine concentrations were also assessed using HPLC and changes in hippocampal protein expression determined using two-dimensional gel electrophoresis. Despite clear efficacy in adult rats, paroxetine failed to show an antidepressant effect in adolescent rats in the forced swim test. Adolescents also displayed more pronounced anxiogenic responses to paroxetine than adults in a variety of tests. These behavioural differences were reflected in differential 5-HT, dopamine and proteomic changes in the brain. Adult paroxetine-treated rats displayed decreased 5-HIAA, and increased dopamine turnover, but no change in dopamine, DOPAC or 5-HT in the striatum, or serotonin transporter (SERT) binding in the ventral tegmental area. In contrast, adolescent rats displayed decreased 5-HIAA and HVA concentrations, and increased SERT binding. Paroxetine differentially altered hippocampal protein expression in adolescent rats, particularly in a number of proteins involved in neurotransmitter synthesis, vesicular trafficking and intracellular signaling. Despite the greater adverse impact of paroxetine on the adolescent brain and behaviour, adult rats displayed higher plasma concentrations of paroxetine than adolescents. The immature brain appears to respond paradoxically to paroxetine, producing anxiogenic and anhedonic effects in adolescents. Drug-induced upregulation of SERT binding density may underlie these behavioural changes as well as idiosyncratic effects of paroxetine on intracellular signaling proteins and neurotransmitter synthesis. Therefore, the current caution in the use of paroxetine in young people is clearly warranted.

Keywords: paroxetine, chronic paroxetine treatment, adolescent depression, selective serotonin reuptake inhibitors (SSRIs), rats

Differential effects of intrinsic motivation and identified motivation on learning in Japanese junior high school students

The purpose of this study is to explain intrinsic motivation and identified motivation on academic performance of Japanese junior high school students. Specifically, we investigated the difference between these effects by meta-cognitive strategy which regulated self-academic work. Intrinsic motivation is the most autonomous motivation and exists when people freely choose to perform an activity out of a sense of interest. In contrast, the identified motivation involves an individual’s recognition and acceptance of the value. Although intrinsic motivation and identified motivation are strongly correlated, these constructs are theoretically distinct. Despite this fact, little research has examined differential effects of these motivations on learning. We conducted the same research two times, and the second one was done one year after the first one. A total of one hundred seventy three participants completed two sets of questionnaires both times. The first set was the Autonomic Motivation Scale for Japanese Junior High School Students which was based on Ryan and Connell’s Self-Regulation Scale for academic use. The other set was the Meta-Cognitive Strategy Scale. Both scales were rated on a 4-point Likert scale 1(= not at all) to 4(= completely). We also added an academic performance scale the second time. Internal consistency of intrinsic motivation, identified motivation, meta-cognitive strategy has ranged from α = .92 ~ .85. By covariance structure analysis, the intrinsic motivation was revealed to be independent of academic performance, in addition, the identified motivation dependent on it through meta-cognitive strategy. Concerning Fit indices, GFI=.99, AGFI=.94, RMSEA=.04, suggested that the model fits the data quite well. Our results indicate that intrinsic motivation and identified motivation show statistically-differential effects on the academic performance and the meta-cognitive strategy of Japanese junior high school students. Furthermore, the identified motivation is a significant factor in academic performance.

Keywords: motivation, academic performance, meta-cognition, high school students, Japan
Discrimination of deceptive and truthful responses using the alpha event-related desynchronization

KIM, S. (Chung-Ang University), LEE, J-H. (Chung-Ang University), JUNG, K-H. (Chung-Ang University)

Lying is a more cognitively complex task than telling the truth. Lying requires the retrieval of information from memory, response inhibition, and conflict monitoring. To directly measure cognitive load, many brain signal methods have been used, and among them, event-related desynchronization (ERD) of brain waves has proven to be a useful tool in measuring cortical activation levels during a wide range of cognitive tasks. Electroencephalogram (EEG) alpha power desynchronizes when individuals are mentally active, and reflects increasing task demands. When lying, relatively more cognitive complexity is experienced, and this phenomenon should be reflected as alpha band ERD. In this context, our study assumed that increased cognitive effort during deception will generate increased ERD. This aim of this study is to attempt to show that ERD can be used as an effective detection measure of deception. Participants completed a manipulation scale questionnaire and the Implicit Association Test (IAT). After a baseline EEG measurement, they performed the “Jack’s beanstalk” task. We developed a program where a dice was rolled and Jack climbs up the number of steps rolled on the dice. Participants had to decide whether to enter the presented number (truthful response) or a different number (deceptive response). The computer played the role of a second player, but the participants believed it was a real person. The goal of the task was to reach the top of the beanstalk. Telling the truth involved a small reward but no risk, whereas lying increased the possibility of reaching the top of the beanstalk but involved monetary risk. EEG and skin conductance data was acquired using a Laxtha Poly-G-I monitoring device. Data analysis is currently in progress, however, we predict that deceptive responses will represent more alpha band ERD than truth telling so that ERD will be able to discriminate deceptive responses from truthful response. These results would suggest that alpha band ERD could detect deceptive responses. Thus, ERD may be a valuable tool in measuring deception. Finally, this study may provide an opportunity to complement the limitation of other measurements of deception detection, such as the standard polygraph.

Keywords: lying, event-related desynchronization

Dispute resolution and psychology

ENGLAND, M.

The aim of this study is to encourage an appreciation of psychological aspects of dispute resolution theory and practice by outlining and explaining some psychological and multi-disciplinary aspects of dispute resolution theory and practice. Participants are to have an appreciation that there are definable psychological aspects of dispute resolution theory and practice. Participants will also appreciate the potential for the application of this knowledge and for further research in the area. There is considerable scope and corresponding opportunity for the application and research of psychological aspects of dispute resolution.

Keywords: dispute resolution, theory and practice, application and research

Do features of stimulus influence effects of idealized media portrayals on implicit self-image?

XU, X. (Wuhan Institute of Physical Education), ZHANG, J. (Chinese Academy Society)

The primary purpose of this study was to employ measures of implicit body image based on pictures and words versions in an effort to more completely explore the consequences of exposure to ideals of beauty on beliefs about the self among Chinese young women. One hundred and twelve female Wuhan Institute of Physical Education undergraduates, who are majoring in sport psychology, sport mass media and kinesiology, between the ages of 18 and 22, participated in exchange for partial fulfillment of a course requirement. Participants were presented via computer with a series of 20 magazine advertisements obtained from popular magazines. Fifty six of all participants saw 20...
nonperson/nonbeauty product advertisements (for example, sporting car) in the control condition. Alternatively, advertisements contained unrealistic standards of female beauty in the experimental group. After exposure to the advertisement, participants were assessed on implicit self evaluation about their body by pictures or words irrespectively. The design of this assessment was a 2(Condition: Beauty vs. Control condition) × 2 (Attribute Target: Picture stimulus vs. Word stimulus) within-participant design. The difference in Implicit Association Task (IAT) effects between the picture and word IAT versions was revealed in a significant main effect of attribute target factor, $F(1,108) = 44.901, p = .000$, partial $\eta^2 = .65$. However, there was not a significant main effect of condition factor, $F(1,108) = 2.651, p = .106$. Additionally, the interaction effect of two factors was not significant, $F(1,108) = 0.624, p = .431$. Even the results showed that participants were more susceptible to IAT effect with picture stimulus than words stimulus affected by media portrayals; people may be able to adjust, correct, and protect their self-evaluations on an implicit level, which was supported by previous research on explicit self-report measures of body image. We discussed the reasons why the result by the measures of implicit self image evaluation was not dissociated with that by the measures of explicit level.

Keywords: implicit body image, beauty ideals, self evaluation, implicit association test, explicit self-report

Do socially anxious people have utterance difficulty? An examination of Eysenck’s working memory theory in social anxiety

HOSHINO, T. (University of Tokyo), TANNO, Y. (University of Tokyo)

It is well known that socially anxious people have difficulty in making speeches in other persons’ presence, or on the phone, and so on. The performance deterioration like this can be caused by anxiety, and Eysenck (1998) points out the possibility that anxiety could impair the function of working memory in a high anxiety group (e.g., anxiety disorders). The aim of this study was to determine whether the function of working memory in socially anxious people could be impaired in utterance situations, compared to non-socially anxious people. Forty-five undergraduate students took part in the study. About a month before starting the experiment, 277 undergraduate students underwent the screening test. To determine the high and low social anxiety group, the Fear of Negative Evaluation scale (FNE; Watson & Friend, 1969) was used. Twenty-four participants who scored more than 1 SD above the mean made up the high social anxiety group, and 21 who scored more than 1 SD under the mean made up the low social anxiety group. The Reading Span Test (Daneman & Carpenter, 1980) was used to examine the function of working memory in high and low social anxiety group. In the experimental session, participants first underwent FNE to ensure the validity of high and low social anxiety group. Then the Reading Span Test (RST) was performed. In this study, participants were required to perform RST twice, one was the paper-and-pencil test, and the other was responded verbally (utterance test). The order of the two tests was randomized for each participant. A two way ANOVA (social anxiety × way of answering) revealed that the interaction effect was significant. As a result of multiple comparison analysis, the performance on the utterance test was significantly worse than the paper-and-pencil test in high social anxiety group. But such a difference was not observed in the low social anxiety group. Also, no difference was observed on the performance on the paper-and-pencil test between two groups. These results lend support for Eysenck’s theory of social anxiety under certain situations. Most importantly, the performance deterioration of working memory occurred selectively in the utterance situation in the high social anxiety group, but not in the paper-and-pencil situation. This suggests the possibility that the speech difficulty in socially anxious people could be caused by an impaired working memory system.

Keywords: working memory, anxiety, reading span test, Fear of Negative Evaluation Scale, speech

Do the media contribute to whether or not British teenagers feel confident?
JANSSON-BOYD, C. (Anglia Ruskin University), BLOOMFIELD, S. (London Metropolitan University)

This study set out to explore whether there is a relationship between media exposure and self-esteem in United Kingdom adolescents. One hundred and nine participants aged 13 to 14 provided information on their levels of use of television, the Internet, magazines, and movies. They also completed a Rosenberg self-esteem scale (Rosenberg, 1989), providing measures of global as well as positive and negative self-esteem (Owens, 1994). A significant positive correlation between boys’ Internet use and their global self-esteem was found ($r = .283, n = 52, p < 0.05$, two-tailed) and between Internet use and positive self-esteem ($r = .428, n = 52, p < 0.05$, two-tailed). Results indicate that the Internet can aid self-esteem in adolescent boys.

Keywords: media exposure, self-esteem, adolescents, Rosenberg self-esteem scale, global self-esteem

Does leadership matter? Performance implications of arbitrarily assigning team leaders

RADFORD, K.

Teams are widely regarded as essential to efficient project work structures. How teams are led and managed can have a substantial impact on performance and outcomes. Using leader-categorization theory as a conceptual basis, this study aimed to investigate the influence of an arbitrarily assigned leader on team performance in a controlled setting. The influence of gender, task difficulty, and task satisfaction were also investigated. Sixty undergraduate psychology students served as participants. The experimental task, which was completed in a room with no other teams or people (other than the researcher) present, involved re-ordering lyrics of nine current and past “Top 40” songs that were differentiated by difficulty level. Team members were asked to order the lyrics provided on an A4 sheet of paper with their correct line number. Of the 20 3-person teams, ten were arbitrarily assigned a leader, while ten acted autonomously. Performance outcomes were accuracy and speed of task completion. After participating in the study, participants completed a satisfaction questionnaire. Results revealed that assigned leader teams had better overall performance outcomes than autonomous teams did. Specifically, led teams had more accurate results than autonomous teams did. As task difficulty increased, there was a decline in the performance of both team types. However, there were no significant differences in time taken to complete each activity, task satisfaction or gender distribution. The study found support for leader categorization theory, suggesting that arbitrarily assigning leaders in teams induces role expectations that impact overall team performance. The study has potential implications for assigning team roles within organisations to influence team performance. Specifically, this research provided support for assigning team leaders to work projects in order to increase overall team performance.

Keywords: leader categorization theory, role expectation, team performance, task difficulty

Does the pattern for autobiographical memory and arousal vary among breast cancer patients with and without PTSD?

MAKKAR, S. (University of Delhi)

This study examined how breast cancer patients diagnosed with and without post traumatic stress disorder (PTSD) varied in memory patterns and arousal. A mixed method study was chosen to address the research objective. Thirty breast cancer (Stage I-III) patients were chosen for the study who completed the screening tool Detailed Assessment of Posttraumatic Stress (DAPS; Briere, 2001) and Autobiographical Memory Test (AMT; Williams and Broadbent, 1986). Their arousal level was assessed before and after the retrieval of memories in response to cue words. Among the thirty patients, five demonstrated PTSD symptoms and the other 25 did not fulfill the PTSD criteria. PTSD group recalled more over-general memories on the AMT while the non-PTSD group recalled more specific memories. In addition, PTSD as compared to non-PTSD women displayed higher levels of arousal. The narratives of the life experiences as revealed in the word cueing test
surfaced prominent themes across the responses. Themes that emerged were beliefs, health, work, society and social relationships. This study suggests that a life threatening illness like breast cancer can precipitate PTSD symptoms and result in changes in cognitive and physiological domains. Thus, research is needed to examine the effects of PTSD symptoms on immune responses, cancer outcome, and adherence to medical regimens.

Keywords: post-traumatic stress disorder, cancer patients, memory patterns, arousal, autobiographical memory

Dominant hemisphere of typical developed and autistic children between Picture-Based Personality Tests: A near-infrared spectroscopy study

HIRAISHI, H. (Kyoto University), INOMATA, S. (Tokai University), HAYAKAWA, Y. (Tokai University), MATSUMOTO, M. (Center for Developmental Clinical Psychology and Psychiatry, Nagoya University & Japan Science and Technology Agency), MATSUMOTO, H. (Tokai University), HAIDA, M. (Tokai University & Tokai University Junior College of Nursing and Medical Technology)

Children with Autistic Spectrum Disorder (ASD) have the abnormality of their central nerve system and this causes their unique cognitive functions. Personality tests have been used clinically for a long time to identify various characteristics from a person’s responses. However, it is not yet known how the assessment stimuli are processed in the brain. Therefore, we compared with their dominant hemisphere of typical developed children (TD) and ASD between picture-based personality tests. 17 TD (male 14; female 3) and six male ASD junior high school students were participated. Written informed consent was obtained from all participants and their guardians. Four Rorschach pictures, two TAT pictures and three PF-study cartoons with half the dialogue written in Japanese and the other half left blank were used. In all three test conditions, a common stimuli presentation procedure was used: a black cross was presented 30 seconds before and after a stimulus plate was presented for 40 seconds through a 19-inch wide liquid crystal display. The participant was asked to answer in a whispering tone as part of each set of standard verbal instructions. During the testing Oxyhemoglobin (Oxy-Hb) changes in the participant’s forehead were recorded by Near Infra-Red Spectroscopy (HITACHI Medical CO., Ltd., JAPAN). Oxy-Hb volumes were averaged in each hemisphere and calculated the Laterality Index (LI). LI shows which cerebral hemisphere is activated or not as the range from 1 to –1. In TD, there was a significant difference in the tests ($p<0.05$), and there is a significant difference between Rorschach and PF-study ($p<0.05$). In ASD, there is no significant difference in all factors. When compared with TD and ASD, there is a significant difference between LI of PF-study ($p<0.001$). The significant difference between dominant hemispheres of TD (left) and ASD (right) during the PF-study suggested that ASD lack the social brain system (Brothers, 1990; Castelli et al., 2002) that is related to a neural circuit comprising the amygdala, superior temporal sulcus, and prefrontal cortex in the left hemisphere.

Don’t forget father

MATTHEWSON, M. (University of Tasmania), BURTON SMITH, R. (University of Tasmania), MONTGOMERY, I. (University of Tasmania)

The aims of this study were to test Bögels’ and Phares’ (2008) model of anxiety acquisition in children by investigating whether differences in children’s anxiety exist when their parents exhibit high levels of self-reported anxiety compared to children whose parents exhibits low levels of self-reported anxiety. It also investigated whether mothers and fathers differentially predict sons’ and daughters’ anxiety. Ninety one families with children between the ages of 8 and 12 years participated in the study. Children’s biological parents completed measures of anxiety and parental support effectiveness. Children completed measures of anxiety and parental support satisfaction. This study revealed that mothers and fathers high in trait anxiety had children higher in anxiety than did mothers and fathers...
low in trait anxiety. The results also showed that both mothers' and fathers' anxiety significantly and differentially predicted sons' and daughters' anxiety. Specifically, observable anxiety (state anxiety) modelled by mothers had a significant impact on daughters' endogenous anxiety (trait anxiety), while the observable anxiety modelled by fathers had a significant impact on sons' endogenous anxiety. Moreover, fathers' informational support satisfaction significantly predicted daughters' trait anxiety; however, fathers' perception of their informational support provisions significantly predicted sons' state anxiety. The findings of this study give further support to Bögels' and Phares' model with regard to the differential contribution mothers and fathers make in predicting non-clinical symptoms of anxiety in children. The outcome of this study shows that the opposite-sex parent may have a greater impact on children's anxiety than first thought. Therefore, the information fathers convey to their children and the way in which that information is given may be an important part of fathers' role as encouragers of appropriate risk taking behaviours in their children and promoters of the world outside the home. This study clearly shows that the role of fathers should not be overlooked in investigations of children's anxiety.

**Effect of influence effectiveness by hierarchical level in the use of interpersonal influence**

SANTILLE, A. (LAB SSJ), ANDRADE DA SILVA, G. (Universidade de Sao Paulo), SAMARTINI, A.L.S. (Fundação Getulio Vargas), OTTA, E.

This study explored the effectiveness of influence tactics by hierarchical level in the organizational environment. The sample consisted of 47 superiors, 125 peers and 102 subordinates. A model of Univariate Analysis of Variance (ANOVA) with Repeated Measures was used. Rational persuasion (β=0.205) was the only tactic responsible for the effectiveness of the influence (p< 0.01) when used in upward influence attempts. Consultation had positive effects on the effectiveness of the influence among peers (β=0.096) and subordinates (β=0.06), probably because it allows greater involvement of the target in the task proposed by the agent, not to mention that is more socially accepted to obtain cooperation. Exchange (subordinates β=0.125) and coalition tactics (peers β=-0.08; subordinates β=0.095) had negative effects on the effectiveness of the influence in lateral and downward influence attempts. At least among peers, legitimating tactics (β=0.115) showed positive effects on the effectiveness of the influence. This is maybe due to the respect and recognition of norms and organizational policies. To conclude, to influence superiors the use of reason or argumentation seems to be the most common accepted behavior because it shows intellectual ability and negotiating skills of the agent. Rational persuasion contributed positively to the effectiveness of the influence, except over subordinates. In general, respondents preferred using soft tactics (rational persuasion, consultation) and disliked using hard tactics (exchange and coalition tactics).

**Keywords:** influence tactics, organisation, superiors, peers, subordinates

**Effect of objective housing characteristics on well-being: A conditional growth model**

NAKAZATO, N. (Kwansei Gakuin University), SCHIMMACK, U. (University of Toronto), OISHI, S. (University of Virginia)

Relatively few studies have examined how internal and external determinants contribute to well-being, using domain-specific indicators of well-being. To cite an example, the authors’ prior study examined top-down and bottom-up effects on housing satisfaction. The study revealed that stability in housing satisfaction before and after moving should be explained by top-down effects of life-satisfaction on housing satisfaction. However, the stability of individual differences was relatively low. This finding suggests that objective housing characteristics have strong bottom-up effects on housing satisfaction. The aim of this study is to test this prediction. The analysis is based on the German Socio Economic Panel survey. We used data concerning participants who moved into a new
house only once in the years from 1991 to 2007 (N = 3658). Participants’ annual reports of housing satisfaction were used as outcome variables. For the analysis, a conditional two intercepts and two slopes growth model was used. The analysis was limited to eleven years from five years before moving to five years after moving (intercept before moving = five years before moving; intercept after moving = five years after moving). Variables regarding housing characteristics after moving were entered as predictors of intercept after moving. The model fit indexes showed good fit, \( \chi^2 (94, N = 3658) = 144.99, p < .001; \) CFI = .992; RMSEA = .012; SRMR = .020. Housing characteristics significantly predicted the intercept after moving of housing satisfaction. Housing size (unconditional \( \gamma = .003, 99\% CI = .00|.005\)), heating (\( \gamma = .80, 99\% CI = .23|1.38\)), ownership (\( \gamma = .75, 99\% CI = .50|.99\)), and condition (\( \gamma = .69, 99\% CI = .41|.97\)) positively influenced the intercept after moving. In contrast, house type variables negatively influenced it in comparison with family house (row house: \( \gamma = -.10, \) n.s.; low-rise: \( \gamma = -.29, 99\% CI = -.52|-.05\); high-rise: \( \gamma = -.48, 99\% CI = -.85|-.10\)). The result showed that housing characteristics had long-term effects of moving on housing satisfaction. Specifically, heating, ownership, and condition positively predicted the intercept after moving. In contrast, high-rise negatively predicted it. Future studies should also consider moderator effects on housing satisfaction (e.g., personality traits; residential area).

Effect of quality of relationship in the use of interpersonal influence in upward influence attempts

SANTILLE, A. (LAB SSJ), ANDRADE DA SILVA, G. (Universidade de Sao Paulo), SAMARTINI, A.L.S. (Fundação Getulio Vargas), OTTA, E.

The present research investigates the quality of relationship in the use of interpersonal influence in upward influence attempts. The sample was composed of 47 leaders. A model of Univariate Analysis of Variance (ANOVA) with Repeated Measures was used. The results showed what key influence tactics built more effective relationships in upward influence attempts. In general, the quality of relationship was positively affected by the use of consultation and personal appeals (\( \beta = 0.116 \) and \( \beta = 0.129 \)) in work-related influence attempts. Collaboration had negative effect (\( \beta = -0.104 \)). Rational persuasion (\( \beta = 0.200 \)) and legitimating tactics (\( \beta = 0.115 \)) had positive effects upon the quality of relationship when used by female leaders. Inspirational appeals (\( \beta = 0.069 \)) and coalition tactics (\( \beta = 0.082 \)) had positive effects upon the quality of relationship when used by male leaders. A significant effect of gender upon the use of tactics by the agent was observed, showing better interactions with the opposite sex. When the leader was male, his relationship was better with a woman; when the leader was female, her relationship was better with a man. These findings have important implications for how organizations can understand leaders’ use of influence tactics and the effects of these tactics upon the quality of relationship within the workplace, since influence has been considered an essential variable in the executives’ performance.

Effect of repeated forensic interviews

INOUE, A. (Hokkaido University), NAKA, M. (Hokkaido University)

Repeating interviews can lead to new information, but several studies have shown that people are then also more susceptible to creating false memories, especially when children are interviewed (Ackil & Zaragoza, 1998). It is therefore recommended by the forensic interview guideline that an interview should be conducted only once. On the other hand, Hershkowitz and Terner (2007) have shown that if one uses non-suggestive questions, repeated interviews are not harmful. In this study, we conducted interviews based on the forensic interview guideline twice to investigate its effect on the recall of new information and the creation of false memories with college students. Fifteen college students participated in a study in which they thought they had to perform two coloring tasks. Between the two tasks, they were instructed to take a break and
watch a DVD. It contained a short story about a girl that goes to read a book in the park near some children who play on a swing. After subjects completed the second coloring task, they were interviewed about the unintentionally learned events. The first interview was conducted five minutes after the subjects had watched the story, whereas the second interview was conducted one week later. The interviews proceeded through the three stages prescribed by the guidelines: rapport, narrative and question phase. The content of the DVD was divided into 190 items. On average 43.3 items were correctly recalled at both sessions. Participants often referred to information during the first interview, which they did not name during the second interview \((M = 6.1)\). They also frequently recalled new information, which were correct items in the second session that had not been mentioned before \((M = 6.8)\). Participants recalled very little incorrect information. On average 1.5 incorrect items were recalled at both sessions. A few incorrect items \((M = 0.5)\) were mentioned during the first interview, but not at the second. Participants recalled few pieces of incorrect information \((M = 0.6)\) in the second session, which they had not recalled before. Participants recalled relatively few correct items, but their number increased when the interviews were repeated. On average seven pieces of new information were correctly recalled at the second session, which had not been mentioned before. The number of incorrect answers was very low in both sessions, which suggests that the production of incorrect information was kept to a minimum due to the forensic interview method. At the second session, hardly any new incorrect information was recalled, suggesting that repeated interviews may not create false information. The results show that repeated interviews draw out more correct information without creating incorrect information. However, the low number of incorrect answers may result from the simple and unambiguous content of the DVD and participants, who were college students and not young children. Furthermore, it is unclear whether the missing items were forgotten or merely not mentioned.

**Keywords:** forensic interviews, repeating interviews, false memories, recall, children

**Effect of self-esteem on the preference of the roles in the persuasion game which simulates sales situations: An investigation using the Settoku Nattoku Game (SNG) sales version**

NISHIMURA, T. (Hiroshima International University), ISHIDA, C. (Hiroshima International University), HARA, A. (Hiroshima International University)

The aim of present study is to investigate the effect of self-esteem on the preference of the roles in the sales situations. For the purpose of this study, we used a negotiation game which simulates the sales situation, named the SNG (Settoku Nattoku Game) sales version (Sugiura et al., 2006). 34 undergraduate students were participated in the game. The method was based on Sugiura et al. (2006). Firstly, participants are divided into two groups and assigned the role of seller (persuader) or buyer (persuadee). Each seller was given 15 minutes to approach any buyers freely to explain his/her new idea of cell phone. When buyers accept the idea from a seller, they were required to sign their name and the final price of that cell phone on a list carried by the seller. Then all participants exchange roles, and the same procedure is repeated. Sellers were requested to raise the total sales amount as much as possible. On the other hand, buyers were requested to buy good cell phones as much as possible within a limited amount of money (150,000YEN). As soon as each negotiation session ended, participants answered some questions about the levels of satisfaction in just before the session. For some scores of satisfaction after each negotiation session, \(2 \times 2\) mixed ANOVAs were carried out. As results, the people with high self-esteem tend to evaluate their behavior positively when they play the role of a seller. On the other hand, the people with low self-esteem tend to tend to evaluate their behavior positively when they play the role of a buyer. Taken together, the level of self-esteem would influence the orientation of the role in the situation of negotiation. In the sales situation, people with high self-esteem would prefer the role of a seller; on the other hand, people with low self-esteem would prefer the role of a buyer. These results are discussed from viewpoints of
the relationship between self and interpersonal behavior in social psychology.

Keywords: self-esteem, sales situation, satisfaction, negotiation, interpersonal factors

Effect of social self-regulation and group identification on university adjustment

NAKAGAWA, T. (Miyagi Gakuin Women’s University)

Recently, many companies in Japan have come to review whether student candidates have the necessary social and communication skills for doing a job. It should be reasonable that such business relevant skills may develop in the process of university adjustment. Firstly, we focused on group identification (Roccas, et al., 2008) – individuals’ degree of identification with the faculty and peers – as a direct factor to enhance their adjustment. Students with high identification are more likely to cooperate with other group members (Simon, et al., 1998) to promote the value of their faculty, which might serve as a source of their social identity. This identification process should be thought of as adjusting students to university. Thus, we predicted that group identification would promote adjustment to university. Secondly, we explored the predictor of group identification and highlighted an individual difference, especially estimating the effect of social self-regulation (SSR; Harada, 2008) on it. People with high self-control appear to effectively handle various situations they encounter. Accordingly, we predicted that SSR would promote group identification. In summary, our research model examines whether group identification may mediate the relationship between SSR and adjustment to university. We conducted a questionnaire survey of 266 respondents from a university in Tokyo and asked them to rate the following scales: (1) ability to regulate self according to the situation (independent variable); (2) identification with the faculty to which they belong (mediator); and (3) fit and grade point average (outcome). Our analysis was divided into measurement and structural models. As a measurement model, we conducted exploratory factor analysis (EFA) for SSR and group identification. EFA revealed three factors for SSR (emotional control, assertiveness and persistent effort) and two factors for group identification (affective identification and cognitive identification). Next, we performed structural equation modeling to test the validity of our prediction. As predicted, both types of group identification mediated the relationships between SSR, except persistent effort and fit, while only cognitive identification mediated SSR and grade point average. We concluded that SSR should play an important role in predicting university adjustment via group identification.

Keywords: social self-regulation, group identification, university adjustment, social identity, communication skills

Effect of stimulating the plantar skin on force discrimination in the ankle joint

SUZUKI, H. (Iwaki Junior College), MIZUGUCHI, T. (Iwaki Junior College), KIZUKA, T. (University of Tsukuba)

The plantar is the first point of contact between a person and the ground during physical movement. Sensory feedback from the skin is believed to impact the regulation of force in the ankle joints. Force discrimination plays an important role in this process. This study using flat and textured sole plates investigated how different stimulation to the plantar influences force discrimination in the ankle joint. Participants (n=9; 4 men, 5 women; average age 25.2 ± 3.4 years; average height 172.5 ± 5.1 cm; average weight 66.7 ± 6.5 kg) were healthy, right foot dominant people. Each participant was tested over a two-day period. One flat (Flt) acrylic board and one textured (Tex) board covered at 2 cm intervals with dome-shaped urethane cushions (8 mm wide, 2.3 mm high) were used as stimuli and presented in random order. Using the double-staircase psychophysical method, force discrimination was measured by asking the participants if the comparison stimulus (Cs) was “heavy or light” compared to the standard stimulus (Ss). The muscle recruitment pattern was isometric plantar flexor muscle contraction. Ss was set to 30% MVC. Cs was changed by units of 200g. The differential-threshold and the standard deviation of the upper and lower differential-thresholds were evaluated. Results of the t-test showed that force discrimination thresholds were...
significantly lower in the Tex group compared to the Flt group (p<0.05). There was no significant difference in the standard deviations for the upper and lower limen. Force discrimination threshold was significantly lower in the Tex group. This may be explained by stronger skin sensation from the textured stimulus and by higher spatial resolution of pressure distribution due to the placement of the cushions at 2 cm intervals, the threshold for two-point discrimination. There was no significant difference in the standard deviations of upper and lower discrimination thresholds for either group. These results indicate that differences in skin stimulus do not affect the range of correct responses when measuring force discrimination.

Keywords: plantar skin, force discrimination, skin stimulus, sensory feedback, muscles

Effect of text messaging and messaging partner's diversity on attitudes about interactions and adaptation in Japan

FURUTANI, K. (Hijiyama University), HIKITA, A. (Hiroshima University)

The aim of this study was to investigate the effects of text messaging and messaging partner's diversity on attitudes about interactions and adaptation in Japanese students. The participants in this study were elementary, junior high and high school students in Japan (N = 634). Their text messaging, diversity of messaging partner (kin and friends), attitudes about interaction (e.g., trust, communication tolerance, text-message dependency, among others) and adaptation (depression and loneliness) were assessed. Among elementary school students, those that were heavy users of text messages and had a high diversity of friends showed more communication tolerance. Those that were light users of text messages and had a diversity of friends were less dependent on text messaging. However, text-message dependency was high in those that had a high diversity of friends and a low diversity of kin. Students that were light users of text messages and had a high diversity of kin and friends had a high degree of trust. Conversely, heavy users of text messages had low trust. Students that had a high diversity of kin and friends were less lonely. But, loneliness was high in students with light use of text messaging and a low diversity of friends. These results suggest that the type of school moderated the effect of text messaging and the mail partner’s diversity. Use of text messaging in high school students and diversity of friends had a variety of effects.

Keywords: text messaging, messaging partner diversity, attitudes, Japan

Effect of the classroom structure on children's multiple motivation in Japanese elementary classrooms

NAKAYA, M. (Osaka University)

Children engage in learning in classrooms where they are influenced by social context (Evertson & Weinstein, 2006). A teacher’s classroom management behaviors construct such a context, so these behaviors can influence children’s motivation and academic achievements. This study examined the effects of teacher’s classroom management behavior on children’s academic and social motivation, especially children’s goals. Several classroom observations and questionnaires were administered to 100 sixth grade children and their teachers in three elementary classes. The public elementary school was located in the suburbs of the city of Osaka, Japan, which has a population of about 270,000 people. These surveys were administered three times, in July, December and February, 2007. The questionnaires consisted of three parts: 1) Teacher’s Behavior Scale (11 items, α=.78), Explanation, Positive Expectation, Affiliation, Mutual Respect, Teacher’s Motivation; 2) Classroom Structure Scale (8 items, α=.85), Norms, Commitment, Comfortableness; and 3) Children’s Multiple Goals (12 items, α=.78), Compliance Goal, Prosocial Goal, Academic
Mastery Goal, Academic Performance Goal, Assertive Goal. Semi-structured interviews were also conducted in the first and last semester, where teachers were interviewed about the cognition of their classroom. An example question was “Do you think about the interpersonal relationships and classroom atmosphere in the class?” Each teacher’s answers were analyzed from a qualitative perspective. Correlational analysis indicated that the relationship between teacher’s classroom management behaviors, children’s perceptions of the classroom, and children’s multiple goals were somewhat different among classes. Teacher’s classroom behaviors in the first semester influenced classroom structure and multiple goals at the second and third semester. In class A, the teacher’s positive expectation promoted children’s mastery goal mediated by classroom commitment. Furthermore, comfort structure mediated effects of the teacher’s affiliation behavior on prosocial goals. In contrast, such relationships were not found in class B. Results indicate that teacher behaviors affect classroom structure and children’s multiple goals. The importance of social climate in children’s learning processes will be discussed.

Effects of adult attachment, accident proneness, anxiety on safety awareness: Evidences from Chinese construction workers

LI, T. (Peking University), WU, J. (Nanyang Technological University)

The aim of this research was to investigate the accident proneness, adult attachment, trait and state anxiety on safety awareness of Chinese construction workers. A total of 587 construction workers from two construction companies in Beijing provided data for the study. Accident Proneness Scale for Construction Workers (Li, et al., 2008) was developed and used to measure accident proneness, and a Relationship Questionnaire (RQ, Bartholowew, 1991), State Anxiety Inventory (SAI) and Trait Anxiety Inventory (TAI) Chinese Versions, and Safety Awareness Questionnaire (Choudry, 2007) were used to measure workers’ adult attachment, anxieties and safety awareness. The results showed that, compared with insecure workers, secure participants get lower scores on accident proneness, state and trait anxiety, and higher scores on safety awareness. Both SAI and TAI had significant positive correlation with accident proneness, and negative correlation with safety awareness. Path analysis showed that adult attachment influenced accident proneness and safety awareness, while SAI and TAI acted as a medium for the accident proneness to safety awareness. Accident proneness and attachment can influence the safety awareness via the mediating effects of the anxiety.

Keywords: adult attachment, accident proneness, anxiety, safety, Chinese construction workers

Effects of background music on comprehension of poems

MORI, T. (Hiroshima University), SHIMIZU, M. (Tezukayama University), FUJI, T, (Tsubo Elementary School)

Music is popular in our life and used for mood control in music therapy. However, only a few applied studies of music have been done in educational psychology. The purpose of this research was, therefore, to investigate the effects of background music on the comprehension of poems. Three experiments were conducted in this research. In experiment 1, 40 students were asked to rate their own mood on a multiple mood scale before and after listening to a recited positive or negative poem with a positive or negative background music. In experiment 2, 16 students were asked to rate the impression of a recited poem after listening to music, and in experiment 3, 60 students were given a comprehension test of the recited poems. The tested poems were positive and negative verses. Three conditions were employed; congruency condition (positive poem with positive music and negative poem with negative music), incongruity condition (positive poem with negative music and negative poem with positive music), and control condition (positive and negative poems without music). Experiment 1 showed that when students listened to the positive poem with the positive
background music and the negative poem with the negative music, their affectionate mood was rated higher, and their activity mood was rated lower when they listened to the negative poem with the positive background music and the positive poem with the negative background music. These results suggest that the feeling congruency between poem and background music would induce positive mood and that incongruity between them would reduce positive mood. Experiment 2 showed that the positive poem made more strong, bright and peaceful impressions than the negative poem regardless of music types. These results suggest that the music had little influence on the impression of poem. Experiment 3 showed that students in the congruency condition scored higher in the poem comprehension test than those in the incongruity and the control conditions. These results suggested that the incongruity produced some distraction, which led to a low score in poem comprehension. In conclusion, background music facilitates the comprehension of poetry. Congruency of mood, (e.g., positive or negative) between music and poem must be considered as an important condition for poem reading education.

Keywords: background music, poetry, comprehension

Effects of incidental emotional states on A-B-C model

HONG, L. (Tsinghua University)

The purpose of this study is to examine the effects of incidental emotional states on A-B-C model. A convenience sampling method was adopted to collect data, and the participants were 500 college students from Beijing (mean age=21.14, SD =7.22). The effects of incidental emotional states on A-B-C model were examined by Incidental Affect Scale, Integral Affect Scale, College Stress Scale, and Belief Inventory. Findings indicated that incidental emotional states are not only directly exerted ‘C’, but moderate the relationship between ‘A’ and ‘C’. The A-B-C model was significantly affected by incidental emotional states.

Keywords: incidental emotional states, A-B-C model

Effects of intergroup and intragroup status on ingroup bias

SUGIURA, H. (Hiroshima University), SAKATA, K. (Hiroshima University)

Ingroup bias is the systematic tendency to evaluate one’s own membership group (the ingroup) more favorably than a non-membership group (the out-group) (Hewstone, Rubin, & Wills, 2002). Some previous research suggests that ingroup bias is affected by intergroup factors such as intergroup status, intergroup conflict, and the frequency of intergroup contact (e.g. Bettencourt, Dorr, Charlton, & Hume, 2001). However, real social groups are hierarchically structured by not only intergroup status but also intragroup status, and a number of investigators have suggested that intragroup factors also influence group behavior (Branscombe, Spears, Ellemers & Doosje, 2002).

We predicted that intragroup status may also be affected by ingroup bias like intergroup status. In the present study, we aim to show an interaction effect between intergroup status and intragroup status that affects ingroup bias. University students (n=70) participated in a laboratory experiment. Participants were led to believe that, on the basis of their responses to a test measuring their style of thinking, we could classify them into one of two groups. We manipulated intergroup and intragroup status by the results of a first task which pretended to test perceptual ability and a second task in which subjects were asked to mark a sentence ostensibly written by an ingroup member and another by an outgroup member and to give their impressions of the author. Results show high status intragroup members of a low status group were inclined to feel friendlier toward the authors of the ingroup than the outgroup. In a high status group, low status intragroup members tended to feel friendlier toward the authors of the ingroup over high intra-status members; further, the more they felt they could improve their personal status, the more they would not favor the outgroup author. This interaction effect implies the possibility that intergroup and intragroup status may elicit ingroup favoritism and outgroup derogation. It is worth noting the relevance of present findings to hierarchical structures which are decided by a group and where personal abilities influence

**Effects of methadone therapy on changing of positive and negative mood affect in addicts**

MOSAVI AMIRI, S. J. (Medical Clinic of Dr. Mosavi), HOMAYOUNI, A. (Islamic Azad University)

The pharmacology of methadone is so straightforward, so unequivocal and so simple for medical professionals. The benefits of such short-term addiction treatment with methadone are substantial. It is a safe, effective, relatively inexpensive medical intervention in solving the problems of addiction. However, some physicians and doctors and even healthcare providers who themselves prescribe methadone to addicts often have inadequate information and are unfamiliar with psychiatric and psychological aspects of how it works. So for better understanding of these aspects the study aimed to investigate effects of Methadone on changing of positive and negative mood affect in addicted. Nineteen addicted people were randomly selected and before methadone therapy with a pretest, Watson’s Positive Affect and Negative Affect (PANAS) was administered to them. One month later after methadone therapy again Watson’s Positive Affect and Negative affect (PANAS) was administered to them. PANAS assesses: interest, distress, powerfulness, fear, enthusiasm, pride, agitation, nervousness and panic. Data were analyzed with dependent T test. Findings showed significant differences between PANAS components. Methadone therapy increased interest, powerfulness, enthusiasm, proud and decreased distress, panic and agitation in addicted. However there is not any significant difference between nervous components. The findings indicated that using methadone drug in addition to reducing physical symptoms of addiction, can significantly reduce mental problems in addicted people and can be regarded as a proficient drug for treating of addiction and as a results individuals can have a normal, productive, healthy, socially acceptable and self-fulfilling lifestyle.

**Effects of parent–child relations and social support on school adjustment of junior high school students**

KITAMURA, M. (Gakushuin University)

The purpose of this study was (1) to examine relations among parent-child relationships, social support and school adjustment; (2) to investigate how often junior high school students have feelings of unwillingness to go to school; and (3) to find out what kind of factors induce/reduce those feelings. Junior high school students (N=104) completed a questionnaire on parent-child relationships, social support and school adjustment, and answered 3 items on feelings of unwillingness to go to school. Parent-child relationships with love and respect for the child’s autonomy had direct effects on having high expectancy for social support and having feelings of school adjustment. Moreover, the expectancy for social support from friends or school teachers also had a positive effect on the feelings of school adjustment. Furthermore, parent-child relationships were categorized into 4 groups: “love/respect the autonomy”, “control/doting”, “neglect/disinterest” and “rejection/over-possessive”. The “love/respect the autonomy” group exhibited higher scores on social support and school adjustment than the “rejection/over-possessive” group. The results about feelings of unwillingness to go to school were as follows: (1) the frequency of feelings of unwillingness to go to school was positively correlated with feelings of school adjustment; (2) “relationships” with friends or school teachers, unspecified feelings of “anxiety/distress”, “physical condition” and “school performance” were detected as factors which induce the feeling of unwillingness to go to school; and (3) “ibasho (existential place)” and “self-confidence” factors, which reduce the feeling of unwillingness to go to school, emerged in all groups. This study revealed that parent-child relationships with love and respect for the
child’s autonomy and high expectancy for social support had an influence on the feelings of school adjustment. It also determined the factors which induce/reduce the feelings of unwillingness to go to school and investigating those factors more specifically is our future task.

Keywords: parent-child relationship, social support, school adjustment, junior high, unwillingness to go to school

Effects of physical attractiveness, gender role conformity, and overqualification in female recruitment in Hong Kong

MAK, H.L. (The Chinese University of Hong Kong)

The present study investigated the effect of physical attractiveness, gender role conformity, and overqualification in female recruitment in Hong Kong. A total of 101 participants, who were full-time employees in Hong Kong, were asked to rate 8 fictitious job applicants based on their resumes, including 7 items capturing their impression towards the applicants, and 1 item for their decision of whether to invite the applicant to a selection interview. The results indicated that female applicants who were of high physical attractiveness, high gender role conformity, and being overqualified were rated more favorably in the process of personnel selection, and raters’ attitude towards homosexuality also had an effect on the process of female recruitment. The findings reflected that there was an interaction effect between physical attractiveness and overqualification, with the effect of physical attractiveness more profound among applicants who were overqualified than applicants who were not. Besides, the results also revealed that raters’ attitude towards homosexuality interacted with their ratings for applicants of different levels of gender role conformity. Raters who had a more negative attitude towards homosexuality rated women who did not conform to their gender role expectations less favorably than raters who had a less negative attitude towards homosexuality. The study discusses the implications of the results and ways to reduce the effects of biased ratings in the process of personnel selection.

Keywords: physical attractiveness, gender roles, overqualification, female recruitment, Hong Kong

Effects of relational efficacy on secure base and safe haven functions in romantic relationships

ASANO, R. (Nagoya University), YOSHIDA, T. (Nagoya University)

According to attachment theory, a secure base and safe haven are sources that contribute to an individuals’ well-being by facilitating one’s problem resolution and personal growth (Collins & Feeney, 2000; Feeney, 2004). This study investigated how relational efficacy influences secure base and safe haven functions through the mediation of the supportive interactions in romantic relationships. Relational efficacy, was inspired by collective efficacy (Bandura, 2001), which is a partners’ shared belief, refers to a couple’s belief that they can mutually coordinate and integrate their resources to prevent and resolve any problems (Asano, 2009). We hypothesized that relational efficacy would facilitate the secure base and safe haven functions, an effect that would be mediated by support provision and reception. Participants were 102 dating heterosexual couples from some Japanese universities. One member of each couple was asked to complete a questionnaire with his or her romantic partner. The average age of the males was 22.32 (SD = 4.82) years old and that of the females was 19.97 (SD = 1.57) years old. They had been in relationships for an average of 15.99 (SD = 15.03) months. Data from individual relationship partners were nested within couples. The intraclass correlation coefficient of all the assessed variables was significant. To account for this nonindependence, we employed multilevel structural equation modeling which allowed us to describe the hierarchical structure of within couples and between couples (i.e., at the individual level and pair level, respectively; Kaplan, 2009). Results suggested that relational efficacy increased both the secure base and safe haven at the pair level. Moreover, this effect was mediated by support provision and reception at the pair level. Our study highlights a shared belief between partners and social support interactions to understand the mechanisms of good functioning in intimate relationships. We
found that romantic couples with strong relational efficacy could take care of each other and consequently have both the secure base and safe haven functions. Future research must use a longitudinal design such as a daily dairy to further examine these consequences (Bolger et al. 2003).

**Keywords:** romantic relationships, relational efficacy, attachment theory, multilevel structural equation modeling (SEM)

**Effects of sanction on leaders' behaviors in resource dilemmas**

LI, Y. M. (Chinese Academy of Sciences), LI, S. (Chinese Academy of Sciences), HONG, Y.Y. (Nanyang Technological University), ZHAI, C. X. (Chinese Academy of Sciences)

Previous research on Resource dilemmas has shown that leaders are likely to harvest more than followers. However, there are few studies examine effects of a sanction system on leaders' cooperative behaviors in Resource Dilemmas. Therefore, we conducted an experiment to investigate whether and how a sanction system could improve leaders' cooperative behaviors in Resource Dilemmas. Participants were lead to believe that they were going to play a resource game with another five participants. They were assigned to leaders or followers according to their alleged performance in a leadership test. They read an introduction about the game with or without a sanction system, and the specific sanction system was either salient or not salient. Participants were then asked how much they decided to take from the common resource. Results of the experiment showed that participants who were leaders took less from the common resource in salient sanction condition than in not salient sanction condition and no sanction condition. Followers took less in salient sanction condition than in no sanction condition. In salient sanction condition, leaders took less than did followers. Additionally, the results showed that leaders felt less entitled to take more than did followers. These results indicated that a sanction system could improve leaders' cooperative behaviors in the resource dilemma as well as followers, but leaders were more sensitive to sanction and they were more cooperative when sanction information was salient. However, these effects may be limited to the leaders who were selected by ability because in our experiment leaders were participants who got best scores in the leadership test. As suggested by our results, leaders selected by ability felt less entitled to take more, they may feel more social responsibility than leaders who are appointed by authority only.

**Keywords:** resource dilemmas, leadership, followers, sanction system, salient sanctions

**Effects of time perspective on perceived well-being and resiliency**

GUTHRIE, L. (Tennessee State University), KNOX, P. (Tennessee Board of Regents)

Resiliency, typically viewed in terms of traumatic experiences and subsequent reactions (Lopez & Snyder, 2003), is explored here from a positive psychological perspective. Qualities such as self esteem and good problem solving skills (Maluccio, Pine, & Tracy, 2002; McCubbin, Thompson, Thompson, & Fromer, 1998) have been associated as predictors of resilience. Perceived psychological well-being and time perspective also merit examination. Three hundred and fifty-nine university students (78% African American women) enrolled in introductory psychology and elementary statistics classes in the Mid-South, completed the Resiliency Attitude Scale (RAS; Biscoe & Harris, 1994), Zimbardo Time Perspective Inventory (ZTPI; Zimbardo & Boyd, 1999), and the Scales for Psychological Well-being (PWB; Ryff, 1995). Controlling for self-identified past trauma, no differences were found by gender for ZTPI, resiliency, or psychological well-being. No significant differences were found between ethnic groups for resiliency. Differences for subscales were found for PWB Autonomy [F(2, 279)=7.471, \( p = .001 \)], Purpose in Life [F(2, 279)=3.488, \( p = .032 \)], Self-Acceptance [F(2, 279)=6.409, \( p = .002 \)], and ZTPI Past-Positive [F(2, 278)=3.744, \( p = .025 \)]. White females scored lowest on significant PWB subscales. African American men (M=29.55, SD=2.274) and women (M=29.44, SD=2.827) scored highest on ZTPI Past-Positive subscale with White women scoring the lowest (M=27.7917, SD=2.992). No significant differences for RAS, PWB, or ZTPI subscales were found based on “experienced
trauma prior to or since age 16”. In conclusion, the findings suggest that African Americans are more nostalgic regarding the past and maintain closer family ties than Caucasian participants as evidenced by scores on the ZTPI Past Positive subscale. This is consistent with prior research indicating African Americans, more often than Caucasian Americans, tend to be involved with and to live in homes with extended family members (e.g., Bell-Tolliver, Burgess, & Brock, 2009). In contrast to other studies of PWB, African American participants also reported a greater sense of autonomy, self-acceptance, and purpose in life than Caucasians, with White women scoring lowest for each category. The skewed sample offers one explanation for our findings. Being part of the “in-group” may affect subjective well-being (Bettencourt & Dorr, 1997) and the African American collectivistic orientation (Kernahan, Bettencourt, & Dorr, 2000) offer alternative explanations.

Keywords: time perspective, well-being, resilience, African American, caucasian

Effects of trust and self-esteem on attitudes toward a new group following social rejection

ISOBE, C. (Hiroshima University), YANAGISAWA, K. (Hiroshima University), URA, M. (Hiroshima University)

We examined the effects of general trust and self-esteem on attitudes toward a new group and group members after experiencing a social rejection. One model of belonging (Gardner, et al., 2005) suggests that individuals respond to social rejection by engaging in direct and/or indirect reparative strategies. Though many studies have supported this model, the role of personality as a moderator of the model has not been clarified. Therefore, we conducted the following experiment to investigate the effects of general trust and self-esteem on this model. First, participants (N = 72) were asked to communicate with two-strangers through a computer network. In the last communication, social rejection was manipulated by rejecting the participant’s request to share in the conversation. Then, participants were asked to take part in the next communication task with members A and B. Before starting the next communication task, they were asked to read the conversation record of the other communication group including members A and B, in which member ‘A’ was rejected. Participants were also asked to complete an attitude scale about members A, B, and the new group. Multivariate analysis indicated that the more general trust individuals have, the more positive was their attitude, because people high in general trust were not affected by one rejection experience and they could believe that they will be accepted the next time. The lower a person’s self-esteem was, the lower was the difference in the attitude score about A and B (attitude score about B — attitude score about A). This possibly indicates that a person with low self-esteem predicted that he/she would be accepted by A but rejected by B. We showed that after experiencing a social rejection: (1) People high in general trust tend to accept new members regardless of what kind of person they are; and (2) people high in self-esteem are likely to become sensitive to who new members are.

Keywords: social rejection, self-esteem, group communication, trust, group acceptance

Effects of work values on marriage retirement desire, among female Japanese university students

OSANAI, Y. (Taisho University)

In Japanese culture, there are some females who think “When I get married, I want to quit working.” However, this plan can cause conflicts between employees and employers. To solve such problems, we should learn the work values of the people who have such a life plan first. In this study, I coined the term Marriage Retirement Desire (MRD) to refer to the above life plan. Accordingly, the aim of this study was to investigate the relationship between MRD and work values among female Japanese university students. Participants were 107 female Japanese university students at private university A in Saitama Prefecture, Japan. The mean age was 19.76 years (SD=1.33). I utilized an item rated using a 5 point scale that measures the subjective strength of MRD and to measure work values, I utilized the items developed by Morinaga (1994, 22 items 5 point-
scale). The results showed that the item “The atmosphere of the office is good” had a significant positive influence on MRD ($R^2 = .156$, $p < .01; \beta = .262, p < .01$). At the same time, the item “There is gender equality in your workplace” and the item “There are job training opportunities” had significant negative influences on MRD among them (there is gender equality in your workplace $\beta = -.243, p < .05$; and there are job training opportunities $\beta = -.200, p < .05$). From these results, we can interpret that females who seek a good workplace atmosphere but do not seek gender equality and job training opportunities at work, want to quit their job when they get married. We can see that the $R^2$ values are not high, which mean that we cannot fully explain MRD with work values only.

**Keywords:** Marriage Retirement Desire (MRD), work values, university students, females, Japan

### Efficacy of yoga on the locus of control of female students

LOHAN, U. (Kurukshetra University), GILL, A. (Kurukshetra University)

To find out the level of locus of control among students and to find if significant differences exist between the locus of control of yogic and non yogic students. The research study employed was a descriptive survey method. The sample consisted of 60 female students in the age group of 18-25 years and was purposively selected. The sample consisted of 30 yogic and 30 non yogic students. Rotter’s (1966) Scale of Locus of control was administered to the subjects. Data were analysed by computing $t$ values. A significant difference was found between internal and external locus of control of yogic female students. Similar results were found in the case of non yogic female students. In the case of students who were practitioners of yoga, internal locus of control was found to be higher compared to their non-yogic counterparts. The non yogic female students were found to be exercising external locus of control. Yoga reduces the effects of strain and stress and induces feelings of calm and peacefulness, combats depression and anxiety, counteracts helplessness and weakness, thus, increases self esteem and internalized locus of control. Hence, it can be empirically stated that yoga provides a path that takes one from an external to an internal locus of control.

**Keywords:** locus of control, yoga, students, stress, anxiety

### Emotional correlates of dispositional altruism

DINIZ, P. (Victoria University of Wellington), GOUEIA, V. (Federal University of Paraiba), MILFONT, T. (Victoria University of Wellington)

Research has shown that those who uphold higher levels of dispositional empathy, emotional contagion and feelings of embarrassment are more likely to help others (Batson, 1991). Other studies have proposed an ‘altruistic personality’ that depends more on personal attributes, like social emotions, than on situational variables (Rushton et al., 1981; Carlo et al., 1991). In line with these empirical findings, the aim of this study was to assess the relationships between specific social emotions (empathy, emotional contagion and embarrassment) and dispositional altruism. A survey questionnaire was administered to 408 undergraduate students from public and private Brazilian universities. Most of the participants were female (60.3%), single (83.9%), with a medium self-reported economic status (60.1%), and with ages ranging from 17 to 58 years ($M = 22; SD = 6.39$). Participants answered the Embarrassment Feeling Questionnaire, the Empathy Quotient, the Emotional Contagion Scale, the Self-Report Altruism Scale, the Scale of Social Desirability, and demographic questions. Partial correlation analyses, controlling for social desirability, showed that emotional contagion and empathy (cognitive and emotional factors) are strongly correlated to dispositional altruism ($r = .27, p = .001; r = .30, p = .001; r = .30, p = .001$, respectively). On the other hand, feelings of embarrassment were not correlated to dispositional altruism ($r = -.03, p > .05$). These findings indicate that those who are susceptible to the emotion of others and who can empathize with others’ positions and feelings also tend to have higher dispositional altruism. However, dispositional altruism was not associated with feelings of embarrassment in the present...
sample. Implications of the findings for social research are discussed.

**Keywords:** empathy, emotional contagion, embarrassment, dispositional altruism, social research

### Emotional intelligence, alexithymia, and interpersonal problems

**BESHARAT, M.A. (University of Tehran)**

The aim of this study was to examine the relations of emotional intelligence with alexithymia and interpersonal problems in a sample of students. A correlational analysis was performed to assess the kind of association that exists among emotional intelligence with alexithymia and interpersonal problems. Three hundred and fifty seven students (147 boys, 210 girls) from the University of Tehran were included in this study. All participants were asked to complete the Emotional Intelligence Scale (EIS), Farsi version of the Toronto Alexithymia Scale (FTAS-20), and Inventory of Interpersonal Problems (IIP). The results revealed that emotional intelligence was negatively associated with both alexithymia and different aspects of interpersonal problems including assertiveness, sociability, intimacy, and responsibility. Results of regression analysis revealed that emotional intelligence can predict alexithymia and interpersonal problems regarding assertiveness, sociability, intimacy, and responsibility. It can be concluded that emotional intelligence is associated with alexithymia and interpersonal problems. Results and implications are discussed.

**Keywords:** emotional intelligence, alexithymia, interpersonal factors

### Emotional intelligence: An exploration of the construct in adolescents

**THAYER, M. (Queensland Health), BRAMSTON, P. (University of Southern Queensland)**

Emotional intelligence is an emerging psychological construct with varying definitions, measures, and applications. According to the ability model of emotional intelligence, the construct can be defined as the set of abilities that explain how we perceive, understand, and express our emotions and those of others. Research with adults shows preliminary evidence for the discriminant validity of the construct from general intelligence, personality, and well-being and positive affect, but little research has been conducted which critically examines the construct amongst adolescents. This study explored the construct with adolescents by testing the discriminant validity of emotional intelligence scores with general intelligence, personality and well-being. The study involved adolescent students (N = 29) from a regional Australian high school aged 12 – 17 years (M = 14.5, SD = 1.2). The Shipley Institute of Living Scale (a measure of IQ), a new performance-based measure of emotional intelligence – the Mayer Salovey Caruso Emotional Intelligence Test: Youth Version (MSCEIT:YV), a 50-item pool of personality items related to the Big-Five Personality Factors as found on the International Personality Item Pool (IPip) on the IPip website, and, the Personal Wellbeing Index – School Children (PWI-SC) were administered in the above order. Surprisingly, no significant results were found for the multiple correlations between emotional intelligence and general intelligence, personality and well-being. However, the study had low power (Power = .38), and so the results should be interpreted with caution. To conclude, it would appear that emotional intelligence, as measured by the MSCEIT:YV, is independent and distinct from general intelligence, personality and well-being, which is in contrast to the adult research which shows a slight but definite overlap with these constructs and emotional intelligence.

**Keywords:** emotional intelligence, adolescence, general intelligence, personality, well-being

### Emotionally positive stimuli direct attention upwards in visual space: Findings from happy and sad schematic faces

**MCDOWALL, J. (Victoria University of Wellington), LOVEGROVE, A. (Victoria University of Wellington)**

This study aims to explore the relationship between visually presented emotional schematic faces and attention on a computer monitor. It
extends a recent finding that emotionally positive words are processed faster when they appear at the top of a computer monitor, and that negative words are processed faster when at the bottom of a monitor. Forty participants were shown schematic faces, one at a time, in the middle of a computer monitor. Faces were shown with either a smile (upturned mouth,) or a frown (downturned mouth,). After 250 msec each face was replaced by a target letter (p or q) presented either at the top or bottom of the monitor. Participants were asked to identify the letter as quickly as possible through the appropriate keyboard press. Participants completed 100 trials (50 smiling and 50 frowning), with half the target letters appearing at the top of the monitor and half at the bottom. Reaction Time (RT) was the dependent variable and Face Emotion (smiling, frowning) and Target Position (top, bottom) were the independent variables. RT to targets presented at the top of the computer screen was quicker than those presented at the bottom but only if they had been preceded by a smiling face. This finding is consistent with a small number of recent studies suggesting that emotionally toned stimuli appear to act to direct attention in visual space and that specifically emotional stimuli of a positive nature appear to direct attention upwards. The implications of this finding for the presentation and layout of visual material relevant to those in an educational setting as well as to those involved in the layout of advertising and other forms of visual material is discussed.

Keywords: schematic faces, emotionally positive words, emotionally toned stimuli, visual presentation

Employee share ownership and psychological ownership: Investigating the impact on employee attitudes and behaviours

This theoretical paper considers how Employee Share Ownership (ESO) schemes may have an impact on employee attitudes and behaviours at work; specifying ways forward for research focusing on the notion of Psychological Ownership (PO). The concept of PO has recently become popular in the ESO literature as a possible key factor in explaining the effects (or lack of them) of ESO on employee commitment, motivation and performance. However, PO appears to have been given more than one definition and has been positioned inconsistently in different models of ESO. A “possession” based definition of PO has been used in some ESO studies (e.g. “This is MY organisation; “OUR” company, see Van Dyne and Pierce, 2004). In reviewing the literature, the role of this often theorised concept, its potential relationship with United Kingdom (UK) ESO plans, and the potential avenues for future research are explored. In light of the relatively recent introduction of PO in ESO literature, it is proposed that: the design of the ESO plan; the feelings of influence and control that the employee experiences within the organisation; the information received about ESO and the company; the level of equity owned and the feelings of possession experienced as a participant in ESO, may all help explain how ESO has an impact on attitudes and behaviours. Although it is theorised (in many different ways) that ESO can enhance employees’ sense of PO and lead to changes in behaviour and attitudes, these connections have not yet been tested convincingly in research. Contributing to the PO and ESO literature by taking into consideration the specific nature of UK ESO plans will assist in further understanding the impact of ESO, and how feelings of PO can evolve and have an effect on attitudes and behaviours. As stated by Pendleton et al. (1998), the underdevelopment of conceptual models in the ESO literature to guide research and analysis has contributed to diverse and often contradictory findings within the employee ownership literature (e.g. performance and employee attitudes). Psychological ownership is an emerging area in the ESO literature, and may be one way to help explain the contrasting findings.

Keywords: employee share ownership (ESO), psychological ownership (PO), attitudes, behaviour

Employment status and its impact on psychological well-being and health
ANDERSON, S. (University of South Australia)

Due to a combination of social, political and economic changes over the past few decades, an array of different work arrangements has emerged. This has meant that employment status is no longer restricted to those in and out of work but is spread over a continuum of work arrangements including unemployment, underemployment, part-time, and full-time employment. As a result of these changes, there is a growing need for researchers to investigate the psychological impact of the continuum of work status in order to understand the impacts of current trends in the workforce. It is particularly important to investigate working conditions as they are experienced for young people, given their reduced power to negotiate adequate work roles, and the consequences for the individuals’ later life-span trajectories and well-being. Therefore, this study has been designed to examine the relationship between work status and various measures of psychological well-being and health, using a longitudinal study of South Australian school-leavers. A further aim of this study was to examine the factors that moderate these relationships. The implications of these findings for policy and future research concerning the links between work status and psychological well-being are discussed.

Keywords: work arrangements, employment status, well-being, health

Episodic memory inhibition and spreading activation: compared the implicit memory test to the explicit one

HOTTA, C. (Junior College), TAJIKA, H. (Kobe Shinwa Women’s University), NEUMANN, E. (University of Canterbury)

First, we aimed to replicate the findings of the previous suppression studies by showing that intentional suppression effects can be obtained by using recognition and implicit memory (word/non-word) tests. Second, we aimed to examine whether inhibiting target items intentionally would impair recognition and implicit memories for items semantically and phonologically related to target ones. After participants studied pairs of unrelated words, the cue words from each pair were presented either 0, 4, 12 times during the Think/No-Think phase. They were asked to either avoid thinking of the word (Suppress condition) or to recall it (Response condition). Finally, they were asked to recognize (Experiment 1), or judge word or non-word (Experiment 2), each of the targets and the nonstudied items, semantically and phonologically related to the items, as accurately and quickly as possible. The results showed that more target words were recognized correctly in the 0 condition than 12 repetitions under suppression condition. Also, they were slower in rejecting explicitly (Experiment 1), and implicitly (Experiment 2), nonstudied words that were semantically and phonologically related to target words under the 12 suppression condition, compared to the baseline condition. The present results are consistent with the findings of the previous studies of semantic inhibition effects. These results suggest that the episodic inhibition of suppression words might explicitly and implicitly spread to nonstudied words semantically and phonologically related to the target words.

Keywords: intentional suppression, recognition test, implicit memory test, semantics, phonology

Evaluation of a litter prevention campaign at the 2006 Commonwealth Games

CURNOW, R. (Community Change), CURNOW, K. (Community Change)

A litter prevention campaign was evaluated to assess its impact on littering behaviour during the 2006 Commonwealth Games in public domain areas, around games venues, and in key public corridors to and from venues. The campaign consisted of mass media advertising, clean up, and changes to ‘binfrasstructure’ (i.e., the addition of recycling bins, bin positioning and signage). Using behavioural observation, 2,009 observations of disposal behaviour were collected at 41 locations in both urban and regional areas, immediately prior to the start of the campaign in the lead up to the Games, during the Games, and one month after the Games. A systematic assessment was conducted on factors known to influence disposal
behaviour such as the amount of litter on the ground, presence of appropriate ‘binfrastructure’ for disposal of items and venue infrastructure designed to provide a welcoming & pleasant environment for patrons. Four hundred and eighteen venue patrons were also surveyed to determine their level of support for the campaign. Before the games, as a proportion of total disposals (binning & littering), littering behaviour accounted for 33% of all disposals, similar to a ‘baseline’ level of 30% established in a 2005 state-wide assessment. Littering rates dropped significantly to only 9% during the Games, but were not sustained post-Games. During the games littering was reduced for both urban and regional locations but statistically significant reductions were found only in urban settings. The marked reduction in littering rates achieved during the games appeared not to be sustainable without the presence of a high profile event, appropriate ‘binfrastructure’ and associated mass media campaign. A need for ongoing community engagement, development and support of local programs was considered likely to assist in sustaining longer term behaviour change. Continuation of temporary efforts to improve ‘binfrastructure’, maintenance and cleaning of venues beyond special events was seen as vital to embed the social expectation to be seen to be doing the right thing in public places.

Keywords: litter, mass media, binfrastructure, behaviour change, litter

Evaluation of emotion and regulation of emotional expression in sadness and anger: Perspectives of emotional suppression and controllability of emotion

OKUMURA, Y. (Kyushu University)

People sometimes evaluate their emotions; for instance, they feel ashamed for having been angry or, to give another example, they feel that their sadness is important and necessary. The present study investigated the relationship between the evaluation of emotion and the regulation of emotional expression. The regulation of emotional expression was seen from two viewpoints: emotional suppression and controllability of emotion. A four categories model of regulation of emotional expression is therefore proposed including: controlled suppression, uncontrolled suppression, controlled expression, and uncontrolled expression. A questionnaire was administered to university students (N = 186: 76 men, 108 women, gender not identified = 2; Mean Age = 19.28). The questionnaire consisted of three scales: 1) Evaluation of emotion scale (Okumura, 2008); 2) Emotional suppression tendency scale (Kashimura & Iwamitsu, 2007); and 3) Controllability of emotion scale from Feelings experience scale (Nakata, 2006). The results indicated that, in the case of anger, participants with high controllability rated ‘negative evaluation of emotion’ as low and ‘positive evaluation of emotion’ as high. In the case of sadness, the result showed an interaction between suppression and controllability only for men; when suppression was rated as high, participants with low controllability (uncontrolled suppression) exhibited higher ‘negative evaluations of emotions’ than those with high controllability (controlled suppression). The model of the process of expression by Kennedy-Moore & Watson (1999) suggested that emotions evaluated negatively (unacceptable) is hard to express. However, the results of this study suggest that the evaluation of emotion is not related directly to suppression, but that controllability plays an important part in the relationships. The findings suggest that the viewpoints of suppression and controllability can be used for the evaluation of emotion related to the regulation of emotional expression, and to identify the features of a relationship.

Examination of the availability and utilization of learning resource materials for effective teaching in secondary schools in Kaduna Metropolis

KATO, R. (Ahmadu Bello University Zaria), OHIDAH, E.O (Ahmadu Bello University Zaria), YUWANA, M. (Kaduna Polytechnic, Kaduna)

The study examined the resource materials available for teaching in secondary schools in Kaduna Metropolis.
Kaduna metropolis and the evaluation and utilization strategies used for effective learning in Schools. The hypotheses tested were: There is no significant difference in the mean responses of private school and public school on availability of resource materials. There is no significant difference in the mean responses of private and public school teachers regarding the criteria used for evaluation and utilization of resource materials. There is no significant difference in the response of principals and teachers regarding availability of resource materials in secondary schools. Questionnaires were responded to by 123 principals and 346 teachers in selected private and public secondary schools in four Local Government Areas in Kaduna Metropolis. Seventeen learning resource materials and fifteen criteria were identified as important for effective learning. The data collected were analyzed using mean statistics and t-test was used to test the hypotheses. Resource materials like maps, globes, bulletin board etc. are readily available in schools than others. The study further revealed that private schools followed more of the criteria identified for evaluation and utilization of resource materials than public schools. It was also found that resource materials are more available in private schools than public schools. The Government of Nigeria, in particular, Kaduna State Government and education managers really need to work to ensure that resource materials are available in schools and that they are properly utilized to enhance learning.

Examsing how “So” functions in a qualitative research interview

CHRISTENSEN, S. (University of Southern Queensland), BROOKS, C. (University of Southern Queensland)

The general aim of this study was to describe some of the discursive practices for managing qualitative research interviews. The specific aim was to examine the form, function, and location of so-prefaced utterances in a qualitative research interview. A conversation analysis (cf., Sacks, 1992) of 266 lines of transcribed talk from New Zealand Interview 2 (van den Berg, Wetherell, & Houtkoop-Steenstra, 2003) on race relations in New Zealand during the 1980s was completed. First, so-prefaced turn construction units were identified in the transcript. Second, talk immediately before, during, and after each so-prefaced turn construction unit was examined to see whether it: (a) was located during an on-going action or upon completion of an action; (b) marked inferential connections in the talk or launched a new course of action; and (c) was part of an upshot, gist, stand-alone “So”, turn-change, or topic-change device. Three actions were observed, the first of which involved the interviewer using “So” to launch a new question after an answer had been received, receipted, and allowed to stand as complete. Next the interviewer used “So” to reformulate this question to be about the ‘qualities’ of New Zealand role models and to relaunch it during the respondent’s on-going but meandering answer. Finally, the respondent used “So” to reject the etic formulation of the qualities of Sir Edmund Hillary and to replace it with an alternative. However, concurrent with this reformulation, the respondent accepted as unproblematic the emic formulation of the relaunched question. “So” is an undervalued speakers’ resource. It helps organise and design turns, manage question-answer sequences, and so shapes the overall structure of a qualitative research interview. Interviewers and respondents use “So” to set and maintain a joint understanding of actions produced in a qualitative research interview. This finding displays how interviews are socially constructed and culturally informed events.

Keywords: research interviews, discursive practices, conversation analysis, managing qualitative research interviews, so-prefaced utterances

Examining how questions function in a qualitative research interview

CHRISTENSEN, S. (University of Southern Queensland), FIECHTNER, A. (University of Southern Queensland)

The general aim of this study was to describe some of the discursive practices for managing qualitative research interviews. The specific aim was to examine the form, function, and location of questions in a qualitative research interview.
A conversation analysis (cf., Sacks, 1992) of 266 lines of transcribed talk from New Zealand Interview 2 (van den Berg, Wetherell, & Houtkoop-Steenstra, 2003) on race relations in New Zealand during the 1980s was completed. First, question-like utterances were identified in the transcript. Second, morphosyntactic clauses were categorised using Quirk, Greenbaum, Leech, & Svartik’s (1985) taxonomy. Third, the talk immediately before, during, and after each question turn was examined to see whether it was: (a) located on completion of a previous action; (b) marked by lexical elements and/or prosody; (c) repaired or abandoned; and (d) elicited a type-conforming response from the recipient. There was no direct association between the syntactic form and function so questions could be produced from declarative, interrogative, and imperative clauses in qualitative research interviews. There was no unambiguous intonation contour that marked questions, and participants used sequential, semantic, and interactional features (e.g., repairs) in the talk to recognise a question, and produce a relevant response in the qualitative research interview. Morphosyntactic form, intonation, and sequential position are inseparable in questions produced in a qualitative research interview. Recipients use these resources to recognise utterances as questions. Interviewer-interviewee interactions in the answer sequence shape intelligible answers so that are relevant to the question. Thus answers are responses co-produced by the interviewer and interviewee. These findings display how interviews are socially constructed and culturally informed events.

Keywords: research interviews, discursive practices, questions, managing qualitative research interviews, conversation analysis

Examining how response tokens function in a qualitative research interview

CHRISTENSEN, S. (University of Southern Queensland), GREENWAY-SHORTEN, C. (University of Southern Queensland)

The general aim of this study was to describe some of the discursive practices for managing qualitative research interviews. The specific aim was to examine the form, function, and location of response tokens in a qualitative research interview. A conversation analysis (cf., Sacks, 1992) of 266 lines of transcribed talk from New Zealand Interview 2 (van den Berg, Wetherell, & Houtkoop-Steenstra, 2003) on race relations in New Zealand during the 1980s was completed. First, response tokens were identified in the transcript using Gardner’s taxonomy (Gardner, 2001). Second, the frequency was calculated for different classes of response tokens. Third, how the interviewer and the interviewee used response tokens to maintain or change speakership, maintain or change topic, and formulate answers were examined. Response tokens are a pervasive feature in qualitative research interviews accounting for 11.47% of all words spoken. The interviewer produced 60.7% and the respondent produced 39.3% of these. Continuers (e.g., Mm mhm), news-markers (e.g., Right), and acknowledgement tokens signalling hesitancy (e.g., Uhm), delicateness (e.g. Mm) and certainty (e.g., Yes) were oriented to points of grammatical completion in the talk and located at transition relevant places. Their function was therefore consistent with Gardner’s taxonomy. Response tokens were oriented to speakership enabling a speaker to hold the floor but allowing a recipient to signal continuing listenership or project an upcoming speaker’s bid. Response tokens shape the trajectory of a qualitative research interview by being oriented to the immediately prior turn. Response tokens manage multi-turn answers by marking mutual understanding as an ongoing accomplishment and by dealing with insertion sequences that divert talk away from the research question. Thus, they shape the overall structure of a qualitative research interview by helping to organise and design turns and speakership. These findings display how interviews are socially constructed and culturally informed events.

Keywords: response tokens, research interviews, discursive practices, managing qualitative research interviews, conversation analysis
Examining how simultaneous talk functions in a qualitative research interview

CHRISTENSEN, S. (University of Southern Queensland), WHITEHEAD, M. (University of Southern Queensland)

The general aim of this study was to describe some of the discursive practices for managing qualitative research interviews. The specific aim was to examine the form, function, and location of simultaneous talk in a qualitative research interview. A conversation analysis (cf., Sacks, 1992) of 266 lines of transcribed talk from New Zealand Interview 2 (van den Berg, Wetherell, & Houtkoop-Steenstra, 2003) on race relations in New Zealand during the 1980s was completed. First, simultaneous talk was identified in the transcript. Second, acknowledgement tokens and continuers (cf., Gardner, 2001) that were produced in overlap with other talk were excluded. Third, the remaining instances were categorised using Ferguson’s (1977) interruptions taxonomy and Jefferson’s (1984) notes on the interactional properties at overlap onset. Simultaneous talk occurs at or near a transition relevant place where speaker change can legitimately occur. Judging a break in the continuity of the first speaker’s talk was difficult and subjective. This undermines using Ferguson’s criteria to categorise simple, overlap, butt-in, and silent interruptions. However examining the sequential, semantic, and interactional properties of the talk prior to, at, and following overlap onset, shows how a recipient closely attends to the talk in progress. Thus simultaneous talk is aligned to the syntactic complete-ness, adequacy, or dysfluency of questions, answers, and other actions produced in a qualitative research interview. Simultaneous talk is typically treated as interrupting, and is maligned in ‘how to interview’ textbooks. A focus on speaker change and breaks in verbal continuity overlook a recipient’s fine-grained attention to the current speaker’s talk. The orderly, lawful, and recurrent onset of simultaneous talk in qualitative research interviews point to its role in progressing this conversation. This finding displays how interviews are socially constructed and culturally informed events.

Keywords: simultaneous talk, research interviews, discursive practices, conversation analysis, managing qualitative research interviews

Examining physical activity participation and mood among overweight women with type 2 diabetes

MOORE, M. (Victoria University), MORRIS, T. (CARES, Victoria University)

The aim of this study was to examine the relationship between physical activity (PA) and depression among overweight women with Type 2 diabetes (T2DM). Participants were 61 overweight (BMI ≥ 25) women with diagnosed T2DM, aged between 33 and 70 years (median age = 62 years; IQR = 37). Following standard consent procedures, 600 questionnaire packs (containing information and demographic forms, mood and physical activity questionnaires, supporting letter from a Diabetes Specialist, and a reply paid envelope) were mailed out through the Baker/International Diabetes Institute. Interested overweight, diabetic women completed and returned the questionnaires, indicating consent. Response rate was low (10.2%; 61/600). Results indicated that a substantially greater proportion of participants (83.6%) reported depression (n = 51) than no depression (n = 10). There was no significant relationship between total PA and depression (r = -.15, p = .26); work-based PA and depression (r = -.06, p = .62); or leisure based PA and depression (r = -.14, p = .27); There was a significant negative correlation between the amount of active house-work and depression level (r = -.25, p = .048). There was no significant difference in depression between women in active (action, maintenance) or inactive (pre-contemplation, contemplation, preparation) stages of change (χ2(1)=.17, p = .68). To conclude, there was no relationship between depression and total, work-based, or leisure-based PA. Those with higher levels of depressive symptoms engaged in less house work (sub-type of leisure PA) than those with fewer depressive symptoms. Depression was not related to stage of change. Although the substantial number of participants reporting depression in this sample complements extensive evidence of a strong reciprocal relationship between depression and diabetes, it is greater than reported estimates of
1 in 3 diabetics having depression. The high proportion of depression in this sample may have masked any differences in PA level between those with and without depression, and may, in part, be the result of a small sample, and/or the combination of three factors (diabetes, overweight, and women) that each has a high propensity for depression. In future research, larger sample sizes should be employed and samples should include adequate numbers of participants at all depression levels.

Keywords: Type 2 diabetes, physical activity, depression, stages of change

Examining some discursive resources used in qualitative research interviews

CHRISTENSEN, S. (University of Southern Queensland)

The general aim of this research was to describe some of the discursive practices for managing qualitative research interviews. The specific aim was to examine some regularities in the sequential organisation of a qualitative research interview that the participants use to make this talk orderly, meaningful, and accountable. A conversation analysis (cf., Sacks, 1992) of 266 lines of transcribed talk from New Zealand Interview 2 (van den Berg, Wetherell, & Houtkoop-Steenstra, 2003) on racism and race relations in New Zealand during the 1980’s was completed. The cumulative findings of four empirical studies of question formats, response tokens, simultaneous talk, and so-prefaced utterances conducted by Australian psychology honours students will be presented. Participants organise their co-presence in New Zealand Interview 2 using the normative rules for turn-taking, repair, and adjacency pairs. Thus self and other are the basic parties to the conversation; the turn construction unit is the basic metric; and projected completion points are the local basis for speaker-change. Research interviewing is motile, locally involved, and so requires close cooperation between the participants. The interviewer and the respondent use social rules derived from ordinary, everyday conversations to manage questioning, answering, and other practical actions accomplished in the qualitative research interview. Thus, fine-grained analysis of actual talk shows that interviews are socially organised and culturally informed. This finding conflicts with conventional, neo-positive assumptions of a neutral interviewer and a passive respondent who is a vessel of answers that is common in social psychology.

Examining the wounded healer phenomenon: Australian students’ clinical psychology career aspirations and their mental health

WATSFORD, C. (University of Canberra)

It has been suggested that mental health professionals, including psychologists, may be at risk themselves of poor mental health. The present study had two aims, which were to (a) examine whether students’ with high clinical psychology career aspiration reported having a mental illness more often than students’ with low clinical psychology career aspiration, and (b) to investigate the extent to which the “wounded healer paradigm” was predictive of clinical psychology career aspiration. The study utilised a cross-sectional correlational design, and used a group administered survey. Participants comprised of 330 undergraduate and postgraduate University of Canberra psychology students. Results found students with high clinical aspirations reported having a mental illness significantly more often than students with low clinical aspirations, and found the wounded healer paradigm significantly predicted clinical psychology career aspiration amongst psychology students. The study contributes additional research to the literature on the wounded healer phenomenon; however, further research is required.

Keywords: wounded healer phenomenon, clinical psychology, mental illness, psychology students, Australia

Exercise and social physique anxiety among adolescents

CHEN, L-J. (National Taiwan Sport University), KU, P-W. (National Changhua University of Education)
This study was designed to investigate the link between exercise and social physique anxiety (SPA) among adolescents and examine the independent effects of exercise on SPA beyond demographic, psychological and behavioral factors. Participants were recruited from 18 high schools in Taiwan. Eight classes in each school were then selected randomly. A total sample of 4230 adolescents aged 12 to 19 resulted (2223 boys and 2007 girls). Participants completed measures of demographic variables (age, gender, social economic status (SES), weight status), exercise, weight loss, smoking, drinking behaviors, and psychological variables (the nine-item SPA scale, Rosenberg self-esteem scale, contour drawing rating scale, and experience of being teased). The SES was examined by parents’ occupation and education based on Hollingshead’s ‘Two Factor Index of Social Position’. The ‘Self-Ideal Discrepancy’ from the contour drawing rating is considered to be an indication of body dissatisfaction. A three-step forced entry multiple regression analysis was performed to determine how much of the variance in SPA was explained by exercise and other variables. The predictors entered into the model were exercise, followed by demographic variables. Then, psychological and behavioral variables were added in the final step. Examination of the regression coefficient showed that exercise was a significant negative predictor of SPA, accounting for 2.4% of the variance in SPA ($B(SE) = -2.34(.27)$, $p < .001$). Demographic variables were entered for the next step, adding 14.7% of the variance. Exercise was still related to SPA significantly ($B(SE) = -1.14(.26)$, $p < .001$). When behavioral and psychological variables were added to the model, the variance increased 20.1%. The final model revealed that all variables, except SES, were significant predictors, explaining 37.2% of the variance in SPA. The exercise-SPA relationship remained statistically significant even after multivariate adjustment ($B(SE) = - .69(.22)$, $p = .002$). In conclusion, this study further explores the exercise-SPA relationship with a broad range of variables. Exercise accounts for a significant amount of unique variance in the presence of demographic, psychological and behavioral variables.

Expectations, responsibility and attributions: An investigation into customers’ perceptions of service failures and recoveries

CALLAGHAN, R. (Griffith University)

Service encounters are likely to be familiar experiences for most people in the developed world. Consequently, customers can hold quite firm expectations regarding the level of service they are likely to receive. However, despite organisations’ best intentions to satisfy customers, occasionally service failures occur. A recovery attempt by the organisation often follows. A commonly reported recovery is for organisations to accept some level of responsibility for the failure. This study explored customers’ perceptions of service failures and recoveries by investigating the effects of customers’ pre-service expectations and service providers’ self-attributed responsibility for a failure on customers’ subsequent evaluations. Attribution theory provided the major theoretical framework for the study and this was compared with competing theories. In the main study, participants consisted of a convenience sample of 255 students and non-students (188 females, 65 males and 2 of undisclosed gender) with a mean age of 29.1 years. Written scenarios were employed and participants were asked to adopt the role of a restaurant patron who experienced a service failure and recovery attempt. As anticipated, customers with high pre-service expectations evaluated the failure and recovery more favourably than did customers with low or no expectations. However, contrary to predictions customers with no expectations made more favourable evaluations than did those with low expectations. A 2 (expectations: high versus low) x 3 (self-attributed responsibility: high (concession) versus medium (excuse) versus low (denial)) between-subjects factorial ANOVA did not reveal the hypothesised main effect of responsibility, or a two-way interaction effect. Attributions of locus, stability and controllability mediated the relationship between expectations and customer evaluations. When trust was incorporated into this model as an additional mediator trust mediated the relationship between expectations and customers’ attributions and these attributions, in turn,
mediated the relationship between trust and customer evaluations. In summary, these findings demonstrated the value of attribution theory as an explanatory framework for understanding customers’ perceptions of service failures and recoveries. The findings also have important implications for organisational marketers, particularly in the management of customer expectations and the selection of effective recovery strategies.

Keywords: service failure, service recovery, customer’s perceptions, customer evaluations, attribution theory

Explorers of care workers at a day service for people with dementia

HORI, K. (Yokohama National University), ANDO, T. (Yokohama National University)

Providing care for the demented elderly is a serious problem in Japan where the population is aging rapidly. In 2000, the long-term care insurance system was introduced and care was socialized. Therefore, in Japan, the profession of care workers has a short history, and as a result, various problems have emerged. Experiences of care workers at a day care service for elderly people with dementia were investigated from the perspective of care workers’ interactions with users, in order to improve the quality of care and the mental health of the staff. Interviews inquiring about work experiences were conducted with care workers. The results were analyzed by referring to data obtained by participant observations. Exploratory analysis was then conducted and a structural model was constructed. Results indicated that care workers were sympathetic to the needs of users with dementia, and at the same time, felt embarrassed and sad. They considered care giving mainly as providing emotional support. Moreover, they hoped to provide care in order to facilitate the user’s life with their family, after they returned home. Care workers felt sympathetic to families looking after the users at home, but sometimes doubted the words and behaviors of the family. They also felt pressure from the families. Care workers gained self efficacy through an understanding about the care of people with dementia. However, they also experienced “difficulties of understanding” users with dementia. This generated a dilemma between the ideal and reality of care, between the ideas of the care workers and those of colleagues and the users’ families. It also caused a feeling of helplessness in the staff. It is suggested that an interactive perspective to the “difficulty of understanding” could deepen the tolerance of users and reduce this dilemma.

Keywords: dementia, care staff, quality of care, elderly people, mental health

Exploring predictors of sustainable living using a cross-discipline, psycho-social approach

WILSON, L. (Queensland University of Technology), TURRELL, G. (Queensland University of Technology), STRODL, E. (Queensland University of Technology)

Climate change has been described as the ultimate threat to human health and wellbeing. A number of health disciplines, including psychology, share a common mission to promote health and well-being and it is becoming clear that the most practical pathway to achieving this mission is through interdisciplinary collaboration. In order to achieve meaningful reductions in individual ecological footprints, individual citizens will need to dramatically alter their energy consumption and day to day habits. Any interventions will need to be evidence based and there will need to be a rapid transfer or communication of information from the point of research, into practice. This research explores the predictors of the environmentally friendly behaviour using a cross-disciplinary psycho-social approach. Through consultation with industry experts and local council liaison officers the aim of this research is to provide data that is both theoretically driven and as practice relevant as possible. Following a qualitative pilot study, and in consultation with an expert panel and industry experts, we constructed a self-administered mail survey which was distributed to a random sample of 3000 residents of Brisbane and Moreton Bay. The survey was primarily informed by the Theory of Planned Behaviour and asked about attitudes, norms, perceived control and intention, as well as a number of other constructs such as
environmental concern and altruism. A second, follow-up survey was conducted four weeks after a receipt of a completed survey, which specifically asked about recent walking for transport and switching off lights behaviours. Thus far there has been a response rate of 40% (N = 1175) for the initial survey and approximately 65% for the follow-up survey. Attitudes (r =.44) prescriptive norms (r =.19) environmental altruism (r =.25) and environmental concern (r =.17) are all significant predictors of switching off lights and similar results are emerging for other sustainable practices. As a result of the contact with industry and academic experts, we have been able to forge alliances with a number of state and local government representatives who are keen to apply the findings of this research in real world applications. This research will inform a comprehensive and practical model for predicting sustainable living behaviours and, importantly, at least three local councils have expressed an interest in making use of the results of this study as part of their ongoing community engagement programs.

Keywords: sustainable living, environment, ecological footprints, psycho-social approach, Theory of Planned Behaviour

Exploring the impact of purpose in life and seeking of neotic goals on depression and anxiety in a student population

AROUTZIDIS, A.S.

The research presented aimed to explore the impact of Purpose In Life (PIL) and Seeking Of Neotic Goals (SONG) on symptoms of depression and anxiety in university students. Three hundred and ninety eight female and male students ranging from young adulthood to middle aged, completed measures of PIL, SONG, Zung Self-Rating Depression Scale, and Zung Self-Rating Anxiety Scale. Interpretation of the results revealed that a high level of PIL predicted lower depressive and anxious symptomatology, and a low score of SONG predicted lower scores of depression- and anxiety-related symptoms, verifying the hypotheses outlined at the outset. Additionally, a gender difference was evident amongst total scores of depression which found that females reported significantly higher scores than males, as predicted. However, PIL, SONG and anxiety scores did not significantly differ in males and females as predicted. Furthermore, the study investigated the relationship between depression and anxiety by analysing the underlying factors of the SAS and SDS scales and further validated the tripartite model of positive affect, negative affect and somatic anxiety in a university sample. The findings of this study showed a general trend that when an individual has meaning in life and thus a purpose, they are protected from the detrimental effects of depression and anxiety, highlighting PIL as a buffer. SONG in comparison was found to increase signs of depression and anxiety, indicating that an intense motivation to find a meaning in life may hinder and thus deter an individual from ever reaching that goal and as a result increase their levels of anxiety and depression.

Keywords: Purpose in Life (PIL), neotic goals, depression, anxiety

Facial electromyographic study of accumulative negative affect related to social exclusion

KAWAMOTO, T. (Hiroshima University), NITTONO, H. (Hiroshima University),URA, M. (Hiroshima University)

Social exclusion is ubiquitous in human society and has a strong effect on cognition, emotions, and behavior. Previous studies have demonstrated that a short period of face-to-face ostracism provokes negative affects and lowers the level of the four fundamental belonging needs: belonging, control, self-esteem, and meaningful existence (Williams, 1997, 2001). It has been reported that this effect can also be caused by ostracism on the Internet, even when the ostracizing others are computer-generated players (Williams, 2000; Zadro et al., 2004). Functional magnetic resonance imaging studies have indicated that social exclusion provokes social pain that is reflected in activation of the anterior cingulate cortex (Eisenberger, et al., 2003). However, the time course of negative affects resulting from social exclusion remains unclear, because previous studies have focused mainly on post-exclusion feelings, or experiences
of overall social exclusion. Therefore, the increased negative affects in response to social exclusion were investigated by measuring facial electromyographic activity over corrugator supercilii and zygomaticus major as an index of negative and positive affects, respectively. University freshmen \((n = 23)\) individually participated in an experiment in which they played a simple computer-simulated ball-tossing game (Cyberball) with two computer-generated players. First, they were asked to observe the other two players tossing the ball to each other (observation condition). Then, they joined in the game (inclusion condition). The computer was programmed such that the other players suddenly excluded the participants (exclusion condition). Similar to previous studies, participants reported negative affects and a reduction in the four fundamental belonging needs. The activity of corrugator supercilii increased continuously in all conditions during the game period and increased dramatically in the middle of the exclusion condition. This increase was associated with lower self-esteem ratings and higher negative affects across individuals. In contrast, the activity of zygomaticus major continuously decreased in all conditions during the game period and no significant differences in activity were observed among the three conditions. These findings indicate that the negative affects produced by social exclusion may accumulate during exclusion. It is suggested that corrugator supercilii activity can be used as a valuable real-time index of negative affects in social exclusion research.

**Keywords:** social exclusion, facial electromyographic activity, belonging, meaningful existence, self-esteem

Facial emotion perception in people with schizophrenia and their non-psychotic siblings: A functional magnetic resonance imaging study

**HUIJIE, L.** (Chinese Academy of Sciences), **RAYMOND, C.** (Chinese Academy of Sciences)

Schizophrenia is a heritable disorder. However, molecular genetics and related research areas have not unmasked the nature and mechanisms of this disorder. Therefore, many researchers begin to explore the pathology mechanism from other approaches. High-risk study is one of the promising approaches. In this study, we mainly focused on facial emotion perception in schizophrenia and their non-psychotic siblings, and attempted to explore whether facial emotion perception is the potential biological marker of schizophrenia. Functional magnetic resonance imaging (fMRI) was used to assess the emotional related cortical physiology in 12 patients with schizophrenia, 12 non-psychotic siblings of patients and 12 healthy controls, during the facial emotion perception task. The results indicated that patients with schizophrenia demonstrated abnormal activation in emotional processing, mainly on the social brain and the limbic systems in comparison with healthy controls. Compared with healthy controls, patients demonstrated lower activation in frontal gyrus, lentiform nucleus, thalamus, and caudate nucleus when processing the positive emotions, while showed lower activation in frontal gyrus, parahippocampal gyrus, and fusiform gyrus when processing the negative emotions. Siblings of patients demonstrated abnormal activation in left frontal gyrus, bilateral superior and middle temporal gyrus, bilateral parahippocampal gyrus, and bilateral insula in contrast with healthy controls. These fMRI data showed direct evidence of abnormality in dorsal and ventral systems in siblings of the patients. The current findings suggest facial emotion perception may be a potential biological marker of schizophrenia in neuromechanisms.

**Keywords:** schizophrenia, facial emotion processing, schizophrenia, neuromechanisms, functional magnetic resonance imaging

Factors affecting environmental practice career choice: A test of social cognitive career theory and values-beliefs-norms theory

**BULMER, W.** (Queensland University of Technology)

Social Cognitive Career Theory (SCCT) and Value-Belief-Norms Theory (VBN) were selected as theoretical frameworks for investigating environmental practice career choice. The initial study aim was to test the theoretical hypotheses
of SCCT and VBN theory to assess their suitability for investigating career choice goals in environmental practice students. The secondary aim was to investigate the relative predictive power of SCCT and VBN models and to determine whether the combination of VBN and SCCT as an additive model produced a significant improvement in the prediction of environmental practice career goals. Participants consisted of 640 students, enrolled in a range of environmental practice courses from across seven Queensland universities. Participants completed a 20 minute online questionnaire that contained measures for SCCT, VBN theory and background variables. Analyses consisted of a range of multiple regression and mediation analyses. The theoretical hypotheses for both SCCT and VBN theory were supported. When background variables were investigated as a predictive model they explained 10% of variance in career choice goals. When SCCT, VBN and background variables were combined, the full model significantly predicted 37% of variance in career goals. Outcome expectations, interests, social supports, and ascription of responsibility were all significant predictor variables in this full model. SCCT separately predicted 28% of variance in career choice goals. This was significantly larger than the 12% predicted by VBN theory. When the VBN model was combined with the SCCT model, VBN variables significantly improved prediction of career choice goals by 4%. When the VBN model was combined with the SCCT model, a large proportion of the original VBN predictive value was redundant in the combined model. However, the addition of VBN variables is still useful as VBN theory explained a significant and unique 4% of variance in career choice goals, not explained by SCCT. Based on this application of SCCT and VBN theory in explaining environmental career choice, implications for training, development and human resource management in this rapidly growing and diversifying sector are discussed.

Factors influencing the university students’ motivation for learning: A cross-sectional and longitudinal analysis

MATSUSHIMA, R. (Kyoto Notre Dame University), OZAKI, H. (Kyoto Notre Dame University)

In Japan, the levels of both academic motivation and academic ability are decreasing in proportion to the increasing number of students attending higher education. Some studies show that the level of academic motivation of university students varies depending on the stage in the university cycle that the students are in. Therefore, it is essential that we consider the factors influencing the motivation according to the stage that each student is in when we examine the academic motivation of the students. The main purpose of this study was to examine the factors which influence university students’ motivation for learning using a cross-sectional and a longitudinal study. In Study, a questionnaire was administered in 2006 to 183 first year to third year students in a cross-sectional study. In Study II, other questionnaires were administered 3 times to 54 students from January 2005 in a three year longitudinal study. The major findings from Study I and II were as follows: (1) Motivation for learning was lowest in the second semester of the first year in both the cross-sectional and the longitudinal studies; (2) in addition to interest in classes, successful adaptation to university life and good future prospects led to an increase in the students’ academic motivation in all years. On the other hand, daily life outside of studying, loss of interest in their studies and getting used to university life led to a decrease in the students’ academic motivation in all years. Thus, other factors beside contents of classes and the ways of teaching were also shown to influence students’ academic motivation; and (3) the combination of factors was different for each year level. In addition, certain factors were seen to have a stronger influence on motivation for some year levels than for others. From these results, the level of motivation for learning and factors influencing academic motivation varied for each year level. We concluded that the students’ stage in the university life cycle should be considered when examining motivation for learning.
False consensus effect on socially inconsiderate behavior and prosocial behavior

YOSHITAKE, K. (Nagoya University)

The false consensus effect (FCE) refers to the tendency to overestimate consensus for one’s own judgments and behaviors. Past studies (e.g., Ross et al., 1977) examined the FCE in ambiguous situations. However, the judgments and behaviors in the ambiguous situations cannot generally make social evaluation (negative-positive). This study examined whether participants produced the FCE for social inconsiderate behavior and prosocial behavior which received social evaluation (negative-positive). This study also investigated the relationship between the FCE for social behavior and assumed-competence (Hayamizu et al., 2003). Undergraduate students (N = 217) completed a questionnaire consisting of social behavior items and assumed-competence scale, and estimated the percentage of the consensus for social behavior items. There was a total of 27 items in social behavior. Fifteen items described situations that were negative (socially inconsiderate behavior) and the other twelve items were related to positive behavior (prosocial behavior). Assumed-competence scale (ver. 2) consisted of 11 items. Each item was a statement where the participant inquired about the range which undervalues others. The results indicated that the participants overestimated the consensus for social behavior; thus, the false consensus phenomenon showed robustness. Moreover, the results revealed that the participants who frequently exhibited socially inconsiderate behavior produced a stronger FCE (t (100) = 6.04, p < .001). Finally, the results showed that high assumed-competence underestimated the agreement of prosocial behavior (t (203) = 3.41, p < .001). These findings suggest that and the participants justified themselves by predicting that the judgments and behaviors of others were similar to those of their own. Moreover, assumed-competence related to positive social behavior (prosocial behavior). This study examined FCE for social behavior which received evaluation socially. The results showed the stoutness of FCE which confirmed preceding research.

Female drug addicts’ personality: Using Five-Factor and Eisenckian Model

DEO, S. (Pune University)

There is paucity of studies on the personality of female addicts employing Five-Factor Model as well as Eysenckian Model, especially in an Indian context. Therefore, an attempt is made in the present study to explore the personality-addiction relationship on female drug addicts. A sample of 50 female addicts and a comparison sample of 50 female non-addicts matched on age, education, income/occupation were administered Revised Eysenck Personality Questionnaire (EPQ-R) and Revised NEO-Personality Inventory (NEO-PI-R). A difference score was calculated for each pair for each personality variable. MANOVA was used to find out the differences on personality variables. Facetwise analysis and exploratory analysis were carried out. The results supported the hypotheses. Female addicts scored high on Eysenckian Psychoticism (P), Neuroticism (N) and low on Lie scale; and high on Neuroticism (N), and low on Agreeableness (A) and Conscientiousness (C) of the NEO-PI-R. The results demonstrated the cross-cultural applicability of Eysenckian as well as Five-Factor Model in the area of personality of addicts and also provide an evidence for validity of EPQ-R and NEO-PI-R in an Indian setup. Female addicts scored high on Eysenckian Psychoticism (P), Neuroticism (N) and low on Lie scale; and high on Neuroticism (N), and low on Agreeableness (A) and Conscientiousness (C) of the NEO-PI-R than the comparison group.
Financial planning and well-being

IRVING, K. (Queensland University of Technology), GALLERY, N. (Queensland University of Technology), GALLERY, G. (Queensland University of Technology)

The aim of this paper is to provide a review of the theoretical and research literature on the ways in which financial planning can enhance well-being. In reviewing the literature, the paper develops a conceptual framework for thinking about the extended value of financial planning, beyond financial outcomes, by examining the process of planning in the financial domain and its relationship to life satisfaction, living an intentional life, attainment of life goals, and the development of a sense of mastery. An essential element of psychological well-being is engagement in life tasks and roles. Planning can be considered a life management strategy that enables individuals to control and structure their lives. Having meaningful goals and the plans to achieve those goals enable individuals to experience higher levels of life engagement and well-being (MacLeod et al., 2008). Recent research on well-being suggests that domain-specific behaviors contribute to domain-specific satisfactions, which in turn contribute to an individual’s overall satisfaction with life (Easterlin, 2003; 2006). Thus changes in domain satisfaction, such as financial satisfaction, are likely to affect changes in life satisfaction. This paper analyses the financial planning process through the key mechanisms of resource appraisal, functional goal setting, and progress towards and attainment of goals, and identifies the ways in which these activities may have an impact on subjective and psychological well-being. This conceptual analysis and synthesis is aimed at expanding current thinking about the value of financial planning to considerations of subjective and psychological well-being. This improved understanding will be of benefit to researchers, financial educators, financial counsellors and financial planners.

Keywords: goal setting, financial planning, psychological well-being, satisfaction

Flow state and performance in competition

KOENH, S. (Central Queensland University), MORRIS, T. (Victoria University)

Flow state is characterized by enjoyment and a positive experience in the activity. Therefore, flow state plays an important role in sport competition as the experience helps athletes to get the most out of themselves, which could make a difference between winning and losing. The aim of this study was to examine flow dimensions as predictors of performance outcome, and differences in flow experience between successful and unsuccessful athletes. The sample consisted of 188 tennis players between 12 and 18 years of age ($M = 14.18; SD = 1.50$). Participants completed the Flow State Scale-2 (FSS-2; Jackson & Eklund, 2002) following the tennis competition and match results were obtained from the tournament organizers. Overall, 111 participants won and 77 lost their competition match. Regression and t-test analyses were applied. The nine predictor variables of flow state explained 13% of the variance in games won (only significant predictor was autotelic experience, beta = .27). Measuring performance by games lost, 16% of the variance was accounted for. Sense of control (beta = -.47) was a significant negative predictor of performance, whereas concentration on the task at hand (beta = .32) was a significant positive predictor. A Bonferoni adjusted p value was calculated to account for repeated measurement and to uphold the 5% significance level. Based on the adjusted .006 cut-off level, significant differences in flow state between winning and losing participants were found for challenge-skills balance, clear goals, sense of control, and autotelic experience. The d values for these variables were moderate, ranging from .47 to .66. An interesting, but unexpected, finding was that athletes’ concentration levels rise when performance is not optimal, indicating concentration might be more important for athletes losing rather than winning their competition. It is possible that athletes perceived higher concentration when they consciously needed to adjust to match challenges, whereas during a winning performance their focus might be on autopilot. Differences in flow between winning and losing performance were confirmed, showing several flow characteristics were significantly higher for participants who won their competition match.
Forgivingness and gratitude among older people

NETO, F. (Faculdade de Psicologia e de Ciências da Educação), PINTO, C. (Porto University), MULLET, E. (Institute of Advanced Studies)

This study examined whether the three constructs of forgivingness found in adults – propensity to lasting resentment, sensitivity to circumstances, and willingness to forgive – were also present among older people. It sought also to determine whether gratitude accounted for a significant portion of the variance beyond that of socio-demographic variables in the study of forgivingness. One hundred and nine older people (65 females and 44 males; mean age 70.3 years) participated in the study. The same three-factor structure that was found among adults was also found among older people. Hypotheses of a negative correlation between lasting resentment and gratitude, and a positive correlation between overall propensity to forgive and gratitude, was supported. Additionally, results using multiple regression models indicated that gratitude explained a significant amount of variance of lasting resentment, and overall propensity to forgive.

Keywords: forgiveness, gratitude, older people, resentment

Fruits and vegetables consumption and associated factors among in-school adolescents in seven African countries

PELTZER, K. (HSRC), PENGPID, S. (University of Limpopo)

This report examines fruits and vegetables consumption and associated factors among 13 to 15 year-old in-school adolescents in seven African countries. This is a cross-sectional survey with a total sample of 17656 school children aged 13 to 15 years from nationally representative samples from seven African countries. Univariate and multivariate analyses were conducted to assess the relationship between fruits and vegetables and sociodemographics, behaviour variables, mental distress and protective factors. Thirty six percent and 23% of 13 to 15 year old boys and 32.6% and 22.3% of the 13 to 15 year old girls had inadequate fruits and vegetables consumption (less than one or more per day). In multivariate analysis, inadequate fruits consumption was associated with going without food (OR = 1.50, \( p = .001 \)), smoking (OR = 1.52, \( p = .004 \)), lack of care giver connectedness (OR = 1.41, \( p = .000 \)), being male (OR = 1.23, \( p = .012 \)) and higher education (OR = 1.56, \( p = .001 \)) and inadequate vegetables consumption was associated with lack of care giver supervision (OR = 1.57, \( p = .000 \)), no close friends (OR = 1.55, \( p = .000 \)) and have less education (OR = 0.73, \( p = .002 \)). The results stress the need for intervention programs aimed at increased consumption of fruits and vegetables among adolescents. Interventions to increase fruit/vegetable intake in adolescents need to target socio-environmental factors such as greater availability of fruits/vegetables.

Keywords: fruit and vegetable consumption, adolescent food consumption, mental distress, care giver connectedness, education

Functional and dysfunctional anger response tendencies in secure and insecurely attached adults

CALTABIANO, M. (James Cook University), MAVER, J. (James Cook University)

Attachment theory argues that there exists different attachment-related strategies in affect regulation developed from a lifetime of interactions with significant others. The present study used an emotional Stroop task to explore functional and dysfunctional anger response tendencies of securely and insecurely attached adults. It was hypothesized that secure individuals would show greater interference when naming the colour of functional anger items, whereas those with insecure attachment (anxious and avoidant individuals) would show greater interference when naming the colour of dysfunctional anger items. The sample (\( N = 60 \)) consisted of 13 males and 47 female first and second year Psychology students. With regard to attachment style as measured by the Attachment Style Questionnaire, 31 participants identified as secure, 20 were avoidant and 4
participants identified as anxious. Included in the emotional Stroop task were 12 functional (negotiate, clarify, discuss), 12 dysfunctional (retaliate, revenge, attack), and 12 control target items. Each stimulus item was randomly presented three times in one of three colours (red, green or yellow), which made 36 trials per condition and a total of 108 experimental trials. The design was a 3x3 mixed factorial design defined by target type (functional, dysfunctional, control) and attachment style (secure, anxious, avoidant). The dependent variable was the reaction time to target stimulus. Data analysis indicated no significant main effect for target word, no significant main effect for attachment style, and no significant interaction for attachment and target. Reaction times for functional and dysfunctional anger items did not reflect the relational schema underlying participants’ attachment style. The experimental results provide some evidence that the cognitive representation of anger is not dependant on attachment style.

Keywords: anger, attachment style, stroop task

Gaming experience and knowledge as predictors of gaming skills

The current study examines self-reported gaming experience and knowledge as predictors of actual gaming skills. Over 50 military service members completed the Game Experience Measure (GEM) and the Game-Based Performance Assessment Battery (GamePAB) as part of a research study conducted in the Defense Equal Opportunity Management Institute (DEOMI) Simulation Training Lab. The GEM is an instrument that measures an individual’s prior experience with and knowledge of gaming. It assesses general gaming experience, frequency of play in various genres of games, level of experience with respondent’s favorite games, and level of experience with various gaming controllers. Overall gaming knowledge and specific knowledge of first-person shooter games are also measured. The GamePAB measures the participant’s demonstrated level of gaming skills. It uses standard first-person shooter navigation controls in two separate tasks components. The first task requires the participant to follow a leader through an environment while imitating the leader’s movements and responding to questions about the surrounding virtual environment. The second task has the participant aim their weapon at a moving target, requiring the participant to keep the weapon on track and fire when prompted. Linear regression results indicate that the following/navigation task was significantly predicted by: overall gaming experience ($β = 0.49; p < .001$); general gaming experience (e.g. frequency of play $β = 0.56; p < .001$); first-person shooter knowledge ($β = 0.34; p < .05$); and general gaming knowledge ($β = 0.30; p < .05$). First-person shooter knowledge significantly predicted shot reaction time ($β = -0.38; p < .05$), while general gaming knowledge significantly predicted aiming skill ($β = 0.365; p < .05$). The task of imitating the leader’s movements was not significantly predicted by any experience or knowledge measure. Overall, these results demonstrate that self-reported gaming experience and knowledge may significantly predict some aspects of gaming skill, but may not provide a sufficiently accurate representation of an individual’s level of gaming performance. These findings suggest the need to provide additional training on basic gaming skills prior to participating in Game Based Simulations.

Gender differences in face recognition ability

LU, Y. (Tinjin Normal University), MA, H. (Tianjin Normal University)

The present study aims to explore gender differences in face recognition ability and the results will affect a lot for applied purposes in justice. Based on the ‘leaning–test’ memory recognition paradigm, the experiment is a three-factor $2 \times 2 \times 2$ mixed design, manipulating participants’ gender (between-group factor, male/female), photo gender (within-group
factor, male/female) and external features of face photos (hair, neck, etc., between–group factor, with/without). The dependent variable is $d'$ which is calculated by using hit and false alarm rates which was retrieved in the test stage. Participants are 120 college students. When dealing with photos with external features, all participants show better performance in identifying a female face than male face; and female participants show better performance in identifying female faces than male participants. When the face photos have no external features, all participants are still better at identifying female faces than male faces; but there are no differences between male and female participants when they remember face photos. To conclude; (1) females remember more faces with external features than males; there is no difference in face recognition between females and males while recognizing faces with no external features; (2) females are better at identifying female faces which shows the females’ own gender bias; males are also better at identifying female faces which shows the existence of a reverse gender bias; and (3) participants are better at identifying photos with external features than those without external features; with external features, the females’ own gender bias is more significant.

**Keywords:** gender differences, face recognition, external features

### Gender differences in gaming experience and ability

**MOESER, E.** (Defense Equal Opportunity Management Institute), **TRAME, E.** (Defense Equal Opportunity Management Institute), **TAYLOR, G.** (University of Central Florida/Army Research Institute), **CREPEAU, L.** (Defense Equal Opportunity Management Institute)

The military is increasingly using Game Based Simulation (GBS) for training a variety of tasks. Traditionally, the focus has been on using GBS for training operational tasks (e.g. pilot and infantry training); however, GBS is now being incorporated into non-kinetic interpersonal skills training. The Defense Equal Opportunity Management Institute (DEOMI) is collaborating with other Department of Defense agencies to develop GBS in the areas of Military Equal Opportunity, diversity management, and cross-cultural competency training. An important first step in this training development is to determine the average gaming experience and skill level that DEOMI students possess, as this will determine the amount of time needed to train basic gaming skills before conducting full simulated training interactions. The current study examines gender differences in student responses to the Game Experience Measure (GEM) and the Game-Based Performance Assessment Battery (GamePAB). The GEM is an instrument developed to measure participants’ prior experience and knowledge of video games, while the GamePAB is an actual performance measure that incorporates common tasks from standard first-person shooter games. Over 50 participants from all branches of the military and the United States Coast Guard completed the survey. Results from the GEM sessions indicate significant gender differences in the self-reporting of gaming experience and knowledge, with males scoring higher on experience in general ($t = 2.42; p < .05$), experience in specific gaming genres ($t = 2.84; p < .01$), various controllers ($t = 2.29; p < .05$), and overall experience ($t = 2.80; p < .01$). Male participants also showed higher scores on first-person shooter game knowledge ($t = 5.40; p < .01$), as well as general gaming knowledge ($t = 3.23; p < .01$). GamePAB results demonstrate higher scores for males on basic navigation (following a leader; $t = 3.43; p < .01$) and aiming skills (keeping weapon on target track; $t = 2.68; p < .01$). These results indicate that female service members may require additional training on basic gaming skills before engaging in interactive GBS training.

**Keywords:** gaming, training, military, game based simulation

### Gender differences in traditional and internet commerce: What is different between both stages?

**PALACÍ, F.** (Spanish National University for Distance Education), **RUIZ, M.** (Spanish National University for Distance Education), **SALCEDO, A.** (Instituto de Consumo de Castilla la Mancha), **GARCÉS, J., LÓPERZ-ARAUJO, B.** (Spanish National University for Distance Education)
Consumption is a fundamental activity among people living in 21st century society. We can find in the biography many variables related to consumption experiences. This situation becomes more complicated considering internet commerce as a new consumption stage that has experienced significant growth in the last few years. Considering this situation, the present research had two main objectives. The first objective was to determine which variables relate to the consumption experience between men and women, and at this point we aimed to identify gender differences related to consumer behavior. The second objective presented a comparison between the traditional consumption stage and the new consumption internet stage. Our aim here was to determine how gender differences apply to both stages. Our question was: what is different and what is similar? For these purposes we worked with two independent samples. The first one comprised 233 traditional shoppers and the second 205 internet shoppers. We compared men and women’s punctuations for different consumption variables in the two samples. In the traditional stage men and women present differences in many variables, such as perceived service quality, perceived fairness, word of mouth and positive affect. In the internet stage we find gender differences in only 3 of the variables: involvement, re-buy intention and diversion. Our results reveal significant gender differences between men and women in traditional markets but in the internet market such differences between men and women tend to disappear.

Keywords: gender differences, traditional commerce, internet commerce, consumption, shoppers

Gender on ice

SARRIS, A. (University of Adelaide)

This study examined the experiences and attitudes of women towards living and working in remote and isolated Antarctic stations. The participants were 14 women who participated in Australian Antarctic expeditions between 1985 and 2000 and who were interviewed for the study. On the basis of a thematic analysis of interview data, two recurring and pervasive themes were identified: (i) reference to the Antarctic environment as one of the best aspects of their experience and the reason they would recommend the Antarctic to their friends as a good place to work, and (ii) reference to a plethora of social issues, including the impact of interpersonal conflict on individual and group functioning. These themes are discussed within the context of the organisational culture of Australian Antarctic stations. The implications for expeditioner selection and recruitment procedures are outlined and recommendations are presented.

Keywords: Antarctica, isolated Antarctic stations, social issues, interpersonal conflict, remote

Group membership and drinking motivations: A study on the role of perceived group norms on self-reported alcohol consumption among Italian adolescents using the Theory of Planned Behavior

CARRUS, G. (University of Roma Tre), FIORENTINO, D. (Sapienza University of Rome), CECCANTI, M. (Sapienza University of Rome), DEIANA, L. (S. Francesco Hospital, Local Sanitary Unit of Nuoro), RITA, A. (Addictions and Abuse Pathologies Unit, Local Sanitary Unit of Rieti), BONIFAZI, A. (Addictions and Abuse Pathologies Unit, Local Sanitary Unit of Rieti), GIULIANI, A. (Addictions and Abuse Pathologies Unit, Local Sanitary Unit of Rieti)

The study tested the role of group and individual variables in the prediction of alcohol consumption among Italian adolescents. Starting from the Theory of Planned Behavior (TPB), we tested the relative power of "descriptive" vs. "prescriptive" social norms in predicting self-reported alcohol consumption. A paper-and-pencil questionnaire was administered to 876 Italian high school students, measuring the usual TPB components (attitudes, subjective norms, perceived behavioral control, behavioral intentions and behavior) plus two additional components: perceived norms of the group of friends and past behavior. Four different drinking motivations previously identified in the literature were also measured (i.e., coping with negative emotions, enhancing positive experiences, conformism, and social motives). As
expected, perceived norms of the group of friends, which represent a "descriptive" normative source, emerged as a better predictor of intentions to drink, compared to the classical TPB construct of subjective norms, which represent a "prescriptive" normative source. Hierarchical multiple regressions showed also that past behavior is a strong and independent predictor of alcohol consumption. Concerning drinking motivations, results showed a link between social motives and self-reported drinking behavior: as predicted, social motives also mediate the relation between group norms and drinking behavior. Results confirm the hypothesized interplay between individual and group factors involved in alcohol consumption among adolescents. Taken together, these findings confirm also the adaptability of the TPB to this particular behavioral domain. However, variables at the individual and group level (such as past behavior and perceived group norms) might play a role that goes beyond that of attitudes, subjective norms and perceived control in shaping drinking behavioral intentions.

Keywords: group membership, social norm, motivation, behaviour, alcohol

Gynecological cancer survivors: Assessment of psychological distress and unmet supportive care needs

WHITFORD, H. (Cancer Council Australia)

This preliminary investigation provides findings of a study of gynecological oncology survivors and their psychosocial well-being and unmet supportive care needs, and further contributes to the evaluation of the CaSUN, a new Australian measure of such needs in cancer survivors. In a cross-sectional self-report study, 45 gynecological cancer survivors (0.9 to 11.6 years since diagnosis), completed clinical measures of anxiety (SAI), depression (BDI-II), post-traumatic stress disorder (IES-R), quality of life (FACT-G), optimism (LOT-R), coping style (B-COPE), and the CaSUN ‘strength of unmet needs’ outcome. Results indicated a total of 28.9% of participants reported clinical levels of anxiety, 20.0% reported mild-to-severe symptoms of depression, and 15.6% were in the clinical range for a probable diagnosis of post-traumatic stress disorder (PTSD). Strong positive associations were found between strength of unmet needs and anxiety ($r = .66$), depression ($r = .68$), and post traumatic stress disorder (PTSD; $r = .61$). Poorer quality of life (QOL; $r = -.76$), younger age ($r = -.21$), and greater time since diagnosis ($r = .20$) were also associated with stronger unmet needs. Multiple linear regressions showed clinical measures of anxiety, depression, PTSD, total QOL, optimism, and self-blaming coping style only explained 56.4% of the variance on the CaSUN ‘strength of unmet needs’ outcome thus suggesting the new measure explained still further variance. Alternatively, for the strongest unmet need (fear of recurrence), a model including anxiety, optimism, PTSD, and emotional well-being accounted for 40.7% with emotional well-being the strongest predictor ($\beta = -.55$, $p = .01$). In conclusion, this study highlighted the type and frequency of psychological and unmet supportive care needs of gynecological cancer survivors suggesting good feasibility for completing another larger study utilizing the CaSUN as an appropriate addition to our understanding of survivorship. As in previous studies, these findings suggest fear of recurrence of cancer is perhaps the most prominent unmet need of such survivors. Furthermore, we make suggestions to consider clinical interventions concentrating on impacting emotional well-being across the cancer journey to address such fears as this appears a particularly important factor.

Keywords: gynecological oncology, emotional well-being, unmet needs

Hardiness and self-esteem as predictors of job stressors

NEMAT TAVOUSI, M. (Islamic Azad University)

The purpose of this study was to examine the relationship between the outcomes of work stress and two of the potentially protective resources (i.e., hardiness and self-esteem). One hundred Azad University staff, with a mean age of 38.18 ($SD=5.32$), completed a questionnaire packet which included the Personal Views Survey (PVS; Hardiness Institute, 1985), Self-esteem Scale (Rosenberg, 1965), and the Measures of Job Stressors (Spector & Jex, 1998).
The latter consisted of the Interpersonal Conflict at Work Scale (ICAWS), Organizational Constraints Scale (OCS), and Quantitative Workload Inventory (QWI). As expected, and consistent with previous studies, hardiness and self-esteem had a negative correlation to the job stressors, and could significantly predict interpersonal conflict, organizational constraints, and quantitative workload. Some possible mechanisms underlying the stressors-outcome relationships and their implications have been discussed based on the control model of the job stress process.

**Keywords:** hardiness, self-esteem, work stress, organizational constraints, quantitative workload

### Hasty behavior and driving behaviors

PARK, S.J. (Chungbuk National University), LEE, S.C. (Chungbuk National University), YUN, B.Y. (Chungbuk National University)

This paper aimed to introduce a new concept regarding hasty behavior and the relationship between hasty behavior and driving, and to suggest the direction of hasty behavior research. For this paper, we collected studies related to hasty behavior and created a summary of hasty behavior’s characteristics. Lee and Park (2007) became interested in the predisposition of taking action in a hasty manner, and found that hasty behavior is the result of time pressure, discomfort, isolation, boredom, and expectation of rewards. Since that study, Lee and Park (2008) have suggested that hasty behavior means not only to simply do one’s work hurriedly, but also includes the ideas of positivity or a sense of purpose. They confirmed the five factors of haste and found two hasty behavior domains – missing confirmation and the need for achievement. They reported that mistakes or accidents, if combined with a lack of confirmation and a need for achievement, were all connected to task performance positivity and to accomplishing the goal. Kim, Park, and Lee (2009) investigated the relationship between hasty behavior and driving behavior – violation, error, and lapse. Violations were not affected by missing confirmation domain. However it was found that drivers with high scores in the missing confirmation domain made more errors and committed more lapses. Therefore they have insisted that to link hasty behavior and mistakes or accidents is possible. The hasty behavior, or “Pali-Pali” culture, of Koreans is quite famous. However, it is not easy to fund research on hasty behavior. The concept of hasty behavior, as achieving an optimal goal while increasing the speed of action, being recently considered, is not familiar. Researchers with regard to hasty behavior have shown new meaning related to hasty behavior. The items in the hasty behavior questionnaire may not actually be applicable to humans as a whole, regardless of age and culture. The relationship between the two hasty behavior domains is not clear; continuing research should resolve these issues. Furthermore, an awareness of personal hasty behaviors should enable individuals to predict mistakes, accidents, and achievement in task performance.

**Keywords:** driving behaviour, hasty behavior

### Hepatitis B and HIV-related stigma in China

CHEN, Y. (Chinese Academy of Sciences), SHI, K. (Chinese Academy of Sciences)

Many patients suffer from HIV-related stigma in China, and even more suffer from hepatitis B stigma. These two kinds of illnesses are both chronic, hard to cure, and can be transmitted through sexual contact, which seems a significant indicator of stigma. A majority of researchers concentrate on HIV-related stigma in both China and overseas, while hepatitis B stigma remains grossly understudied. This study tried to compare hepatitis B and HIV-related stigma towards the patients and their families. The dimensions of illness characteristics influencing these two kinds of stigma in Chinese culture were also discussed. Possible stigma reduction strategies were suggested. Questionnaire surveys were carried out in universities, and 179 individuals responded. The questionnaire contained three parts: the stigma towards the patients, which included negative stereotype, bias, and the tendency of discriminate, the stigma towards the patients’ family members, and the participants’ perception of the illnesses’ characteristics. Structured interviews were used to help get a
better understanding of the results. The data analysis shows that the HIV-related stigma towards both patients and their family members is significantly stronger than the hepatitis B stigma, especially concerning the negative stereotype to the patients. Also, the stigma towards the patients’ family members is related to the stigma towards the patients. Behavioral causality/control of the illness is an important indicator to hepatitis B stigma, while getting in contact with an affected person may be an effective way to reduce it. In the meantime, sexual transmission is the most important indicator that causes HIV-related stigma. In conclusion, the participants demonstrate both hepatitis B stigma and HIV-related stigma, and they are significantly different in both force and manifestation. Besides, the illness stigma extends to the patients’ families. Furthermore, statistically significant correlations are found between the facts concerning illness and the illness stigma.

Keywords: stigma, China, HIV, Hepatitis B, sexual transmission

Homeless people in Japan: Psychological characteristics and the need for psychological support

TAKAHIRO, Y. (Chubu University)

Awareness of poverty and homelessness is increasing in Japan as it is worldwide. Although there has been much discussion about ways of supporting homeless people, little attention has been given to these supports from the point of view of psychology. The purpose of the present qualitative study was to describe support services to homeless people in Japan provided by a nonprofit organization (NPO) to which the researcher belongs, report the psychological characteristics of homeless people, and discuss the need to offer psychological support to them. The NPO was established in 1985 in Nagoya, one of the major cities in Japan, with the goal of helping poor people including the homeless by providing medical services and support for an independent life. The researcher has belonged to the NPO since 2008 and has engaged in consulting services as a volunteer once a week. In the study, the psychological characteristics and symptoms of homeless people were surveyed based on interview and consultation records between April 2008 and March 2009. 511 clients used the services for a year, where 161 clients (31.5%) needed support for their financial needs and independent life, and 57 (11.2%) needed medical care. Interviews with the homeless revealed that they were ashamed of being homeless and distrusted others, which became an impediment to their acceptance of support from others and/or welfare benefits such as public assistance. It was also shown that homeless people have a high level of feelings of isolation, depression, and suicidal ideation. The study revealed the importance of psychological supports such as mental health care and psychological empowerment in relation to the quality of support services promoting the independent living of homeless people.

Keywords: homelessness, Japan, poverty, psychological characteristics, psychological support

How can we increase dedication in physicians from emergency departments? A proposal from Spanish hospitals

LISBONA, A. (Spanish National University for Distance Education), BERNABE, M. (Miguel Hernández University (UMH)), MARTÍN-ARAGÓN, M. (Miguel Hernández University), TEROL, M.C. (Miguel Hernández University)

The Dual Process Model (Schaufeli & Bakker, 2003) suggests that job demands are associated negatively with engagement. Physicians from emergency departments are exposed to high overload, less rest time, and have more difficulty finding substitutes for vacancies than other hospital departments. The aim of this paper was to analyze the dedication response of physicians’ exposure to different job demands and produce an intervention proposal. The design study was cross-sectional and the sample was composed of 87 physicians from all public hospitals of Alicante Province (Spain). The mean age of participants was 40 years (SD=7.8) and 54.8% were male. Job-demands were evaluated by items ad hoc. Dedication was measured by UWES Scale (Schaufeli & Bakker, 2003) and descriptive analysis, ANOVA and t-test were carried out. Results showed medium dedication levels of
physicians ($M=2.94; SD=.73$) in accordance with UWES Manual. Physicians with more time to recover from work shifts showed higher levels of dedication than physicians with less time to recover ($F= 5.236; p=.007$). The same applied to those physicians who work in departments that quickly cover vacancies ($t=-2.64; p=.018$). Results show the relationship between job demands and dedication among physicians from emergency departments. Theoretical and practical implications of these results are discussed.

**Keywords:** emergency departments, physicians, hospitals, dedication response, job demands

### How ethical leadership contributes to private enterprise success: Evidence from China

MO, S. (University of Reading), MO, S. (Zhejiang University), WANG, Z. (Zhejiang University)

While the importance of ethical leaders within organizations has been emphasized more recently, little attention has been given to the effectiveness of ethical leadership on external stakeholders. Previous research highlighted that inter-organizational relationships cannot be well understood without recognition of leaders’ behavior, particularly for Chinese private enterprises whose leaders play a critical role in building reputation and guanxi networks. So this study responds to how ethical leaders work effectively in private enterprise success by providing a multi-level ethical leadership model. On the basis of social learning theory, this study applies multiple-case study method to examine three private enterprises in China (Vanke, Alibaba and Tencent). The influence of leaders’ ethical behavior on various stakeholders is studied. Results show that ethical leadership influences stakeholders within organizations (for example, employees), as well as external stakeholders (for example, suppliers and customers) in the Chinese culture context. A multi-level ethical leadership model is created, which proposes that ethical leadership is not only useful within organizations, but also effective in dealing with external stakeholders. Ethical leadership can facilitate private enterprise success by providing ethical values and reputation to both internal and external stakeholders.

**Keywords:** Organisational leadership, Ethical leadership, inter-organizational relationships, Guanxi networks, Organizational reputation

### How feedback influences individual performance in interactive Simon tasks: The role of self-structure

TAO, T. (Peking University), WANG, L. (Peking University)

The standard Simon effect shows that responses are faster if they spatially correspond to the stimulus signaling them. The interactive Simon effect is a similar effect that occurs when the Simon tasks are shared by pairs of individuals. The present study aimed to examine the influence of feedback and self-structure on Simon effect. Participants (Peking University graduates) were randomly assigned to two conditions after fulfilling the measurement of self-structure. Participants in each condition completed the interactive Simon task with a confederate, during which participants would receive either positive or negative feedback on their performance. Results showed that participants’ responses were faster with stimulus-response correspondence than with non-correspondence, and individuals with low independent self responded faster than individuals with high independent self. More important, a significant interaction indicated that the effect of feedback on reaction time differed among individuals with different self-structure. Overall, this study contributes to the understanding of the interactive Simon effect. The findings suggest that the influence of feedback is moderated by self-structure. Namely, individuals with low independent self respond faster in negative feedback conditions than in positive conditions; while in high independent self individuals, the effect reversed.

**Keywords:** Simon tasks, feedback, performance, responses, self-structure

### How personality affects the perceived leadership behaviors in the Chinese culture: A multi-source perspective

YAO, D. (The Chinese University of Hong Kong), YAO, J. (The Chinese University of Hong Kong), TO,
C. (Mobley Group Pacific (HK)), CHEUNG, F. (The Chinese University of Hong Kong)

The present study aimed to integrate moral leadership into Quinn’s (1988) Competing Values Framework, as moral leadership was of great salience in the Chinese literature. This study would also examine the relationship between personality and leadership behaviors in the Chinese work setting. A total of 152 senior executives in Hong Kong or Mainland China completed the Chinese Leader Roles Scale and the Cross-Cultural Personality Assessment Inventory (CPAI-2) in an online survey. Their 111 superiors and 334 subordinates provided ratings on executives’ leadership performance as well. Exploratory Factor Analysis showed that moral behavior was a distinct component in Chinese leadership, aligned with the universal leadership dimensions in Quinn’s model. Multi-source data revealed that two CPAI-2 scales – Leadership and Responsibility – were generally predictive of multiple leader roles in executive self ratings and subordinate ratings. Veraciousness, a culturally-relevant personality dimension, was effective in predicting perceived leadership from superiors. This study has developed a systematic measure of moral component in Chinese leadership, which appropriately reflects the core value of Confucian philosophy. Moreover, the predictive power of culturally-relevant personality scales on leader roles suggests that personality traits that are congruent with the culture help to elicit leadership behaviors that are prescribed for the environment. These findings have addressed the importance of using indigenous constructs in managerial assessment.

How reading habits influence attentional blink

YUAN, J.C. (Fu-Jen University), HUANG, Y.I. (Fu-Jen University)

Attentional Blink (AB) is when we present two targets and insert some distracters in-between, i.e. if the SOA are between 200ms to 500ms, then the detection of 2nd target (T2) will be backward influenced by 1st target (T1). When SOA of T1 and T2 is very short, then the correct rate of T2 recall will become a U curve. Our studies based on the AB paradigm we want to know the Chinese user they have both vertical and horizontal reading and writing habit. We test if AB effect will also happen in upper/lower arranged visual field for the subject their mother language is Chinese. In the first experiment we presented the stimulus horizontally or vertically. Targets are the digits and distracters are English characters. In the second experiment we used the traditionally radical of Chinese characters as the distracters, and target is digits same as experiment 1. All the dependent variables are the correct rate of T1 and T2 response. Both experiments examine how the temporal and spatial relationship between two visual targets (T1, T2) will result to the AB deficit and Lag 1 sparing. We also examine the attention allocations of visual field of Chinese user. We found that when the stimuli were present horizontally, then no matter T1 and T2 at the same visual field or not, there are AB and Lag 1 sparing. When stimuli were present vertically, if T1and T2 at the different visual field, then there is AB effect, but no Lag 1 sparing. This results illustrates the attentional zone could be oval-shaped, which means the horizontal attentional field is bigger than the vertical. In English users, there is a left visual field superior AB effect, and this is same as in Chinese version of our experiment. Beside we also got upper visual field superior AB effect. Since English reader has left to right reading habit and has the left visual field superior AB effect. And our experiments results found the Chinese reader have left and upper visual field superior AB effect. So we got the idea that attention engagement are influenced by the distracters of AB effect, are caused by the reading habits.

Keywords: attentional blink, China, reading habits

How work engagement relates with occupational stress and the purpose of working?

OBATA, S. (Tedukayama University), MORISITA, T. (University of Tedukayama Graduate School)

Work Engagement is a positive, fulfilling, work-related state of mind that is characterized by
vigor, dedication, and absorption (Schaufeli, 2001). The aim of this study is to examine how Work Engagement relates with occupational stress, the purpose of working for workers. We made a set of questionnaires including NIOSH Generic Job Stress Questionnaire (the Japanese Version), Utrecht Work Engagement Scale (Japanese version, 9 items), 12 items about the purpose of working. We requested employees of 5 organizations (finance company, printing office, food company, car dealer, nursing care institution) for cooperation. We obtained replies from 710 employees (404 males 306 females, average age 38.8). Correlation between Work Engagement and the other variable were calculated. Results of analysis showed as follows: 1) Work Engagement has a negative correlation with all stress reactions (feeling anxiety, fatigue, depression, etc.); 2) job stressors and personal relations at workplace were negatively correlated with Work Engagement, and a rewarding job and cognitive vocation to the job were positively correlated with Work Engagement; 3) buffer factors and social support from the supervisor was positively correlated with Work Engagement; 4) purpose of working and working as a contribution to the company and society and working for improvement of ability were positively correlated with Work Engagement; and 5) the older group and married group showed higher Work Engagement scores, compared with the younger group and unmarried group, respectively. It was clarified that Work Engagement is related to personal relationships, social support, and other particular factors. It is considered that improving these factors may be the key for workers to work willingly. The results also indicate that working for positive purposes is important for workers. These results may contribute making strategies to improve worker’s well-being.

Keywords: Work engagement, Well-being, stressors, support, job stress

Identification of WISC-III for the gifted children in Khartoum State

AHMED, K. (Sudan Academy of Sciences)

This study aimed at investigating the identification of WISC-III for the gifted children in Khartoum State, as well as to assess their full scale intelligence quotient (FSIQ) and to find out the difference between performance and verbal intelligence quotients (PIQ & VIQ). The researcher applied the WISC-III to all children (293) in gifted schools in Khartoum State. The number of males was 145 (49.5%) and females were 148 (50.5%), whose ages ranged from 8-13 years. All the pupils were from 4th grade and 5th grade. A descriptive approach was used. The study revealed that the highest intelligence score registered was 142. The overall average on the FSIQ score was 110.85 and on the PIQ score, 117.80, while the FSIQ scores 117.63. The study’s results revealed that no significant statistical differences were found between male and female participants but there was scatter found on arithmetic test (-3), digit span test (-3) and coding test (+3) on overall average for subtests. To conclude, gifted children obtained a higher degree of performance intelligence than verbal intelligence (POI + PSI > VCI +FDI). Finally, the study presents some recommendations and suggestions.

Keywords: gifted children, intelligence, WISC-III

Identity and Wellbeing: A Social Psychological Exploration from India

KAPUR, P. (University of Delhi), MISRA, G. (University of Delhi)

The notion of religious identity, in a multicultural society of India, has implications for well being. The experience of well being is investigated in relation to people’s mode of identity formation. The study involves people from four religious traditions, i.e., Hinduism, Islam, Christianity and Sikhism (N= 200). They were asked to distinguish their identities at the physical, social and spiritual levels, in addition, their past, present and estimated well being was determined. Multiple methods of assessment are employed to study identity and well-being. Results suggest that nature of identity shapes the experience of well-being. A strong identity provides a protective function. Implications for health policy and individual interventions are indicated.

Keywords: religious identity, India, well-being
Immigrant expectations and perceptions of New Zealand work-related practices

MALINEN, S. (University of Canterbury), JOHNSTON, L. (University of Canterbury)

The aim of this research was to investigate recent immigrants’ reasons for moving to New Zealand and how they perceived work-based behaviours and attitudes in New Zealand. Understanding whether immigrants have a realistic view of New Zealand, and the work-related values and practices, is important for improving the retention of immigrants. Recent immigrants’ reasons for moving to New Zealand and their levels of job satisfaction, work-family conflict and levels of workaholism were measured. Immigrants’ beliefs about New Zealand society’s attitudes to work and leisure were also measured. These were compared to a group of individuals who had only ever worked in New Zealand. Lifestyle choices were rated as the most influential motivation for moving to New Zealand, more so than work-related reasons. Overall, job satisfaction was high and work-family conflict was low, for participant groups. The two groups showed comparable levels of work enjoyment but those who had only worked in New Zealand showed higher levels of drive to work. Beliefs about the extent to which 3 work practices – a positive work-life balance, flexible working hours, being able to be in constant touch with the workplace – were valued by employers and by New Zealand society were related to workaholism related behaviours and to levels of job satisfaction and work-family conflict, for both participant groups. This research suggests that the image that is portrayed of New Zealand attracts individuals seeking a better lifestyle, and that immigrant’ perceptions are indeed met, providing confidence for the retention of immigrants. The findings bode well for the process of acculturation of immigrant workers into New Zealand workplaces and New Zealand society more generally.

Keywords: immigrants, work-related practices, New Zealand

Implications of person and organization fit across organizational types, and its impact on organizational effectiveness

YANG, H.C (Ajou University), LEE, Y.J. (Ajou University), KIM, D-Y. (Ajou University)

The aim of this study was to investigate the differences among organizational types. Also, it was tested if the relationship between personal characteristics and organizational effectiveness variables would be moderated by collegial relations (an organizational environment factor), because it was thought that personal characteristics are reflected in the type of organization, as claimed by the attraction-selection-attrition framework (Schneider, 1987), and that person and organization (P-O) fit (Kristof, 1996) like congruence between personal characteristics and organizational environment would enhance organizational effectiveness. 70 employees from public, 86 from private, and 67 from hybrid organizations were surveyed to see if organizational characteristics would be reflected in employee characteristics variables such as personality (Costa & McCrae, 1992), intrinsic motivation (Amabile et al., 1994), perceived colleague relation (Pierce et al., 1990), job satisfaction (Scarpello & Campbell, 1983), organizational citizenship behavior (OCB; Organ, 1988), and turnover intention (Becker, 1992). The characteristics of the organization were reflected in levels of the personal characteristics measured. Private organization members reported the highest levels of extraversion, intrinsic motivation and turnover intention. But public organization members showed highest levels of agreeableness, and hybrid members showed highest levels of OCB and job satisfaction. These results reflect the fact that employees in public organizations face greater restrictions from rules and regulations, but private employees are likely to experience more freedom and competition. Also, in the case of South Korea, a higher level of job security and a higher level of pay offered by hybrid organizations may have a positive effect on job satisfaction. The results of a three-way interaction showed that the effect of collegial relation depends on the different types of organization, and significantly moderates the relationship between personal characteristic
factors and organizational effectiveness variables (job satisfaction, OCB and turnover intention). These results are interesting because there was evidence that P-O fit was related to organizational effectiveness and P-O fit would enhance organizational effectiveness, too. The results partially support the idea that the characteristics of the organization influence the behavior and the attitudes of the organization’s members. Also, the results suggest that providing a positive atmosphere may increase P-O fit.

**Keywords:** person-organization fit, organizational effectiveness, organizational characteristics, employee characteristics

### Implicit and explicit effect of subliminal mere exposure

**KAWAKAMI, N. (University of Tsukuba), YOSHIDA, F. (University of Tsukuba)**

Recent research on attitude change has shown that implicit and explicit attitudes are influenced by different processes. According to the APE-Model (Gawronski & Bodenhausen, 2006) it is assumed that changes in associative knowledge structures should lead to changes in implicit attitudes, whereas changes in propositional knowledge should lead to changes in explicit attitudes. For example, in the case of evaluative conditioning on self-esteem, implicit measures showed changes but explicit measures did not. On the basis of these studies, we predicted that subliminal mere exposure effect (repeated exposure to a stimulus enhances its likability) would occur for implicit but not explicit measures (Experiment 1). In Experiment 2, we proposed that subliminal mere exposure effect would also occur for explicit measures through discussion in pairs of participants who were exposed to the same stimuli. Ten abstract paintings that received equally favorable ratings in a pretest were used as stimuli. As an implicit measure, we used the Affect Misattribution Procedure (Payne et al., 2005) designed to assess implicit likability for exposed stimuli and non-exposed stimuli. To measure explicit likability, a self-reported scale (dislike-like) was used. In Experiment 1, participants (N=32) were subliminally exposed to five of the ten paintings. Immediately afterward, the implicit and explicit likability toward the exposed and non-exposed paintings were individually measured. In Experiment 2, the general procedure was identical to Experiment 1; the only exception being that pairs of participants (N=60; 30 pairs) who were exposed to the same paintings were asked, through discussion in pairs, to indicate how much they liked these paintings. The results of Experiment 1 revealed that significant effect was observed only for implicit measure. That is, exposed paintings were evaluated as more implicitly likable than the non-exposed ones. In Experiment 2, however, consistent with our predictions, significant effects were observed for not only implicit measure but also explicit measure. We demonstrated that subliminal mere exposure may influence implicit attitudes but did not affect explicit attitudes. Moreover, results in Experiment 2 suggest that explicit attitudes would also change through discussion in pairs that were exposed to the same stimuli.

### Implicit attitudes toward regional diversity in the Ukraine

**NAYDONOVA, L.M. (Kostyuk’s Institute of Psychology)**

The Ukraine has regional differences in historical, cultural and economic aspects. Political electoral technology in the Ukraine has used the idea of regional diversity as two poles of the Ukraine – East and West. It is sometimes used in a negative separating context. The main goal of our research was to evaluate youth implicit attitudes toward the regional diversity, identifying the necessity of focusing psychologists’ attention. A new version of the Implicit Association Test (IAT) (Greenwald, Nosek, Banaji, 1998) was proposed for evaluating the regional diversity attitudes. Categories for East-West dimensions were the cities and towns of the regions. Categories for Positive-Negative dimensions were enthusiasm, sincerity, unity, greatness, independence, loyalty and opposites. The research included interviews and other direct methods. A sample of West, East and Central regions of the Ukraine was investigated (n=300). We confirmed some expected relationships, such as that the distance
of difference in youth regional diversity attitudes consist of the native region. But there were some abnormal tendencies of negative attitudes in the Central region. There was a discrepancy in the results of direct and implicit methods also. The finding allows us to propose special organized group discussions for changing the distance in a difficult case. We confirmed the possibility of using IAT for measuring attitudes toward regional diversity. The situation with attitudes toward regional diversity in the Ukraine needs psychologists’ attention. Dynamic regional diversity attitudes are important indicators for efficacy and correctness of political electoral technology in the Central region of the Ukraine.

Implicit theories of domestic violence

BAX, N. (Charles Sturt University), TYSON, G. (Charles Sturt University)

Implicit theories, or personal explanatory beliefs, held by Australians in relation to the cause and prevention of domestic violence were examined in this study. Implicit theories of domestic violence are important as they influence the adequacy and appropriateness of the help victims request; the functionality of public policy and laws enacted to manage the issue; and contribute to the development of social norms that serve to sanction or condone violence within families. Whilst beliefs associated with individual and contextual causes of domestic violence are empirically well documented, public perception of the importance and effectiveness of its cultural and social causes, and preventative strategies is less clear. A total of 281 participants’ completed an online survey that rated 30 causal explanations and 24 prevention strategies of domestic violence. Principal component analysis identified individual, and to a lesser extent contextual and socio-cultural factors as important causes of domestic violence, whilst therapy, community intervention and education were identified as effective domestic violence preventative approaches. The findings are consistent with ecological or multi-factorial explanatory models of domestic violence, however the level of endorsement of each factor was found to be somewhat dependent on the participants’ age, gender and prior experiences of domestic violence. The results of this study suggest that Australians’ are aware of the complexities associated with the aetiology of domestic violence, and that domestic violence prevention strategies targeting these causes will be generally well supported. Gender differences appear to be related to the theoretical orientations that underpin the causal attributions, therefore, preventative programs need to be targeted accordingly. The relationship between age and the level of endorsement of preventative strategies also suggests that programs that target younger generations may do well to advance a model of domestic violence that is reflective of its complexity. Finally, the implicit beliefs evidenced in this study imply that victims are held responsible, to some extent, for managing the violence in intimate relationships. Education and awareness campaigns that address the complex issues and barriers associated with leaving violent and abusive relationships are therefore imperative.

Keywords: implicit theories, domestic violence, public policy, social norm

Implicitness’ of implicit theories of intelligence: The problem of measuring implicit theories

UEBUCHI, H. (Tokyo Gakugei University)

Implicit theories of intelligence (ITI) have effects on motivation and adaptations (Dweck, 1999). However, ITI have been measured by paper and pencil questionnaires, which is a problematic method because explicit variables measured by paper and pencil questionnaires have the possibility of relation of social desirability. Therefore, the aim of this study was to examine the relationship of explicit variables of ITI and social desirability. The participants were 88 college students. The materials used were the Scales of Social Desirability (Tani, 2002; subscales: self-deception and impression-management); and the Scale of Implicit Theories of Intelligence (Fujii & Uebuchi, 2008a, 2008b).
Participants responded by group at college lesson times. The correlations of implicit theories of intelligence and self-deception ($r = .35$) and impression-management ($r = .29$) were significant. Explicit variables of ITI had relations of social desirability. However, Fujii & Uebuchi (2008a, 2008b) have found that implicit variables (measured by Implicit Associate Test (IAT)) of ITI were not related to social desirability. Therefore, ITI measuring by implicit method would be valid.

Keywords: implicit theories of intelligence, motivation, adaptation, social desirability

Impressions from point-light displays of dance expressions: Differences in dance experience of observers

SHIKANAI, N. (Ritsumeikan University), ISHII, M. (Tokyo Institute of Technology)

It is known that biological motion produced by point-light displays (Johansson, 1973) gives a good representation of walking (Cutting and Kozlowski, 1997; Dittrich et al., 1994), gender (Cutting and Kozlowski, 1977; Lamothe et al., 2006), facial expressions (Bassili, 1978), emotions (Clarke et al., 2005; Dittrich et al., 1996; Pollick, 2001), playing sports and their visual cues (Abernethy et al., 1993; Abernethy et al., 2001; Shim et al., 2005; Ward et al., 2002), and dance (Dittrich et al., 1996) with kinematic information. In information processing, we could not only identify motion, action, but also perceive or recognize impressions and sensitive images, but few studies have focussed on them. The purpose of this experiment was to measure how observers perceive emotional impressions from point-light displays. Dancers were instructed to express three emotions: joy, sadness, and anger, using their entire bodies but without using facial expressions. Each emotion was expressed for about 15 seconds, and repeated twice to avoid inadvertent improvisation. The dancers wore dark clothing and the 13 markers were attached to their bodies: the head, shoulders, elbows, wrists, thighs, knees, and toes. Each expression was capture using a 3D motion capture system (Motion Analysis Inc.) with 10 cameras and recorded by digital video camera. The dancers were then judged for the best and most expressive movements of each emotional expression by themselves. Thus the appropriate expressions of the three emotions were selected for this experiment. Using these data of expressions, point-light displays were made with the 3D animation software MotionBuilder (Autodesk Inc.). Five dance experienced and seven dance inexperienced observers participated. The participants were requested to watch and rate how compatible each emotion was with each dance of point-light, and to evaluate impressions on a 5-point Likert scale. These impressions were 7 items (happy, lonely, sharp, solemn, dynamic, flowing, and natural). The results showed that both experienced and inexperienced observers tend to identify each emotion that the dancers intended to express. Our findings indicate that particular impressions from point-light displays have differences in dance experience of observers.

Keywords: dance, point-light displays, dance expressions, Kinematic information, emotions

Impressions of sounds in rural nature area: Evaluations by college students in rural nature area

MATSUMOTO, J. (Nagano College of Nursing), NOSAKA, T. (Nagano College of Nursing), KITAYAMA, A. (Nagano College of Nursing), HONDA-SUMI, E.

We investigated evaluation of impressions of sounds in rural nature area. In a previous study university students in urban areas participated and rated their impressions of the sounds heard in rural nature area or their impressions of the landscapes they imagined for the sounds. Both ratings varied, but many found some of the sounds nostalgic and rated some of the landscapes they imagined as nostalgic. In the present study we examined whether college students in rural nature area rated impressions of the sounds similarly as the students in urban areas had done. 30 college students living in rural nature area participated in two experiments. First they heard the sounds in rural nature area and rated their impressions of them. Next they also heard the same sounds and rated their impressions of the landscapes they imagined for them. As a result, both ratings were not distinctive and the patterns of the
impressions were similar between the sounds and the related landscapes. Both of the impressions of the sounds in rural nature area and the impressions of the landscapes they imagined for the sounds were not the same between students in rural nature area and students in urban areas. This suggests that familiarity to a sound may weaken the impression of the sound as well as of the image of landscape created by the sounds.

Keywords: impressions of sounds, rural, landscapes, familiarity

**Improving student wellbeing, academic performance, and group work skills using peer mentoring**

TELLEY, A. (RMIT University), CHESTER, A. (RMIT University), XENOS, S. (RMIT University), LI, J. (RMIT University), RYAN, R. (RMIT University)

The first year university experience has been shown to contain unique challenges for students as they adjust to the self-directed nature of higher education. Further to transition, there is often the need to work collaboratively. This study evaluated the efficacy of a peer mentoring program embedded in tutorials in a first-year engineering course, by comparing peer mentors supporting group work with the same information provided by regular classroom tutors. Students (n = 77; 69 male, 8 female) were measured at the beginning and end of semester on group work self-efficacy, satisfaction with life, and feelings of depression, anxiety, and stress. Results revealed a 100% retention and pass rate in the peer tutored group compared to 96% in the control group. A significant difference was found between groups on group task grades when controlling for high school ENTER score. Only the peer mentored group showed significant improvements in group work efficacy across the semester, and had significantly higher satisfaction with life compared to the control group at the end of the semester. Although no differences were found between the groups in depression, anxiety and stress at the end of semester, peer mentored students’ anxiety lowered across the semester. This research indicates peer mentoring designed around a specific assessment task may benefit students academically, and subsequently lower their feelings of anxiety. Future research should investigate if and how a synthesis between the psychosocial and instrumental support functions of peer mentoring is possible.

Keywords: student well-being, academic performance, group work skills, peer mentoring, anxiety

**Improving the provision of a culturally safe psychological service, within in an Urban Private Practice in NSW Australia**

HEARD, T. (University of Newcastle), BRAUNSTEIN, R. (Private Practice, Tharawal Aboriginal Medical Service)

The aim of the current study was to improve the provision of a culturally safe Psychological service, through increasing practitioner cultural competence through structured cultural mentoring. A pre post repeated measures survey within one private practice within an urban area of NSW was conducted. One Psychologist from the private practice completed the survey. The participant undertook a process of engaging a cultural mentor to provide the private practice with support and assistance to improve the provision of a culturally safe psychological service to an Australian cultural minority group i.e. Australian Aboriginal and Torres Strait Islander people. Following the engagement of the consultant the participant was supported to complete three activities, which included: cultural mentoring i.e. a structured cultural exchange process which aims to improve the cultural competence and understanding of the participant; experiential learning activities; and a structured process of identifying the target population and engaging with the key community within a culturally respectful manner. Following six months the participant repeated the survey. The Tracey Westerman “Cultural Competence Test” which is a tool that is designed to assess a respondents capacity to integrate culturally appropriate assessment, engagement and interventions skills into clinical practice. The tool is divided into four domains: knowledge, skills, beliefs/attitudes, resources and links and organizational influences. The results of the pre and post test results show an increase in cultural competence across all domains with the exception of the resources and
Abstracts of the 27th International Congress of Applied Psychology

links domain which remained steady at 70%. The largest increase was recorded in the organisational influences domain (39% increase) and an equal increase of 10% was recorded across the knowledge, skills and beliefs and attitudes domains. This study supports the effectiveness of engaging cultural consultants to improve the cultural competence of Psychologists within a private practice setting. Through the provision of culturally safe Psychological services and supporting Psychologists to work within a cultural context, the professions of psychology and cultural mentors can work together to improve the health and wellbeing of Indigenous Australians. Initiatives, through the Australian Psychologists Association, State Psychology Registration Boards and Australian Universities, to strengthen the ethical and profession obligations to work in partnership with cultural mentors are urgently needed.

Keywords: culturally safe psychological service, cultural competence, structured cultural mentoring, private practice

Impulsivity is the most important predictor for non-suicidal self-injury among all borderline personality features

LAI, C. (The Chinese University of Hong Kong)

Non-suicidal self-injury (NSSI) among adolescents has become one of the leading public health problems and is attracting more and more research attention these years. The phenomenology of NSSI and the underlying mechanism, however, are still unclear. The present study examined the prevalence of NSSI and the relationships between NSSI and various borderline personality disorder (BPD) features among Chinese community adolescents in Hong Kong. A number of 4,782 Chinese adolescents (68.5% girls, aged between 11 and 19 years) were surveyed twice in two consecutive years. They completed measures on NSSI and various BPD features. Results revealed that 15.0% of participants have engaged in NSSI in the past year, with considerable variations in the prevalence and frequency of different NSSI behaviors. Impulsivity was the most important predictors for NSSI. In the presence of impulsivity, other BPD features would be unnecessary in predicting NSSI. Among the three types of impulsive behaviors, substance use contributed the largest amount of unique variance in NSSI and it was also the most powerful risk factor and protective factor for later engagement and discontinuance in NSSI. Implications for classification issues of NSSI in the diagnostic and statistical manual (DSM) system and treatment strategies were discussed.

Keywords: Non-Suicidal self-injury, borderline personality disorder, adolescence, impulsivity

Individual differences: multidimensional Bradley-Terry model using reversible jump Markov chain Monte Carlo algorithm

USAMI, S. (University of Tokyo)

The Bradley-Terry model has been widely and effectively used to rank stimuli from paired comparison data in sensory tests, sports data and certain psychological measurements. Existing approaches for paired comparison data analysis, however, have a number of limitations. First, among applied Bradley-Terry models in which multidimensionality is assumed, the effects of individual differences are not considered. Second, in these multidimensional Bradley-Terry models, the number of dimensions is generally evaluated only after analyzing several models with different dimensions separately, thus causing computational inconvenience. In this study, a multidimensional Bradley-Terry model is proposed, which considers the effects of individual differences. The proposed model allows estimation of parameters for both scale values of stimuli and individual differences in multidimensional space. A procedure of parameter estimation is presented that uses a reversible jump Markov chain Monte Carlo (RJMCMC) algorithm to estimate the optimal number of dimensions as well as associated parameters simultaneously. To assess the utility of the RJMCMC algorithm, the averages and standard deviations of the posterior probability for models with different dimensions over 50 different data sets are calculated under various conditions by the simulation studies. The simulations showed that
RJMCMC algorithm were effective and practical. Moreover, in the example using real data from sumo tournaments, a 2-dimensional model was optimal from both statistical and interpretative points of view. In this case, the scale values (strength of players) changed with time and using the time periods of tournaments as a stratification variable regarding individual differences enabled clear and accurate interpretation of the data. The proposed method provides a general framework for analyzing various types of paired comparison data. A number of approaches could potentially enhance the capabilities of the proposed model. One approach is extension of the model to polytomous data, since the Bradley-Terry model is generally restricted to binary data. Another approach is extending the model to consider the factors that affect judgments. These approaches are discussed in the conclusions more intensively.

Keywords: Multidimensional Bradley-Terry model, paired comparison data, individual differences, Reversible jump Markov chain Monte Carlo (RJMCMC) algorithm

Individual psychological characteristics of the propensity to take risks in people with different levels of affluence in terms of social instability

MIHEJEVA, N. (Daugavpils University)

The aims of this study were to compare the individual psychological characteristics of people of different income levels and their influence on the propensity to take risks, and to analyze the propensity to take risks in conditions of social instability. The tests utilised in this research were the scale of Marvin Zuckermann, the Ehlers-Schubert method, the Temperament Aizenk’s method, statistical ANOVA, and LISREL-8PS. The research tasks were performed and the objectives achieved. Socio-philosophical analysis was conducted on individual psychological characteristics of the propensity to take risks in people with different income levels in terms of social instability. The program LISREL-8PS made it possible to create a theoretical model of psychological profile of the respondents. Respondents with low income were found to be more likely to take risks than the group with high income. The study could serve as a platform for scientific discussions and has prospects for development (e.g. in cross-cultural direction).

Keywords: risk, propensity to take risks, social instability, individual psychological characteristics, income levels

Individual values, attitudes and driving behaviour

AUSTERS, I. (University of Latvia), MUZIKANTE, I. (University of Latvia), RENGE, V. (University of Latvia)

The aim of the present study was to find whether attitudes towards aberrant driving moderate value–behaviour relations. Previous research has showed that values predict violations of traffic rules (Renge, Austers, & Muzikante, 2008). Iversen’s (2004) longitudinal study showed that attitudes towards aberrant driving behaviour predict reckless driving in future. One of the attitudes’ functions is to express values; therefore, we hypothesized that attitudes will moderate value-behaviour relations in driving situation. We explored: (i) values in relation to driving behaviour by regression analysis; and (ii) value-attitude-behaviour relations by using simple mediation analysis (SOBEL test for SPSS). 527 lay drivers (mean age 30 years, 54% male, mean annual mileage 23,210 km) participated in the study. Participants filled out a questionnaire containing the Portrait Value Questionnaire (Schwartz et al., 2001), Drivers Behaviour Questionnaire (Austers & Renge, 2007; Reason et. al., 1990), and Attitudes Toward Aberrant Driving Behaviour questionnaire (Iversen, 2004). Age and gender were entered at the first step into stepwise regression analysis, and ten values were entered at the second step. Values types of Achievement and Tradition significantly contributed to the model. Single mediator analysis showed that attitudes mediate values–behaviour relations. Particularly, attitudes towards aberrant driving behaviour mediated value-behaviour relations in case of Benevolence, Universalism, Security, Tradition, and Conformity values types. Results of current research show that values predict driving behaviour. All the values mentioned above have negative relations with attitudes toward aberrant driving and driving violations –
the higher values rating the more negative attitudes towards aberrant driving behaviour and less driving violations. Attitude change is one of the methods to strive with traffic violations, our findings point to a possibility of a better intervention method based on values, since values are more stable personality characteristics than attitudes.

**Keywords:** attitudes, driving behaviour, values, aberrant driving, attitudes

**Influence of affect and companionship on impulse buying**

CHEUNG, W.Y. (The Chinese University of Hong Kong)

The aim of this study was to investigate the effects of pre-shopping affect (both positive and negative) and companionship on impulse buying tendency. One hundred and seventy seven Hong Kong university students took part in a policy-capturing study. After being selected in a preliminary study, eight scenarios were used with four designed for studying positive affect and companionship and four designed to study negative affect and companionship. High reliability was found, suggesting that participants used a consistent policy for responding to all scenarios. The results of a manipulation check also indicated that participants projected themselves into all scenarios, which allowed for deeper processing of the stimuli. Only positive affect was found to be significantly associated with impulse buying tendencies, in which lower positive affect led to greater tendency to buy on impulse. This study found that lower positive affect could lead to greater impulse buying tendency and two possible explanations were given.

**Keywords:** impulse buying, companionship, affect, university students, Hong Kong

**Influence of cognitive bias on young cyclists’ road crossing intentions at non-signalized intersections**

KINOSADA, Y. (Osaka University), USUI, S. (Osaka University)

Previous research suggested that even when cyclists possessing the right-of-way at non-signalized intersections noticed cars coming from cross roads, they tended to believe the drivers would give way. Such cyclists’ biased judgments may lead to accidents. This study seeks to verify if young cyclists’ unsafe road crossing intentions at non-signalized intersections are influenced by cognitive bias, using the Theory of Planned Behavior (TPB). One hundred and twenty-three university students completed a questionnaire about bicycle crossing behavior at potentially hazardous non-signalized intersections. Every situation was depicted differently by a scenario and a picture. Situations were designed with three factors: priority (cyclist moving on a major or minor road); distance (near or far car on the cross road); and psychological state (whether the cyclist is in a hurry or is calm). Only psychological state was a between-participant factor. Thus, questionnaires contained four situations. For each situation, participants rated TPB components (i.e., attitude, subjective norm, perceived behavioral control, and intention) and additional items (i.e., expecting cars to yield, self-serving bias, and unrealistic optimism) on a seven-point scale. Three additional items were averaged to create a cognitive bias variable. Three-way ANOVAs with repeated measures and all items as dependent variables demonstrated that the psychological state had neither a significant main effect nor an interaction. Therefore, the psychological state was collapsed, and four situations were reconstructed with the remaining factors. Hierarchal regression analyses with intention as the dependent variable revealed that adding cognitive bias as a predictor significantly increased the amount of variance explained in three out of four situations except for minor-far situation. Participants’ unsafe crossing intentions were biased when crossing non-signalized intersections especially when possessing the right-of-way, which was consistent with the previous study. Thus, interventions should focus on how to lower cyclists’ cognitive bias. The unique discovery of this study is that cognitive bias influences crossing intentions even if cyclists are on a minor road and the car is close. Although the mean score of crossing intention in this situation was low, the importance of considering cyclists’
cognitive bias was suggested to predict their unsafe intentions.

**Keywords:** cycling, crossing intentions, cognitive bias, theory of planned behaviour

**Influence of cultural-value orientations and perceived parental expectations on career interest**

LI, X. (Chinese University of Hong Kong), LEUNG, S.M. (The Chinese University of Hong Kong), ZHOU, S. (The Chinese University of Hong Kong), HOU, Z.J. (The Beijing Normal University)

Even though career interest is often regarded as an intra-personal variable (that is, interest as a person-level variable), researchers have pointed out that career interest is often influenced by cultural as well as relational factors. Hence, this research study aimed to achieve two purposes. First, we aimed to examine the relationship between cultural-value orientation (traditionality and modernity) and career interest. Second, we wanted to examine the relationship between career interest and parental expectations, as family and parental expectations on career choices and goals are likely to influence the career interests and choices of students. Participants of this study were university students in Hong Kong, Beijing, and Wuhan. Participants completed a number of instruments, which were the Living Up to Parental Expectation Inventory (LPEI) (Wang & Heppner, 2002), a Career Interest Inventory (a Chinese language interest inventory based on Holland’s theory of career interest), and the Multidimensional Scale of Chinese Individual Traditionality (MS-CIT) and Multidimensional Scale of Chinese Individual Modernity (MS-CIM) (Yang, 1996; Yang, 2003). The number of participants from Hong Kong, Beijing, and Wuhan was 643 (369 female and 274 male), 271 (152 female and 119 male), and 427 (175 female and 252 male), respectively. Since there were regional differences on the test scores (between Hong Kong and Beijing/Wuhan students), separate analyses were conducted for the two groups. For each group, six regression analyses were conducted using each of the Holland interest scores as dependent variables, and the Perceived Parental Expectation scores from the LPEI (personal maturity, academic achievement, dating concerns) and the Traditionality and Modernity scores and gender as predictor variables. The results suggested that (a) for Chinese mainland students, Traditionality was significantly related to Investigative and Social interests, and Perceived Parental Expectation showed significant predicting effect on the two interests; (b) for Hong Kong students, Traditionality was significantly related to Social, Enterprising, and Conventional interests, and Perceived Parental Expectations were significantly related to Investigative, Social, and Enterprising interest; and (c) gender effect significantly contributes to the relationship between cultural-value orientation and career interests. The details of the analyses, and convergence and divergence of findings on the two student groups, as well as theoretical and practical implications, will be examined and discussed.

**Keywords:** cultural-value orientations, parental expectations, career interest, relational factors, Chinese students

**Influence of empathic–affective reactions on interpersonal behaviors of Japanese junior high school students**

SUZUKI, T. (University of Tsukuba), SAKURAI, S. (University of Tsukuba), HAYAMA, D. (University of Tsukuba), KURAZUMI, T. (University of Tsukuba), NISHIMURA, T. (University of Tsukuba), MURAKAMI, T. (University of Tsukuba), SAKAGUCHI, N. (University of Tsukuba), NABEKURA, T. (University of Tsukuba)

A new scale of empathic-affective reactions for Japanese junior high school students, based on 4 categories (positive or negative emotions X parallel or reactive outcome) was developed. The relationship between envy and empathic-affective reactions was then investigated in order to demonstrate the characteristics of the scale. Finally, the influence of empathic-affective reactions on prosocial and aggressive behaviors was examined. Junior high school students (n = 203) responded to the Empathic-Affective Reactions Scale, The Envy Scale, the Prosocial Behavior Scale, the Overt Aggressive Behaviors Scales and Rational Aggressive Behaviors Scales. Factor analysis of the Empathic-Affective Reactions Scale revealed 3 factors: Positive
empathy (positively parallel and reactive emotions), Negative sharing (negatively parallel emotions), and Sympathy (negatively reactive emotions). These subscales had high reliability. Partial correlation analysis revealed that envy was negatively correlated with Positive empathy ($r = -0.18$) and positively correlated with Negative sharing ($r = 0.36$). Regression analysis of empathic-affective reactions to prosocial behaviors revealed significant effects of positive empathy ($B = 0.26$) and sympathy ($B = 0.35$). Also, regression analysis of overt aggressive behaviors revealed only the significant effects of positive empathy ($B = -0.26$). Results suggest that positive empathy has the positive potential of promoting prosocial behaviors and restraining overt aggressive behaviors, whereas sympathy has the positive potential of promoting prosocial behaviors.

Influence of lighting on perception of object color

BLIUMAS, R. (Vilnius University), VAITKEVICIUS, H. (Vilnius University), BLIZNIKAS, Z. (Vilnius University), DAUGIRDIENE, A. (Vilnius Pedagogical University), KULIKOWSKI, J. (The University of Manchester), STANIKUNAS, R. (Vilnius University), SVEGZDA, A. (Vilnius University), VILIUNAS, V. (Vilnius University)

Energy saving and reliable lighting sources as the light-emitting diodes (LED) are rapidly developing. Implementations of LED depend on their subjective properties. Attractiveness of the same colored objects illuminated by two light sources, with the same correlated color temperature but different spectra, can be different. Sensitivity to changes of color under different lighting can be also different. We address the problem of influence of lighting upon color attractiveness and capability to discriminate color differences. Standard A, D65, D55 and LED light with the same correlated color temperature were used. The Munsell, Farnsworth Munsell 100 Hue Test samples and 28 two colors plates were used. It was found that attractiveness of colored plate under different lighting depends on their chroma. The changes in the capability to discriminate color differences are explicitly observed for the older subjects in greenish-yellowish and blue regions.

Keywords: lighting, perception of object color, color attractiveness, energy conservation, light-emitting diodes

Influence of one’s view on the past for orientation to growth and sense of fulfillment among undergraduates: Self-formation process from the view point of psychological time

ISHIKAWA, A. (Chuo University)

This study aimed to clarify the self-formation process from the view point of psychological time. Self-formation is considered a phenomenon of change or growth of self. Reviewing previous studies, it was suggested that the self-formation process consists of one’s view on the past affects orientation to growth and how the latter affects sense of fulfillment. The first purpose of this study was to develop a scale to measure one’s view on the past. The second purpose was to clarify the self-formation process by clarifying the influence of one’s view on the past for orientation to growth and the influence of orientation to growth for sense of fulfillment. In survey1 we first categorized and organized “one’s view on the past” based on free descriptions by 109 university students (average age 19.18 years, $SD=1.02$). It became clear that “one’s view on the past” is comprised of elements related to “connection of psychological time”, “attitude to the past”, and “perception of the past”. Secondly we created a list of 94 preliminary “one’s view on the past” measurement items. In survey2 we requested 252 university students (average age 19.56 years, $SD=1.10$) to answer the questionnaire constructed from 3 scales using the 5-point rating scale: “one’s view on the past”, “orientation to growth”, and “sense of fulfillment”. The results of a questionnaire on survey2 were that factor analysis on “one’s view on the past” yielded 5 subscales (connection of psychological time, positive attitude, negative attitude, practical attitude, and negative perception). Furthermore, factor analysis on “orientation growth” yielded 2 subscales (growth orientation and effort orientation). Structural equation modeling demonstrated the
validity of the above hypothetical causal relation between “connection of psychological time” and “growth orientation”, “positive attitude” and “growth orientation”, “positive attitude” and “effort orientation”, “practical attitude” and “effort orientation”. It also indicated that “negative perception” negatively influenced “sense of fulfillment”, but “orientation to growth” did not influence “sense of fulfillment”. These results support that “one’s view on the past” influences “orientation to growth” in the self-formation process.

Keywords: self-formation, psychological time, fulfillment, orientation to growth, view on the past

Influences of career as a nurse and status in a clinical unit on interpersonal stressors of Japanese hospital nurses

MATSUMOTO, T. (Osaka University), USUI, S. (Osaka University)

A major issue in Japanese hospitals is interpersonal stressors among nurses. In Japan, there have been many studies on nurse burnout. These studies have suggested that nurse burnout involves human relations. However, few studies have focused on interpersonal stressors among nurses. This study therefore examined influences of career as a nurse and status in a clinical unit on interpersonal stressors of Japanese hospital nurses. 624 nurses in Japan participated in the study. They completed a questionnaire about interpersonal stressors, number of years worked as a nurse (under four years, over four years but under seven years, over seven years but under fifteen years, or over fifteen years), and status in a clinical unit (supervisory nurses vs. nonsupervisory nurses). Items about interpersonal stressors were included to measure the frequency of stressors caused by human relations. Factor analysis revealed that interpersonal stressors among nurses consist of five factors: “disagreements with doctors,” “not understanding staff,” “errors they commit,” “negative behavior by doctors,” and “concealing real thoughts.” A one-way ANOVA with career as a nurse was conducted for each factor of interpersonal stressors. The result revealed that disagreements with doctors was significantly higher in the group with over four years but under seven years experience and in the group with over seven years but under fifteen years experience than in the group with under four years experience. Furthermore, a one-way ANOVA with status in a clinical unit was conducted on each factor of interpersonal stressors. However, only the data of participants who worked as a nurse more than seven years was analyzed because all other participants except one were nonsupervisory nurses. The result of ANOVA revealed that “disagreements with doctors” and “not understanding staff” were significantly higher for supervisory nurses than for nonsupervisory nurses. This study found that “disagreements with doctors” increase among nurses who had worked fifteen years in Japanese hospitals. In addition, the study suggested that if they hold supervisory status, both “disagreements with doctors” and “not understanding staff” increase.

Keywords: Japanese, interpersonal stressors, nurses, burnout

Influences on youth gambling: Do past behaviour and impulsivity improve the predictive utility of the theory of planned behaviour?

O’CALLAGHAN, F. (Griffith University), AVIS, S. (Griffith University)

The present study used the theory of planned behaviour (TPB) to examine the behavioural decision-making dynamics, cognitive and social influences, and underlying beliefs of different categories of gamblers. The efficacy of the TPB in predicting gambling intentions and behaviour was evaluated together with the influence of past behaviour and impulsivity in an extended model. A prospective design with two waves of data collection, one month apart, was utilised. Participants were first year psychology students between the ages of 17 to 27 years (mean age = 19.94 years). At time 1 (T1), 143 participants completed an online questionnaire, with intention to gamble in the next month as the target behaviour. At time 2 (T2), 92 participants completed a follow-up online questionnaire, with frequency of gambling since T1 as the target behaviour. Results showed that attitude, subjective norm (SN), and perceived behavioural control (PBC), predicted intention to gamble. However, when past behaviour and impulsivity
were included in the extended model, PBC was no longer significant. Actual gambling behaviour at T2 was predicted by intention to gamble and past behaviour. Contrary to the TPB, PBC did not contribute to the prediction of actual gambling behaviour. As expected, impulsivity moderated the intention–behaviour relationship, and differences in attitudinal beliefs were found between non-problem, at-risk, and problem gamblers. The results highlighted the importance of past behaviour and impulsivity as additional constructs in the TPB, and identified specific attitudinal beliefs to be targeted in strategies to effect changes in problematic gambling behaviour.

**Information processing speed in older adults**

CASTELLANI, M. (La Trobe University)

This study was designed to explore the multifactorial nature of visual processing speed. It was based on the conceptual framework that components of processing speed may be specific to the sequential stages of input, central and output processing. The influence of age, memory and fluid intelligence on each of the components was also examined. A sample of 92 normal adults ranging from 61 to 89 years was assessed on a battery of visual tasks. Input processing speed was measured by two high speed computerised visual tasks, central processing speed was measured by a visuospatial working memory task and an inhibition task, and output processing speed by handwriting tasks. Factor analysis revealed three, relatively uncorrelated, constructs of perceptual speed, mental rotation speed and psychomotor speed. The perceptual speed factor and the motor speed factor were predicted by a general processing speed measure but not age, fluid intelligence or memory. The mental rotation (central) processing speed factor was predicted by fluid intelligence only. Future studies may explore a wider variety of information processing speed measures and different sensory (input and output) modalities for further classification. These classifications could prove useful in neuropsychological assessment, where specific processing modalities may be compromised.

**Keywords:** visual processing speed, stages of input, age, memory, fluid intelligence

**Insecure adult attachment and perception of facial emotions**

HUANG, Y. (National Taiwan University), HUANG, Y-L. (National Taiwan University), CHEN, S-H. (National Taiwan University)

This study aimed to empirically examine the effect of insecure attachment on the perception of facial emotions. Individuals with high anxiety or avoidance attachment may be more vigilant to the cues relevant to negative information in the appraisal process of availability and responsiveness of their significant others. Thus, we hypothesized that they may be more likely to accurately perceive negative facial emotions. One hundred and thirty undergraduate students completed the Revised-Adult Attachment Scale and computerized Diagnostic Analysis of Nonverbal Accuracy 2-Taiwan version (DANVA2-TW). Results revealed that, participants with high anxiety attachment exhibited less accurate perception overall for facial emotions, especially fear emotions, whereas participants with high avoidance attachment displayed a negative bias toward anger emotions. In addition, participants with high anxiety attachment tended to perceive neutral facial emotions more as sad emotions and less as happy emotions, whereas participants with high avoidance attachment tended to perceive neutral facial emotions as anger emotions. The findings suggest that high anxiety and avoidance attachment may lead to negative emotions. The mechanism of insecure attachment and perception of facial emotions will be discussed.

**Keywords:** insecure attachment, facial emotion, anxiety, avoidance

**Integrating special needs students in regular classrooms: Beneficial or detrimental? An attempt of a data based answer from a systemic approach**

Participation of special needs students in regular classrooms is already part of current common sense. Decades ago, the respective desiderates appeared in agreements or declarations of various countries and organisations (e.g. Salamanca Declaration, 1994; Convention on Rights of Persons with Disabilities, 2006). However, because of complexity and multiple determination of the issue, neither the terms addressed nor the concepts elaborated nor the educational systems implemented share common ground (cf. Haeberlin, Bless, Moser & Klaghofer, 2003; Eurydice, 2007). Therefore, only systemic approaches combined with data-driven evaluations can serve as a sound basis for applicable research (cf e.g. Kronig, 2007; Rollet, 2008). In this poster a Swiss project (of Sonderpaedagogisches Zentrum Bachtelen [SZB] at Grenchen, Canton Soleure) evaluating conditions for integrations of special need students in regular classrooms are described. Distinctive for its theoretical basis is an understanding of “integration” as a bi-polar concept (with “separation” and “inclusion” at its ends) which takes part of a systemic approach referring to properties of the individual concerned (e.g. special needs, developmental stage) as well as the surrounding conditions of the social (familiar) and the educational system. Within this approach (incorporating education of special-needs pre-schoolers, students and apprentices in the comprehensive, family based accompaniment of social work education) beneficial and detrimental effects of different degrees of integration are to be identified. For this purpose quantitative and qualitative data are collected at different levels (e.g. figures of the educational system at canton, municipality, school) and in different perspectives (e.g. appreciations of principals, teachers and parents; interviews, tests and related diagnostics of special needs and of regular children, pupils and apprentices; structured observations of classroom-behaviour) and entered into multi-level configuration analyses (e.g. hierarchical least-squares, frequency configuration) in order to identify patterns that allow designs of educational systems apt to assist special needs persons with appropriate integrative arrangements and interventions. Depending on the progress of the project which began in autumn 2009, samples and design as well as results regarding characteristics of each level (e.g. concomitance between financial and personal equipment and integrative approach of the school) and perspective (e.g. teachers’ and apprentices’ appreciation of insertion into the working process) are presented and submitted to first conclusive interpretations (e.g. about features of the family based and/or subsidiary accompaniment of integrative interventions). Recommendations for milestones of the cantonal frame and the institutional and interventional changes in the SZB and associated institutions are given.

Keywords: special needs, educational systems, integration

Intellectual entrepreneurship: The combination of thought and action

MIRZASAFI, A (Isfahan University), SIADAT, A. (University of Isfahan)

Writers who have studied and discussed entrepreneurship have offered different definitions and types for it. Hisrich (1991) defines entrepreneurship as a process of creating new things through spending time and effort, and accepting financial, psychological and social risks in order to obtain financial resources, personal satisfaction and independence. There are three types of entrepreneurship including personal, organizational and social. But there is forth type that has been neglected and is called intellectual entrepreneurship. Most common classes of entrepreneurship are based on their context and environment rather than their nature and essence. In fact, intellectual entrepreneurship represents a combination of idea and action. So, the purpose of this article is to review intellectual entrepreneurship dimensions and characteristics. The method of this research is descriptive-analytical, and data will be collected through library sources and electronic data bases. A complete process of entrepreneurship requires risk- taking, creativity and grace. Having all these traits requires system thinking and divergent thoughts. Intellectual entrepreneurship is not a combination of two thoughts of entrepreneurship and rationality.
that can approach idea and action. Intellectual entrepreneurship covers techniques and indices that can equip entrepreneurship.

Keywords: intellectual entrepreneurship, entrepreneurship, system thinking

**Interrelation of some physiological indicators and psychological features of students in the conditions of examination stress**

CHUIKOVA, T. (Bashkir State Pedagogical University), GALYAUTDINOVA, S. (Bashkir State University), GALYAUTDINOVA, L. (Bashkir Psycho-Medico-Pedagogical Committee)

This work is directed to studying the interrelation between a blood pressure change and frequency of warm reductions of students during the examination and some psychological data. The secondary indicator – an Index of Robinson (IR) was used for a total estimation of reaction to a stressful situation of the cardiovascular system. The diagnostics of psychological characteristics of examinees was spent by means of the Colour Test of Ljusher before the beginning of the examination. Measurement of examinees in the conditions of examination stress of physiological indicators has allowed allocation of four groups of students conditionally. The first group was characterised by physiological indicators corresponding to norm (IR = 9000-10000). The stress is not revealed. Physiological changes in the second group of students (IR = 10000-12500) were an indicator of “moderate stress”. Changes of physiological indicators from 14500 and more characterised the fourth group as examinees “the frank stress”. The correlation of the physiological indicators of students in the conditions of examination stress by the psychological characteristics on section of the test of Ljusher “Stress sources”, has shown the following: If we classify the negative factors of the specified section under four ranges (A,B,C,D), we can characterize the groups of the examinees by the correlations that are given below. The first group on section “Stress Sources” is presented by factors of ranges A and B. The second group is presented by ranges B and C. In the third group – B, C and D. The fourth group where the stress is the most expressed, has all ranges with the maximum growth of factors in a range of B. In this group the tendency to nervously-somatic pressure and aspiration to recognition is shown. The allocated four groups on a parity of physiological indicators and personal characteristics are interesting from the position of studying the deep reasons of the revealed parities.

Keywords: Index of Robinson, stress, exam stress, physiological changes, physiological indicators

**Intervention engagement in a mental or physical exercise program predicts episodic memory performance in older women**

EVERS, A. (Charite - Campus Benjamin Franklin), KLUSMAN, V. (Department of Psychiatry, Charite, Campus Benjamin Franklin), SCHWARZER, R. (Free University), HEUSER, I. (Department of Psychiatry, Charite, Campus Benjamin Franklin)

Positive effects of mental and physical activities on cognitive performance in old age have been demonstrated. To further understand this relationship, we studied the association between the degree of an individual’s intervention engagement and the degree of its cognitive benefit. Older healthy women (N=161, y=70-93) participated in a randomly assigned 6-month exercise or computer course (thrice weekly, each 90-minutes). To predict episodic memory performance at post-testing, pre-measured episodic memory (FCSRT) and two different measures of adherence were used: number of courses attended and time-spent on this intervention engagement. Time-spent was calculated in hours the participants spent on all attended courses adding the actual time for getting to and from the sites where the courses were held. Average course attendance was 69% in the exercise group and 85% in the computer group. In the exercise condition, baseline measurement ($\beta = .66$) and course attendance ($\beta = .17$) were predictive of high test scores ($p < .001$, $R^2 = .45$). A positive interaction emerged between course attendance and baseline measure ($\beta = .17$, $p < .10$, $R^2 = .47$). In the computer course, the baseline measure was equally strong ($\beta = .63$). Here the amount of time-spent contributed to the prediction ($\beta = .17$, $p < .10$), but not course attendance.
itself. The interaction term indicated that women who performed low at baseline but spent a large amount of time outperformed those with the same low baseline but less time-spent ($ß = -.17, p = .053, R^2 = .46$). The effects of an intervention engagement on episodic memory depend on pre-intervention cognitive status and time-spent on this engagement, whereas sheer number of courses attended is of lesser importance. Those women with a low baseline performance have a higher potential for episodic memory gains, if they engage in a challenging activity. Travelling activity to the courses provides a beneficial effect which might be explained by unspecific stimulating effects occurring during travel time.

**Keywords:** episodic memory, cognitive performance, physical activity, older people, interventions

### Investigation affective, political attitudes and economic dependency in men to their spouse: An attitude assessment study

REZAEI DEHNAVI, S. (University of Isfahan), SHAHGHOLI GAHFAROKHI, S. (Payeme Noor University of Fereidoonshahr)

The purpose of this study was to assess the attitudes of men living in Shahrekord (a city in Iran) about their Affective, Political and Economic Dependency towards their spouse. 130 married men participated in this study by completing the questionnaire developed and validated by the researchers. The data was analyzed through ANOVA. The results indicated that men expressed that they had dependency towards their spouse in affective and economic aspects, but their dependency in political attitude was not significant. Thus to conclude, men may hold political attitudes that have no relationship to the perspectives of their spouse.

**Keywords:** married men, spouse, affective dependency, political dependency, economic dependency

### Investigation of psychosocial predictors of internalised homonegativity in two age cohorts of lesbian and bisexual women

ROBERTSON, H. (University of Western Sydney), MALCOLM, J. (University of Western Sydney)

Internalised homonegativity (IH) is examined in the present study utilising a minority stress framework. Two possible psychosocial predictors of IH, perfectionism and lesbian/gay community attachment are investigated as is the relationship between IH and the mental health outcomes of depression, anxiety and stress. This study attempts to further illuminate the discussion of IH by investigating differences between two distal age cohorts of lesbian and bisexual women; under 30 years and 40 years and over. 128 lesbian and bisexual identified women aged 19 to 65 years completed an online survey. IH scores for the two cohorts were analysed using a one-way between groups analysis of covariance (ANCOVA), with perfectionism and lesbian/gay community attachment as the covariates. Three factorial between groups analysis of variance (ANOVA) were employed to examine the relationship between IH and the mental health outcomes of depression, anxiety and stress. The age cohorts differed significantly on IH with the younger cohort having significantly higher mean IH scores than the older cohort. Results indicated that only sense of community significantly affected IH scores. Results also showed that high levels of IH were significantly related to depression, anxiety and stress regardless of age. This study provides evidence for the association between age cohort and IH, as well as verifying the link between lesbian/gay community attachment and IH and the association between IH and the mental health outcomes of depression, anxiety and stress. This study suggests that IH is an important psychological process in the health of lesbian and bisexual women that is impacted upon by social factors. Although IH appears to be stronger in the younger cohort, high IH levels prove to be harmful no matter what the age, indicating the significant role IH plays in the life of lesbian and bisexual women and the need for IH to be addressed at both the individual and social level.

**Keywords:** internalised homonegativity, perfectionism, lesbian women, bisexual, depression
Investigation of the cognitive process of evaluating student learning outcomes by means of the university evaluation reports

There is an increasing demand for measuring student learning outcomes to improve the quality of education in higher education. A fundamental question is what is the important evidence that reflects the effect of the increase and decrease of student learning outcomes. In the psychological field, psychometric approaches to develop objective tests to measure the ability of student learning outcomes have suggested some standardized tests. These are useful methods to measure learning outcomes based on the students’ achievement. In our approach, we attempted to measure learning outcomes based on the effectiveness of institutional performance, not on the student achievement itself. Effectiveness of institutional performance is usually measured in documents (text, numerical data) and site visit analysis by evaluators (academics, experts, presidents). Therefore, we analyzed the cognitive process of evaluator’s judgment of rating the universities by means of the university evaluation data. The aim of this study was to clarify the key evidence for learning outcomes focusing the attention on the evaluator’s judgment process of effectiveness of institutional performance. As a data, we extracted the part of the evaluation reports of the National University Corporation Evaluation (reported in 2009, Japan), which concerns the description of the learning outcomes. The data consisted of the results of evaluation judged by 4 point scale and the text data which shows the reason they used for the judgments for 357 departments of 87 universities. The relationship between the categorical judgment toward the departments and the variety of description on the text were analyzed by experts. The result showed that two types of information were used for the judgment of learning outcomes on the text. One is the quantitative information expressed by indicators (e.g. graduation rate, employment rate, the number of awards). The other is qualitative information expressed by institutes’ practices. From the quantitative information, differential thresholds of each indicator and the frequency of the appearance were measured. This revealed the evaluator’s tendency for categorizing the effectiveness of institutional performance. Some useful evidences for measuring the learning outcomes were suggested analyzing the evaluator’s cognitive process. This result is applicable to university evaluation.

Keywords: evaluation, student learning, university, quality of higher education, institutional performance

Investigation of the relationship between emotional intelligence and social adjustment and academic achievement of guidance school students in Tehran, Iran 2008

MOHAMADTABARKASGARI, S. (Allameh Tabatabaei University), TAHERI, M. (University of Tehran)

The aim of this study was to investigate the relationship between Emotional Intelligence, Social Adjustment, and Educational Progress, as well as the difference between female students’ educational progress and male students’ educational progress in guidance school. To study the hypotheses, the sample consisted of 300 students, including 150 boys and 150 girls, selected through cluster sampling. Our data consisted of the Emotional Intelligence questionnaire of 33-questions, by Siberia Shearing, and Rotter’s Internal-External Locus of Control Questionnaire (30-questions), which ask questions about student behavior and personal information. The statistical methods used for data analysis were the Pearson Correlation and the independent t-test. According to the results, all of the hypotheses were certified. The main findings are as follows. There is relationship between emotional intelligence and students’ social adjustment; emotional intelligence and students’ educational progress; and students’ social adjustment and students’ educational progress. Furthermore, there is a difference between female students’ educational progress and male students’ educational progress. The results show the importance of emotion...
intelligence, and social adjustment for education progress. The results of this study as well as many other studies in Iran and other countries, are important for parents; many scholars; and those in charge of the country’s education (as well as those in other countries).

Keywords: emotional intelligence, social adjustment, educational progress, gender, guidance school

Investigation of the relationship between self-esteem and views of society in university students

MINEO, N. (Chuo University)

This study aimed to clarify the relationship between self-esteem and views of society in adolescence. Reviewing previous studies, it is suggested that environmental perception and self-consciousness interact with each other. The first purpose of this study was to clarify the characteristic views of society by university students. The second purpose was to clarify the relationship between self-esteem and views of society in university students. In survey 1, we categorized and organized views of society based on free descriptions by 111 students (average age=19.50, SD=1.25). In survey 2, we requested 312 students (average age=20.05, SD=1.45) to answer the questionnaire constructed from 4 scales: views of society (5-point rating scale), image of society (Semantic Differential method, 7-point rating scale), social cognition (as above) and self-esteem (5-point rating scale). In grouping the free descriptions 12 categories were identified: “whole society”, “meritocracy”, “economy and life”, “politics”, “peace”, “culture”, “media”, “human relations”, “people”, “self and society”, “method for evaluating society”, and “unclassified item”. The results of questionnaire survey 2 factor analysis on views of society yielded 4 subscales – “negative evaluation to society”, “positive evaluation to society”, “selfish people”, and “guarantee that rewards effort”. Factor analysis on self-esteem yielded 2 subscales – “sense of self-approval” and “sense of self-inadequacy”. Cluster analysis of standardized scores on the 2 subscales of self-esteem identified 4 types of self-attitude – arrogant group (high “sense of self-approval” and low “sense of self-inadequacy”), self-affirmative group (both high), equivocal group (both low), and self-abnegating group (low “sense of self-approval” and high “sense of self-inadequacy”). Four groups were compared using one-way ANOVA on 4 subscales of views of society. As a result, the main effects of group were significant on all subscales. The results of multiple comparisons showed arrogant group with significantly higher scores on “negative evaluation to society” than the other groups, and significantly higher scores on “selfish people” than self-affirmative group and equivocal group. The self-affirmative group showed significantly higher scores on “positive evaluation to society” and “guarantee that rewards effort” than the other groups. The results indicate that a more affirmative attitude to self leads to a more positive view of society.

Keywords: self-esteem, views of society, university students, self-consciousness, environmental perception

Is apathy a kind of laziness? A case study using ecological momentary assessment of a Japanese university student

OSANAI, Y. (Taisho University)

In general, we have interpreted apathy as a lazy feeling. According to the perceived apathy theory, however, domain-specific apathy (DSA) is an experience that demotivates our important activities (Osanai, 2009). The aim of this study was to find out what kind of activities apathetic participants wanted to do. This is a case study based on the Ecological Momentary Assessment. In this paper, I focused on a male university student. I gave thorough instructions to him before starting the research. I directed him to carry the questionnaire at all times and to fill out the questionnaire when he felt apathetic. In this paper, I chose the following question as an object for analysis. “If your motivation increases, what do you want to do? In addition, is it an important activity for you?” He filled out the questionnaire 11 times during the research period (March – August, 2008). Ten of these times he spoke about his studies at university. For instance, “I'd like to study more seriously. It is important for my future.” There was one response about clearing his mind, which was “First of all, I want to feel refreshed. Then, I want
to motivate myself. I think it is important for my future.” Thus, in his case, what he wanted to do when he was experiencing apathy was to study. We can picture his state of mind as "I should probably study but I don’t want to." This apathy can be classified as DSA. At the same time, we can learn that the apathy that he perceived was not a feeling related to laziness. At least in his case, we might be able to consider the apathy as a kind of obstacle. In conclusion, I think we should pay more attention to DSA so that we might have the possibility to help their symptoms.

Keywords: domain-specific apathy (dsa), laziness, male, university, case study

Is it possible to forgive a murderer?

ROURKE, J. (University of Victoria), GIFFORD, R. (University of Victoria)

Transgressions, especially traumatic ones such as the murder of a loved one, can have deep psychological and physical effects on a person. Following such a transgression, engaging in forgiveness is associated with positive well-being (Enright, Rique, & Coyle, 2000). Given that many believe certain acts, such as murder, to be unforgiveable, this could render the victim in a never-ending negative state. The aim of this study was to assess, using Enright’s (2001) widely accepted four-stage model of forgiveness, whether or not it is possible for someone to forgive murder; an act classified by many as unforgiveable. This murder case, anger was not an emotion experienced by the victim. However, she did need to acknowledge and experience other negative feelings: fear, loss and grief. Enright’s second stage (Decision) requires the victim to make a conscious, deliberate decision to forgive. In this case, forgiveness was not a conscious decision, but rather something she immediately felt in her heart, and knew must be done.

Enright’s third stage (Work) was fully applicable to this murder case. Empathy, understanding, and compassion, all core elements of this stage, were pivotal in this woman’s experience of forgiveness. Enright’s fourth stage (Discovery) was also fully applicable to this woman’s experience. This stage involves the victim moving on from the transgression and experiencing a life change as a result. Through forgiving her husband’s killers, this woman experienced a profound change in her worldview and since then, has made a career of working with offenders and lecturing nationally and internationally about the value of forgiveness. Using Enright’s (2001) model, this case study suggests that it is possible to forgive a murderer. Although the first and second were not present, at least not in the way described by Enright (2001), they could be considered present if Enright’s (2001) model addressed a broader spectrum of negative emotions (not just anger), and if it acknowledged that for some, forgiveness may be a spontaneous decision. Enright’s third and fourth phases were fully present in this particular forgiveness process.

Is it possible to guarantee quality of service and physicians' job wellbeing in emergency departments?

LISBONA, A. (Spanish National University for Distance Education), BERNABE, M. (Miguel Hernández University (UMH)), MARTÍN-ARAGÓN, M. (Miguel Hernández University), TEROL, M.C. (Miguel Hernández University)

A quality accreditation department is a management strategy increasingly common in hospitals to guarantee a quality service to citizens. However, to have certain quality indicators could reduce wellbeing of physicians due to the imposition of working procedures. The aim of this paper was to analyze physician dedication from emergency departments based on the presence of different quality indicators. The design study was cross-sectional, with a sample composed of 87 physicians from public hospitals of Alicante Province (Spain). The mean age was 40 years (SD= 7.8), and most of the participants were locums (36.9%) and civil
servants (25%). The quality indicators of departments were assessed by check-list and dedication response was measured by UWES scale (Schaufeli & Bakker, 2003). Descriptive analyses and t-tests were carried out. Results showed medium dedication levels of physicians (M=2.94; SD=.73). Physicians who are working in a department that has a defined mission, vision and objective, showed high levels of dedication (t=1.98; p=.04). However, for departments with a system to self-evaluate work results, physicians show less dedication (t=3.2; p=.00). Results suggest a relationship between quality indicators and dedication response. Discussion suggests that some quality indicators could be considered as a job demands, and practical implications are discussed.

Keywords: quality of service, physicians, emergency departments, quality indicators, job wellbeing

Islamic view of nature and values: Development of scientific thought

FARUQI, Y. (Flinders University)

This paper discusses the basic tenets of Islam and the Islamic view of nature that were influential in the development of science in the so-called ‘Golden Age of Islam’. Furthermore, it presents a discussion regarding the role that Muslim scholars played in the development of scientific thinking in the Middle Ages. They were inspired by the Islamic view of nature that is, mankind had a duty to ‘study nature in order to discover God and to use nature for the benefit of mankind’. It argues that the Muslims were not just the preservers of the ancient and Greek knowledge, but that they contributed original works to the different fields of science. This knowledge was transferred to Western Europe and subsequently played an important role in revitalizing a climate of learning and exploration in Europe, leading to the Renaissance in the sixteenth and seventeenth centuries. These findings have been the catalyst for present day Muslim scholars, who have emphasized the importance of Islamic science, as the means of understanding Western science. There is also a strong body of opinion within researchers of Islamic science that the abandonment of Islamic values and the rapid adoption of Western science and technologies have led to conflict in social, educational and scientific fields in Islamic countries. The article examines how these two views can be reconciled in order to build bridges between modern science and Islamic science.

It’s not easy to be good parents: Role obligations of parents in Chinese families

HUANG, C.H. (National Taiwan University), WEI, C.F. (Taipei Municipal University of Education)

This study used an “obligation-based” perspective taken by children to explore role obligations of parents in Chinese families. According to Huang (1989), filial piety is the most important value or moral virtue in Confucian societies. Huang (2004) and Chen (2005) proposed that vertical goals were highly valued and represented social expectation and role obligation. The Chinese also put more emphasis on face than Westerners. Furthermore, King and Myers (1977) used “moral face” and “social face” to explain the concepts of face and “mianzi”. We hypothesized that, on academic event, when parents in the stories took forced intervention, the perception of obligation-fulfilling rated by children was higher than mild intervention. In contrast, on moral event, when parents took mild intervention, the perception of obligation-fulfilling was higher than forced intervention. Participants were recruited from Taipei Municipal University of Education. There were 60 participants completing the questionnaires, with an average age of 20 years. A self-developed questionnaire was used to evaluate whether the parents in the stories fulfilled their role obligations. It was a 2 (academic or moral event) × 2 (mild or forced intervention) between-subject factorial design. Participants had to indicate how much they agreed with the statements on a 6-point Likert-type scale. The main effect of parent-child conflict events was significantly different (M academic >M moral), however the main effect of intervention was not significantly different. The interaction showed
that, on academic event, the effect of intervention was significantly different (M forced > M mind), but not on moral event. The results showed that pursuing vertical goals was rated as more likely to fulfill parents' obligation from children's perspectives. After all, it is the most important parental obligation to help their children achieve vertical goals.

**Japanese life-patterns: Career development and work/family/leisure balance**

ABE, S. (Baika Women's University), YAMASHITA, M. (Kinki University), MAEDA, H. (Kobe Shinwa Women's University), YAGI, R. (International Economy & Work Research Institute)

This study was designed to examine the differences in the influences of the satisfactions with work, family, and leisure on the perceived happiness among three levels of career development. 1770 participants responded to a questionnaire survey. Survey items were Career Development Scale (15 items, 5-point scale), Work, Family, and Leisure Satisfaction (each 1 item, 5-point scale), and Perceived Happiness (2 items, 5-point scale). In order to compare the models of relationships among the levels of Career Development, path analysis using structural equation modeling (simultaneous analysis of multiple groups) was conducted. The results showed that Perceived Happiness was mainly affected by the Family Satisfaction. In addition, it was also found that the higher the level of Career Development was, the more strongly the Work Satisfaction influenced the Perceived Happiness. From the results, it was suggested that the importance of taking career development into consideration in discussing the work-life balance.

**Keywords:** satisfaction, perceived happiness, career development, work-life balance

**Knowledge, attitudes and perceptions of secondary school learners in selected South African schools towards HIV and AIDS**

SODI, T. (University of Limpopo), MUTHIVHI, E. (University of Venda), MAUNGANIDZE, L. (University of Venda)

In Sub-Saharan Africa, HIV/AIDS has reached epidemic proportions and is considered to be the leading cause of death. In light of this sad picture, it is important to put in place measures to prevent the spread of the epidemic. Such preventive measures will need to be supported by research that would shed light on HIV/AIDS. The aim of the present study was to assess the level of knowledge, attitudes, and perception of secondary school learners towards HIV/AIDS. The adapted version of the Human Science Research Councils’ KAP Survey questionnaire was administered to Grade 10 to 12 learners in two secondary schools in Vhembe district, in Limpopo Province (South Africa). The systematic probability sampling process was followed. In each school, participants were selected randomly, using the school register. The majority of the participants (71%) were found to be aged between 14 to 18 - an age category that is expected to be in Grades 10 to 12 in South African schools. The study found that the two main sources of HIV/AIDS information were radio and television, with the internet, magazines and newspapers being less popular sources of information. Regarding knowledge about HIV/AIDS, the majority of the participants considered sharing injection needles with a HIV positive person and unprotected sex to be the two main sources of HIV transmission. In terms of attitudes towards HIV/AIDS, the responses were found to be mixed. Though most participants’ perception of HIV/AIDS was positive, there were considerably large numbers of participants who seemed to have misconceptions about this viral condition. Based on these results, it is recommended that government sponsored HIV/AIDS awareness campaigns like Khomanani National Government Campaign, Soul City, Soul Buddyz, Love life, Gazlam, TshaTsha and Takalani Sesame should be continued.

Language syndromes in childhood in consequence of lesion of the brain structure and in consequence of dysfunction of cerebral regions

ALEXANDROVA, N. (Deutsch-Russische Sprachbrücke e.V.)

Rapid and complete rehabilitation of the verbal communication in aphasia in childhood in consequence of lesion of the brain structure is thought to be the brain plasticity phenomenon. At the same time in some forms of aphasia and in case of Landau-Kleffner-Syndrome (LKS), contrary to established opinion about the greatest plasticity of brain in early childhood, the prognosis of the disease can be poor and the language communication stays undeveloped. The aim is to expose the dependence of the involution of aphasia in childhood on its etiology and on the nature of disorder. Aphasics in childhood described in literature can be divided into the following groups: Aphasics in consequence of structural brain injury, LKS, a combination of the syndromes mentioned above and the description of aphasia corresponds with LKS diagnostic criteria, but the authors call it “aphasia in childhood”, “Wernicke aphasia”, “sensory aphasia.” Aphasics in childhood as a consequence of structural brain injury and LKS differ in course, symptomatology and outcome as well as in the correlation of the age of the onset and the prognosis for the disease. In aphasia as a result of structural brain injury, the prognosis is better in cases of injury in early childhood, on the contrary in cases of LKS the prognosis is better when the onset is in the school age. The two types of language disorders in childhood (in consequence of lesion of structure and in consequence of dysfunction of cerebral regions) are at the same time identical and different in their characteristics. The symptoms of the fall-out are identical: both destruction and dysfunction of the definite cerebral region lead to the similar manifestation which is connected with the specificity of functioning of the corresponding cerebral region. But the course of disease, the possibility of compensation and the outcome of organic and dysfunctional language syndromes are different. Each having their own logic in development.

Keywords: aphasia, brain plasticity phenomenon, Landau-Kleffner-Syndrome, verbal communication

Lay people’s beliefs on how to psychologically cope with a disaster

SANZ, J. (Complutense University of Madrid), GARCÍA-VERA, M.P. (Complutense University of Madrid), GUTIÉRREZ, S. (Complutense University of Madrid)

A fairly extensive body of literature now exists on mental health literacy (lay people’s knowledge and beliefs about mental disorders which aid their recognition, management or prevention), but that literature is mainly focused on disorders such as depression and schizophrenia. Very little research has been done on post-traumatic stress disorder and, especially, on how to psychologically overcome a disaster or a similar traumatic event. The aim of this study was to examine lay people’s beliefs about the usefulness of different behaviors to cope with a disaster. A sample of 576 Spanish adults (52.6% females; age range 18 -85 years; mean age = 38.5 years) completed a questionnaire and rated the perceived efficacy of 28 different behaviors for overcoming a disaster. The questionnaire was derived from a content analysis of salient literature, especially self-help guides covering such topics as disasters, trauma or post-traumatic stress disorder. The coping behaviors perceived as more useful were those focused on seeking social support, doing relaxing-enjoyable activities, accepting the situation as a challenge, and replacing negative thoughts with ones that promote good mood. Coping behaviors not recommended by self-help guides (e.g., withdrawing from family and friends; thinking about the “why”) were also rated as less useful by participants, but some coping behaviors recommended by self-help guides (e.g., finding out about the impact of trauma and what to expect) were underrated. ANOVAs and t-tests revealed some sex and age differences on the perceived efficacy of coping behaviors. Spanish lay people have beliefs on how to overcome a disaster and its consequences that, in general, are coherent with those proposed by professionals. However, misconceptions about the usefulness of some coping behaviors still prevail among the Spanish general public. Future
self-help guides and educational materials aimed at the general public should concentrate their efforts on those misconceptions.

**Keywords:** disasters, mental health literature, post-traumatic stress disorder, lay people's beliefs, coping strategies

**Lay people's knowledge about the psychological consequences of a disaster**

SANZ, J. (Complutense University of Madrid), GARCÍA-VERA, M.P. (Complutense University of Madrid), GUTIÉRREZ, S. (Complutense University of Madrid)

Research on mental health literacy (lay people's knowledge and beliefs about mental disorders which aid their recognition, management or prevention) has made considerable progress over the past 15-20 years, but it has been mainly focused on depression and schizophrenia, and other mental disorders have been neglected. The aim of this study was to examine lay people’s knowledge about the psychological consequences of a disaster, especially about post-traumatic stress disorder (PTSD) symptoms. A sample of 601 Spanish adults (56% females; age range 18-88 years; mean age 37.8 years) completed a three-part questionnaire and rated with what frequency PTSD and other psychopathological symptoms, as well as some positive psychological reactions, might appear after a disaster in mild-moderated injured victims, relatives and friends of deceased victims, and general people living in the area where the disaster occurred. Participants rated that, after a disaster, PTSD symptoms falling into the general clusters of re-experiencing and arousal, symptoms of other anxiety disorders, and posttraumatic growth experiences are more frequent in injured victims than PTSD symptoms falling into the cluster of avoidance (except for avoidance of thinking about the trauma, avoidance of reminders of the event, and psychogenic amnesia) and depressive symptoms. This pattern of ratings was different for the affected general population or the relatives and friends of deceased victims (e.g., depressive symptoms were rated as equally or more frequent than PTSD symptoms in relatives-friends). Spanish lay people are reasonably knowledgeable about the psychological consequences of a disaster. However, misconceptions about some PTSD and depressive symptoms still prevail among the Spanish general public. Future educational materials aimed at the general public should concentrate their efforts on those misconceptions.

**Lay theories of depression in Japan: Analysis on answer data of a knowledge sharing community site**

KATSUYA, N. (Nihon University), OKA, T. (Nihon University), SAKAMOTO, S. (Nihon University), ASAKAWA, A. (Nihon University), YAMAMOTO, M. (Nihon University)

We investigated the lay theories of depression among Japanese. People have formed their naive theories based on their direct and/or indirect experiences on mental illnesses such as depression. These naive theories include the causes, characteristics, and treatments of mental illnesses. We predicted these lay theories may be expressed through different kinds of communication media such as the Internet. Thus, we examined the contents of an online knowledge sharing community site to extract these lay theories. We analyzed the log data of one of the most popular knowledge sharing community sites in Japan, Yahoo! Chie-bukuro ('Yahoo! Answers' in English) that were provided by Yahoo Japan Corporation to the National Institute of Informatics. Users of this site post various kinds of questions and/or post the answers to these questions. Out of over three million questions posted from 2004 to 2005, we selected 3866 questions which included the word "depression". In addition, we coded and selected the questions which referred to the characteristics of depression, such as "what is depression" (Characteristics)? and the questions that referred to the diagnosis of depression such as "Is it depression" (Diagnosis)? Then, we examined the contents of answers to these questions using text mining software. Out of the questions that gained over ten answers, highly-frequent questions are about coping with symptoms, image of depression, negative
reaction from others, and the characteristics of depression. Some answers were posted by a person who has experienced depression. As for the Diagnosis questions, the words expressing depression co-occurred with the words “oneself”, “human”, “hospital”, “symptoms”, “psychic treatment internal medicine”. Cluster analysis indicated clusters about symptoms, disease, consultation, and background. As for Characteristic questions, the words expressing depression co-occurred with the words “human”, “oneself”, “symptoms”, “disease”, “medicine”. Cluster analysis indicated clusters about symptoms, vulnerability, and background.

In a knowledge sharing community site, many questions about depression were posted and gained many answers from many different kinds of people based on their direct and indirect experience. Knowledge sharing community sites may play a role not only as information sharing media but also as self-help groups.

**Leader’s color preference and subordinate’s perception of leadership style: The moderating role of gender differences**

YU, K. (Peking University), WANG, L. (Peking University), XIAO, S. (Peking University), SHI, S. (Peking University), HU, Y. (Peking University)

Subordinate’s perception of leadership style has important practical implications in modern organizations. Researchers have been exploring many factors that could impact on it. This study aimed to examine the relationship between leader’s color preference (black or white) and subordinate’s perception of leadership style, and the moderating effect of subordinate’s gender. Two hundred and fifty-three participants from 6 organizations were randomly assigned to two groups. Participants in each group read a simple description of a fictitious leader with the same traits (such as intelligent, diligent, deft, etc.) and the leader’s color preference of either black or white for each respective group. After this, participants were required to imagine the leader’s characteristics and then rate the leader on the 15-item Paternalistic Leadership Scale, which included dimensions of authoritarianism, benevolence, and morality. Results showed that leader’s color preference did not show a significant effect on subordinate’s perception of leadership style. However, the interaction between color preference and the subjects’ gender is significant in two dimensions of leadership styles. For benevolence, male subjects rated the leader higher on this dimension when the leader liked white ($t = -2.794, p < .01$), while female subjects’ judgments were not affected by color preference of the fictitious leader ($t = .895, p > .30$). For morality, male subjects’ judgments were not affected by color preference of the fictitious leader ($t = -1.349, p > .15$), whereas female subjects judged the black-preference leader higher in morality ($t = 2.084, p < .05$). For subjects’ rating on the leader’s authoritarian, the interaction between subject’s gender and the leader’s color preference fell short of significance ($F = .098, p > .10$). Based on the above results, color preference of the leader was found to be a factor for the subordinate’s perception of leadership style, whereas gender differences played a moderating role in two of the three dimensions of leadership style: benevolence and morality. The relationship between leader’s color preference and subordinate’s perception of leadership style differs among subjects with different gender.

**Keywords:** leadership, leadership style, subordinates, colour preference, gender

**Leadership and safety behaviours in nuclear power plants: A structural equation model**

GRACIA, F. (University of Valencia), MARTÍNEZ CÓRCOLES, M. (University of Valencia), TOMÁS, I. (University of Valencia), PEIRÓ, J.M. (University of Valencia)

The aim of the present study was to determine how leader behaviours influence employee safety behaviours. From the Empowering Leadership model (Arnold et al., 2000) to conceptualize leadership and determine the specific mechanism by means of which leaders influence safety behaviours, two important factors (safety culture and team safety climate) have been included to help us hypothesize a safety model. The proposed model tested the
following hypotheses: 1) leader behaviours will influence employee safety behaviours by means of safety climate; 2) safety culture will be a modulator in the relationship between leadership and team safety climate; 3) safety culture will predict team safety climate; and 4) safety culture will predict employee safety behaviours. Our sample was composed of 566 workers from a nuclear power plant. The four variables were assessed using four questionnaires which measured leadership, team safety climate, safety culture, and safety behaviours. Four confirmatory factor analyses conducted with Lisrel 8.8 (Jöreskog & Sörbom, 2006) supported the one-factor structure in each questionnaire. With the purpose of providing our hypotheses with empirical support and to test the proposed model, a structural equation analysis based on Lisrel 8.8 was performed. All coefficients in the tested model were statistically significant \(p<.01\) and the four hypotheses were confirmed. The goodness of fit indices values provided evidence that the proposed model was empirically significant \(\chi^2=4.36, df=2, p<.01;\) \(\text{RMSEA}=0.053;\) \(\text{CFI}=1.00;\) \(\text{NNFI}=0.99;\) \(\text{AGFI}=0.97).\) When strong safety culture exists, both empowering leaders and non-empowering leaders are more likely to create a team safety climate than if safety culture is weak. Better safety results are obtained when safety culture is combined with empowering leadership. Empowering leaders in organizations with a strong safety culture will contribute to a more developed team safety climate and, as such, to a higher number of safety behaviours.

**Keywords:** nuclear power plants, leadership, safety, safety, structural equation model

### Leadership and value congruency

**STAUfENBIEl, K.** (University Münster), **ROWOLD, J.** (University Dortmund), **HELL, W.** (University Münster)

The aim of this study was to test the influence of value congruency between leader and company on value-based aspects of the leadership behaviour, such as the communication of values. Since there are more and more companies defining their own values, there is an urgent need to investigate the influence of these values on the behaviour of the company’s leaders. The hypothesis was that value congruency would not have an affect on transactional leadership behaviour but would influence transformational, ethical and authentic leadership behaviour. A good fit between the values of the company and those of the leader was assumed to go along with an augmented extension of transformational, ethical and authentic leadership behaviour. Data was collected in an institution for elderly and disabled people. Leadership behaviour of 35 leaders was evaluated by at least one direct employee. The leaders completed a questionnaire about their personal values which were subsequently analyzed in relation to congruency with the company’s values. The collected data disproved the hypothesis. Value congruency was unrelated to transformational, ethical and authentic leadership behaviour. However, in post hoc analyses, significant correlations between leadership behaviour and single types of values were found. For example transformational leadership correlates with the value type “achievement“. Another post hoc analysis confirmed the interrelation between value congruency and affective commitment that has been previously reported in the literature. Leaders are able to lead in a transformational, ethical and authentic way even if their personal values are not in congruence with the official values of the company. Therefore, companies can teach theirs leaders to communicate the values the company stands for. Following this study there was no need to assess the leaders’ personal values for personnel selection and development. However future research should investigate whether the congruency of values has an impact on leaders’ well-being.

**Keywords:** leadership, value congruence, company, leadership behaviour, values

### Learn yoga to improve mental poise

**KHANNA, D.** (Panjab University), **LOHAN, U.** (Kurukshetra University), **KHANNA, M.** (D.N College, faridabad, Haryana)

The aim of this electronic poster is to highlight the significance of yoga for improving mental poise and fitness. It will also focus on the various yogic strategies through which one can improve one’s mental poise. To achieve the above aim,
the poster will depict various Yogic techniques of Ashtang Yog which can improve our mental poise. Asanas, Pranayamas and various Shudhi Kriyas will specially be high-lightened to show the practical implications of these Yogic practices. It is anticipated that through this virtual presentation of different techniques of Yoga, people will learn how to perform these Yogic exercises which improves mental poise. Yoga, which is an ancient art of India and practiced for thousands years by Saints and Sages now has become a way of life. In this stressful and strenuous modernize life Yoga, if practiced daily, can become a way to improve not only physical health but also mental health.

Keywords: yoga, mental poise, fitness, stress, mental health

Learning from others and self: Reflection on experiences of success and failure

FUJIMURA, M. (Fukuoka Jo Gakuin University)

How do individuals learn to perform achievement tasks? By observing others or from their own experiences. This study investigated the extent to which individuals observe and evaluate the outcomes (success vs. failure) of the actors (others vs. self). In a questionnaire survey conducted for this study, undergraduate female students (N=121) were asked to list two tasks that they intended to learn: one that they were highly interested in and one for which they had a low level of interest. Two versions of the questionnaire (high-interest tasks vs. low-interest tasks) were used, and the participants were instructed to evaluate their experiences (instances of other’s success, other’s failure, own success, and own failure). Further, we assessed their responses, observations, and reflections using a 2 (outcome: success vs. failure) × 2 (actor: others vs. self) within-subjects factorial design. The result showed that the participants observed the high-interest task higher than the low-interest task. Further, a 2 (outcome) × 2 (actor) ANOVA on the reflections was conducted separately for both tasks. The analyses for both tasks revealed that there was no significant main effect and significant one-way interaction between the outcome and the actor (high–interest tasks: F(1,120)=92.70, p < .001; low–interest tasks: F(1,120)=52.91, p < .001). The simple-effects tests revealed that the participants evaluated other’s success higher than their own success, they focused on their own failure more than other’s failure, and they equally evaluated their own failure and other’s success for both the tasks. These results suggest that with regard to performing both high- and low-interest tasks, individuals learn from others as well as from their own experiences. The investigation of the effect of reflection on self-efficacy and motivation for learning tasks remains an important issue for future research.

Keywords: success, failure, achievement tasks, learning tasks, reflection

Linking career theories in counseling psychology to volunteerism

MICHALOS, S. (Cleveland State University)

Within counseling psychology, the study of careers and vocational interests has extensively been explored. The extant literature focuses on the interplay between prominent career theories and a whole slew of other factors including career choices for women, different ethnicities, age groups, and the disenfranchised. Of course, the literature is not limited to only these variables, but there is a distinct lack of literature and research on how career theories are linked to volunteerism. The purpose of this review is to examine the extent to which career theories are linked and connected to volunteerism in America. Of the numerous career theories that aid in explaining career development Holland, Super, and Lent will be described. The content of this electronic poster will explore the theoretical links between prominent career theories and volunteerism. There will not be a method or results section. Future research studies should be conducted to validate what areas of volunteering match career interests. In addition, researching career constructs in terms of volunteering can further validate the theoretical link between career and volunteerism. The reader will be able to articulate the connections between “good,” well-meaning individuals and volunteerism and the benefits volunteering provides. In addition, potential research studies will be discussed to
further validate the link between career theories and volunteering, as well as, the large-scale benefits that volunteerism provides.

Keywords: counselling psychology, volunteerism, America, career development

Longitudinal twin study comparisons between high ability reading and low ability reading groups: Preschool through Grade 2

MCGOWAN, D. (University of New England)

The study addressed the question of whether Low Ability (LA) reading looks genetically and environmentally more like High Ability (HA) reading or normal range. It was hypothesized, heritability of LA reading will be lower than HA reading as shared environment will be a bigger factor at the low end of the continuum and genes a bigger factor at the high end. This was a genetically sensitive longitudinal study of same-sex twins from preschool through grade 2 (max n=993) from the US, Australia and Scandinavia. Two sets of probands were selected, 1 SD or 1.5 SD above or below the sample mean. Standard print knowledge, reading and spelling tests administered. Scores were standardised and behavioural genetic analysis carried out. Analyses indicated genetic influence; strong (.51 to .82) from kindergarten through grade 2 and modest in preschool (.26) for the complete sample (preschool n=993; kindergarten n=938; grade 1 n=876; grade 2 n=827). The shared environmental influence; strong in preschool (.56), modest in kindergarten (.30) and small in grades 1 and 2 (.07 and .03 respectively).

Analyses of the extreme groups of readers at both ends of the spectrum showed lower genetic influence for the LA group compared to the HA group for each year level and a higher or equal shared environmental influence for the LA group compared to the HA group for each year level. This study, which provides a first time examination of the full range of reading abilities in the same sample, suggests there is substantial shared environmental influence for the LA group that is not seen in the normal range or for the HA group by grade 1. Shared environmental factors may be preventing the expression of the good genes so children who are not at genetic risk of becoming poor readers are failing to learn to read and appear in the LA grouping. These children are likely to respond well to intervention and reach grade level outcomes. The children who fail to reach grade level outcomes with the same intervention may have bad genes supported by an impoverished literary home environment. This group probably needs more intense and longer intervention programs.

Keywords: reading, high ability reading group, genetic influence, shared environmental influence, interventions

Looking for an ideal boss - employees’ vision in different cultural contexts

PELLEGRINI, M. (IIIT), SCARATTI, G. (Cattolica University of Milano), NOCERA, A. (University of Verona), PAPPALARDO, P. (University of Padova)

The objective of this research (in a cross-cultural prospective) is to explore the perceptions of employees in great detail concerning what they recognize to be the ideal leader. The sample consists of a group of 600 employees, working in 42 European companies in various sectors (industry, distribution, energy, finance, service and food). The survey instrument is an on-line questionnaire (126 items) on Leadership-style Grid feedback 360° (Blake and Mouton - Managerial Grid Model). The main focus is on employee’s ideal leadership style, with comparisons in three different cultural contexts (Italy, Germany and Czech Republic). By using the non-parametrical method, Kruskal Wallis, we noticed significant differences in all analyzed profiles. Post hoc analysis (pglobal = 0.01/3=0.003; pglobal = 0.05/3 = 0.017; Bonferroni’s correction) highlights that Italian employees distinguish themselves from Germans and Czechs on 9.1 style (mr(I) = 68.32, mr(D) = 44.23, mr(CZ) = 41.50) and from Czechs in Opportunistic style (OPP; mr(I) = 58.40, mr(CZ) = 45.93) and 1.1 style (mr(I) = 58.63, mr(CZ) = 44.53), Germans from Czechs in 1.9 style (mr(D) = 56.87, mr(CZ) = 37.37) and 5.5 style (mr(D) = 40.06, mr(CZ) = 58.34) and Germans differentiate from Italians in 9.9 style (mr(I) = 36.97, mr(D) = 61.81). In addition, Germans differentiate from Czechs and Italians in the Paternalistic style (PAT; mr(I) = 57.67, mr(D) = 31.81, mr(CZ) = 63.04). Lastly, Italian employees
describe their ideal leader to present a marked orientation to results with an inclination to the opportunistic style, whereas German employees describe their ideal leader to be able to balance result-orientation with relation-orientation and, in general, be less paternalistic than the Italian and Czech ideals.

Keywords: ideal leader, employee perceptions, managerial grid model, leadership orientation, paternalistic leadership

Magnetic stimulation affects the visual spatial remapping mechanism in the brain

CHOU, Y.J. (National Dong Hwa University), CHANG, W.C. (National Dong Hwa University)

The present study aims to determine the relationship between the spatial remapping mechanism and the moving directions of saccadic eye movement, as well as the brain regions in charge of the remapping system, using Transcranial Magnetic Stimulation (TMS) and the eye tracker. The study was a within-subject design, with three independent variables: saccade direction (left to right, right to left, top down, and bottom up); time from saccade onset (within 200ms and others), and TMS (real TMS or sham-TMS). The participants’ task was to trace the dots on the screen and orally report the position of a bright green probe. At the same time we used the eye tracker to record the relative time between the probe onset and the saccade onset time. Real TMS and sham-TMS were discharged randomly in three brain regions, FEF, LIP, and V5, in the cerebral cortex. The dependent variable was the magnitude of mislocalization, i.e. the difference between the apparent position and the real position, in visual degree. The results showed that the largest magnitude of mislocalization was found for the direction of bottom up, compared with others. Furthermore, it was significant that the effect of TMS interfered with the magnitude of mislocalization when applied on the brain regions.

Keywords: magnetic stimulation, visual spatial remapping, brain, saccadic eye movement

Making of a medical professional: The role of resident training

HORNG, R-Y. (National Chiao Tung University), HOU, S-H. (National Chiao Tung University), WANG, Y-D. (National Chiao Tung University), HORNG, R-Y. (National Chiao Tung University)

Medical practices involve complex technical, legal and social systems. Long periods of residency training are thus required before a beginning doctor can practice medicine independently. During residency training, a beginning doctor practices medicine under close supervision of senior doctors. This kind of supervised learning is essential to assist the smooth transformation of a beginning doctor to a competent medical professional. This study aimed to investigate the role of residency training in the development of a competent medical professional and to propose a model of professional development in medicine. Twenty attending doctors (senior, 11; junior, 9) were interviewed about their learning experiences during residency training. Senior and junior attendings’ responses were analyzed to extract similarities and differences regarding their views on the role of residency training on practicing medicine as a professional. Consensus and differences between senior and junior attendings’ views on the role of residency training suggest that beginning doctors do not have the competence to practice medicine independently. Medical practice requires not only medical knowledge, but also knowledge of the environment which supports medical practice and knowledge about the patients and their social milieu. Moreover, medical profession requires not only medical competences, but also the attitude, awareness and commitment to the life-long learning and the deep reflection upon the meaning of the profession. Senior doctors play a significant role in mentoring the resident doctor’s development into a responsible medical professional. Medical education is not complete upon the graduation from the medical school. The making of a doctor requires long and extensive clinical practices during which senior doctors must help educate their juniors to become a competent medical professional. Medicine places a very high standard for the performance quality of its practitioner, the
Management aptitude and its influencing factors: A case study of two private enterprise founders and their top management teams

YONGRUI, L. (Beijing Normal University), YIBEI, L. (University of Colorado at Boulder), LIHENG, X. (Beijing Normal University)

The aim of this poster was to investigate the management aptitude of the founders and their top management teams of private enterprises in China. Biodata interviews and questionnaires were utilised. Firstly, two investigated founders not only possessed the common traits of entrepreneurship including self-confidence, dominance and administrative skills, contingent, enterprising and hard-working, but also personal trait of tackling interpersonal difficulties. Secondly, family and education background, some key events of life experience as well as personal values and business philosophy impacted on the formation and development of the founders’ management aptitude respectively. Thirdly, the formation and development of Top Management Team’s management aptitude was mainly affected by the founder’s personal characteristics, also closely linked with the needs of the industry characteristics. There are certain commonly shared psychological characteristics of top managers under the current Chinese cultural background.

Keywords: management, China, entrepreneurship, psychological characteristics, personal values

Measurement equivalence of the 15-item version of the Workaholism Battery across workers from New Zealand and Taiwan

HU, C. (National Chengchi University), WANG, Y. H. (National Chengchi University), HUANG, J.C. (National Taipei College of Business), MCMILLAN, L. (Simply Strategic)

The phenomenon of workaholism is worldwide and prompts the need to examine whether measures of workaholism developed in the U.S. can be applied in other countries. The Workaholism Battery developed by Spence and Robbins (1992) has been used to measure workaholism in different countries and merits research attention on its construct equivalence across different cultural settings. We collected data from full-time employees in New Zealand (N = 320) and in Taiwan (N = 1226). Consistent with the existent empirical studies that examined the factor structure of the Workaholism Battery using the original 25-item scale, both samples were also not able to replicate the workaholic triad proposed by Spence and Robbins (1992). Therefore, we examined the measurement equivalence of the shortened 15-item version of the Workaholism Battery proposed by Huang, Hu, and Wu (in press). Confirmatory factor analyses were used to examine the construct validity of the scale within each sample and the measurement equivalence across the two samples. Cluster analysis was used to examine whether different types of workaholics can be formed within each sample. Results of single-group confirmatory factor analyses provided support for the convergent and discriminant validity of the 15-item Workaholism Battery within each sample. Results of multi-group confirmatory factor analyses suggested that configural invariance, partial metric invariance, and partial scalar invariance were established. Furthermore, different types of workaholics can be differentiated based on their scores on the 15-item Workaholism Battery. Based on the above results, both samples perceived workaholism as a three-factor concept, different types of workaholics can be identified by the 15-item Workaholism Battery, and cross-cultural comparisons of latent means is feasible. Implications for future workaholism research and managerial practice are discussed.

Keywords: workaholism, cross-cultural, construct validity, managerial practice

Measuring self-perceived employability of Chinese college graduates

Luo, Z. (Chinese Psychological Society), Fu, J., Zhang, T.
Employability is a critical requirement for college graduates to obtain career success. The primary objective of this study was to develop a reliable and valid instrument for measuring self-perceived employability of graduates in Chinese colleges. Based on interview (19 graduates), open-ended investigation (310 college students), enterprise discussion (18 human resources managers), and counseling of experts (12 college vocational advisers), the study made a survey about factors which influence college students successful employment. An employability questionnaire for college graduate students was constructed according to the survey. Exploratory Factor Analysis (EFA) (a sample of 550 graduates) and Confirmatory Factor Analysis (CFA) (a sample of 978 graduates) were performed, and the relationships between employability with other measures were examined. EFA found that the self-perceived employability of Chinese college graduates consists of 4 dimensions: personal trait, vocational ability, practice experience and job-search methods. The scale has a satisfactory reliability (internal reliability: $\alpha = .964$, retest reliability is 0.690) and a satisfactory validity (CFA: $\chi^2/df = 3.221$, GFI=.870, AGFI =.856, IFI =.907, TLI =.902, CFI = .907, RMSEA =.048). The correlation between employability and job-search self-efficacy is .682. These findings support that the four-factor-model is valid; the scale can reliably measure the self-perceived employability of Chinese college graduates.

Keywords: employability, college graduates, career success, job search, Chinese

Memory impairment in Parkinson`s Disease

Parkinson`s disease (PD) is a neurodegenerative disorder characterized by motor and cognitive impairments. In relation to cognitive impairments, memory deficits are frequently reported. The nature of this memory dysfunction is not known yet. PD has been related to a pattern of impairment on memory task associated with executive dysfunction. Recent findings, however, suggest that PD patients exhibit deficits due to a specific memory dysfunction. The aim of our research is to provide clear evidence that memory process are not intact in PD. We evaluated 20 patients with PD without dementia and 15 participants from the general population matched for age and educational level. To study the executive implication in memory deficits, we analyzed the performance in tasks of free recall, cued recall and recognition, and in tasks with high and low cognitive demands. A profile analysis revealed that patients with Parkinson`s disease exhibited: 1) deficits in free recall tasks that did not improve significantly when external cues were provided or when recall was requested by recognition, and 2) deficits in tasks with high cognitive demands that did not significantly improve when those demands were reduced. Memory deficit in PD cannot be reduced to a failure in the executive function but are due to a specific process deficit.

Keywords: Parkinson’s disease, cognitive impairment, memory impairments, executive dysfunction, free recall tasks

Men charged with domestic abuse: Forensic contrast study

ARMAS-VARGAS, E. (Universidad de La Laguna), BENCOMO-HERNÁNDEZ, I. (Instituto de Medicina Legal), MARTÍN-CABALLERO, R. (Universidad de La Laguna), BETHENCOURT-PÉREZ, J.M. (Universidad de La Laguna)

The Courts of Violence against Women look for the assessment of men charged with domestic abuse in parallel with the psychological evaluation of female victims. The following are included among the forensic criteria taken into account in the assessment of men charged with domestic abuse: self-esteem, anxiety, personality, distorted thoughts, habitual violent behaviour in situations of domestic abuse, relationships, communication, criminal and psychopathological records, consumption of toxic substances, psychological treatments, jealousy, aggressive behaviour (verbal and physical), irritability, negativity, hostility, lying, resentment, impulsivity, anger, irrational beliefs
about women, danger, history of violent behaviour, empathy, etc. In our study, we wished to bring to forensic psychological assessment other variables that have been demonstrated to have valid content and discriminant significance. We used 22 variables of personality (ATRAMIC) and 4 variables of self-esteem (CAE). The sample comprised 102 males, of which 39 were in the control group (social skills workshop), 32 in the clinical group and 31 in the forensic population (charged with domestic abuse against their partners). We wished to explore whether there were differences between the groups (clinical, forensic, and control) in the variables or criteria described; and identify predictive factors using discriminant analysis. Results showed the following: (1) Using the discriminant function, $81\%$ of the cases in the control group and the men charged with domestic abuse group were correctly classified. The variables with the highest discriminant power were: Fear of Rejection of Criticism, Extreme Caution, Transparency, Hypercontrol, Guilt and Empathy; (2) in the control and clinical groups, the discriminant function correctly classified $78\%$ of cases. The variables with the highest discriminant power were: Failure to make Adjustments when Lying, Selective Privacy, and the variable “I-self”. Furthermore, (3) in the clinical group, and men charged with domestic abuse against their partners group, the discriminant function correctly classified $87\%$ of cases. The variables with the highest discriminant power were: Failure to make Adjustments when Lying, Self-Deception, Self-Control when Lying, No Honesty or Admission that they had Lied, Mistrust, Insecurity, Hypercontrol, Control, Self-Criticism, Being Coherent and Lack of Sensitivity. To conclude, sufficient differences were found to support a sensitive model for differentiation using the ATRAMIC and CAE instruments, based on the samples used in this study.

Keywords: domestic abuse, forensics, discriminant factors, males

Mental illness stigma and contact: An integrated threat theory approach

SOEBAGYO, J. (University of Canberra), BROWN, P. (University of Canberra)

Mental illness stigma can decrease the quality of life for sufferers. It is therefore important to explore factors which contribute to stigma and to examine methods for reducing stigma. One method that has previously been successful in decreasing stigma and prejudice is providing positive contact with people with a mental illness. This study aims to explore the role of contact and to determine if the Integrated Threat Theory of prejudice (ITT; Stephan & Stephan, 2000) could be applied to an understanding of mental illness stigma. The participants of this study consisted of 222 psychology students (167 females, 57 males) studying at the University of Canberra. Participants completed self-report questionnaires relating to contact, threat, and stigma before and after participating in a mental illness education program. As hypothesised, there was a negative relationship between contact and the four threats (realistic threat, symbolic threat, intergroup anxiety, and negative stereotypes) which make up ITT. Moreover, each of the four threats and stigma had a significant positive relationship. A hierarchical regression analysis found that the four threats explained a significant proportion of the variance in stigma above that which was explained by age, gender, quality and quantity of contact. The study also aimed to explore if the positive contact provided by a mental illness education program would result in reduced stigma and perceived threat. Although stigma levels decreased after receiving the contact, this difference was only marginally non-significant. However the intervention resulted in significantly lower levels of symbolic threat, intergroup anxiety and negative stereotypes. The results of this study provide support for applying social psychological models of prejudice to understanding the stigma and prejudice associated with mental illness. The results also provide new information which may help in the fight to increase quality of life for people suffering from a mental illness.

Keywords: mental illness stigma, integrated threat theory, quality of life, prejudice, mental illness

Meta-stereotype and its effects: Based on analysis of different social classes

HE, W. (Shanghai Normal University)
The present study examined the other-stereotype, meta-stereotype, intergroup relation, and their relationships. The sample consisted of 52 higher social class members and 69 lower social class members. Two different questionnaires were constructed for higher social class members and lower social class members in a former study. Each questionnaire elicited traits constituting meta-stereotype, other-stereotype and intergroup relations (the desire for contact, outgroup attitude and perceived intergroup relation). The result showed: (1) For both higher and lower social class, most aspects of meta-stereotype were positive, while other-stereotype was relatively negative; (2) For both higher and lower social class, desire for contact was passive, outgroup attitude and perceived intergroup relation were at middle level and outgroup attitude of higher social class was significantly higher than that of lower social class; (3) For higher social class, the relationship between intergroup relation and meta-stereotype was not significant, intergroup relation was only positively related with some aspects of other-stereotype. But for lower social class, the relationships between intergroup relation and meta-stereotype, some aspects of other-stereotype were very significant; (4) In the intergroup relation structure model of higher social class, other-stereotype had a positive effect on outgroup attitude, and outgroup attitude had a positive effect on desire for contact. Meanwhile, in the structure model of the lower social class members, meta-stereotype had a positive effect on outgroup attitude, and outgroup attitude had a positive effect on desire for contact and perceived intergroup relation. In conclusion, the meta-stereotype has a significant impact on intergroup relations for lower social class while other-stereotype has significant impact on intergroup relations for higher social class.

Keywords: other-stereotype, meta-stereotype, intergroup relations, social class

Methodological aspects and psycho-social implication of the authentication counselling

DMITRIEVA, V. (Saint-Petersburg State University)
efficiency of this method applied to increase the productivity of the social operators in different areas of societal activity.

Keywords: authentication counselling, self-realization, personality, intelligence, ontopsychology

Migration and health anxiety: Explain!

WILLIAMS, K. (MENSANA Intercultural Psychological Consultancy)

In an attempt to cross-fertilize Cross-Cultural and Clinical Psychology, the presentation seeks to explain why Hypochondriasis (Health Anxiety) appears to be the “chosen psychopathology” of immigrants, when compared to natives. The proposed Control-Compensation Model of Mood-and Anxiety Disorders aims to demonstrate how the entire spectrum can be construed as attempts to (dysfunctionally) compensate for (a perceived) loss of control, with Hypochondriasis incidence found increased in migrant populations. As an advance on the Terror Management Theory (i.e. culture buffers against mortality-awareness, e.g. Greenberg et al 1997) and the Mortality Salience Hypothesis (i.e. mortality salience increases other-culture intolerance, e.g. Rosenblatt et al 1989), the presentation proposes the Reverse Mortality Salience Hypothesis (i.e. other-culture intolerance increases mortality salience, Williams 2004). Results show that when compared and contrasted, the history of empirical findings as to the above (cf Still 1961; Ward 2001), as well as the author’s own current clinical practice, reveal the robustness of the process hypothesized above. Hypochondriasis (Health Anxiety) indeed appears to be construable as one possible dysfunctional coping-mechanism used to counter the effects of Culture Shock. In conclusion, mindfulness of the proposed process-pattern, aids the attribution and treatment of Culture-Shock-induced Somatization, by orienting patients and practitioners towards Culture Learning. This would mean a timely re-focusing of resources at a time of hugely increased global mobility, like the present.

Keywords: hypochondriasis, migrants, culture shock, reverse mortality salience hypothesis

Mirror self-recognition in children with and without autism spectrum disorder

SUZUKI, K. (Tohoku University), HOSOKAWA, T. (Tohoku University Graduate School of Education), SUZUKI, T. (Tohoku University Graduate School of Education), NOGUCHI, K. (Miyagi University of Education), HONGO, K. (Tohoku University Graduate School of Education)

Several studies suggest some aspects of self-awareness are diminished and/or atypical in children with autism spectrum disorder (ASD). However, there are few studies that report whether individuals with ASD show temporally extended self-awareness (awareness of one’s place in and continued through time). In this study, we intended to examine temporally extended self-awareness in children with and without ASD, using a mirror self-recognition paradigm. The participants were 10 children with ASD (ASD group), aged 7-12 years of age (social age 2.5-4.6 years), who enrolled in a primary school for children with special needs in Sendai, Japan. The control group comprised 23 children without ASD, aged 2.5-4.5 years of age, enrolled in a nursery school in Sendai, Japan. Two visual feedback conditions were set (1-sec delayed image / live image). The task was performed in a within-subjects design and the rouge task was performed. The experimenter covertly put a sticker (2.0cm in length) on the child’s forehead and then moved the child to the front of a video screen. The child was seated facing the video screen and required to play the JANKEN (scissors-rock-paper) game with a specular image on the video screen. The child was seated facing the video screen and required to play the JANKEN (scissors-rock-paper) game with a specular image on the video screen. The responses to the covertly placed sticker (mark directed behavior) were categorized into 2 behaviors: remove or touch the sticker, and no response. In the analysis, we examined the association of mark directed behaviors with visual feedback conditions, in two groups. The percentages of children who removed or touched the sticker placed on their forehead.
were as follows; of the ASD group, 20% in the 1-sec delayed condition and 50% in the live condition; and of the control group, 48% in the 1-sec delayed condition and 65% in the live condition. Children who could remove or touch the sticker in the live condition but not in the 1-sec delayed condition comprised 30% of the ASD group and 17% of the control group, respectively. For comparison between the two groups, no significant associations were found between responses in delayed visual feedback factors and age factors (SA in ASD group and CA in control group). These findings suggest that children with ASD may be sensitive to detecting synchronicity in their own action and visual feedback in the mirror image, compared with control children who were matched on social age. Also, children with ASD may have specificity for development of temporally extended self-awareness.

**Keywords:** mirror self-recognition, autism spectrum disorder, temporally extended self-awareness, visual feedback, Japan

**Misconceptions about modern psychology among Japanese first-year university students**

NOSE, I. (Nippon Veterinary and Life Science University), KIJIMA, T. (Hokuriku Gakuin University), YAMASHITA, M. (Tokyo Ariake University of Medical and Health Sciences)

In this study, we investigated the misconceptions about modern psychology among Japanese first-year university students. We used questionnaires to identify the kind of misconceptions students have. We also identified misconceptions among Japanese correspondence course students to compare the results of both groups. Participants were 251 first-year university students (86 males, 165 females) in the faculty of human science (HS group), and 32 correspondence course students (4 males, 28 females) in the faculty of liberal arts (LA group). Most of the students in LA have employment (age range 23-66, mean age 40.9) and have already attended some lectures on psychology (as a general education). We conducted a questionnaire about misconceptions on the first day of each class the students took. The questionnaire consisted of 40 question items which seemed correct from a commonsense point of view, but were all incorrect based on the psychological knowledge (e.g., “there is no relationship between the teacher’s expectations for students and the scholastic performances of the students”). The students in HS and LA were instructed to judge whether these question items were correct. Resulting from the overall mean percentage of correct answers, the students in HS have less correct knowledge about psychology than those in LA. The question items with low percentages of correct answers in HS and LA groups included descriptions about “perception”, “memory”, “psychophysiology”, and “personality/intelligence”. These results show that the students in both groups mainly have misconceptions concerning basic psychology. The percentages of correct answers were lower in the HS group than the LA group in all of the lower 10 question items, except for the items about “psychophysiology”. We found that the students in HS have more misconceptions about modern psychology than the students in LA. We considered that this difference arises from not only the academic history of the LA group (attending lectures on psychology), but also social experiences they have had. We also found that the students in HS and LA commonly have less correct knowledge concerning basic psychology. Our results suggest the need for continuing professional education in psychology.

**Keywords:** modern psychology, misconceptions, Japan, university students, professional education

**Modeling the relations among students’ epistemological beliefs, goal orientations and cognitive engagement strategies**

LIU, P. Y. (National Dong Hwa University)

The study proposed a model to explain how epistemological beliefs and goal orientations related to cognitive engagement strategies. It is suggested that epistemological beliefs influenced one’s cognitive engagement strategies through the effects of goal orientations. Participants were 323 eighth grade students in Taiwan. The three variables were measured using the Epistemological Belief Scale, Goal Orientation Scale, and Cognitive
Engagement Scale. The data were analyzed using hierarchical regression with LISREL 8.54 and applied maximum likelihood method. The χ² (χ² (66,N=323) = 235.87, p < .05) of this model was significant, however, the goodness of fit of GFI(.91), NFI(.92), IFI(.94) and NFI(.91) values were over .90, RMSEA(.06) values was less than .05, and PGFI(.66), PNFI(.57) values were greater than .50, which is normally considered as an indication of acceptable fit. The epistemological beliefs significantly influenced deep processing strategies (β = .57, p < .001) and surface processing strategies (β = .18, p < .05) in Model One. However after mastery, approach-performance and avoidance-performance goals added, the epistemological beliefs influencing deep and surface processing strategies were not significant in Model Two. The epistemological beliefs influenced deep and surface processing strategies indirectly through mastery, approach-performance and avoidance-performance goals. This evidence showed the importance of the mediating process of goal orientations between epistemological beliefs and cognitive engagement strategies. The sophisticated epistemological beliefs positively influenced deep processing strategies and surface processing strategies indirectly through goal mastery. The naive epistemological beliefs positively influenced surface processing strategies through approach-performance goals. The sophisticated epistemological beliefs negatively influenced surface processing strategies through avoidance-performance goals.

**Keywords:** epistemological beliefs, cognitive engagement strategies, goal orientation, approach-performance goals, avoidance-performance goals

**Money and attitude: A case study among students of a private institution of higher learning in Malaysia**

MURTI SUBHAYYA, N. (International Medical University), LEE, N. (Open University Malaysia), ALI, A. (Open University Malaysia)

This study aims to investigate the perceptual attitude of students in a private institution of higher learning in Malaysia. Students’ perceptual attitude towards money was determined based on the four-factor construct, namely power-prestige, retention-time, distrust, and anxiety. This four factor construct was first developed by Yamauchi and Templer in 1982. In this paper students’ perceptual behavior was also compared according to gender, credit card usage, pre-university education, and cash affluence. The study was a survey using self-administered questionnaires. Respondents were chosen using a cluster random sampling technique. A total of 311 respondents participated in this survey. Mean scores and SDs were used to describe the money attitude pattern whilst t-tests and one way ANOVAs were used to test for significant differences according to students’ demography. Results indicate that the predominant attitude is time-retention ( = 4.25, SD = 1.02), respondents display attitude that signifies future orientation, this is followed by anxiety ( = 3.77, SD = 0.93) again related to being cautious of protection and security. The subsequent factor is distrust ( = 3.74, SD = 0.96), the feeling of hesitance, suspicious, and doubtful. The least prevalent attitude is power-prestige ( = 2.42, SD = 0.90), attitude of using money to impress and influence others. In terms of demography, gender does have some influence on money attitude; there is a significant difference between males and females on their perceived attitude towards money with regard to anxiety. Having credit cards does not influence respondents’ money attitude significantly, and pre-university education as well as the amount of pocket money does not have any bearing on students’ money attitude. Findings support existing literature and point to the importance of understanding money attitudes. Implications of the study and recommendations for further research are discussed.

**Keywords:** attitudes, money, anxiety, Malaysia, students

**Mood states, self-efficacy and collective efficacy in a young female volleyball team**

REBUSTINI, F. (Universidade do Grande ABC), MACHADO, A. A. (LEPESPE – Laboratory of Study and Researches in Sport Psychology - UNESP - RIO CLARO- SP/BRAZIL)
The aim of the present study was to evaluate the correlation of mood states, self efficacy and the perception of collective efficacy in volleyball athletes. Sample was composed of twelve female athletes (aged 14 to 15 years) belonging to a volleyball team in São Paulo. Data was gathered during 30 sessions of training and games. For the assessment of mood states it was used the POMS test, in its six variables (tension, anger, vigor, depression, fatigue and confusion) and the IEEA (Index of actual emotional equilibrium). Assessments were performed in two different moments: before and after the sessions. The first assessment (M1) was done at the moment the athletes arrived the game settings, before any contact with the training staff; and the second one (M2) at the ending of the training. For the assessment of the self-efficacy and of the perception of collective efficacy it was inserted at the POMS sheet, additional questions regarding individual self and collective perception of performance during trainings. These additional questions ranged in a scale from 1 to 5 (5: very well). For the statistics it was used the Person Correlation Test, considering significant “r” values those close to 1 for a p-value of < 0.01. Results have not shown significant correlation between questions and mood states before training (M1). However, in M2, correlating was significant among the two scales and all the mood states \( r = 0.62; p< 0.01 \). Data analyses indicate that mood states in M2 did not suffer interference of the conditions presented by the athletes in M1. Oscillations in mood states (tension, depression, anger, fatigue and confusion) showed a negative correlation. Vigor and IEEA scores presented to be positively correlated, evidencing the improvement of mood curves associates with better judgment of the performance, in the individual assessment as for the collective one. Correlations among the additional questions and the similar patterns of mood in the two scales put in evidence the influence of self-efficacy in the perception of collective efficacy.

Keywords: mood, self-efficacy, collective efficacy, athletes

Mother’s personality disposition and conduct disordered child’s perception of the mother

The present study aims to discover the personality disposition of three groups of mothers having children with conduct disorder (CDC), dysthymic disorder (DDC), and normal children (NC), as well as the children’s perception of their mothers. Participants were 30 male children in each group, aged 9 to 13 years, meeting the criteria for conduct disorder (experimental group) and dysthymic disorder (control group), and normal criterion (control group), according to the DSM IV, and their mothers were assessed. The Neo Five Factor Inventory and Parent-Child-Relationship Scale were administered on mothers and their children respectively. The mothers of CDC (CDM) and DDC (DDM) had high neuroticism and low agreeableness compared to the mothers of NC (NM). The CDM had more extraversion than DDM and NM. The CDC perceived their mothers as less loving, more rejecting, neglecting, demanding and punishing compared to the other two groups. The CDM’s extraversion and agreeableness were positively correlated with the CDC’s perception of CDM as indifferent and rewarding respectively. The relationship between extraversion and indifference suggests a lack of emotional closeness between the mother and child. The relationship between agreeableness and rewarding implies that agreeableness is a preferred characteristic in CDM. The poor score on agreeableness shows mothers’ incapability to cater to their children’s desires. The CDM’s high neuroticism and extraversion with low agreeableness, resembling an externalized pattern of behavior, could have an immense role in shaping the child’s behavior in the same direction. This personality of CDM fails to confer CDC with a stable cognitive structure for such a significant person in their lives, and cannot assure the children a sense of security. It could become difficult for a child to find a stable caregiver image of his mother owing to the cognitive competition he could face in deciphering the positive characteristics of the mother being amalgamated with a variety of negative ones, consequently forming an ambiguous cognitive structure of the mother. Presumably, a child’s immaturity makes him unable to integrate behaviour of wide variability into a meaningful gestalt perception of his mother. Thus, the child with poor attachment
perhaps develops a negative internal model of the mother which breeds ground for hostility and externalised behavior in himself.

Music effects and emotional reactions on simulated driving performance and vehicular control

BRITES, J. (Universidade Lusófona Humanidades e Tecnologias), SANTOS, I. (Universidade Lusófona Humanidades e Tecnologias), BAPTISTA, A. (Universidade Lusófona Humanidades e Tecnologias)

Road-Traffic accidents are a leading cause of death in Portugal. The automobile is currently the most popular and frequently reported location for listening to music. Music increases driving risks by competing for attentional space; the greater numbers of temporal events which must be processed, and frequency of temporal changes which requires large memory storage, distract operations and optimal driving capacities. The present study explored the effects of music on PC-controlled simulated driving and assessing emotional reactions by means of Skin Conduction Responses (SCRs) and Heart Rate (HR). The sample was composed of 39 drivers, 21 males and 18 females, with a mean age of 25.41 (SD=5.45). The participants had passenger car licenses for on average 5.5 Years. The results showed that music consistently affected both simulated driving speed and perceived speed estimates. Moreover, that simulated driving while listening to fast-paced music would increase HR and SCRs. Disregarded red traffic-lights, lane crossings, and collisions were most frequent with fast-paced music. Implications of the study point to a need for driver education courses to raise public awareness about the effects of music during driving.

Keywords: driving accidents, music, attention, Portugal

Musical ability and reading ability

AU, A. (James Cook University), MENG, W-J. (China National Institute for Educational Research), CALTABIANO, N. (James Cook University), CALTABIANO, M. (James Cook University), WALKER, A. (James Cook University)

The present study investigated whether better musical ability was related to better reading ability, on the basis that music is related to memory that is crucial to reading acquisition, music improves auditory temporal processing that is relevant to phonological processing, and children undergoing music training have improved reading skills. Forty-one undergraduates participated in various language tasks. Musical intelligence of multiple intelligence, pitch discrimination, rhythmic and melodic patterns identification and music reading were also examined. Participants were divided into high- and low-ability groups based on their overall musical ability, their ability to discriminate pitch, to identify music pattern, to read music, and their musical IQ. Results indicated that participants with formal music training were better in pitch discrimination, music reading and musical IQ. However, they did not perform better than their counterparts who received no musical training in language proficiency, irregular word and pseudo-word reading. Participants who had better musical abilities also did not outperform their low-ability counterparts in these language measures. None of the music measures correlated significantly with the language measures. It was concluded that music training, though it can improve individuals’ musical ability and musical IQ, does not necessarily lead to better reading ability. The age group of participants and the sensitivity of the music test used might provide insights on the current findings. The relationship between musical ability and reading ability requires further investigation. Practical implications of music in various cognitive tasks were discussed.

Keywords: musical ability, reading ability

Narrative family therapy, eye movement desensitization and reprocessing (EMDR) and adoption: an intervention protocol

PRADO GASCO, V. J. (Universidad de Valencia), PÉREZ-MARÍN, M. (University of Valencia), MOLERO-ZAFRA, M. (Sintest Psychologists)
From the model of Narrative family therapy we use tales that could symbolically represent in therapy settings a person or a legal entity, both individual and collective, and which expresses a personal identification, a family tie, a community link or a socially recognized status or personal worth. Externalisation, in narrative family therapy, is a process to “get out” from the person any element or quality that is transformed in some with entity (White, 1991; White y Epston, 1993). In psychotherapy, externalising is the use of language to convert problems that affect the person or family on to an independent entity. This transformation allows people to fight against them or to view them from a new perspective. Externalisation technique through the metaphoric use of tales as external representation of family entity and individual’s worth inside the family system is applied in children adoption cases. The objective here is not to fight against the external representation of the family. We use tales inside the symbolic techniques that permits families to work together with meanings, individualism and cohesion within their members, and after adoption. We present a therapeutic protocol that combined EMDR and narrative family therapy externalisation techniques. We expose in a format of clinical case report the therapeutic work with a family that have adopted a child who suffer of a simple phobia. Using the protocol we describe above we carried out an analysis of the therapeutic issues and benefices of EMDR and narrative therapy in these family processes. This protocol has been useful to manage the phobia symptoms and to improve the adoptive family identity and cohesion. The combined approach we describe could help adoptive families to understand and to interpret the meanings from the construction that family systems make of their own world and relieve psychological symptoms that children could present.

Keywords: narrative family therapy, externalisation, adoption, symbolic techniques, family identity

Need for cognitive closure and task factors on information searching behaviors on internet

CHUNG, W. (National Tsing Hua University)
The aim of this study is to explore the effects of need for cognitive closure and task factors on information searching strategies on the Internet. Need for cognitive closure refers to a desire for an answer to a question and an aversion towards ambiguity on information acquisition (Webster & Kruglanski, 1994). Meanwhile, information science researchers have long assumed that the tasks participants are engaged in are essential to information seeking and retrieval interactions (Marchionini, 1995; Wilson, 1981). Thus, this study focuses on how the two theoretical frameworks affect individuals’ information searching behaviors on the Internet. There were 92 students, mostly undergraduate in a public university in Taiwan, participating in this study. First, the Scale of Need for Cognitive Closure (SNCC) was assigned to the participants and a questionnaire was used to collect demographic data. After analyzing the questionnaires, we chose 10 high scorers of SNCC and 10 low scorers from the participant pool then assigned them two information searching tasks: a closed-structured question and an open-ended question. We videotaped how they did the two searching tasks on the computer screens and recorded all searching activities. Last, we had interviews with them while the screen capture video was played, identifying their information searching strategies over the two tasks. No matter how high the scores of SNCC were, those 20 participants showed similar strategy use for each task. They tended to locate information, browse the webpage structures, and directly find the targeted item for the closed-structured task. For the open-ended task, the participants scanned through the information, looked carefully on one single page, and then tried to recognize one from a group of possible items. The results seem to be in favor of task factors over need for cognitive closure on individuals’ strategy uses on the Internet. The core ideas of need for cognitive closure and how task requirements initiate one’s motivation and strategy are discussed in this present study. The differences between real information searching behaviors and those behaviors in our controlled laboratory settings and applications for classroom instructors are discussed at the end as well.

Keywords: cognitive closure, motivation, information search, internet usage

Needs analysis for an Indigenous school-based social and emotional wellbeing program

SWANELL, S. (University of Queensland), HAND, M. (The University of Queensland), MARTIN, G. (The University of Queensland), SHEEHAN, N. (Swinburne University)

The aim of the current study was to conduct a needs analysis among Aboriginal and Torres Strait Islander year eight students, their parents, community elders and school teachers from regional (Mount Isa and Ingham) and metropolitan (Brisbane) Queensland as to what elements are important for the development and maintenance of a school-based social and emotional wellbeing program. 79 Indigenous students from three schools in regional and metropolitan Queensland participated in the Aussie Optimism Program (AOP), a 20 week school-based mental health promotion program developed for Australian year eight students (Roberts, 2000). A total of 15 teachers (Indigenous and non-Indigenous) were trained to deliver the program. Feedback from students, parents, community elders and teachers was collected via surveys and discussion groups. Feedback from Indigenous students, parents, community elders and teachers indicated an urgent need for Indigenous school-based social and emotional wellbeing programs. Furthermore, respondents thought that the key themes contained in AOP (resilience and social skills) were suitable for Indigenous school children. However, respondents considered most of the AOP content culturally inappropriate, not engaging or irrelevant to Indigenous youth. The role plays, scenarios, language and illustrations were deemed as particularly inappropriate. High rates of illiteracy among Indigenous students were also highlighted as a potential problem, given the majority of exercises in Aussie Optimism require students to complete work books. There is an urgent need for the development of Indigenous school-based social and emotional wellbeing programs which contain content relevant to Indigenous values such as spirituality, family and country and are delivered in a way which will empower and engage Indigenous children.
Keywords: Indigenous students, school-based program, social and emotional wellbeing, illiteracy

Neuropsychological assessments of depressiveness for suicide prevention

SUGAWARA, M. (Shokei Gakuin University), ITO, Y. (Iwate University), KAWABATA, T. (Shokei Gakuin University)

Following the death of a relative (especially a spouse, beloved, parent or child) there are periods of grief, anxiousness, insomnia, disturbances and depressive complaints. After depression, bitterness, isolation, and irritability may appear too. Suicide may be briefly defined as the human act of self-inflicted, self-intentioned cessation. In countries reporting to the World Health Organization—including the G8—Japanese suicide rates have maintained a higher level during the last five years (2.4 times to the United States of America (USA), 3.4 times to the United Kingdom (UK), and Italy). The key to reduction of suicide lies in recognition and diagnosis—the perception of premonitory depressive signs and clues. Three kinds of psychological tests (Harm avoidance, Carroll Rating Scale for Depression, and Beck Depression Inventory) were adopted for the evaluations of depression in 220 graduate students. The correlations were evaluated between electroencephalographic topography-potentials and the three kinds of depressive scales. Electroencephalographic (EEG) potentials recorded monopolarly from 16 placements over frontal, central, parietal, temporal, and occipital scalp locations in the international 10-20 system with linked mastoides or ear lobes. Electrodes were also placed on the lateral canthus and above the supercilium of the left eye in order to measure the electrooculographic and electromyographic responses. The Fpz was the earth electrodes. The statistical significance of neuro-physiological and psychological differences was evaluated by ANOVA. From results of structural equation modeling and multiple comparisons, the effect of HA1 (HA1: anticipatory worry versus optimism) was ascertained on depression among HA (HA2: fear of uncertainty versus confidence, HA3: shyness versus gregariousness, HA4: fatigability and asthenia versus vigor). The EEG analyses presented the prominent decrease of α-power spectrum at frontal lobes and, β-power decrease at left frontal lobes on depressiveness. These electrophysiological signs might be indicative of depressive levels.

Keywords: depression, suicide, electroencephalogram (EEG), structural equation modeling

New micro-cognitive metrics from cognitive system theory: Objective mapping of ADHD and dyslexia versus peer group

BURTON, P. (Australian Catholic University)

A scientific account of human cognition remains to be settled. This paper describes a specific model of cognition, developed from a five axiom analysis (investigating learning, experience, cognitive control, knowledge and the self-model), of the mind-brain interaction process. It reflects a convergence, from diverse evidence, to an explanation of the nature and role of consciousness, highlighting consciousness as the means of control in human cognition. The theory describes major transitions in the human form of this control towards adulthood. In particular, basic human cognition, initially similar to the processing of other mammals, is shown to respond to exogenous control leading to the development of new kinds of sequentiated cognition (punctuated cognition). Building further on this second level of cognition, a new more elegant and flexible form of conscious control emerges corresponding to advanced (vector-targeted) cognitive processing associated with the self-model. The major survival benefit of this elaborated cognitive competence is to complement the instrumentally reactive form of response more complex environmental challenges with a more deliberate, navigational mode of tasking. At each stage of advancement, it is the emerging flexibility of new kinds of conscious control over cognition that lead each transition. The ultimate transition to self-conscious control reflects the cognitive acquisition of an implicit two-dimensional field of control, wherein decision-making automatically collates foregone choices. These are captured to contextual behavioral repertoire, each one a systematic enhancement of behavioural options underpinning future
intelligent performance. This model imputes a cognitive aspect to endogenous eye-blinking, reflecting the internalised gating system of punctuated cognitive development. Data will be presented from a preliminary study supporting this proposed role and suggesting that eye-blink analysis may prove to be of significant value in the assessment of cognitive performance generally. For ADHD and dyslexia, abnormal cognition diagnoses that have been quite resistant to any objective cognitive function assessment, objectively discriminating mapping metrics (from principal components of individual variance in blinking during a structured task) may afford an effective recognition, mapping and therapy-tracking tool.

Noise-stress relationship: Moderation effects of individual need for closure

Previous research suggests that stressful noise, (when the noise is higher than 90 decibels) influences both physiological (for example, increased blood pressure) and psychological levels (negative effects on behavior or relationship; Evans & Cohen, 2004). The aim of this research is to verify if individual differences on Need for Cognitive Closure (NCC; Kruglanski, 2004), moderate the negative effects caused by noise. The NCC is an epistemic motivation that can be conceptualized as individual disposition but can be activated also by specific environmental characteristics such as noise, mental fatigue or temporal pressure. Thus, individuals with need for closure can better sustain an environment that activates closure through noise as it fits their motivation (De Grada & Livi, 2009). Seventy-nine employees of a motor factory who are exposed to environmental noise were recruited. Each participant completed the shortened version of the Need for Cognitive Closure Questionnaire (Pierro & Kruglanski, 2006), the scale aimed to measure the dispositional tendency of Need for Closure with five subdimensions (Desire for predictability, Preference for order and structure, Discomfit with ambiguity, Decisiveness, Closed-mindedness); the Noise Sensitive Scale (Weinstein, 1978) that measures the subjective level of noise sensitivity; and the Job Effort Scale (Brown & Leigh, 1996) that measures the level of job efforts performed. The hypothesis is that NCC moderates the noise-stress relationship: thus, subjects with a high score on NCC and high in noise sensitivity reduce negative effects of environmental noise on job effort. To test these hypothesis we have used a moderation analysis (Aiken & West, 1991), with Need for Cognitive Closure, Noise Sensitive and Need for Cognitive Closure*Noise sensitive as predictors, and Job effort as criterion. The results corroborate the hypothesis; indeed the results indicate a moderation effect of the NCC showing that individual differences in epistemic motivation reduce negative effect of noise on stress. Thus, individuals are motivated to closely adapt more to a stressful situation as their cognitive epistemic structure better fits the noisy environment, reducing stress in turn.

Keywords: stressful noise, need for cognitive closure, noise, mental fatigue, stress

Non-suicidal self injury among Japanese adolescents: Comparison between non-suicidal self injury among adolescents from a normal population and among adolescents from a hospital referred sample

The aim of this study was to compare non-suicidal self-injury (NSSI) among adolescents from a normal sample to NSSI among adolescents from a hospital referred sample. A total of 632 adolescents from a community sample and 48 adolescents from a hospital referred sample participated in the study. The adolescents from the community sample completed a questionnaire that consisted of experiences of eight kinds of NSSI, as well as the
Adolescent Dissociative Experiences Scale (A-DES), Children’s Depression Inventory (CDI), and the State-Trait Anxiety Inventory for Children (STAIC-Trait). Adolescents from the hospital referred sample completed the questionnaires of A-DES, CDI, and STAIC and they were interviewed about their experiences of NSSI and suicidal ideation. Participants were divided into four groups; non-NSSI group among community population (C-nNSSI), NSSI among community population (C-NSSI), non-NSSI among hospital referred sample (H-nNSSI), and NSSI group among hospital referred sample (H-NSSI). The score of A-DES, CDI, and STAIC were compared. Between C- NSSI and H- NSSI, the methods of NSSI were also compared. The results of ANOVA revealed that H-NSSI scored higher on A-DES, CDI, STAIC than H-NSSI. H-NSSI tended to engage in NSSI with using implements, for example knives. About 80% of H-NSSI experienced suicidal ideation. H-NSSI experienced higher dissociation, depression, and anxiety than C-NSSI. H-NSSI have suicidal ideation thus they are clinically at risk.

Keywords: non-suicidal self-injury, adolescents, adolescent dissociative experiences, state-trait anxiety, children’s depression

Obesity: A socially acceptable target of prejudice?

PENNEY, E. (University of Sydney), MADIWALE, S. (University of Sydney), LAWSIN, C. (University of Sydney)

This study examined the applicability of the Motivation and Opportunity as Determinants (MODE) model, a model previously applied to racial discrimination, to predict whether implicit weight prejudice would necessarily result in behavioural discrimination towards obese targets. This sample consisted of 186 undergraduate students (121 female, 65 male) with a mean age of 19.74 (SD = 3.90). A personalized Implicit Association Test (pIAT) was used to measure participants’ implicit weight prejudice and the Motivation to Control Prejudiced Reactions (MCPR) scale was used to measure participants’ motivation to hide weight prejudice. These factors were used to predict subsequent expressed (or hypothetical) and actual behaviour, as measured by a mock Students’ Representative Council (SRC) election task and a Lost Email task. Exploratory analyses of open-ended qualitative responses were conducted to determine the reasons that participants discriminated against obesity. The MODE model was not found to predict the prejudice-behavior relationship; however, both weight prejudice and discrimination were highly prevalent in the sample, p < .05. Exploratory analysis revealed that 21.2% of participants explicitly stated that they voted for a candidate for no other reason than that they were thin. Furthermore, 42.9% used a positive adjective, such as ‘likeable’ to describe the thin SRC candidates, whilst 0% used a negative adjective to describe the thin candidates. The MODE model was concluded to be an inappropriate model for weight prejudice due to the qualitative differences between weight and racial prejudice. It was concluded that many consider obesity to be a socially acceptable target of prejudice; therefore, the relationship between prejudice and behaviour may be more complex than the factors considered by the MODE model. Future research should attempt to affect positive change and reduce the social acceptability of weight prejudice, without ignoring appropriate health messages about the serious health consequences associated with obesity.

Keywords: obesity, weight prejudice, discrimination, Motivation and Opportunity as Determinants (MODE) model

Occupational stress and mental health of Maharashtra police constables

RAKSHASE, B. (Arts, Commerce and Science College)

The aim of this research was to assess the level of occupational stress and the level of positive mental health of Maharashtra Police Constables. To assess the level of occupational stress of Police constables researcher the Occupational Stress Inventory- Revised by Osipow was used, and to assess the level of positive mental health the Mental Health Inventory by Shrivastava was used. The samples were divided on the basis of their tenure, that is, below the fifteen years of service and above the fifteen years of service. It is found that the constables who have
completed fifteen years of service have more occupational stress than constables who are below fifteen years of service. Further it is also found that the constables who have less tenure have good mental health than the constables who have more job tenure. Job tenure is one of the important factors which affect level of occupational stress and mental health.

Keywords: occupational stress, positive mental health, occupational stress inventory, job tenure, police

On group counseling with domestic violence female offenders

LANG, Y.C. (Da-Yeh University)

This study will be in cooperation with a Women’s Jail in Taiwan to help female prisoners to adjust their behaviors and attitudes toward their family members. They have all committed domestic violence, many hurting their husbands severely, so it is very important to let them explore their inner self, and find a way to make peace with both themselves and their family members. Another aim of this study is to analyze the lives of these females in order to understand the causes and motives behind their violent events. The program will includes 12 sessions with approximately 12 female prisoners, and each session will last for 2 hours. Since this program is designed to start in March, 2010 and ends in June, it is in the preparation stage at the moment. However, three questionnaires will be used to evaluate the participants’ behaviors and attitudes toward family, relationships and the group dynamic, and a measurement will be used to understand their personality. As for group counseling, the researcher will try to use Solution-Focused Brief Therapy together with psychodrama and art therapy to create a supportive and warm atmosphere to let all participants feel accepted and willing to share their life stories with others. The results will be analyzed in June and a report will be finished by the end of July, 2010.

Keywords: domestic violence, female offenders, group counseling, prisoners, solution-focused brief therapy

On the concept of efficacy in public health care organizational development

RAGNEKLINT, R. (Lund University)

This study aimed to explore the use of the efficacy concept by conducting an epistemological trip from a modernistic, “objective” understanding of the concept to a postmodern, value contingent understanding. The use of questionnaires (N=340) for health care personnel employed at the clinics were examined and a diary-in-group method with political representatives of health care services, administrators and health care professionals (N=12). The study was carried out in a large medical care district in southern Sweden. It concerned the social construction of the concept of health care efficacy as applied to the merger of two surgical clinics, one of them a large university clinic, the other a clinic of lesser size in the same health care district. In the questionnaires subjects reported a strong criticism against the merger (~40%) and some 45% felt they had little or no influence over their work conditions and the organizational changes decided upon. Strong criticism was directed against the responsible political level. Concerning the interpretation of the concept of efficacy, despite the organizational decisions, some 80% of subjects declared that they experienced a sense of efficacy in their daily work. In the discussions and the interviews that took place between political leaders, administrators and care personnel, there was considerable criticism over the way political decisions were made. A clear breach between views regarding care and views concerning political matters was evident. The investigation considers various aspects of the efficacy concept, the seemingly self-evident economic rationality being questioned as based mainly on strict budgetary principles applied to small accountancy units. The examination puts into light the importance of longitudinal and macro aspects, and in addition, efficacy concepts such as time to reflect, making a worried patient feel relaxed, and cooperation with other clinics or external partners. It also unmasks a clear difference concerning the efficacy concept as interpreted by different hierarchical categories in the health care organization. The investigation shows the importance of motivating the
employees included, and finally, shows the major social and ethical implications of efficacy interpretations.

Keywords: public health care, organisational development, health care efficacy, health care providers, Sweden

Organizational development based on personal skills

URIBE-RODRIGUEZ, A.F. (Univesidad Pontificia Bolivariana Bucaramanga)

Through the development of skills is achieved alignment with the organizational environment and competitive advantages are obtained that provide great benefits to organizations. Skill development is today an essential practice to align talent with the organization's strategic plan, and thus not only create value have the talent required to meet the challenges of the workplace. Therefore, our research question was “what are the methodologies used to develop skills in leadership of organizations of consumer products in Colombia?” The research design was transactional. The population consisted of 12 human resources managers in various national and multinational organizations in the real sector. The sample consisted of 5 people working in the area and human resources in real sector organizations. This group was women aged 18-43 years, all with professional training in psychology, and two with specialization in human management. For data collection, management used the questionnaire-based Human Talent Development Processes (Uribe and Duke, 2008). The results showed Training, Coaching, Assignment and Outdoor Training committees are developing methods that 100% of organizations surveyed use for the development of skills of people in leadership positions. The programs had 80% self-use. Job rotation was 20% for instruction and training, and mentoring of use 0% as developing methods for people in leadership positions in companies surveyed. Moreover, the results show that 80% of those surveyed use some methodology or tool in order to measure the level reached after the intervention in leadership development. By contrast, 20% do not perform any measurement of people after having experienced some form of development. Similarly, 80% of companies surveyed indicated some kind of monitoring during the development of people in leadership positions. 20% of all subjects surveyed did not make any follow-up during the development process. Assessment center, performance evaluation, and behavioral event interview were identified using the methodologies among the surveyed companies are. 360 degree evaluation was the least used tool to measure the level of skills development because of the great control of variables and factors. Regarding monitoring of development processes, we conclude that the vast majority of organizations surveyed, with both on track to accompany people who are in formal development process skills, and these accompaniments are performed in both the area of human management as the heads of people. It is realized that the responsibility for these processes is increasingly shared and that people belonging to different and unrelated to human processes within organizations, are becoming more involved and see the value added of these processes for themselves and their teams. On the other hand, we can also conclude that firms do not generate single development actions without a previous diagnosis, and perceived that these processes involve high development costs, both in physical resources, such as people's expectations. Another important aspect to mention is that the actions generated by these organizations are framed in different development projects, some with a corporate standard, others that are generated due to specific situations.

Overclaiming as socially desirable responding: Investigating the effects of item desirability, forgiving wording, and the predictive ability of trait fear of negative evaluation and embarrassment within the study setting

SACCONI, E. (University of Adelaide)

Overclaiming occurs when questionnaire respondents claim knowledge of or an opinion about something that the researcher has in fact fabricated (Phillips & Clancy, 1972). The primary aim of this study was to advance knowledge of possible determinants of overclaiming. It was
hypothesized that it might arise, at least in part, from image-preservation concerns in the respondent. Thus, the theory of overclaiming as socially desirable responding was investigated. Participants were 101 native English-speaking Flinders University Psychology students. Respondents completed a questionnaire that measured perceived desirability of domains, overclaiming, trait fear of negative evaluation and embarrassment within the study setting. There were two instruction wording conditions; standard instructions and ‘forgiving wording’. Overclaiming was higher on socially desirable items compared with neutral items. Forgiving wording significantly reduced overclaiming overall and for socially desirable items but not neutral items. Neither trait fear of negative evaluation, nor embarrassment within the study setting predicted overclaiming. Results indicate that overclaiming is linked with image-presentation concerns and can be considered a manifestation of socially desirable responding. However, explicit concerns about making a poor impression are not related to overclaiming. The results underscore the need for caution when interpreting self-report data, particularly when responses pertain to socially desirable activities.

Keywords: overclaiming, socially desirable responding, item desirability, forgiving wording, trait fear

Paranoid ideation, God concept and attachment in college students

HADDADI KUHSAR, A.A. (University of Tehran), GHOBARY BONAB, B. (University of Tehran)

The aim of the current research is to investigate any relationship between dimensions of mental health and the concept of God in students of Medical Sciences. To this end, 513 students from Tehran Medical Sciences University and Iran Medical Sciences University were selected by means of proportional stratified sampling. Religious Concept Survey (Gorsuch, 1968), Paranoid dimension of Symptom Check List 90-Revised (Deragotis, et al., 1973) and Adult Attachment Scale (Collins, 1996) were administered on them. Regression analysis was used to analyze data. Results indicated that paranoid ideation of college students can be predicted from the quality of attachment, and God concept (wrathfulness). In other words, students who perceive God as a wrathful entity, are more prone to experiencing paranoid ideation. In addition, an anxious attachment was associated with more paranoid ideation, however dependable attachment was associated inversely with paranoid ideation. The authors concluded that Paranoid Ideation can be predicted from conceiving God as a Wrathful entity. Moreover, anxious attachment style can predict Paranoid Ideation in college students.

Keywords: paranoid ideation, god concept, anxious attachment, medical students

Parental internal states reference and theory-of-mind (ToM) ability in autistic children

COX, I. (Deakin University), HAMILTON, D. (Deakin University)

This study investigated whether the quality, frequency or frame of parental internal states (IS) to children with Autism Spectrum Disorder (ASD): differed from typically developing children (TD); or was related to theory-of-mind (ToM) and emotion recognition (ER) abilities. Firstly, it was predicted that parental IS reference would be ‘low’ (low quality, low frequency, and independent frame) in the groups of children with ASD and ‘high’ (high quality, high frequency, and joint frame) for TD children. Secondly, it was expected that children with ASD exposed to ‘high’ parental IS reference would score higher on ToM and ER measures than children with ASD not exposed to ‘high’ parental IS reference. 31 child-parent dyads recruited from Government and private Primary schools, a Government Disability Support Agency, and a Speech Pathologist’s client list around Melbourne and Geelong, were grouped by age (5 - 6 years and 10 -12 years) and diagnosis (ASD and TD). Parental IS reference was recorded, transcribed, and coded in to seven categories to determine the quality, frequency, and frame. Children were tested for verbal, ToM and ER abilities using verbal and non verbal measures. Hypothesis testing involved a multivariate analysis of variance (MANOVA) and an independent-groups t-test. Contrary to predictions, no significant differences were
found: in the quality, frequency, and frame of parental IS reference between children with and without ASD; or between children with ASD exposed and not exposed to ‘high’ parental IS reference and ToM or ER abilities. Exposure of parental IS reference to children with ASD and TD children is comparable. The quality, frequency, and frame of parental IS language showed no bearing on ToM and ER ability in children with ASD. Parental IS reference fluctuates with their child’s development, whereby: categories change from sensory, emotion, and obligation towards more cognitively challenging categories; the frequency diminishes; frame of reference changes from independent to joint; and ToM and ER abilities improve.

Keywords: parental internal states, children, Autism Spectrum Disorder, theory of mind, emotion recognition

Perceived and actual impact of text messaging on young adults’ driving performance: Self-report versus driving simulation

BEER, M. (The University of Adelaide), BALDOCK, M. (The University of Adelaide), WARD, L. (The University of Adelaide)

This two-stage study had three aims: first, to provide a descriptive portrayal of young adults’ self-reported engagement in text messaging while driving, perceptions relating to personal risk, and expectations about the detrimental effects of text messaging on driving abilities; second, to assess the extent to which writing/sending and reading text messages affects brake reaction time to critical events, lateral position variability and speed; and third, to determine whether prospective predictions about driving performance while text messaging relate to simulated driving performance. An online questionnaire was completed by 252 drivers (151 females, 101 males), aged 18 to 24 years. The repeated measures driving simulator experiment involved 42 participants ‘driving’ through a simulated environment displayed on a computer screen, using a steering wheel, brake and accelerator pedals. The three conditions were a control drive, text message reading and text message sending. The majority of participants reported they had engaged in text messaging while driving, with many doing so on a regular basis. The majority of the sample also predicted that text messaging would have at least a moderate negative effect on their driving performance. No gender differences emerged in self-reported engagement in text messaging while driving, but females predicted the negative effects to be larger than did males. Optimistic bias was found in drivers’ personal risk likelihood ratings relative to those for their peers and the average motorist, when considering the likelihood of being involved in a crash and of being caught by the police if concurrently text messaging. When sending and reading text messages under simulated driving conditions, brake reaction times were longer, while lateral position variability and speed variability were greater compared to the control condition. No relationship was found between drivers’ predictions and simulated driving performance. Results provide insight into subjective and objective factors relating to text messaging while driving and contribute to the small empirical base regarding the impacts of text messaging on driving.

Keywords: text messaging, driving performance, young people, self-report, driving simulation

Perceived causes of the difficult situation, locus of control, and the behavior tendency towards cheating

WANG, J. (Chiba Institute of Science)

This study aimed to examine the effects of perceived external and internal causes of a difficult situation and locus of control on tendencies towards dishonest behaviors, which might make the difficult situation more favorable. Ninety-five Japanese college students participated in the study. They were presented with a scenario depicting one student taking a scholarship examination. The difficult situation was set as the student realizing that he/she could not gain a good mark during the examination because of certain external and/or internal causes. Participants were asked to image themselves as the student and judge the importance of the given external and internal causes, and then evaluate the motivation and
possibility to cheat under the situation. The results of multiple regressions showed that the perceived importance of external cause was positively related to the motivation for cheating. Whereas the perceived importance of external cause and perceived unethicalness of cheating were positively or negatively related to the possibility for cheating, respectively. However, locus of control showed no relationship with both motivation and possibility of cheating. These results provided an empirical support to Bandura et al.’s (2002) mechanisms of moral disengagement based on social cognitive theory. The lack of relationship between locus of control and behavior tendency suggests that locus of control may have less influence in difficult situations where causes are clear. Implications of these results on prevention of organizational wrongdoing were also discussed.

Keywords: locus of control, dishonest behaviors, cheating motivation, organizational wrongdoing, behavior tendency

### Perceived fatigue and stress tolerance in young athletes

ARRUZA, J.A. (University of the Basque Country), BALAGUÉ, G. (University of Illinois), SILVIA, A. (University of the Basque Country), IZASKUN, A. (University of the Basque Country), OIHANE, O. (University of the Basque Country)

The aim of this study was to analyze and evaluate the importance of perceived fatigue and its relationship with stress tolerance in young athletes selected for elite level. Participants were 30 athletes, males and females, from 10 different sports. They were between 12 and 20 years of age. The study employed a descriptive and correlational design, and was multivariate, focusing on mood and stress tolerance. The following measuring instruments were used to measure mood: Profile of Mood States (P.O.M.S.; Mc.Nair, Lorr & Droppleman, 1971) and the abbreviated scale, Fuentes, et al. (1994). To measure stress tolerance the Recovery-Stress Questionnaire for Athletes, translated to Spanish, (RESTQ-Sport: Kellmann and Kallus, 2001), 76 items version, was used. The RESTQ-Sport questionnaire consists of 12 General Stress and Recovery scales along with seven Sport-specific Stress and

Recovery scales. The athletes completed the questionnaires from their homes using a web-based service (Teskal) during the 2007-2008 season. The SPSS statistical software was used to analyse the data. The sample shows a Mood State profile very similar to Morgan’s (1980) “Iceberg Profile”. The average score for the negative dimensions is very low, and the mean values for the positive dimensions are high, as seen in high performing athletes. When looking at stress tolerance, we see a low mean score in the dimensions that generate stress, while the values of the stress-recovery dimensions are high. Overall, the sample shows low mean values of perceived fatigue, with moderate significant negative correlations with physical fitness ($r = - .40$, $p < .05$) and with self-efficacy ($r = -.37$, $p < .05$), which are stress-recovery dimensions. There is also a positive and significant correlation with emotional fatigue ($r = .38$, $p < .05$), a stress-generating dimension. These results highlight the importance of perceived fatigue, measured with the P.O.M.S., because it cuts across stress tolerance, and helps us better understand the behavior of athletes geared to elite level performance. A reduction on the levels of perceived fatigue will increase the young athletes’ stress tolerance, maintaining high self-efficacy, feeling more fit and avoiding overtraining states.

Keywords: perceived fatigue, stress tolerance, elite athletes

### Perceived racism and mental health in Australia: The premier quantitative study

GRIGG, K. (RMIT University)

The present study aimed to provide the first quantitative exploration of the relationship between perceived racism and mental health in Australia. The sample consisted of 180 (males = 72, females = 108) participants recruited via flyers from around universities in Melbourne, via lectures at RMIT University in Melbourne and via e-mail from around Australia. Ages ranged from 18 to 66 years ($M = 27.11$, $SD = 9.54$). Sixty two participants were self-identified as non-indigenous Australian. One hundred and eighteen non-Australian participants were
processed as frequently (self-identified as Asian (n = 45), Middle-Eastern (n = 3), African (n = 2)), occasionally (self-identified as mixed (n = 27)) and infrequently (self-identified as European (n = 41)) identified as non-Australian. Participants completed a 90-item self-report questionnaire assessing levels of perceived racism (General Ethnic Discrimination Scale; GEDS), mental health outcomes (Depression, Anxiety, Stress Scales; DASS, Rosenberg Self-Esteem Scale; RSES) and demographic variables (age, gender, SES, Acculturation Index; AI, Multigroup Ethnic Identity Measure; MEIM). The following four hypotheses were tested. Hypothesis one: There will be a difference in the prevalence of self-reported racism across racial/ethnic groups. Hypothesis two: Higher levels of self-reported racism will predict higher levels of self-reported negative mental health outcomes. Hypothesis three: Demographic variables will be related to levels of self-reported racism. Hypothesis four: Demographic variables will moderate the effect of self-reported racism on self-reported negative mental health outcomes. Perceived racism was found to be more prevalent among non-Australian minority racial/ethnic groups than non-indigenous Australians and among more highly visible minority racial/ethnic populations than those less visible. Moreover, perceived racism predicted higher psychological distress, depression, anxiety and stress and its negative relationships with mental health outcomes were partly moderated by levels of acculturation and ethnic identity. Perceived racism did not significantly predict self-esteem. Greater acculturation to Australian culture was also found to be related to less perceived racism, whilst having a stronger ethnic identity was related to perceiving more racism. The results of this study predominantly concur with previous research from around the globe, which allows prior conclusions and inferences to be generalised with more confidence to Australia and Australia’s minority racial/ethnic populations. Moreover, the current study provides an impetus for changes to legislation and tougher policies on racism in Australia.

**Keywords:** racism, mental health, Australia, depression, anxiety

**Perceptions and beliefs on domestic violence in the Southeast of Mexico**

**Keywords:** domestic violence, perceptions, gender differences, Mexico

**Perceptions of control of space as a factor in responsibility attribution and behavioural intent towards another person’s litter**

**Keywords:** domestic violence, perceptions, gender differences, Mexico
Environmental studies have investigated both socio-demographic and attitudinal variables, in relation to pro-environmental behaviours. The aim of this study was to investigate two other factors that have also demonstrated potential to influence these behaviours, but have previously received little attention - responsibility attribution and perceptions of control of space. Using responses (n = 193) from 1000 questionnaires delivered to high/low SES suburbs, differences in attributions and intent were explored across three areas of control of space conditions of (respondent’s) yard, the street and the local park. Socio-demographic variables and attitudes towards litter (ATL), place attachment (PA), and community social responsibility (CSR) scores were assessed for their impact on both responsibility attributions and behavioural intent measures. Repeated measures ANOVAs revealed that control of space influenced both self responsibility attribution and behavioural intent measures in a similar manner. Multiple regression analysis revealed that only Age was (weakly) influential for self responsibility attributions whilst responsibility attributions to self (relative to council) and place attachment (PA) were influential on behavioural intent measures. A meditational regression analysis found that responsibility attributions only mediated behavioural intent and PA for the yard, but not the street or park. Overall, the factors involved in personal responsibility attributions and behavioural intent were quite distinct. The findings suggest that responsibility attributions and behavioural intent may be unique and separate elements of pro-environmental behaviour, and therefore should be investigated further. Control of space is discussed as a potential new direction for research through environmental design elements, and future environmental programs.

Personal construct analysis of a vice-principal on conflicts in a high school as workplace through High Tea Method by using repertoire grid technique

INOUE, T. (Meiji Gakuin University), ITO, T. (Wako University)

The purpose of the present study was to explore the structure of conflict of a stakeholder in a high school by conducting the High Tea Method, which the authors had developed, by using repertoire grid technique. A vice-principal of a suburban high school participated in the study. First, he was asked to point out his experience of conflict in his workplace. An interview with those sentences of his conflict experience was conducted by repertoire grid method. A second interview was then conducted to interpret the constellation of MDS output. Results showed that the participant summarized four clusters of his conflicts in his experience as his personal attitude construct. High Tea Method, as well as PAC Analysis developed by Naito (1997), is found to be a significant tool to search for inner structure of personal construct. The specific methodological features of High Tea Method were also discussed. The combination of High Tea Method and repertoire grid technique was found to be useful for exploring the subjective structure of human individuals.

Personal determinants of inclination to risk of sportsmen-divers

VOLIANIUK, N. (University of Educational Management of the Academy of Pedagogicak Sciences of Ukraine), LOZHKIN, G. (National Technical University)

Psychology which is more actively involved in solving problems important for sport, encounters the necessity of semantic space comprehension of the personal aspect of the risky behaviors of sportsmen. Risk is an inherent peculiarity of many kinds of sport. The degree and justification of risky behavior of sportsmen determine the efficiency of their training and sport activity. The aim of this research lies in determining individual and psychological peculiarities of personality of sportsmen-divers which are naturally connected with inclination to risk. The methods and organization of the research involved: theoretical methods, analysis, synthesis, comprehension and generalization of
literary statements; psycho diagnostic methods, among the latest – O. Sannikova’s test-questionnaire of qualitative characteristics of inclination to risk, Korzhova’s questionnaire, Kettel’s personal questionnaire 16-PF, and Losenkov’s questionnaire of impulsivity. Statistical data processing and graphical presentation of the results were carried out on the basis of the statistical programs package SPSS 10.0. On the basis of the analysis of individual and psychological peculiarities of a sportsman-diver personality with maximum expressiveness of inclination to risk (Risk-max), the psychological portrait was built and its main characteristics are independence, aggressiveness, dominance, stubbornness (E+); social courage, riskiness, spontaneity (H+); practicality, independence, responsibility, strength of mind, self-satisfaction, (I-). Sportsmen-divers with minimum expressiveness of inclination to risk are characterized by dependence, lack of self-sufficiency, helplessness, sensitivity (I+); sagacity (N+); conservatism (Q1-). Moreover, such sportsmen are not self-confident, reserved while expressing their feelings, and they have a narrow circle of acquaintance (H-). Obedience is characteristic to them and it is displayed by dependence on other people, they need support and seek it in social environments, they are inclined to be guided by group regulations. Furthermore, they are conformal, modest, gentle (E-).

Personality and social anxiety disorder: The impact of personality on treatment outcome

BROCKVELD, K. (Macquarie University), PETERS, L. (Macquarie University)

Social phobia is characterized as a marked and persistent fear of social or performance situations. It is estimated to be one of the worst 30 diseases in terms of disability adjusted life years lost in Australia. Despite empirical evidence for the effectiveness of cognitive behavioural therapy (CBT), clients completing CBT programs will present individual differences, which are believed to contribute to the development of mental health problems. The aims of this research are to investigate differences between personality traits and the expression of symptoms in social phobia; the relation of individual differences and treatment outcome; and whether there are specific subtypes of social fears. An overview of the study will be presented.

Keywords: social phobia, individual differences, personality traits, cognitive behavioural therapy

Personality and symptom factors relevant to continuance in psychoanalytic psychotherapy

GREEN, M. (Glen Nevis Clinic), GRIMWADE, J. (Australian Catholic University), GODFREY, C. (Monash University), DEAN, S. (Monash University), BEAUFOY, J. (Monash University Centre for Developmental Psychiatry and Psychology), TONGE, B. (Monash University Centre for Developmental Psychiatry and Psychology)

The aim of the study was to establish whether patient personality factors or symptomatology were related to patients continuing until the end of a time limited psychoanalytic psychotherapy. Fifty three patients eligible for subsidized psychotherapy at an outpatient clinic were assessed at intake with the NEO-FFI personality inventory and the Brief Symptom Inventory. Statistical analysis compared those who continued until the end of a time limited therapy with those who discontinued. No association was found between the personality or symptom inventory results and continuance in psychotherapy. However, a number of interesting results outside the original hypothesis came to light during the statistical analysis. There was an important difference in the study group’s personality scores as compared to the scores of clinical populations reported in the research literature. Most research which used the NEO as a measure in clinical groups reported significantly raised Neuroticism scores when compared to standardised scores. The other four personality domain scores generally remained within the standardised range. In contrast, within this patient group, NEO scores for all five personality domains were significantly different to standardised scores. Patients in this group exhibited significantly higher Neuroticism, and
lower Extraversion, Openness, Agreeableness and Conscientiousness when compared to standardised scores. In addition, males recorded significantly higher rates of symptomatology than females. Finally, this population recorded a much higher continuance rate than that generally recorded in the literature. Within this population there was no association between personality factors, symptomatology and continuance in psychoanalytic psychotherapy. The population achieved a much higher continuance rate than is commonly reported in the research literature. Contributors to the latter effect might include the intake process operating as a screen to select for those patients more likely to continue. In addition, there may be some aspect of the therapy provided by the clinic which enables patients to continue engagement in psychotherapy.

Keywords: personality factors, psychoanalytic psychotherapy, symptomatology, continuance in psychoanalytic psychotherapy, patients

Personality assessment inventory (PAI) profiles for WorkCover claimants with chronic pain

TUSTIN, D. (Adelaide Psychological Services), MR GILLES HAMMOND, G. (Adelaide Psychological Services)

The aim of this study was to describe features of personality disturbance that arise commonly in WorkCover claimants with chronic pain, and that need to be addressed in psychological therapy for successful return to work. Successful clients referred to a community psychological therapy clinic were administered the Personality Assessment Inventory (PAI). A mean profile will be reported with severe scores identified. A large proportion of clients obtained severe scores on up to 14 of the 31 scales of the PAI. It is concluded that WorkCover clients with chronic pain have complex personality presentations, and that consistent patterns can be identified using the PAI. Therapists need to be prepared to address a range of common issues if return to work is to succeed. As client issues are broader than cognitive and emotional issues, a therapeutic approach is required that is broader than traditional CBT.

Keywords: WorkCover, personality assessment inventory, chronic pain, psychological therapy, return to work

Personality characters and learning modes as the predictors of stress in university students

HOMAYOUNI, A. (Islamic Azad University)

No matter what age you are, if you are under stress it will affect your ability to learn, think and perform at your best. Severe stress releases chemicals in our brains and bodies that can hamper our performance and learning. Because stress is detrimental to our ability to learn, numerous scientists, educators and psychologists have worked hard to develop techniques, exercises and software programs that can help us dissolve it. How people react to stressors depends on the circumstances of each person’s physical and psychological characteristics. So for better understanding of stress especially in the learning process, the study aimed to investigate personality characteristics (introversion-extroversion, intuition-sensing, thinking-feeling, perceiving-judging) based on Jungian personality types, and learning modes (concrete experience, abstract conceptualization, reflective observation, active experimentation) based on Kolb’s experiential learning theory, and stress, in university students. A sample of 131 students were randomly selected from three universities. Hogan-Champagne’s Personal Style Inventory (PSI), Kolb’s Learning Style Inventory (LSI) and Coudron’s Stress Inventory (CSI) were used. The data were analyzed with Pearson correlation coefficient. Analysis showed that in learning modes, there is a positive correlation between concrete experience and stress. In personality characters, there is a positive correlation between introversion and stress, and a negative correlation between extroversion and stress. Also, there is a positive correlation between concrete experience learning mode and extroversion and feeling. More analyses showed that across learning modes, males use the concrete experience mode more than females, and females use the abstract conceptualization mode more than males. To conclude, in regard to introverted individuals, such individuals are quiet, diligent at working alone, and socially
respected, they make decisions somewhat independently of constraints and prodding by situations, culture, people, or things around them, and so facing stress factors interrupts their own world and reduces their function. In learning modes, people with concrete experience like new experience, rely on feeling and sensing, and generally find theoretical approaches to be unhelpful and prefer to treat each situation as a unique case. These factors cause variability in situations and circumstances and how stress comes about. The last finding is that students who believe themselves beyond who they are, and when facing problems beyond their ability, stress has more effects.

Keywords: stress, learning, personality characteristics, learning modes

Personalizing self-talk enhances athletic performance

MAGNUSSON, J. (University of Auckland), VANROON, C. (University of Auckland)

An athlete’s performance can be affected, positively and negatively, by what and how they think (i.e. their self-talk). While there is evidence indicating that the words used for self-talk can impact performance, it is not clear if personalizing these words alters their effectiveness. In this study we investigated if personalised, as opposed to prescriptive or no, self-talk enhanced athletic performance as well as the athlete’s perception of the effectiveness of this mental skill. We recruited Elite (n=30) and Novice (n=30) Taekwon-Do athletes from the International Taekwon-Do Foundation of New Zealand (ITFNZ). Athletes performed a ‘side kick’ against a mounted Adidas Electronic Body Protector (EBP) vest which measured the impact force of the kicks. To determine if self-talk influenced performance, athletes were compared over three self-talk conditions: baseline (no self-talk), prescribed (commonly used coaching words) or personalized (subject-by-subject words generated by a pre-performance interview). In addition to the quantitative EBP measure of kick force, athletes qualitatively rated their own performances following each trial. At the end of all trials athletes completed the Self-Talk Use Questionnaire (STUQ; Hardy et al. 2005) to document their use of self-talk. For Elite athletes, the use of personalized self-talk enhanced performance (i.e. greater impact force of kicks) whereas prescribed self-talk was detrimental to performance. In contrast, Novice athletes performed better when using prescribed self-talk and worse when using personalized self-talk. Qualitatively, Elite athletes rated their overall performance as being better using personalized self-talk compared to no or prescribed self-talk. Novice athletes rated their overall performance as better using either personalized or prescribed self-talk compared to no self-talk. The STUQ data revealed that Elite and Novice athletes preferred to covertly use positively worded short phrases. The execution of an athletic skill (i.e. Taekwon-Do kick) was enhanced when athletes used self-talk words that were personalized to them. It was also found that athletes perceived their performance was enhanced when they used personalized (Elite) or personalized and prescribed (Novice) self-talk. To enhance the effectiveness of mental skills such as self-talk it is therefore important to personalize self-talk words to the athlete as they will be more meaningful and therefore more effective for the athlete. This is especially true for Elite athletes who have a better understanding of their sport and the execution of the skills required to be successful (i.e. they are often better able to formulate effective self-talk words for themselves). In comparison, Novice athletes may not be as aware of the subtle nuances of their skills and therefore require more prescribed self-talk words to help them with their performance. These findings demonstrate the benefit of an individualized approach to working with athletes in order to facilitate their awareness of what is required to successfully execute the skills of their sport and how the use of individualized self-talk words, rather than commonly used words and phrases, can more effectively enhance performance.

Keywords: self-talk, athlete performance, elite athletes, novice athletes, taekwon-do

Personification of artificial objects: Effects of animistic thinking on facial expression perception of cars
Humans have developed an ability to gather different information from facial expressions. Windhager et al. (2008) examined the possibility of applying such facial expression perception to artificial objects. As a result, they found the impression for cars constituting two dimensions: ‘Power’ and ‘Sociability’. Why do we recognize facial expression towards artificial objects? This study focuses on an animistic thinking and examines the relationship between the tendency of personifying artificial objects and the perception of facial expression of cars. Questionnaires were distributed to 257 university students in Japan. The main questions were as follows: 1) The impression evaluation of the car (Windhager et al., 2008) and 2) the animism scale (Ikeuchi, 2009). Towards the former, we selected three kinds of cars (BMW, VW, MARCH) and presented their photos to the respondents. We selected them because BMW, VW, and MARCH represented higher, middle, and lower power dimensions, respectively (Windhager et al., 2008). Then, the respondents were asked to rate against the items of car impression (e.g. friendly, angry) on a percentage scale (100%—strongly agree; 0%—Disagree). The results of factor analysis indicated the following: 1) The car impressions were made up of three factors (‘Power’, ‘Sociability’, and ‘Instability’) and 2) the animism scale constituted two factors (‘Deification’ and ‘Personification’). ANOVA was conducted—the dependent variable was the score of car impression for each factor, and the independent variables were the personification tendency (high/low) and the model (three kinds). As a result, the main effect of the models was significant in all factors. In particular, ‘Power’ and ‘Instability’ of BMW were higher than that of other models, although it’s ‘Sociability’ was lower. Besides, as compared to the low personification tendency group, the high group was more likely to regard cars on aspects of ‘Sociability’ and ‘Instability’. The findings in the present study indicated that the result of Windhager et al. (2008) was reproduced in Japan and that Japanese people might be more sensitive to the state of emotion.

Keywords: emotions, facial expression, animistic thinking, personifying artificial objects, Japan

Pleasant stimuli from the International Affective Picture System (IAPS) may induce low-arousal states in volunteers

The aim of this study was to present the standardization and comparison of the Brazilian norms of the International Affective Picture System (IAPS), an instrument of affective images widely used in research with the North-American norms (Study 1). A further aim was to confirm the existence of pleasant-relaxing pictures (not described in the original study of IAPS) by physiological measures (Study 2). Study 1, the standardization of IAPS for Brazil, was performed with 1,510 Brazilian university students (543 males), who rated 936 visual stimuli for valence, arousal, and dominance following the methodology of the original study. Data of Brazilian and North-American samples were compared through Pearson product moment correlation (level of significance: 5%). Study 2 involved 24 volunteers (12 males) who were recruited for individual sessions in which they viewed a set of 40 IAPS stimuli selected on the basis of valence and arousal normative means. During slide viewing, physiological data (heart rate, skin conductance, peripheral temperature, corrugator and zygomatic electromyography activity) were recorded and the subjects evaluated each picture in terms of pleasure and arousal. The physiological scores for each stimulus were calculated and responses between emotional categories were compared by ANOVA. In Study 1 the correlations between Brazilian and North-American norms were significant. The correlations were higher for valence, followed by dominance and lastly by arousal (r = 0.95; 0.88 and 0.64, respectively). Unlike North-Americans, Brazilians described
some pleasant pictures as low-arousing, and there was a high negative correlation between pleasure and arousal dimensions \((r=-0.84)\), whereas this correlation was much lower in the original standards \((r=-0.27)\). To confirm these observations Study 2 provided evidence of physiological relaxing induced by low-arousal pleasant pictures. Pleasant-relaxing pictures elicited greater zygomatic muscle activity when compared to pleasant arousing \([F(3,69)=6.39, p<0.001]\). There were found to be great similarities between Brazilian and North-American norms for IAPS, however, the original study was based on a unipolar arousal scale and considered all pleasant stimuli as arousing, whereas our standardization detected the existence of pleasant-relaxing pictures and proved their validity through physiological evidence. Our findings suggest that a re-interpretation of the affective space of valence and arousal, based on a bipolar arousal scale, may provide a more accurate emotional assessment.

**Keywords:** International Affective Picture System (IAPS), arousal state, pleasant stimuli, physiological measures, bipolar arousal scale

### Political consciousness of Japanese adolescents after the democratic change of government

**Takahashi, N. (Rissho University), Aiba, M. (University of Tsukuba)**

For the first time in postwar Japan, the Democratic Party won a majority of seats in August 2009 and a change of government happened as a result of an election. Opinion polls conducted before the election showed that most Japanese had low political interest and passive political involvement. However, in the last few elections for the House of Representatives, voter turnout has been high, with either the Liberal Democratic Party (LDP) or the Democratic Party (DP) gaining the largest number of seats. The voting behavior of Japanese adolescents was analyzed from the perspective of political consciousness and fashion. A survey of Japanese adolescents \((n = 387)\) was conducted in September 2009 after the change of government, using a questionnaire that inquired about voting behavior, political interests, frequency of political conversations, political knowledge, level of excitement about the election, apathy regarding the election, sensation seeking scale and the frequency of pro-social behaviors. Voting behavior of respondents were DP voters \((11.6\%)\), LDP voters \((13.0\%)\), other voters \((9.3\%)\), nonvoters \((19.3\%)\), no constituency \((46.8\%)\). Results of a one-way analysis of variance by voting behavior indicated that LDP voters had higher political interest than nonvoters \([F(4,370)=5.30, p<0.05]\), and higher political knowledge than other voters, nonvoters and no constituency \([F(4,373)=6.31, p<0.05]\). LDP and DP voters had more frequent political conversations than nonvoters and no constituency \([F(4,366)=6.31, p<0.05]\). Moreover, DP voters were more excited about the election than others \([F(4,371)=5.27, p<0.05]\). Other voters felt more apathy about the election than no constituency \([F(4,370)=3.95, p<0.05]\). It is suggested that adolescents who become temporarily excited about the expectation of a change of government showed a trend towards supporting the DP. At the same time, LDP lost the election because they had little support among adolescents, who felt apathetic about the election.

**Keywords:** political consciousness, Japanese, change of government, election, voters

### Positive emotion regulation: An ERP study

**Zhang, Q. (Capital Normal University), Yang, Y. (Capital Normal University)**

Using the event-related potential (ERP) measurement, the present study investigated the impact of cognitive reappraisal strategies (enhancing and decreasing) on positive emotion regulation (ER) and subsequent cognitive task. Sixteen young native Chinese-speakers (6 males, 10 females) participated in the study. In each trial a positive picture was firstly presented on the screen and participants were asked to normal view or regulate emotions (enhance or decrease). An emotional word was then presented and participants were asked to judge the pleasantness of the word. ERPs were recorded from 64 scalp electrodes. ERP results
during ER period indicated that the amplitude of LPP (300-800ms) was larger under cognitive reappraisal conditions than under the viewing condition, and the amplitude of LPP was larger at enhancing condition than at decreasing condition. During valence decision, behavioral results showed that reaction times (RTs) were longer at decreasing condition than at enhancing condition, and longer at enhancing condition than at viewing condition. In the meantime, ERP results indicated that amplitudes of N400 (320-430ms) and P300 (450-720ms) evoked by emotional words were modulated by different cognitive reappraisal strategies. Specifically, N400 amplitudes were larger in response to words presented after participants reappraised pleasant emotions than after participants only viewed pictures. The N400 difference between enhancing condition and decreasing condition was marginally significant. In addition, P300 amplitudes were smaller in response to words presented after enhancing or decreasing a pleasant emotion relative to maintaining that emotion. Our results suggested that cognitive reappraisal strategies were effective for positive emotion regulation. More cognitive resources were needed when participants reappraised pleasant emotions.

Keywords: event-related potential, cognitive reappraisal strategies, positive emotion, cognitive task

Positive illusions of social competence in girls with and without ADHD

OHAN, J.L. (Queensland University of Technology), JOHNSTON, C. (University of British Columbia)

Self-concept and self-appraisals are at the foundation of mental health. This project aims to examine how girls with attention-deficit/hyperactivity disorder (ADHD), who are at risk for low self-concept, view their social abilities relative to parent and teacher report, and relative to research assistant ratings of their performance during a social laboratory task. A secondary aim was to test if these over-estimates were related to psychosocial well-being. We compared social self-competence ratings in girls with (n=42) versus without (n=40) ADHD, relative to ratings of the girls’ social competence made by mothers, teachers, and blind raters (research assistants) during a social laboratory task. We also gathered measures of psychosocial functioning. Although both groups of girls over-estimated their social competence relative to all indices (mothers, teachers, and research assistant ratings), girls with ADHD grossly over-estimated their competence. When over-estimates were correlated with measures of psychosocial well-being, a different pattern of results emerged for each group. For girls with ADHD, over-estimates were positively related to maladjustment (e.g., aggression) and negatively related to adjustment (e.g., number of friends). For girls without ADHD, over-estimates were positively related to adjustment. Overall, results suggest that over-estimates of competence function differently in girls with and without ADHD. For girls without ADHD, the often-cited notion that over-estimating one’s performance is adaptive, first made popular by Taylor & Brown (1988), appears to be supported. However, for girls with ADHD, the opposite appears to be true: in this case, the view that these illusions are maladaptive, and that accuracy in self judgment is the cornerstone of mental health may be more appropriate.

Keywords: Attention Deficit Hyperactivity Disorder, social competence, psychosocial well-being, self-concept

Positive psychological resources and student well-being: Optimism, emotional support, and promoting positive outcomes

CONDREN, M. (York University), GREENGLASS, E. (York University)

Post-secondary students, particularly those who are adjusting to the transition from high school to university or college, face a great deal of stress in their daily lives. However, positive psychological resources such as optimism and emotional support can help to mitigate negative outcomes and promote positive ones. This study explores the relation between optimism and emotional support, and how these two resources act together to promote psychological well-being in students. Specifically, the relation between optimism, emotional support, and feelings of vigor, a factor associated with psychological well-being, will be examined, as
well as the relation between optimism, emotional support, and depression. Data were collected at two time points in an internet study of student well-being. 68 first-year university students filled out an online questionnaire at the beginning of the fall semester, and again 6 to 8 weeks later. Variables measured included optimism, emotional support, vigor, and depression. Mediation analysis was used to examine the relation between optimism at Time 1, emotional support at Time 2, and vigor at Time 2, as well as the relation between optimism at Time 1, emotional support at Time 2, and depression at Time 2. Mediation analysis indicated that the relation between optimism and vigor was fully mediated by emotional support. Similarly, the relation between optimism and depression was fully mediated by emotional support. Additional regressions are reported that support the mediating role of emotional support on both vigor and depression. Taken together, the results of this study support a step by step process wherein optimism’s effects on both a positive and a negative outcome are fully mediated by emotional support. Theoretical and practical implications are discussed, including the importance of these findings in developing interventions to increase student well-being.

Keywords: students, well-being, optimism, emotional support

Post-traumatic stress and social processes: A contextual action perspective

DADSON, M. (University of British Columbia), OLSON, T. (University of British Columbia), YOUNG, R. (University of British Columbia)

The paper aims to use a contextual action theory perspective to explore the social processes involved in post-traumatic stress disorder (PTSD). Social processes are at the basis of the formation of the diagnosis of PTSD and its inclusion in the third edition of the DSM (DSM-III; American Psychiatric Association, 1980). The foundation of the PTSD diagnosis highlights contextual and social construction processes (McNally, 2004). Based on the notion that people make sense of their own and other people’s behaviour as goal directed, Contextual Action Theory adapts the perspective that actions have social, personal, and intentional context and relevance; they have a beginning and end, and cluster in such a way that they organize goals (Young and Vaach, in press). In this paper action theory is used to conceptualize a case study that shows the goals, actions and social processes of a combat veteran’s experience with PTSD (Young, Valach, & Collin, 2002). Results describe pre-trauma, post-trauma, and post-therapy social processes of a combat veteran’s experience with PTSD. Using action theory, the paper provides a fuller account of the meaning and purposes of the goals and actions of a veteran with PTSD. For example, over the course of the development and treatment of PTSD, goals change from pre-trauma, “enjoying and caring for his family” to post-trauma, “getting through or surviving the next day ... or even hour” to post-therapy, giving and receiving help with PTSD to other veterans and building better relationships with his family. When an action theory perspective is applied to a veteran suffering from PTSD, it provides a powerful illuminator of the social processes that characterize the disorder. Knowing more about the deeper purposes and the social process that underlie PTSD helps clinicians understand and treat the symptomatic behavior of veterans who suffer from PTSD.

Keywords: Post-traumatic stress disorder, social processes, contextual action theory, veteran, DSM-III

Powerful effects of media on emotional cognitions: Implications for mental health

KHOSLA, M. (University of Delhi)

The aim of the current study was to investigate if laboratory (Study 1) or personally traumatic events (Study 2) cause qualitative differences in affect, cognition and arousal. In a 3x2 factorial design, a between subjects comparison of the type of depression (non-depressed n=30, induced depressed n=30 and depressed n=30), and a within subjects comparison of the type of information (central vs. peripheral detail), were made for affect, arousal, memory, and Retrospective Time Estimation in response to a traumatic film clip in Study 1; and to a personally
traumatic event in Study 2. In study 1 the induced depressed group felt significantly more distressed, angry, and aroused after viewing the clip as compared to the depressed and non-depressed group. The depressed group felt more angry and fearful compared to the non-depressed group; and the non-depressed group felt more distressed than the depressed group. The depressed group had better recognition memory and estimation of time as compared to the non-depressed and induced depressed groups. In Study 2 the induced depressed group felt significantly more distressed, angry, inactive, and aroused, and had better memory for central rather than peripheral details after recalling the personally traumatic event, as compared to the depressed and non-depressed groups. There are significant differences in the way depressed and induced depressed groups respond to film and personally traumatic events. The emo-cognitions mediate special processing patterns whereby similarly toned resources are enhanced and elaborated, in line with the mood-congruency hypothesis (Bower, 1981), with a limited focus creating tunnel memory (Safer et al., 1998) and enhancing memory for central details. Therefore, the laboratory setting leads to similar differences in emotions, cognitions as personally traumatic events. The theory of emo-cognitions proposed here explains the complex interaction between the traumatic event, the type of information, the reactions and the experienced affect. This study provides valuable insights into the significant role of media depictions in the etiology of depression and its prevention.

Keywords: media, emo-cognition, trauma, depression, memory

Predicting adolescent intentions to use sun protection: Extending the Theory of Planned Behaviour

CARASTATHIS, G. (Edith Cowan University)

Compared to all other age groups, adolescents are often cited as having poor compliance for adopting sun-safe behaviours. This is disconcerting because adolescent skin is more sensitive to the effects of ultraviolet radiation thus, posing a significant risk of developing skin cancer in later life. The theory of planned behaviour (TPB) is a comprehensive model that is widely used to explore the underlying influential factors behind behaviours and intentions. Its application toward sun protection, however, is limited, especially within the area of adolescent sun protection. Given this, the aim of this present study was to examine the sun protective intentions of adolescents, using the TPB, whilst expanding the model to incorporate additional influences that have been known to affect the adoption of sun preventative behaviours. Participants comprised of 102 adolescents, aged between 11 and 18 years who were recruited through West Australian schools and convenience sampling. A self-report sun survey, which was based on the standardised TPB methodology, was used to assess the influence of attitudes toward sun protection, subjective norms and perceived behavioural control upon intentions to use sun protection. Additional predictors of unrealistic optimism, descriptive norms, skin type, and age were used to extend the TPB framework. Regression analyses revealed that the TPB predicted 50% of the variance in intentions to use sun protection. With the inclusion of the additional variables the model was able to account for significantly more of the variance (59%) in intentions to use sun protection. Regression analyses, however, revealed that of the additional predictor variables, only age and unrealistic optimism made significant, unique contributions to predicting variance in sun-protective intentions. Attitudes toward sun protection, subjective norms, and unexpectedly, unrealistic optimism were associated with greater intentions to use sun protection. Age was negatively associated with intentions, such that older age was related with lower intentions to use sun protection. The results from this study validate the use of additional variables within the TPB to predict adolescent sun protection, in particular emphasising how unrealistic optimism, age and subjective norms can affect adolescent intentions to protect themselves from the sun.

Keywords: adolescents, sun-safe behaviours, theory of planned behaviour, attitudes, intention
Predicting effects of achievement motivations on positive and negative test emotions

LEE, Y-M. (National Taipei University of Education)

This study aims to analyze and compare the differential predicting effects of achievement motivations on positive and negative test emotions. 310 high-school students (122 male and 188 female) from 3 high schools in Taipei were sampled. These students were administered the scales before and after a math test. The prediction variables in the achievement motivation scales are subjective competence (self-efficiency, task difficulty & success expectation), implicit self-theories (entity & incremental theorists), test meaning (threaten & challenge), and self-consciousness (affection-reflection, appearance-impression & social anxiety). The outcome variables are positive and negative emotions. Hierarchical regression analysis was adopted for statistical methods. Results revealed (a) the explaining variation of prediction effects reached 49.2% - 68.9%, thus it indicated those motivations were intently related to both positive and negative test emotions; (b) that self-efficiency, success expectation, and test meaning of challenge all significantly predict positive test emotion, except implicit self-theories; and (c) task difficulty, implicit self-theories of entity theorists, test meaning of threaten, appearance-impression, and social anxiety significantly predict negative test emotion. To conclude, compared to negative test emotion, positive test emotion is less affected by implicit self-theories and self-consciousness. Corresponding to motivation theories, the results mostly verify our hypotheses. The mechanistic process in which self-consciousness affects negative test emotion, as well as the method for mitigating negative test emotion through cognitive regulation about the test, are worth further exploration.

Keywords: achievement motivation, test emotion, implicit self-theories, self-consciousness

Predicting intention of hearing parents to communicate with their deaf child in sign language: An application of the theory of planned behaviour

FINCHILESCU, G. (University of the Witwatersrand), KLEIN, A. (University of the Witwatersrand)

When a deaf child is born to hearing parents, one of the most challenging decisions to be made is the mode of communication they will use with that child. There is considerable contention as to whether sign language should be used, or whether the child should be forced into lip-reading and orality. The mode of communication selected has profound effects on the deaf child’s cognitive and social development. The present study utilized Ajzen’s (1985) Theory of Planned Behaviour (TPB) to investigate the factors influencing hearing parents’ intention to communicate with their deaf child through the use of sign language. The model proposes that intentions strongly predict behaviour, and intentions are influenced by attitudes, perceived subjective norms and perceived behavioural control. A questionnaire was constructed using the TPB template (Ajzen, 2002). In addition to the usual constructs, a stigma measure was included. A sample of 112 hearing parents with deaf children completed this questionnaire. The results were analysed using multiple linear regression. The results indicated that attitudes, perceived behavioural control and stigma contributed to the prediction of hearing parents’ intentions. Contrary to the theory, subjective norms did not provide a significant contribution to the prediction of intention. Attitude emerged as the strongest significant predictor of intention, followed by perceived behavioural control and then stigma. Additional analyses revealed that attitudes and perceived behavioural control were not significantly predicted by their respective belief-based measures. Parents’ intentions to use sign language as the primary mode of communication is primarily determined by the attitude to sign language and the extent to which they perceived deafness as a stigma. Their beliefs about their capacity to learn sign language is also a determining factor.

Keywords: deaf child, communication, sign language, theory of planned behaviour, deafness

Predictive measures of sales performance: A validation study of test outcomes and manager ratings
COYNE, M. (RMIT University), JACKSON, M. (RMIT University)

The aim of this research was to conduct a validation of a ‘narrow band’ measure of job performance used within sales environments. It was hypothesised that this measure would be a valid predictor of sales specific job performance, but not of broader overall job performance or corporate citizenship. Fourteen managers of financial planners from within a large Australian financial services organisation participated in the study. They were required to complete an online performance rating survey designed to capture manager ratings of employee performance from both a sales and corporate citizenship context for a number of their selected employees. Rating surveys were numerically coded and then paired with the matching employee’s assessment results. These were then analysed accordingly. A chi-square test of independence determined that the ‘narrow band’ measure was a valid predictor of sales specific performance and of broader overall job performance, but not of broader corporate citizenship. An overall accuracy level of 66.6% in predicting sales performance; 66.6% in predicting overall job performance; and 58.3% in predicting corporate citizenship behaviours was also determined. When assessed across three different competency settings, this ‘narrow band’ measure was found to be a good predictor of future job performance across sales specific and overall job performance, but not of corporate citizenship behaviours. This is largely consistent with the body of research. However, the significant relationship between high assessment scores and high overall job performance ratings was not expected, indicating that this tool is not only good at predicting high performers when measured against narrow criteria, but also in predicting broader criterion such as overall job performance.

Keywords: sales performance, predictive measures, validation, test outcomes, job performance

Predictors of suicidal behaviour in mental health patients

OLUJIE, C. (Northern Sydney Central Coast Health)

Predicting suicidal behaviour is a complex multidimensional venture in mental health and public health settings. Mental illness is known to carry a higher risk of suicide and suicide attempt in comparison with the general population. The study aims to identify potential characteristics common to parasuicidal mental health patients and provide the clinician with useful information to better understand and modulate suicidal behaviours. Data was collected from 96 mental health patients with recent history of suicide attempt and were suicidal (as measured by the Beck Scale for Suicidal Ideation, BSS) at the time of the study. The participants completed questionnaire measures of hopelessness, temporal orientation, self-efficacy, neuroticism, pain intensity and problem-solving confidence. Fourteen potential predictors were identified. The 14 variables predicted 43.8% of the variance of the BSS. However, only four of the predictor variables (hopelessness, number of suicide attempts, time incompetence, and pain intensity) contributed to most of the variance. Hopelessness and number of attempts showed the strongest predictive value. Two hypothetical frameworks namely Beck’s Cognitive Sensitization model and Solomon’s Opponent Process theory were considered in explaining the results.

Keywords: suicidal behaviour, suicide, Beck Scale for Suicidal Ideation, cognitive sensitization model, opponent process theory

Preference of background texture in reading sentences with a computer monitor

NAKAYAMA, K. (Kinki University)

When we read sentences on computer monitors or video display terminals, the background of the sentences are usually plain, noiseless white. On the other hand, in paper-based reading, the backgrounds of sentences are noisy to some extent. In this study, the effect of background-noise on the evaluation of readers with computer monitors was examined. Participants read part of a Japanese novel presented on a computer monitor with four background conditions: background with no noise (i.e., plain), with rough texture, with middle texture and with fine texture. The texture was made
with Photoshop based on Japanese paper. Average luminance of the monitor was controlled. The stimuli (i.e., part of a novel) were presented on the computer monitor with the standard format of Japanese paperback. One display corresponded to one page, and one of the background conditions was assigned to each display. Thus, a trial consisted of four displays. The participants were instructed to read sentences at their own pace. When they had finished reading a display, they were asked to evaluate their impression of the display as a whole on a rating scale. A five-point SD scale was used with ten items: flat, calm, comfortable, stable, visible, readable, inexhaustible, plain, natural, and clean. When the participants finished the evaluation and clicked a button, the next display was presented with another background. The order of background conditions was counter-balanced between participants. The results of the experiment show that evaluations were higher in the fine-texture condition than in the no-texture condition in some items. That is, the fine-texture condition was evaluated as being more visible, readable and inexhaustible than the no-texture condition. On the other hand, as there were large differences between participants, the individual difference of preference was suggested. In conclusion, there is the possibility of improving readability by purposely adding some noise to background texture.

Keywords: computer monitor, background texture, reading, preference of background texture, background noise

Prevalence and predictors of persistent cognitive decline in older hospitalised patients: A six-month follow-up study

CHEN, C.C. (National Taiwan University)

Cognitive decline occurs in 16-35.5% of older hospitalised patients, but this decline may be persistent rather than transient. Distinguishing persistent from transient cognitive decline is clinically useful. The aim of this study was to determine the prevalence and predictors of persistent and transient cognitive decline in older hospitalised patients over six months after hospital discharge. For this prospective cohort study, 291 older patients were recruited from five medical and surgical units at a tertiary medical centre in Taiwan. Patients were assessed for cognitive status by scores on the Mini-Mental State Examination at admission, discharge, three and six months post-discharge. Persistent cognitive decline was defined as continuing score reduction and >3 point reduction six months post-discharge. Transient decline was defined as >3-point reduction at some stage, with a total decline <3 points six months post-discharge. The cognitive status of the majority of subjects (57.4%, n=167) decreased >3-point during follow-up. Of these decliners, 59 (35.3%) had persistent cognitive decline, with an average 5.32-point reduction six months post-discharge. Forty-six (27.5%) patients experienced transient cognitive decline. After multiple adjustments in logistic regression analysis, persistent decline was predicted by no in-hospital functional decline (OR=0.16, p=0.002), more re-admissions after discharge (OR=2.42, p=0.020), and older age (OR=1.09, p=0.048). Over half the sample experienced significant cognitive decline following hospitalisation, with more than 35% of this decline being persistent. Identified predictors suggest the need for a new perspective in discharge planning on patients at risk for persistent cognitive decline.

Keywords: persistent cognitive decline, transient cognitive decline, older hospitalised patients, predictors, Taiwan

Preventing burnout: Therapeutic approaches that safeguard both client and clinician from (re)traumatization when working with developmental trauma

STEWART, B. (Brookswood Counselling Services), COOK, A. (Private Practice Clinician), BRADSHAW, R. (Trinity Western University), DADSON, M. (University of British Columbia)

The numerous risks for re-traumatization of clients and vicarious traumatization of clinicians are extremely important to consider when working therapeutically on posttraumatic issues, particularly difficulties resulting from ongoing developmental trauma. Vicarious traumatization of clinicians may inhibit therapeutic effectiveness and contribute to burnout. This
paper addresses issues within the treatment of trauma-related disorders that may put therapists at risk for both vicarious traumatization and burnout. Moreover, current theoretical perspectives on trauma-related disorders will be discussed and practical tools for managing the posttraumatic responses of severely traumatized clients (while also protecting the clinician) will be described. For example, the theory of mentalization (Fonagy, Gergely, Jurist & Target, 2004) offers a helpful attachment-based orientation toward disorders emerging from ongoing developmental trauma (e.g. borderline personality disorder) while providing specific ways of working with the client around managing overwhelming affect. In a similar way, using the specialized tools within mentalizing-based practice (e.g. marked mirroring) may prove not only therapeutic for clients, but may also increase healthy differentiation of the clinician on a neurological level (e.g. mirror neurons), where vicarious traumatization is thought to occur (Rothschild, 2000). Additional theories and practical tools will be discussed, using case examples, as well as ways with which to integrate them into existing clinical approaches.

Keywords: trauma, burnout, post-traumatic stress, therapy

Profiling academically engaged and disengaged students using personal investment theory

KING, R. (The University of Hong Kong), GANOTICE, F. (De La Salle University), WATKINS, D. (The University of Hong Kong)

Personal investment theory is concerned with how persons choose to invest their energy in particular activities, and designates three basic components of meaning as central to understanding this personal investment: sense of self, perceived goals of behavior, and facilitating conditions (Maehr & Braskamp, 1986). Personal investment theory may shed light on why some students are engaged while others are disengaged from the school experience. Academic engagement has been posited as an important multifaceted construct that involves cognitive, behavioral, and emotional components. The aim of this research was to investigate how the different components of personal investment theory are related to academic engagement. 323 Filipino secondary school students were given questionnaires that assessed their academic engagement (cognitive, behavioral, and emotional), sense of self, facilitating conditions, and goal orientations. Correlations were obtained to examine the relationships among the variables. In an effort to determine whether the qualities associated with academic engagement as revealed by correlational analyses involving the whole sample were truly characteristic of highly academically engaged (or disengaged) individuals, a discriminant analysis was conducted focusing on students scoring particularly high or low in academic engagement. Specifically, high and low engagement students were required to have scores at least one standard deviation above or below the mean for the academic engagement composite variable. 49 students with high academic engagement and 59 students with low academic engagement were identified. Results indicated that the different components of personal investment theory successfully discriminated between the high and low academic engagement groups. Students who exhibited high academic engagement had higher scores for the positive sense of self scales (positive academic self-esteem, sense of purpose for schooling, self-reliance), higher scores for positive facilitating conditions (positive parental support, teacher support, and positive peer influence), and higher scores for academic goals (mastery goals, performance goals, and social goals). Performance avoidance goals and negative academic self-esteem failed to discriminate among the two groups. The different components of personal investment theory can shed light on why some students are engaged while others are disengaged from the school experience thus offering a more complex picture of the reasons behind engagement and disengagement.

Keywords: personal investment theory, sense of self, goal orientation, academic engagement

Psychodynamics and the giving of the Ignatian spiritual exercises in Australia

SAUNDERS, P. (Monash University)
This research aims to examine the understanding and use of psychodynamic processes of spiritual directors in the giving of the Ignatian Spiritual Exercises. It aims to develop a deeper appreciation of the relationship between psychoanalytic processes and the giving of the Exercises through the experience of the director. It is hoped that results will inform the formation of directors of the Exercises in the future. This qualitative research is in progress and is using semi-structured in depth interviews. To date, 15 have been conducted. Of the 15 spiritual directors interviewed, 9 were Jesuit priests, 1 religious woman, 2 laymen, and 3 laywomen, with ages ranging between 50 and 90 years. Some received the Exercises as a preached 30-day retreat, some as a directed 30-day retreat and some as a 30 week directed retreat. Most had no formal training to become directors, learning as an apprentice with a supervisor. Others since 1999 have been trained through the Arrupe formation program. Most have had little or no psychology training and most had no experience of counseling or therapy. There were very different views expressed about the place of psychological processes in the giving of the Exercises. The data at this stage suggests that there is little conceptual understanding of psychodynamic processes at work by the directors in the giving of the Spiritual Exercises. Most had little knowledge of psychodynamic concepts, yet most have implicitly used psychodynamics, in an operational sense, in the way they have engaged in the relationship with their exercitants in the giving of the Exercises. The way in which the directors received the Exercises and were formed to give them seems to influence their openness to psychodynamic processes. There is room for improvement in the way directors are formed to give the Exercises to be more aware of the psychodynamics involved in the intimate relationship that occurs between the director and the exercitant in the giving of the Exercises. A very interesting ‘oral history’ component is emerging in this long-term research.

Keywords: Ignatian spiritual exercises, psychoanalytic processes, Jesuit priests, religious, Australia

Psychological and emotional effects of intensive care and emergency department nursing

LUSHINGTON, K. (University of South Australia), BARBIERI, N. (University of South Australia)

Compassion fatigue, secondary traumatic stress and vicarious traumatisation have been found amongst helping professions, as a result of the caring nature of the work and the worker’s level of engagement with traumatised people. Currently, there is a dearth of empirical research exploring these models of helper distress amongst critical care nurses. The aim of this study was to investigate these three models of helper distress amongst a sample of Australian nurses working in an emergency department and intensive care unit. Perceived levels of social support were also investigated in order to ascertain if it provided any buffering to helper distress. Participants were gathered from nurses working in Intensive Care and Emergency Departments at a local metropolitan based hospital serving the city of Adelaide, South Australia. Nurses were asked to complete a demographic questionnaire, the Professional Quality of Life Scale Compassion Satisfaction and Fatigue Subscales (R-IV), the World Assumptions Scale and the Multidimensional Scale of Perceived Social Support. Out of 153 participants 29.4% had elevated compassion fatigue/secondary traumatic stress scores in the clinical range. Benevolence was found to be predictive of compassion fatigue/secondary traumatic stress, burnout and compassion satisfaction levels. Lack of support from a significant other was found to be an important factor for burnout and poor self-worth was predictive of compassion fatigue. Finally, younger age was predictive of compassion fatigue/secondary trauma. There is a need to further explore these models of distress in general and specialised areas of nursing. Education about the effect of working in such a unique role and accessible support services should be available to critical care nurses.

Keywords: helper distress, critical care nursing, social support
Psychological automatism, depression and experience line: Three ways to understand the meanings of an injury in the sport arena

LECOCQ, G. (ILEPS-Cergy, LPA-URCA)

Between peak performances and painful experiences, embedded injuries and excessive behaviors, sporting fields are territories where a comprehensive psychology appears, where a border-line can meet the pain, where an injury can meet some structural dissociation, and where a sportman or a sportswoman discovers what a real human being he or she is. The first purpose of this presentation will be to explore steps which allow an injured sportsperson to discover - through a meaningful way of life - what lies beyond the blackness of a traumatic event. The second purpose of the presentation will be to answer to the question “how does an injury provoked by an intensive sports practice allow the wounded to encounter their real-self and to restart an authentic dialogue with his or her cultural environment?” Three concepts will be explored: 1) Border Line, from which we will discover the meanings of no-limit, loneliness and Hilflösigkeit in the sport arena; 2) Psychological Automatism, from which we will discover the necessity for a sportman to adapt his abilities to an uncertain environment; and 3) Structural Dissociation, from which we will discover how an injury reveals some hidden dissociative parts of a personality. In conclusion we will demonstrate how a deeper integration of body and mind emerges through an injury and how healing requires accessing the wisdom behind the wound.

Keywords: psychological automatism, structural dissociation, border line, injury, sport

Psychological foundation of sex education from the point of Quran and Hadith and it's effect on developing sex education programs

FAGHIHI, A.N. (University of Qom), GHOBARY BONAB, B. (University of Tehran)

The aim of the present study is to explain the psychological foundation of sex education in Islam and its impact on the procedures of teaching individuals to overcome difficulties in this area. The study consists of description and analysis of verses and hadiths related to human needs, tendencies, capabilities and sexual behaviors. It also includes the anthropological foundation and understanding of sexual behaviors that affect the sexual learning process. The results indicated firstly that human sexual tendency and relationships between men and women is completely natural and pure. Secondly, that sexual instinct accompanied by other instincts like kindness, intimacy, affinity, connecting other’s, liking beauty and the tendency towards spiritual beauty constitute a unique structure in human beings. Therefore, sexual instinct is not an animal instinct, but a human-like one. And thirdly, that moderate sexual satisfaction provides characteristic, ethical and intellectual development and leads the human to prosperity in the next world. In conclusion, a sacred outlook towards the regulated sexual relationship can promote people’s characteristic disposition. Through sexual learning, it is essential to develop the sense of being natural about sexual tendency, the necessity of regulated sexual satisfaction, chastity, modesty, cooperation between men and women, developing intimacy and affinity morale, promoting the kindness and friendship and other cognitive, emotional and behavioral skills that all must be considered.

Keywords: psychological foundation, sexual learning, sexual training, sexual instinct

Psychological influence on conflict interaction in an administrative team

LOZHKIN, G. (National Technical University), VOLIANIUK, N. (University of Educational Management of the Academy of Pedagogical Sciences of Ukraine)

Conflict management includes ways of influencing a person or a group of people with the aim of restructuring and developing effective interpersonal interactions. The influence is directed at changing the other person; his aims, assessment, and positions, in the course of interacting with him. The research objective of this study lay in determining the psychological influence types which provide success in solving
conflict interactions in an organization. The methods used were a free self-description questionnaire and a multiple-factor personality determination technique by R. Cattell. Communicative personal potential of influence, which provides the success in solving conflict interaction, is realized through basic and compensatory types. Basic types of influence include social intellect, personal magnetism, frustrating influence and trusted partnership type. It was determined that compensatory types of influence involve manipulative adaptability, militant virtue, responsibility and competence. The success of psychological influence on conflict interaction of personnel is provided by totality of sociocultural and creative characteristics of the manager’s personality in an organization. It has been empirically established that positive perception of other personalities is typical for social intellect and high adaptability and self-confidence is typical for personal magnetism. The frustrating type of influence implies tension and discomfort and trusted partnership type is characteristic of emphatic and altruistic people with underestimated self-esteem. Manipulative adaptability implies the presence of flexibility and persistence. Militant virtue is characteristic of authoritarian personalities with high moral aims but with low reflexion. Responsibility and competence of influence are provided by high intellect and professional reliability. Thus, at the heart of conflict management in an organization lays the coordination of a manager’s ways of influence on personnel usage.

Keywords: conflict management, psychological influence, social intellect, organisation, personality

Psychological reaction to role playing games for medical safety - Educational effect of multitask games

HYODO, Y. (Okayama University), TANAKA, T. (Okayama University)

Role playing games are often useful in risk evaluation and multicultural exchange. We applied the games to medical safety training. Assuming medical scenes, the games were designed for players to perform in a short time with simultaneous multitasks to introduce error factors. Psychological reaction of the players was measured in roles of both nurses and patients who experience difficulties. 24 second-year student nurses were recruited to play the games in the A university, August, 2009. The accuracy in delivering medicine was measured, along with change in evaluation before and after playing games, and impressions survey on games in view of each role to improve in practical applications and educational effects. Three nurse players performed separate tasks, and received reports from other nurses while they suspended the tasks. Patient players gave questions, requests and anxieties to intervene the tasks. In delivering medicine, errors were often found in sorts and quantities of the medicine, where only one group completed the task successfully. Evaluation change in before and after the games was investigated on 43 items. The highest score was found in difficulty to take over others task. The second highest was that there might be some errors left unnoticed, and that the task finished with others does not guarantee the accuracy. 25 other items was also found to increase scores after the game. Several interesting opinions were found in describing “What you learned in the game”, including: “Intervening from others while performing a task disturbs nurses to respond to patients appeal”; “To make a note is important to complete accurate procedures after suspending tasks”; “Nurse players felt impatience and became nervous”; “Even if when there is a shortage of time, it is important to perform slowly and accurately”. Multitask games can be designed to closely simulate actual medical scenes in hospitals, and make players experience and realize the seriousness of errors and the sequence of incidents. In particular, the games have a great impact on awareness, reaction and emotion of players, and it is quite effective in medical safety training.

Psychometric properties of the strength assessment inventory

BRAZEAU, J. (Centre for Excellence for Children and Adolescents With Special Needs), RAWANA, E. (Centre of Excellence for Children and Adolescents with Special Needs- Thunder Bay)
The Strengths Assessment Inventory (SAI) is a novel measure that assesses a broad range of psychosocial strengths in children and adolescents. The purpose of this research was to ascertain the psychometric properties of the SAI. Data was collected from 572 school-aged youths between the ages of 9 and 18. Reliability of the instrument was assessed using measures of internal consistency and test-retest reliability. Construct validity was assessed through factor analytic techniques and inter-scale correlations. Convergent and divergent validity was assessed through correlations between measures of strengths, self-concept, and psychopathology. Overall, the SAI-Y displayed intermediate to high levels of internal consistency, indicating that it is a reliable measure. Additional support for this proposition was demonstrated by the adequate-to-good test-retest reliability coefficients. Factor analysis and inter-scale correlations indicate that the measure has an acceptable level of construct validity. In addition, correlations between the SAI and other measures were all in the expected direction. Collectively, results from this study provide evidence that the SAI has desirable psychometric properties. The measure can be used in assessment and treatment that integrates positive aspects of functioning of children and adolescents.

Keywords: The Strengths Assessment Inventory, psychometric properties, reliability, validity, assessment

Psychopathological disorders in adolescence: A dimensional and psychological approach

Psychopathological disorders in adolescence are often associated with conduct problems in adulthood (violence, substance abuse or dependence, suicide). For a long time, their treatment has been a real public health issue. Several researches have dealt with the impact of psychiatric comorbidity on the severity of symptoms (Toupin et al., 2008; Geller et al., 2004). Others have evaluated individual features involved in this symptomatology (Seog et al., 2008) but few studies have jointly considered both these two explanatory factors. Objectives: Distinguish the elective impact of psychiatric comorbidities and psychological factors (personality, perceived stress, coping strategies) on the severity of symptomatology in psychiatric adolescents. The study recruited 50 adolescents presenting an internalized disorder, and 55 adolescents presenting an externalized disorder, aged between 11 and 17. Self-assessment was used, being the Children Depression Inventory for Children (Kovack & Beck, 1977), State Trait Anxiety Inventory for Children (Spielberger, 1983), Junior-Temperament and Character Inventory (Asch et al., 2009), Metamotivational Style Profile for Children (Sit et al. 2005), and Coping Across Situation Questionnaire, Problem Questionnaire (Seiffge-Krenke et al., 2008). Hetero-assessment (parents): Conners Parents Rating Scale (Conners, 1990) Kiddie-SADS (Puig-Antich, 1978). Preliminary results show that most adolescents presented a comorbid disorder (62%; 67%). Low individual maturity, high perceived stress concerning self qualifications and use of avoidant coping strategies in peer relationships were related to the severity of depressive symptomatology. High harm avoidance and high perceived stress concerning self qualifications were related to the severity of anxiety symptomatology. The difficulty to self-control and low individual maturity were associated with several attentional problems. Low individual maturity was involved in the severity of hyperactive symptomatology. Finally, oppositional symptomatology was essentially explained by a psychopathological factor: ADHD-ODD comorbidity. These results emerge from a dimensional approach of psychopathological disorders and allow specification of individual factors electively involved in their respective symptomatology. This kind of research might improve therapeutic treatment of these disorders.

Keywords: psychopathological disorders, adolescence, treatment, symptomatology

Quality of working life and the worker’s well-being
RIBEIRO, P. E. C. D. (University of Brasilia), PAZ, M. G. T. (University of Brasilia)

The present research has the objective of identifying the relationship between Quality of Working Life (QWL) and the worker's well-being. The QWL is realized through the many actions of an organization aiming to develop improvements and management and technological and structural innovations in the work environment, thereby identifying the worker’s experience as a central element in the organizational dynamic. Five factors are considered in the evolution of the QWL: Support of the worker’s accomplishment (execution and/or performance), Relationships, Professional Respect, Recompenses and QWL Programs. Personal Well-being within organizations is understood in terms of needs accomplishment and the individual’s desire-satisfaction through organizational performance. The systemic vision perspective is adopted to best attend to the study objective, considering QWL as a macro-systemic variable and personal Well-being a variable of micro-organizational level. The basic assumption of this study is that the perception of individuals of the actions of QWL influences how they experience Well-being in organizations. The instrument used to assess Well-being was a one-factor scale, interval scale, five points, composed of 16 items, statistically validated by Paz (2005), with reliability measures (Alpha de Cronbach) from 0.88 to 0.91 in different samples. The other instrument used to assess QWL was an interval scale of five points, composed of 31 items, based on the theory of Walton (1999), validated semantically by Paz (2006), with good levels of reliability and validity. Both were applied to 40% of the population of employees of an organization, representing 94 research participants. The statistical descriptive and inferential analyses were done using the Statistic Program SPSS version 13.0. The results showed that, for this sample, the factor "Relationship" was perceived by most respondents as indicative of QWL among the factors "Relationship" and "Professional Respect" as QWL factors that best predict the Well-being of workers studied. The conclusion is that the organization concerned should pay more attention to the others factors that foster Well-being and a better QWL is also favored when there is a fair system of rewards, when the organization supports the work and can make possible professional respect.

Keywords: quality of work life, workers’ experience, well-being, professional respect, worker’s accomplishment

Rapid situation assessment of injecting drug users and their response to HIV/AIDS in order to prevent HIV/AIDS and develop appropriate harm reduction strategies in Banceuy Prison, Bandung

SUHERMAN, H. (Padjadjaran University), SUMINTARDJA, E. (Padjadjaran University), ALISJAHBANA, B. (Padjadjaran University), JUSUF, H. (Padjadjaran University), DIJKHUIZEN, M. (Radboud University), WIERINGA, F. (Radboud University)

The aim of this rapid assessment of the situation in Banceuy Prison was to identify the existing situation, problems and also opportunities for interventions. Data were collected from the research respondents by conducting in depth interviews among 30 inmates and injected drug users who had stayed at least 3 months in Banceuy Prison. It was assumed that within 3 months they would already know the situation and condition of the prison. The main routes of HIV/AIDS transmission among the respondents are intravenous drug use and unsafe sexual behavior. Knowledge of the inmates on HIV/AIDS and the transmission was low and most of them refuse to change their behavior. Their intention to do the HIV test is high but there are several barriers that hinder them to do the testing as soon as possible. Since most of the inmates have difficulties in completely quitting from injecting drugs, support from others is urgently needed. Programs must be carried out to improve health services for inmates within the prison, developing support groups and increasing their knowledge about HIV/AIDS.

Keywords: HIV, prison, drug use, inmates, support groups

Real behaviors and ideal behaviors at the problematic situations in romantic relationships

AIBA, M. (University of Tsukuba)
The first purpose of the current study was to reveal that adolescents can really take and recognize desirable behaviors. The second purpose was to examine the relationship between real behaviors and ideal behaviors by sex. Three hundred and sixty seven undergraduates in Japan (27% male; mean age=20.2) completed the measure of real behaviors and ideal behaviors at the 10 problematic situations in romantic relationships (Aiba, 2009). Real behaviors were 4 behaviors (2 desirable, 2 not-desirable) per situation and measured by “How much will you really behave?” (Range=1-5). Ideal behaviors were the same as real behaviors and measured by “How much do you think that these behaviors are desirable for the opposite sex?” (Range=1-5). The means of real behaviors and ideal behaviors showed that not-desirable behaviors (thinking alone how to do, asking the lover for a reason) had the highest means in real behaviors at “anxiety for future relationship” and “broken heart”. At other situations, desirable behaviors had the highest means in both real and ideal behaviors. As a result of the correlation analyses between real behaviors and ideal behaviors by sex, there were significant correlations ($r=.18 -.45$) at all situations in females. On the other hand, there were no significant correlations ($r=.07 -.40$) at half of the situations in males. The results indicate that although many adolescents recognize that “thinking alone how to do” at “anxiety for future relationship” or “asking the lover for a reason” at “broken heart” are not-desirable behaviors, they really took those behaviors. Based on sex differences of the correlations between real behaviors and ideal behaviors, it is possible that females can really take and recognize desirable behaviors, but males cannot take or recognize those behaviors.

**Keywords:** romantic relationships, real behavior, ideal behavior, adolescents, Japan

**Reducing stormwater pollution in a small commercial district – do education campaigns work?**

CURNOW, R. (Community Change), SPEHR, K. (Community Change)

The aim of this research was to determine whether a low-cost, 8 month education campaign operating within a small commercial district would be successful at reducing stormwater litter loads and changing people’s littering behaviour. The campaign was conducted with 26 small businesses and the general community in a small suburban commercial district in an Australian city. Campaign elements included brochures, posters, merchant site visits, meetings, a cooperative clean-up event, improvement to council managed infrastructure (including bins), windproof ash-trays, drain stenciling, and clean-up of dumped rubbish. Outcome measures included: (1) monitoring of litter loads in stormwater (kg/day); (2) independent assessments of merchant stormwater and litter management activities, e.g., accumulation of trader waste; (3) observations of littering behaviour; and (4) knowledge and attitudes of merchants and the community using face-to-face surveys. Monitoring occurred at the campaign site and a control site 7 months prior to the campaign, during the 8 month campaign, and at 7 month follow up. The campaign produced mixed results. Compared to the control location: (1) the campaign had a moderate positive effect in reducing litter loads; (2) a modest improvement occurred in the litter and stormwater management activities of traders during the campaign, which receded at follow up; (3) community knowledge of littering and stormwater management (e.g., where stormwater goes, its treatment, etc.) did not improve, and merchant knowledge outcomes were inconsistent with clear improvements evident for only 20% of merchants; (4) community attitudes towards littering and litter management remained largely unchanged, with merchants becoming more pessimistic about change over the monitoring period; and (5) compared to baseline, the community showed some improvements in their disposal actions (using bins) during the campaign, which although maintained at follow up, were not statistically significant. Monitoring the effectiveness of education campaigns for stormwater quality improvement can be complex. To obtain a more substantial and consistent reduction in stormwater litter load, campaigns need to be ongoing, participatory, target both merchants and the community with
equal intensity, include strong incentives and rewards in addition to the use of penalties to stop activities such as illegal dumping, be responsive in using monitoring information to modify the campaign while its operating, be tailored to accommodate local environment features and work schedules of participants, and provide high quality bin-related infrastructure and associated maintenance.

Keywords: pollution, stormwater pollution, education campaigns, littering behaviour, commercial district

Relations among dependency/sociotropy, self-criticism/autonomy, stressful life events and depressive symptoms

MATSUMOTO, M. (Nagoya University), KANAI, A. (Nagoya University)

Personality has been traditionally conceptualized as a diathesis for depressive disorders, and has been particularly congruous in its interaction with stressful life events. Dependency or sociotropy (DEP-SOC) and self-criticism or autonomy (SC-AUT) as personality dimensions of vulnerability have enabled the formulation of the “congruency hypothesis”. This hypothesis includes precise predictions of interactions between personality and stressful life events. However, empirical support for the congruency hypothesis has been mixed. Then, recent research has posited that personalities could serve as outcomes, rather than causes, of depression. For this reason, depressive individuals may have shown both, high DEP-SOC and SC-AUT. In this study, we address a mediating model that links personality vulnerability, stressful life events—interpersonal or achievement-related, and depressive symptoms. Then, we focus on four subgroups of personalities of the DEP-SOC and SC-AUT dimensions: high-high, high-low, low-high, low-low. For individuals who have high-low and low-high as their DEP-SOC and SC-AUT, interpersonal or achievement-related stressful life events could have an effect on their depressive symptoms. Three hundred and fourteen female university students responded to measures assessing the DEP-SOC and SC-AUT dimensions among them as well as stressful life events (interpersonal and achievement-related) and depressive symptoms. We used the Depressogenic Schemata Scale, which yields three factors: Dependence on Evaluation on Others (DEP-SOC), Intention of High Achievement (SC-AUT), and Fear of Failure. Participants in the remaining four groups were then labeled as high depression (N=109), pure DEP-SOC (N=57), pure SC-AUT (N=58), and control (N=90). Regression analysis indicated that among individuals in the pure DEP-SOC group only negative interpersonal life events could predict an increase in depressive symptoms, whereas among individuals in the pure SC-AUT group only stressful achievement-related life events could predict increased depressive symptoms. Among high depression and control individuals, stressful life events were not able to predict depressive symptoms. These findings are discussed in terms of the need to consider DEP-SOC and SC-AUT and stressful life events as causes of depression, and as indicators of the value of investigating the relations between personalities, stressful life events, and symptoms of depressions.

Keywords: personality, depression, stressful life events, dependence, self-criticism

Relations between corporal posture and emotions

ROSARIO, J. (Universidade Federal de Sao Paulo), LEITE, M.P. (Universidade Federal de Sao Paulo), BEZERRA DIogenes, M.S. (Universidade Federal de Sao Paulo), PERSOLI, R.M. (Universidade Federal de Sao Paulo), LEITE, J.R. (Universidade Federal de Sao Paulo)

Many authors empirically suggest that the posture of each individual is a consequence of their emotions. Some have observed that the alteration of one factor modifies the other, and it is easy to imagine if we think about posture as the result of muscular contractions. Anxiety is a very clear example, as it directly affects the cardiac muscle and its rhythm, and the diaphragm and breathing, among other muscles. The inverse is also valid, that anxiety can be diminished by relaxing the muscles. This effect can also be achieved by relaxing the diaphragm with deep breaths. The objective of this work was to search for the existence of a relationship
between corporal posture and subjective emotional narrations. The posture of 28 women, aged 20 to 39 years, outside of the menstrual period, with normal or below weight corporal mass index, and without neurological, psychiatric or orthopedic problems, was photographed. Using tracings made on Corel Draw software it was possible to evaluate the postures. Emotions were evaluated through analogical scales demarcated from zero to ten for sadness, happiness, concern, fear, anger and depression. In order to statistically search for correlation between the postural and emotional evaluations a factorial analysis multivariate technique was used. Indications were found of correlation with values above 0.3 between raised shoulders and anger (0.32), raised shoulders and concern (0.32), valgus knees and anxiety (0.39), and scoliosis (represented by the difference between the angles of Tales) and concern (0.37). The other correlations showed very low results, tending to zero. It was possible to find indications of relationships between some emotions and positions. The biggest difficulty of the work was the subjectivity of the emotional narration, as the auto emotional evaluation is very complicated and may suffer great distortions. Other works and methodologies must be used to understand the extension and depth of these correlations. The importance of these findings may be of great relevance for the evaluation and treatment of diverse orthopedics and psychiatric pathologies.

Relations between personality dimensions and alexithymia

BESHARAT, M.A. (University of Tehran)

The relationship between personality dimensions and alexithymia was investigated in a sample of students. A correlational analysis was performed to assess the kind of association existing among five personality dimensions including neuroticism, extraversion, openness, agreeableness, and conscientiousness with alexithymia and its three components. Three hundred and forty six students (156 boys, 190 girls) from the University of Tehran were included in this study. All participants were asked to complete the Revised NEO Personality Inventory (NEO-PI-R) and Farsi version of the Toronto Alexithymia Scale (FTAS-20. Analysis of the data involved both descriptive and inferential statistics including means, standard deviations, multivariate analysis of variance, Pearson’s correlation coefficients and regression analysis. Alexithymia showed a significant positive association with neuroticism as well as a significant negative association with extraversion and openness. The results also revealed that neuroticism, extraversion, and openness can predict changes of alexithymia and its three components. It can be concluded that personality characteristics will influence cognitive processing of emotional intelligence and regulation of emotions. Results and implications are discussed.

Keywords: alexithymia, personality, emotional intelligence, emotion regulation

Relations of anxiety and depression with the image of God in college students

GHOBARY BONAB, B. (University of Tehran), HADDADI KUHSAR, A.A. (University of Tehran)

The aim of the current research is to investigate the relations of anxiety and depression with the image of God in Tehran medical sciences university. Using a proportional sampling procedure, the Image of God inventory (Lawrence, 1997) and symptom checklist-Revised (Deragotis et al., 1973) was administered on these students. Analysis of data using a multiple regression analysis revealed that the magnitude of anxiety and depression can be predicted from the quality of students’ images of God. Moreover, data revealed that students who had positive and accepting images of God were lower in anxiety and depression than students who had negative and challenging images of God. The authors concluded that positive and accepting images of God were associated with lower anxiety and depression in college students who were studying in medical schools.

Relationship between driver’s attitude and driving anger in Japan

MAKOTO, N. (Kansai University), OZSAMU, T. (Kansai University)

Most research on aggressive driving has focused on identifying aspects of driver personality which will exacerbate it (e.g. impulsiveness, uneasiness, morality, driving anger, etc.). The present study investigated perceivers’ inferences about the driving attitude of persons who engaged in driving anger. There were 167 participants (67 men and 100 women), ranging in age from 19 to 81 (M=29.84, SD=11.75). The driving experience of the sample ranged from 1 to 60 years (M=9.97, SD=10.92). Participants were Japanese driving license holders. The tendency to become angry while driving was measured with the 32-items of the Driving Anger Scale (DAS; Deffenbacher et al., 1994). Aggression, uneasiness/impulsiveness, critical attitude towards the norm, and driving pleasure tendency were measured using the Driver’s Attitude Questionnaire (Fujimoto & Higashi, 1996). Responses to the DAS were subjected to a principal components analysis with a varimax rotation. Inclusion and exclusion criteria were set at 0.40. These procedures resulted in four factors (traffic obstructions, slow driving, hostile gestures, deviant norm). Cluster analysis was performed from the Driver’s Attitude Questionnaire and four clusters were classified. Cluster 1 described a group of drivers confident at driving and critical towards the norm attitude. Cluster 2 described a group of safety driving attitude drivers (subscales score is low). Cluster 3 described a group of high unease drivers. Cluster 4 described a group of drivers who were confident at driving and had a positive attitude towards the norm. A repeated-measures one-way ANOVA was performed for attitude clusters with different DAS subscales. The result indicated that DAS scores was higher for cluster 1 than others. The present study was conducted to investigate the relationship between driver’s attitudes and driving anger, and it found that driving confidence and critical attitude towards the norm drivers felt anger while driving. Emotional arousal can influence perception and information processing; this influence could presumably be strong enough to disrupt driving proficiency sufficiently to increase accident risk (Deffenbacher et al., 1994). That is, driving confidence and critical attitude towards the norm drivers are easily irritated while driving, and more likely prone to accidents in Japan.

Keywords: driver attitude, aggressive driving, personality, driving anger, driving confidence

Relationship between humiliation, shame and guilt and narcissistic personality

AZAMI, R. (University of the Sacred Heart)

The narcissistic personality disorder in DSM-IV largely exhibits grandiosity, excessive need for others’ admiration, and a lack of sympathy. The relationship between the narcissistic personality and shame is often indicated in clinical considerations. Kohut (1971) suggested that the narcissist felt shame when he lost admiration, and concluded that the exaggerated self was at fault. Lewis (1992) suggested that the narcissist was likely to feel shame because he had a tendency to focus on the global self to evaluate his failure. Previous empirical studies have often used the Narcissistic Personality Inventory (NPI; Raskin & Hall, 1979). However, Gabbard (1994) showed that the narcissistic personality was classified into the oblivious type, who was reckless of others, and the hyper vigilant type, who excessively cared about others. It has been observed that NPI assesses the oblivious type. Another recent view has suggested that shame is distinguishable from humiliation (Gilbert, 1998). Therefore, this study aims at examining the relationships between humiliation, shame, and guilt and the oblivious and hyper vigilant types of narcissistic personalities. A questionnaire was filled by 234 participants. First, they were presented with a scenario of getting scolded by the teacher during a seminar class as a social predicament. Then, they were asked to give their responses to words of humiliation, shame, and guilt, their reactions while facing social predicaments, and to rate themselves on the scale of oblivious and hyper vigilant narcissism (Nakayama & Nakaya, 2006). Structural equation modeling revealed that hyper vigilant narcissism elicited the strongest humiliation through feelings of humiliation, shame, and guilt, while oblivious narcissism inhibited shame and guilt.
Humiliation promoted aggressive responses, such as rejection and rebuttal, to others. In contrast, guilt controlled them and furthered the action of improvement. This model showed sufficient goodness of fit: GFI = .99, AGFI = .95, RMSEA = .02. Oblivious narcissism has been the core concept of narcissism. Therefore, researchers have posited that narcissism causes the attack action when the oblivious individual’s self-esteem is threatened. However, it was found that the hyper vigilant individual’s self-esteem elicited aggressive responses mediated by humiliation, while that of the oblivious individual did not.

**Keywords:** narcissistic personality disorder, self-esteem, humiliation, shame, hypervigilant narcissism

### Relationship between psychopathological traits and sexual health in adolescents

URIBE-RODRIGUEZ, A.F. (Universidad Pontificia Bolivariana-Pontificia Universidad Javeriana Cali)

The objectives of this study are to determine whether psychopathological variables are a psychological risk factor for HIV infection in Colombian adolescents. The research is descriptive and quasi-experimental. According to Montero and Leon (2002, 2005) it is included in the category of quasi-experimental "all studies, even with the aim of contrasting the hypothesis of causal relationship, are limited more or less serious" to have success "(p. 608). In conducting an analysis of variance in terms of risk groups according to oral sexual conduct there are significant differences in psychoticism $F(2.344?) = 3.698, \text{MSE} = 0.357, P <0.026$ compared with analysis by post-hoc DSM tests and least significant differences were found in the psychoticism among adolescents who emit high risk oral behaviors and medium risk and a marginally significant minimum difference between low risk and high risk. The results indicate that the more neutral stance, criminal behavior and sensation seeking lower condom use in vaginal sex for adolescents. On the contrary, greater ability to defend one’s rights, make requests and having greater total social skills increase the use of condoms during vaginal intercourse. Similarly, higher sensation seeking may indicate lower condom use in anal intercourse among adolescents. Finally, the results indicate that higher disinhibition, additional scale and psychoticism psychopathological features lower the use of condoms in oral sex among adolescents. With the analysis of post-hoc comparisons using DSM tests the least significant differences were found in criminal conduct and minimal differences between groups of high and medium risk to low risk group. With the lowest scores in the adolescent delinquent behavior low-risk group, but no significant differences were found between groups of high and medium risk. Cognitive behavioral variables and psychopathological traits related to risk levels of vaginal, anal and oral sexual behavior in Colombian adolescents. Using condoms consistently is mediated by factors which are not only individual but social. The characteristics of an environment coupled with the behavioral deficit increases the risk exposure to HIV infection. Psychopathological traits influence the level of knowledge, misconceptions, attitudes, susceptibility and self-efficacy of young Colombians which increases the level of risk exposure to HIV infection. Thus, knowledge, susceptibility and autoeficacy of adolescents with psychopathic traits are more affected by lack of skills and capability to develop self-care behaviors, making it necessary to develop programs to include adolescents with psychopathological disorders.

**Keywords:** HIV, condoms, Colombian adolescents, sexual behaviour

### Relationship between two people in adolescence

NAGASHIMA, A. (Gakushuin University)

The relationship between Borderline tendency and adolescence have previously been demonstrated, however there is a possibility that the relationship also affects borderline tendency. To verify the hypothesis we used semi-structured interviews and it was analyzed by the K.J. technique in order to understand the elements of couple-mind. Participants were ten normal university students, five male and five female. All participants were informed before
the interviews that this was investigation for research and that they were able to refuse participation. The study took place at the psychological laboratory, each interview taking about one hour. Students were presented with some cases about couples by the interviewer, and asked that whether it was a similar experience for them. The recorded data was ordered according to type, the settlement of the same meaning, and whether it was repeated. At the end, the sentences ware typed on 2174 cards and, condensed into ten pieces; “feelings thought to like lover”, “existence of other people or thing”, “jealousy or envy”, “compatibility of character”, “gap of feelings”, “fall out of love”, “perplexity or confusion”, “disgusting”, “thinking about separate from lover”, “becoming lonely feelings”. At first, we expected that the data regarding feelings to the lover could be roughly divided into two categories such as borderline tendency, however, this study demonstrated that there are various and confused feelings between two people and they are very fluid. Additionally, we demonstrated that the relationship with other people or other things is likely to work sometimes negatively or sometimes positively, which remains balanced.

Keywords: borderline tendency, adolescence, relationships, feelings

Relationship between writing strategy and writing performance of Japanese elementary school students

YAMAGUCHI, Y. (Osaka University), NAKAYA, M. (Osaka University)

The purpose of this study was to examine the effective way of writing of elementary school students. Although several studies have been made on the relationship between the writing behavior and the writing performance, there is little agreement on which way of writing is more effective (Galbraith, 1992; Rijlaarsdam & Bergh, 2006; Torrance, Thomas, & Robinson, 1999, 2000). In addition, most of those studies have focused on high school students or undergraduate students and little attention has been given to the writing strategy of children. The participants in this study were 114 fourth-grade students from an elementary school in Japan. They produced a composition about energy savings and completed the writing-strategy questionnaire for elementary school students (21 items). This questionnaire inquired how they planned, drafted and revised. They also completed the questionnaire which inquired about their self-efficacy for writing. All compositions were scored in terms of the number of words written and evaluated in terms of the quality by two raters by using a traditional holistic rating scale. Result of cluster analysis of the writing-strategy questionnaire identified four distinct patterns of writing behavior: a plan-and-develop strategy which entailed content development both prior to and during drafting; a plan-then-write strategy which planned mainly in advance of drafting; a plan-while-writing strategy which planned a little in advance and thought up contents concurrently with drafting, and a no-plan strategy which did not entail content development. The plan-then-write strategy produced a longer and better quality composition than the plan-while-writing and no-plan strategies. The no-plan strategy showed lower self-efficacy for writing than the other strategies. This study identified four kinds of writing strategies in terms of the stage at which writers decided contents for their text. This result corresponded to the previous research which focused on undergraduate students (Torrance, Thomas, & Robinson, 2000). This study revealed that in order to write effectively, it was important for children to decide contents in advance. It seemed that it was difficult for children to think up contents concurrently with writing a text.

Keywords: elementary school students, Japan, writing, writing, self-efficacy

Relationships among creative self-concept variables and employee creative behaviors

SMALL, C. (DEOMI/Florida Institute of Technology), RICHARD, E. (Florida Institute of Technology)

Eighty percent of managers rank creativity as one of the top requirements for corporate success (Walton, 2003). Because innovation is essential to the long-term success of organizations researchers are continuously striving to understand the creative process. This study focused on a relatively new theoretical
approach to studying creativity by focusing on social psychological constructs of self-concept. Creative personal identity (CPI) is the perception of oneself as being a creative person in general. Creative role identity (CRI) is the perception of oneself as being a creative person within a specific role, such as that of an employee. These constructs were examined as predictors of employee creative behavior. Based on a social identity approach, specifically the concept of self-verification, individuals who view themselves as creative in general (CPI) should strive to maintain consistency with that personal identity in order to maintain and affirm creativity as a key part of their overall self-concept. Similarly, individuals who have strong CRI were expected to engage in creative behaviors in order to verify their view of themselves as creative employees. Results of this study show that both creative personal identity ($\beta = .30, p < .01$) and creative role identity ($\beta = .38, p < .01$) predicted employee creative behavior after controlling for experience in the field. Because this is the first study to simultaneously examine CPI and CRI, confirmatory factor analysis was conducted, supporting CPI and CRI as distinct constructs. Additionally, CRI provided incremental validity over CPI by explaining an additional 14% of the variance in employee creative behavior, and CRI fully mediated the relationship between CPI and creative behavior. Creativity is essential for the success of organizations in today’s competitive market. The insight this study provides into the antecedents of creativity in organizations is a first step toward maximizing the creative potential of the workforce. Implications from this study include the use of organizational initiatives to increase employees’ creative role identity. Encouraging employees to view themselves as more creative and develop stronger creative identities is likely to promote creative behavior that confirms their self-view.

**Keywords:** creativity, social identity approach, self-concept, creativity, creative role identity

**Relationships between achievement goals and achievement emotions**

TAKIZAWA, E. (Gakushuin University)

In this study, the relationship between achievement goals and emotions in academic settings (i.e., achievement emotions) was researched. Based on earlier literatures (e.g., Pekrun, Elliot & Maier, 2006), we examined whether different achievement goals predict different discrete achievement emotions using a self-reported questionnaire. The research was conducted in two high schools in Japan. One public high school and one private high school around Tokyo participated in this research and the participants were 326 second grade high school students. The questionnaire included 12 achievement goal items and 48 achievement emotion items. The goal items included mastery-approach goal, performance-approach goal and performance-avoidance goal items. The achievement emotion items were based on the Pekrun’s Achievement Emotions Questionnaire, and included enjoyment, hope, pride, boredom, hopelessness, anger, anxiety and shame items. Each item was translated into Japanese and was changed appropriately for Japanese high school students. Participants engaged in this questionnaire during homeroom hour under teachers’ instructions. To construct each subscale, items which considerably decreased Cronbach’s alpha coefficients were excluded. Multiple regression analyses were then conducted on each discrete achievement emotion to examine which achievement goal is a significant predictor. The results showed that mastery-approach goals were a positive predictor of enjoyment, hope, and pride, and a negative predictor of boredom, hopelessness, and anger. Further, they were a positive predictor of anxiety and shame. Performance-approach goals were a positive predictor of hope, pride, and anger, while performance-avoidance goals were a negative predictor of enjoyment and hope, and a positive predictor of boredom, hopelessness, and shame. Despite difference in the participants’ age and the cultural context, the results in this research were largely consistent with the study of Pekrun et.al. (2006). However, results on anxiety and shame differed from Pekrun’s study and this research. Furthermore, results concerning performance-approach goals were also different, warranting further investigation. Also, to find a more exact causal relationship, achievement goals and achievement emotions should be measured at the different times.
Abstracts of the 27th International Congress of Applied Psychology

**Relationships between factors in promoting a career commitment: The study of Japanese working women**

WATANABE, H. (Doshisha University), UCHIYAMA, I. (Doshisha University)

The labor force participation rate of Japanese women has been on the increase since 1985. However, currently, about 65% of Japanese working women still leave the workforce after childbirth. In prior studies, a strong commitment to career is said to be influenced by various psychological factors such as identity, but the study of “relationships” between these psychological factors influencing women’s commitment levels has not yet been thoroughly examined. Therefore, we examined differences in these relationships between working women with no children and those with children. Three packets of questionnaires were mailed to 500 companies in Japan, and a total of 181 married working women (80 women with no children and 101 women with children) voluntarily responded. To describe their identities, participants were asked to indicate how much they were experiencing each of the feelings in the context of “home” and “work” with 20 adjectives, and also asked to indicate the subjective importance placed on these two contexts. A commitment level for career was assessed by U-GIDS, and attitudes toward motherhood and parenting were assessed by seven items. As a result of path analysis, identity dimension of interpersonal behaviors in the context of “work” predicted the subjective importance of work, which, in turn, positively affected women’s commitment levels. Regarding factors related to the context of “home,” there were differences between two groups. For women with children, commitment levels were determined by their attitudes toward motherhood related to identity dimension of interpersonal behaviors. However, for women with no children, both attitudes toward motherhood and parenting predicted their commitment levels independent of their identities. The career commitment of Japanese working women was determined by the subjective importance placed on work, attitudes toward motherhood and parenting. Interestingly, our result suggests that married working women with children commit to their careers under no influence of parenting attitudes. Furthermore, whether these attitudes are influenced by their identities or not seems to depend on their experiences as a mother. For better understanding of women’s life course differences, future longitudinal studies are needed.

**Keywords:** career, commitment, Japanese, labor force, parenting attitudes

**Relationships between features of collage works, block works, and personality**

KATO, D. (Nagoya University), MORITA, M. (Nagoya University)

In this study, features of the collage works and block works were examined especially from the viewpoints of form and content. If it is possible to reveal certain commonalities between these techniques with respect to psychological assessment, the results would be considered useful in the evaluation of patients or clients when these techniques are applied in psychotherapy or counseling. Ten university students (2 males and 8 females; all subjects were 18 or 19 years old) participated in this study. Participants experienced the collage technique and the block technique in clinical psychology classes. Participants were also asked to complete a TEG (Tokyo University Egogram) questionnaire in this other class. The participants with high CP (Critical Parent) scores tended to correlate with the number of human figures \(r = .56, p < .10\) and plants \(r = -.55, p < .10\) present in their collage works and with the number of basic blocks \(r = -.67, p < .05\). Meanwhile, those with high A (Adult) scores correlated with the number of human figures \(r = .57, p < .10\) present in their collages and the number of basic blocks \(r = -.62, p < .10\). Finally, those with high FC (Free Child) scores tended to correlate with the area of expression \(r = .72, p < .05\) in collage works and the number of specific blocks \(r = .65, p < .05\). Therefore, to conclude, it was revealed that certain significant relationships exist between such features and
personality. Results of this study can be useful as important viewpoints for psychological assessment, and the techniques herein can be applied in several areas such as individual counseling, hospitals, and schools, to better understand the personalities of clients and patients.

Keywords: collage work, block work, personality, psychotherapy, counselling

Research on characteristics of elite fencers’ reaction time of vision

FU, Q. (Capital Institute of Physical Education), LI, J. (Capital Institute of Physical Education)

The study examined the characteristics of fencers’ reaction time (RT) in vision. Subjects were 115 fencers, who were from the National Fencing Team, Jiangsu team and Jiangsu Physical Education School. Grade (Olympic level, national level and province level) and category (Foil, epee and sabre) were tested with MANOVA. The results indicated that there were highly significant differences in identification RT, 4-stimulus selection RT and reversal RT across grades —the higher grade, the shorter RT, while not in the simple RT and 2-stimulus selection RT.

The top two grade fencers did fewer wrong responses than the third one in all types of RT tests, except simple RT. The sabre fencers’ wrong responses were significantly more than epee and foil fencers’, along with the RT test becoming difficult. The epee fencers’ wrong responses were lowest in identification RT and 2-stimulus selection RT test, while the foil fencers’ were, in 4-stimulus selection RT and reversal RT. It was suggested that the elite fencers’ excellent performance was a result of their mental advantage —ability of identification and decision-making in complex situations, and more effective adaptation in changing situations. The results also indicated that mental ability was affected by category in fencing.

Keywords: fencing, reaction time

Research on counselor’s and client’s response matching in solution-focused approach

SHIOMURA, K. (Iwate Prefectural University), TAKAHASHI, I. (Sendai Juvenile Classification Homes)

The present study examined the effect of consistency in the response orientation of counselor and client on impression ratings by the observers toward the counselor and its counseling situations. The 2 x 2 factorial design was applied for this experiment; the counselor’s response orientation (affection-oriented counselor, cognition-oriented counselor) and the client’s response orientation (affective-oriented client, cognitive-oriented client). 78 Japanese university students participated in the experiment. The results showed that the effects of consistency in the response orientation were revealed in the cognition-oriented counselor. In this counselor condition, the counseling situations toward cognitive-oriented client were positively evaluated than affective-oriented client by the observers. The matching effect in the response orientation was obtained only in the cognition-oriented counselor. The involvements for clinical practice of a response matching between counselor and client were explored.

Keywords: response orientation, counselling, affection-oriented, cognition

Research on dynamic assessment in Japanese science education

TERAMOTO, T. (Kokugakuin University), KINOSHITA, H. (Hiroshima HNIV), KADOYA, S. (Hiroshima HNIV)

The present research investigated the effects of Dynamic Assessment in Japanese science classes as a way to improve both diversified views on observation and descriptive abilities for writing observation records. The study also suggested appropriate instructional methods in the Japanese context. The study analyzed how students’ notebook records changed when “Dynamic Assessment” was introduced and when students were instructed to relate “hypothesis” with “observation views” in 6th grade experiment/observation classes. The results indicated that students were able to relate “hypothesis” and “observation views” and to gain “recording strategy” through mutual
interactions as well as with teachers’ appropriate instructions in repeated and similar learning situations. This research supported the idea that Dynamic Assessment is effective for science education in Japan.

**Keywords:** dynamic assessment, science education, Japan

### Research on mental types of Chinese undergraduates

**FU, R.** (Changsha University of Science & Technology)

The aim of the current study was to examine the status quo and mental types of Chinese undergraduates. The Myers-Briggs Type Indicator (MBTI) was used and group testing on 346 undergraduates in China. Four main findings were found: (1) Out of the mental types of today’s undergraduates in China, the best salient, of highest proportion, in comparison to other mental types is ISJT (15.6%), and one of the lowest proportions with the least amount of people is ISTP (1.4%); (2) The number of extroverted undergraduates (E, 56%) is higher than the introverted undergraduates (I, 44%) and the number of sensory undergraduates (S, 27.7%) is higher than the intuitive undergraduates' (N, 21.9%). The number of thinking undergraduates (T, 32.25) is higher than perceptive undergraduates' (P, 50.6%); (3) The important degree of independent variables which influence the dependent variables respectively is, from strong to weak: specialty, ethnic, grade, homeplace, where the affect of gender is very small, and the influence on mental type from political identity is negative; and (4) Though the influence on mental type which results from specialty, ethnic, grade, homeplace, sex, political identity, is not statistically significant, their influence on mental type are respectively important.

### Research on the current status of cultivating creative spirit of Miao and Buyi college students in China

**WANG, H.** (Guizhou Normal University), **LIU, H.** (Guizhou Anshun College), **PAN, Y.** (Guizhou Normal University), **SONG, Z.** (Guizhou Normal University)

The aim of this research was to investigate the current status of culturing creative spirit of college students who were from Miao and Buyi national minorities in China, to offer the consulting for their education. First, we manufactured the Questionnaire of Creative Spirit (QCS) with higher reliability and validity for Chinese College students. Second, we investigated more than 2000 College students of Miao, Buyi and other national minorities who were mainly from four provinces (Yunnan, Guizhou, Sichuan and Chongqing) in southwest of China with QCS. The results were as follows: Firstly, the scores of Miao and Buyi college students’ Creative Spirit were in the level of the middle and above. These students had higher rethinking, and could monitor and evaluate during the process of problem solving. They had higher mean scores in the dimension of rethinking, but lacked enough teachers’ guiding and supporting in their creative spirit culturing. Secondly, Miao and Buyi college students’ creative spirit showed some different characteristics in school and family factors, and had gender, grade, major and school type differences. They also had some differences in the aspects of whether they were a single child or not, whether they were eldest or youngest amongst siblings, the status of family economics, parental education, and so on. Thirdly, the results showed significant interactive effects in major and gender, and major and grade. Fourthly, Miao and Buyi college students had higher scores than other national minorities of college students in the maverick, rethinking, college course, companion influence, and whole creative spirit. However, there were no significant differences between Miao and Buyi college students in above four dimensions and the whole creative spirit. Under the condition of this research, we could make these conclusions: Miao and Buyi college students had higher rethinking; their Creative Spirit was in the level of the middle and above, but lacked enough
teacher guidance and encouragement in their creative spirit cultivating. These college students’ creative spirit showed different characteristics in school and family factors, and had gender, grade, major and school type differences. There were significant interactive effects in major and gender, and major and grade.

Research on the status of subjective well-being and its interactional deciding model of multi-factor

MINGQIU, F. (Chongqing University of Posts and Telecommunications)

The aim of this poster is to summarize the status of subjective well-being and put forward its interactional deciding model of multi-factor. It will summarize the characteristics, dimensions and objective factors of subjective well-being at home and abroad, describe the main theory and related research of it, and to then put forward the model’s assumptions. The findings were that: 1) Genetics have a great impact on subjective well-being; 2) genetics affects the formation of personality, and the personality strongly influences subjective well-being, especially factors such as self-esteem, introversion and extraversion, locus of control, self-concept and optimistic; 3) Subjective well-being has a counter-reaction to people’s personality; 4)Objective factors also affect people’s subjective well-being where culture, economic income, religion, health, social relations, marriage and so forth have significant influences on subjective well-being, but race and gender have a little effect on it; and 5) major life events have a great impact on subjective well-being in the short term, but it will no longer work after people have adapted to them. Based on the existing theories and related research of subjective well-being above, we have proposed the interactional deciding model of multi-factor on subjective well-being.

Keywords: subjective well-being, genetics, personality

Researching on the social identity status of Chinese undergraduates

DENG, Z. (Changsha University Of Science & Technology), OUYANG, W. (Changsha University of Science & Technology)

This paper presents the situation of social identity of Chinese college students, and the influence of factors of empirical research. After investigating the social identity of 565 undergraduates through identity orientation scale (Cronbach а =0. 831).This scale developing by us consisted of four components, namely personal identification (PI alpha = 0.801), relationship identification (RI alpha = 0.812), social identity (SI alpha = 0.794), and collective identity (CI alpha = 0.805). Four conclusions are drawn: first, that identity orientation of undergraduates is mainly composed of personal identity and social identity, and besides its own connotation, social identity consists of relational identity and collective identity; Second, no matter whether personal identity or social identity is concerned, positive factors of identity in undergraduates are higher than negative factors; Third, the factors of influence on the undergraduate social identity are in turn political identity, ethnic, sex, specialty, birth place of undergraduate, grade, but each effect of them is not strong enough; and forth, the effect of political identity, specialty, birth place of undergraduate, grade on social identity shows a diversity of significant difference. Chinese students’ identification tendency is positive, but the influence of social identity on political identity, professional, origin and grade has significant differences.

Keywords: social identity, China, college students, personal identification, collective identity

Resilience in parents of children with cancer: Examining a link to secure attachment and the influences of coping strategies, social support, and family functioning

STEHBENS, D. (Central Queensland University), RONAN, K.R. (Central Queensland University)
Against the backdrop of attachment theory and resilience theory, this cross-sectional and correlational study examined the link between secure adult attachment and resilience in parents whose children have been diagnosed with cancer. Thirteen fathers and 67 mothers, aged between 20 and 64 years, from Australia, New Zealand, USA, and other countries completed a self-report battery consisting of the Experiences in Close Relationships Scale-Short Form (Wei, Russell, Mallinckrodt, & Vogel, 2007), the Connor-Davidson Resilience Scale (Connor & Davidson, 2003), the Goldberg General Health Questionnaire (Goldberg & Williams, 1988), the General Function subscale of the McMaster Family Assessment Device (Epstein, Baldwin, & Bishop, 1983), and the emotion-focused and avoidance-focused coping scales adapted from the Multi-Dimensional Coping Index (Endler & Parker, 1990) for this study. Further questions included indicators of support, demographic and disease-specific factors, and psychosocial indicators relating to the parent and their child. Resilience and secure attachment were correlated with reduced use of emotion-focused coping, greater perception of availability of support, and increased psychological health. Membership of a support group was correlated with increased psychological health. Reduced use of repressive-focused coping and emotion-focused coping was associated with greater perceptions of support. By contrast, findings in relations to family functioning went against expectations. Family functioning was negatively correlated with resilience, secure attachment, psychological health, coping strategies, and support indicators suggesting perhaps a protective but reactive mechanism at work here. Findings provide support for a link between resilience and secure attachment in this sample. This link is influenced by coping strategies, social support, and family functioning.

Keywords: resilience, parents, children with cancer, attachment theory, coping strategies

Retroactive interference and mental practice effects on motor learning

SPITTLE, M. (Deakin University), MALSEED, S. (Deakin University), KREMER, P. (Deakin University)

Mental practice has long been a part of preparation for performance. It has been shown that imaging a motor skill can interfere with the subsequent performance of a motor task. No study, however, has examined how the similarity of an interference task influences the mental practice effects on motor performance. This study examined the effects of a similar versus dissimilar retroactive interference component on the mental practice effects of learning a novel motor skill. Ninety participants (62 female, 28 male) aged between 18 and 51 years (M = 26.81, SD = 9.62) completed a pretest of 10 blocks of 5 trials of throwing a tennis ball into a netball goal ring, followed by an intervention specific to their group (control, mental practice-retroactive interference similar, mental practice-retroactive interference dissimilar), which was followed by a post-test of 10 blocks of 5 trials of the initial throwing task. Participants then completed a Social Validation and Comments Questionnaire. A mixed ANOVA revealed a main effect for Test (F1, 87 = 25.20, p < .05) with the performance for all three groups improving from pre- to post-test. The main effect for Group and the interaction effect were not significant, indicating that there were no differences in the increases in performance between the three groups. The first planned interaction contrast revealed that the control group improved significantly more than the two mental practice groups (F1, 87 = 104.17, p < .05; r = 0.74). The second interaction contrast revealed non-significant results, indicating that there was no difference in the increases in performance between the two mental practice-retroactive interference groups. The control group improved significantly more than the mental practice groups. This suggests that using imagery in conjunction with an interference task may actually disrupt the learning of a novel motor skill. It was also found that there was no performance difference between similar and dissimilar mental practice interference groups, indicating both conditions equally interfered with the learning of a novel motor skill. These findings provide important information about the different theoretical explanations for mental practice effects, in particular the symbolic learning theory and functional equivalence theory.
Keywords: mental practice, motor performance, symbolic learning theory, functional equivalence theory

Road rage: Aggressive behaviour

BRITES, J. (Universidade Lusófona Humanidades e Tecnologias), BAPTISTA, A. (Universidade Lusófona Humanidades e Tecnologias), SANTOS, I. (Universidade Lusófona Humanidades e Tecnologias)

The present study aims for a multi-angular analysis of the road rage phenomenon in Portugal, with a focus on the phenomenon context and the causes of aggressive behaviours in the conduct. The Driving Anger Scale (DAS; Deffenbacher, Oetting & Lynch, 1994) was used to assess road rage and the Big Five Inventory (BFI; John, Donahue & Kentle, 1991) for psychological variables. Participants in this study were 480 drivers, with a mean age of 33.63 years old (SD=10.59), 210 that revealed that they had never been involved in accidents and 270 that already have had at least one accident. The accidents and infractions/violations to the code of the road had happened mainly for males, and in those with a higher number of covered kilometres. It was also found that the emotional instability of women, and the biggest search for sensations in men, leads to more aggressiveness in driving. Drivers between the ages of 18 to 24 years were the ones that on average revealed more aggressive behaviours while driving. The results are discussed in the context of previous literature.

Keywords: road rage, drivers, aggression, gender, Portugal

Safety climate and safety backup behavior among Japanese healthcare workers: Testing a mediation model

MISAWA, R. (Kyushu University)

Although previous studies have found a relationship between safety climate and workers’ safety performance, the mechanisms underlying this relationship remain less clear (Clark, 2006; Zohar, 2003). The present study examined the potential mediating role of two motivational factors (evaluated effectiveness of safety performance, and psychological safety). Based on past research findings, the mediational model that the effects of safety climate on safety performance are mediated by motivational factors was constructed and tested. Data were collected from 341 nurses working at a hospital. The questionnaire consisted of the following scales. 1) Several researchers have suggested that workers’ safety performance consist of multiple dimensions (e.g., Griffin & Neal, 2000). This study proposed a new dimension of safety performance: safety backup behavior, defined as cooperative behavior for avoiding or recovering from hazards which contribute to accidents. Respondents self-rated their frequency of safety backup behavior (8 items). 2) Safety climate was measured in terms of two variables. Hospital safety climate refers to top management practices and policies of safety (8 items). Supervisory safety climate refers to supervisory actions and practices which reflect the priority of safety (8 items). Supervisory safety climate refers to supervisory actions and practices which reflect the priority of safety (8 items). 3) Evaluated effectiveness of safety backup behavior was measured by the extent to which respondents believe that backup behavior is effective for accident prevention (8 items). 4) Psychological safety refers to workers’ perceptions of the consequences of taking interpersonal risks in their work environment (Edmondson, 1999) (7 items). Factor structures and internal consistency for all scales were confirmed. The hypothesized mediational model was tested using path analysis with structural equation modeling. The model provided a good fit to the data (AGFI = .94, CFI = .95, RMSEA = .08). Both of motivational factors, i.e., evaluated effectiveness and psychological safety, had positive relationships with safety backup behavior. Hospital safety climate had only positive relationships with evaluated effectiveness. Supervisory safety climate had positive relationships with evaluated effectiveness and psychological safety. Over all, these results supported the hypothesized model. Thus, organizational and supervisory safety climate were positively associated to evaluated effectiveness and psychological safety, which in turn indirectly enhanced safety backup behavior.

Science education and prevalence of pseudoscientific beliefs

MAJIMA, Y. (Hokkaido University)

It has been claimed that people, even adults, are credulous in believing claims which lack scientific grounds to be true. Some attempts to help people achieve scientific literacy were made, however, they seemed not to be going well. The prime objective of the present research was to investigate to what extent were various pseudoscientific beliefs prevalent in adults. Relationship between these beliefs and educational background during secondary schools, exposure to mass media, and thinking dispositions were also examined. A total of 263 undergraduates (94 females, 169 males) participated in the research. The materials were presented in a booklet consisting of a cover page with instructions, two pages with thinking disposition scales, one page with a belief task, and one page with face-sheet questionnaires that asked educational background, attitude toward science, and frequencies of exposure to mass media. In the belief task, participants were asked whether they knew each of 34 topics or claims (4 scientific, 2 non-scientific, 28 pseudoscientific or proto-scientific). Then, they were asked whether each claim was true, and whether it was scientifically valid. First of all, participants were able to distinguish scientific and non-scientific topics, while they were credulous in believing that some pseudoscientific claims were true. A correlational analysis showed that participants' evaluation whether a topic was true and the judged validity of that claim were strongly correlated in all topics. Meanwhile, their educational background and/or attitudes toward science were correlated with these judgments only on a few topics. It was also shown that the need for cognition scale (Cacioppo & Petty, 1982) was weakly correlated with judged truthfulness or validity in some topics. Present results showed that pseudoscientific beliefs were not so prevalent in adults. Participants seem to generally have good science background. However, in some pseudoscientific or proto-scientific topics, validities of claims were overestimated, and educational background didn’t mediate these judgments.

Keywords: pseudoscience, beliefs, educational background, exposure to mass media, thinking dispositions

Scoping the fireground: The range and bias of information used in decision-making in simulated fireground exercises

CATHERWOOD, D. (University of Gloucestershire), EDGAR, G. (Centre for Research in Applied Cognition, Knowledge, Learning and Emotion), SALLIS, G. (Gloucestershire Fire and Rescue Service (Headquarters)), MEDLEY, A. (Centre for Research in Applied Cognition, Knowledge, Learning and Emotion)

The aim is to improve understanding of the cognitive processes underlying fireground decision-making. The specific aim is to determine the “scope” of information sampled and used by FRS personnel in simulated fireground contexts and whether an increase in the uncertainty of the situation provokes either a narrowing or alternately a broadening of scope. Past research in military contexts (Edgar et al., 2009) suggests that with uncertainty, the scope of information being used may narrow, with potentially risky consequences for decision-making. The method involves the assessment of decision-making in simulated fireground exercises (e.g., Minerva) with operational Fire and Rescue Service personnel in the U.K. The information sampled and used by the Ps is probed with “True/False” questions about central and peripheral items during the exercise. The responses are analysed by the QUASA model (Edgar et al., 2009) using a “dynamic” signal-detection approach to track decision-making over the course of time. Probe questions estimate (1.) “situation awareness” (the knowledge of the situation) and (2.) the “bias” or scope of the decision-maker specifically whether this is widely or narrowly focused. Of particular interest is whether a sudden loss of certainty in the situation induces a narrowing of bias. To date, two preliminary observations of Minerva and Hydra training exercises have taken place in preparation for full testing programmes in February-March. The preliminary data are supportive of the general approach and of the proposal that the bias or scoping of information may shift with a sudden increase in situation
uncertainty. Further testing will provide full assessment of this initial trend. The data will be analysed in terms of the QUASA model and discussed in terms of the interplay amongst situation certainty, confidence and bias. The possibility of individual patterns and variations will also be considered.

Keywords: emergency services, decision making, fireground exercises, situation awareness

Searching Continuous Line (SECLINE): A new technique for assessing retrospective changes in psychological status from line drawings

SUZUKI, T. (University of Tsukuba), TABATA, N. (Toyo University), TAKENAKA, I. (Okayama College), ITO, M. (National Center of Neurology and Psychiatry), FUJI, K. (University of Tsukuba), SAKURAI, S. (University of Tsukuba)

The Searching Continuous Line (SECLINE)-method was developed to measure dynamic changes in psychological status directly from line graphs drawn by participants. The reliability (internal consistency) and validity of the method was assessed. Forty seven university student participants (mean age = 20.2) were asked to complete the following Japanese language 4 self-report questionnaires. (1) K6 Questionnaires of the SECLINE method consisted of line graph forms for each of the K6 items (Kessler, et al., 2002) that measure depressive psychological status. The instruction was “Please remember changes in your psychological status and draw line graphs.” The items were six items of K6. Time-axis from October 23 to December 31 was represented in the horizontal axis. Value-axis was represented in the vertical axis on the left, with labels 4 (always) to 0 (never). The lines drawn by participants on these forms were scanned, and heights of lines were calculated 200 times horizontally along the time-axis. (2) Likert-type K6 Scale consisted of 6 items \( \alpha = .78 - .88 \). (3) Negative Rumination (Ito & Agari, 2001) consisted of 14 items which measured the tendency to ruminate negative thoughts \( \alpha = .91 \). (4) Optimism (Scheier & Carver, 1985) consisted of 8 items which measured the tendency to be optimistic \( \alpha = .68 \). Cronbach’s \( \alpha \) for K6 SECLINE-method was calculated 200 times for each 200 date points. It ranged from .79 to .86. The validity of K6 SECLINE was confirmed by correlations between K6 SECLINE-method and the original Likert-type K6, and correlations with the two variables - negative rumination and optimism. The K6 was hypothesized to relate positively to negative rumination and negatively to optimism. The results showed correlations of K6 between the SECLINE-method and the Likert-type scale were between .75* and .79*. Correlations between K6 value using the SECLINE-method and negative rumination and optimism were between .37* and .47* and between -.25† and -.32* respectively. These results indicated not only that the K6 by the SECLINE-method has sufficient reliability and validity, but also that the SECLINE-method itself is useful for dynamic retrospective data.

Secretary problem: Optimal stopping behavior

LUNG, T.J. (Hsuan Chuang University)

“Secretary Problem” is a sequential observation and selection game. In this game, the decision maker is faced with a set of items (applicants), which are presented to them one at a time in a random order. At each period, the decision maker must either accept it, in which case the search process terminates, or reject it, in which case the next item in a randomly determined order is presented and observed. Searle and Rapoport (2000) found that people always stop too early. The procedure of “Secretary Problem” is like those selections in enterprises, but in the real selection it is difficult to control and manipulate variables. In the presented research, our objectives were to learn how long the enterprises collect the résumés of applicants, how many résumés will be collected before selection, what the behavior model of selectors is, and what the optimal stopping is. We asked selectors to introspect them at the latest selection and found they were more rational than people in the game.
Selected psychosocial variables, type D personality, burnout syndrome, and cardiovascular risks

KEBZA, V. (National Institute of Public Health), SOLCOVA, I. (Institute of Psychology, Czech Academy of Sciences)

As early as the 1980s, professional literature all over the world began to reflect possible connections between the level of cardiovascular disease (CVD) risk factors, selected psychosocial variables, and burnout syndrome. CVD being the most common cause of death worldwide. In this context, one has to realise that up to 80% of premature cardiovascular deaths are identified as preventable (WHO, 2009). With respect to these findings we decided to verify the validity of the mentioned aspects in an empirical survey carried out on a sample of the Czech adult population. Between 2006 and 2008, the prospective survey which focused on potential connections between below mentioned variables and CVD risks was implemented. The sample of participants was obtained by addressing both Czech and international companies, enterprises and institutions, which had previously taken advantage of collaborating with the National Institute of Public Health and other medical institutions to implement prevention programmes aimed at health protection and promotion of their employees. A sample of 78 adults was surveyed regarding their level of burnout, type A behavior, type D personality, life and daily events, socio-demographic data, blood pressure, triglycerides, total, high density lipoproteins (HDL), low density lipoproteins (LDL) cholesterol. A complex life-style intervention was provided during the study. Intervention activities were conceived broadly to cover the areas of diet and exercise, the prevention / giving up of smoking, and also intervention activities in the area of coping with load and stress and training in relaxation methods. As a results of the intervention, significant changes (a decline) in total and LDL cholesterol, A-type of behaviour, tension, frustration, negative affectivity, hostility, life and daily events, and social support (an increase) were found. No changes in burnout, irritability, interpersonal sensitivity, and D-type of personality were proved. Regression analysis showed that burnout that was assigned in 2006 predicted (together with level of irritability) the level of HDL cholesterol in 2008. Similar results were reported (with vital exhaustion) in Koertge et al., 2003.

Keywords: cardiovascular disease, risk factors, personality, psychosocial factors, interventions

Self-concept clarity and women’s sexual health and general wellbeing

HUCKER, A. (Deakin University)

Positive sexual attitudes and experiences are important to the sexual health and general wellbeing of women. Many psychosocial factors are known to be relevant to these experiences, including women’s self-concept. The purpose of this study was to investigate the role of self-concept clarity, a core structural aspect of self-concept, in the sexual health and general wellbeing of women. A total of 261 women aged 18 years and over \( (M = 25.76, SD = 7.90) \) completed an online survey assessing the role of self-concept clarity in three measures related to women’s sexual health and wellbeing: sexual self-efficacy, sexual self-esteem and sexual satisfaction. The questionnaire also assessed four structural dimensions specific to sexual identity (commitment, synthesis/integration, exploration and orientation identity uncertainty) to assess the psychological pathways through which self-concept clarity influences women’s sexual health and general wellbeing. A series of correlations, regressions and path analyses revealed that: i) self-concept clarity is relevant to women’s positive sexual self-efficacy, sexual self-esteem and sexual satisfaction; and ii) the sexual identity dimensions commitment and synthesis/integration mediate the relationships between self-concept clarity and women’s sexual self-efficacy, sexual self-esteem and sexual satisfaction. These findings highlight the importance of including structural aspects of self-concept in explanations of women’s sexual health and general wellbeing, and reveal the relevance of aspects of sexual identity other than sexual orientation in these explanations.
Keywords: sexual health, sexual identity, well-being, women, self-concept

Self-efficacy, emotional states, and perceived performance qualities in young competitive swimmers

RUIZ, M. (University of Jyväskylä), HAAPANEN, S. (University of Jyväskylä), NIETFELD, J. L. (North Carolina State University)

Being able to monitor accurately one’s emotional states and progress is important for self-regulated learning and consequent successful performance. This study examined self-efficacy, performance related emotional states and perceptions of performance in a team of competitive swimmers over six weeks. Participants were 19 swimmers (10 male and 9 female; aged 14.95, SD = 0.97 yrs) competing in backstroke (n = 3), freestyle (n = 7), butterfly (n = 4) and breaststroke (n = 5) modalities. Swimmers’ self-efficacy was assessed on an eight-item instrument successfully used in school settings (Nietfeld, Cao, & Osborne, 2006). The questionnaire, adapted to swimming, asked swimmers to judge the applicability of each statement (i.e. “I can do well in swimming”) on a 5-point Likert scale (ranging from 1 = nothing, to 5 = a great deal). Emotional states prior to best and worst performances were identified using individualized emotional profiling (Hanin, 2000). Emotional states prior to two competitions (weeks 3 and 5) were compared with previously established profiles. A list of performance qualities (one for each stroke) was developed specifically for this study to help swimmers assess their performance. The list was created based on the most important elements of successful performance as identified by expert coaches. Examples of elements include “hands entering water in line with shoulders” (backstroke swimming), “hand-kick rhythm” (freestyle), “kicking with both feet at same time” (butterfly) and “raising head along with body” (breaststroke). Swimmers were asked to rate each element on a scale ranging from 0 (very poorly) to 10 (excellent). Swimming performance was also rated by a coach. Ratings were repeated by the swimmers and the coach at the end of the six week period. Preliminary results indicate no significant relation between self-efficacy scores and swimmers’ perceptions of improvement. Moreover, a discrepancy between the coach’s and swimmers’ ratings was found. A degree of similarity-dissimilarity between emotion descriptors generated by swimmers was assessed by calculating content overlap, using the formula proposed by Krahé (1986). Overlap scores vary from 0 (all descriptors across two situations are different) to 1 (all descriptors are similar). Inter-individual content overlap was low for all four emotion categories (N- M = 0.26 ± 0.19, N+ M = 0.23 ± 0.19, P+ M = 0.19 ± 0.17, and P- M = 0.13 ± 0.15. Additional results will be presented as well as some of the challenges faced with the present study design such as data collection and analysis. Future research directions are suggested. Overall, the list of swimming elements proved useful to measure perceptions of improvement. Swimmers used different emotion words to describe their optimal and dysfunctional performance states.

Keywords: emotional states, Self-regulation, performance, self-efficacy, competitive sports

Self-generation of stimulus choices in imagery: A reactive or preplanned experience?

MCNEIL, D. (University of Ballarat), SPITTLE, M. (Deakin University), MORRIS, T. (Victoria University), MESAGNO, C. (University of Ballarat), EVANS, S. (Victoria University)

Imagery is often used to practice reactive tasks; however, researchers have explained the difficulty in producing unexpected images. Consequently, imagers may preplan the stimulus and practice only the imagery responses. The current study explored response choices when presented with an imagery reaction time (RT) task and whether participants acknowledged the imagery as reactive. It was hypothesized that participants would generate a similar number of possible response choices and they would report the imagery was preplanned rather than reactive. Fifty participants (Mage = 21.76, SD = 1.64) completed 20 trials of a 2-choice, and 4-choice RT task. Participants imagined the stimulus, responded to it, and then completed a questionnaire on their imagery experience after the experiment. The distribution of response choices was similar for 2-choice RT between the
possible responses of blue \((n = 453\) choices, 45.3\%) and green \((n = 479, 47.9\%)\), with a similar RT \((blue \(M = 295.71, SD = 109.38\); green \(M = 295.71, SD = 103.18\)). The distribution of responses for 4-choice RT was similar between the possible responses of blue \((n = 247, 24.7\%)\), green \((n = 225, 22.5\%)\), yellow \((n = 258, 25.8\%)\), and red \((n = 215, 21.5\%)\), with a similar RT \((blue \(M = 299.62, SD = 107.53\); green \(M = 290.08, SD = 92.12\); yellow \(M = 293.17, SD = 93.94\); red \(M = 297.82, SD = 107.47\)). Most participants \((n = 33, 66\%)\) reported pre-planning responses prior to stimulus presentation, some participants \((n = 10, 20\%)\) reported reacting to an unexpected stimulus, and a small number reported a combination of preplanning and reacting \((n = 3, 6\%)\) or choosing the stimulus randomly \((n = 4, 8\%)\). There was an even distribution of response choices; however, participants indicated that they preplanned these response choices rather than producing them unexpectedly in the imagery process. This indicates that imagery can be used to practice responses to stimuli, but it may be difficult to generate unexpected events to practice. Future research and applied implications will be discussed.

**Keywords:** imagery, reaction time, responses, stimulus, preplanned responses

### Service learning in urban poor communities: A qualitative inquiry

**TOLEDANO, L.** (Australian National University), **TOLENTINO, L.** (De La Salle University)

Educational reforms and advocates for social causes lead us to service learning. Service learning is generally understood as a pedagogy that links academic learning and community interaction. It envisions students to apply theoretical concepts learned in class in addressing community needs and problems. In this paper, we aim to identify the enablers and barriers of service learning. In addition, we examine the consequences of service learning for students and community members. By addressing these aims, we develop a service learning framework within the context of higher education. Service learning projects of three undergraduate courses were considered in the study. A multi-method approach was used including survey questionnaires (derived from faculty member, university students and community members) and archival records (e.g., syllabus and operation manual for community service). Results showed that a strong curriculum and service articulation, inclusion of reflection activities, and school and community commitment are enablers of a successful service learning project. In contrast, barriers include insufficient service hours, lack of experience among students, and weak curriculum-service integration of faculty members. The study also revealed that service learning experience enhanced academic learning and personal development of students. On the whole, service learning projects were deemed valuable by the community. Findings of the study revealed that service learning projects are beneficial to both students and community members. Success of service learning pedagogy depends on the extent to which faculty members integrate course content with service experience of students.

**Keywords:** service learning, learning, community, personal development

### Sexual harassment in the military

**TRAME, E.** (DEOMI), **STEINHAUSER, E.** (DEOMI), **SMALL, C.** (DEOMI), **CREPEAU, L.** (DEOMI), **MCDONALD, D.** (DEOMI)

Discrimination and sexual harassment are concerns in all organizations because of their negative impact on morale and productivity; the U.S. military is no exception. One tool that the U.S. military uses to identify risk for Equal Opportunity (EO) violations is The Defense Equal Opportunity Management Institute (DEOMI) Climate Survey (DEOCS). The DEOCS assesses Equal Opportunity (EO), Equal Employment Opportunity (EEO), and Organizational Effectiveness (OE) factors, and is administered by the Department of Defense (DoD). Besides examining members’ perceptions regarding equal opportunity issues, the DEOCS allows members to document their personal experiences of discrimination and/or sexual harassment. Using this information, we are able to identify individuals who have personally experienced discrimination and/or sexual harassment in the workplace during the past 12 months. The task of minimizing incidents of
discrimination and sexual harassment is a daunting one. Still, research regarding job attitudes of both victims and non-victims can provide information that might be utilized to reduce these behaviors among military members. The present study aims to identify the combination of job attitudes (i.e., organizational trust, organizational commitment, and job satisfaction) that best distinguishes victims from non-victims, based on participants’ pattern of responses to the DEOCS’ organizational trust, organizational commitment, and job satisfaction climate factor scales. Using discriminant analysis we are able to determine the most parsimonious combination of job attitudes that distinguishes between the two groups, while eliminating those variables that fail to distinguish them. The results of this study can be used to better understand what combinations of attitudes are prevalent among individuals that have experienced discrimination and/or sexual harassment, as well as those who are not the object of these acts. Ultimately, this information, in conjunction with future research, could be utilized to identify high risk groups and/or inform and leverage the development of organizational reparation initiatives in order to reduce the long-term damage that EO violations can have on individual members and organization morale. This study utilized a sample of more than 10,000 military members that completed the DEOCS. Results and further implications are discussed.

Keywords: discrimination, sexual harassment, equal opportunity, job attitudes, victim

Simon-like and functional affordance effects with tools

PELLICANO, A. (University of Bologna), IANI, C. (Università di Modena e Reggio Emilia), BORGHI, A. (Università di Bologna), RUBICHI, S. (Università di Modena e Reggio Emilia), NICOLETTI, R. (Università di Bologna)

There is a perception that an object stimulus influences our motor behavior even when we have no intention to act on it. It has been observed that left/right responses to spatial stimuli (e.g. arrows) are faster when they correspond to their task, irrespective of left/right orientation, compared to when they do not (Simon-like effect; Pellicano, Lugli, Baroni, & Nicoletti, 2009). Similarly, left/right response results are faster when they correspond to the spatial orientation of the graspable portion of an object tool (Tucker & Ellis, 2004), due to reach-to-grasp actions being activated toward the handle (affordance effect). In the present study, a stimulus-response correspondence paradigm was employed to investigate whether two spatially opposite features of the same tool (i.e., the goal-directed and the graspable portion of a torch) can generate both effects as a function of the task at hand. The stimuli were pictures of horizontally displaced electric torches depicted as switched-on (active-state) and switched-off (passive-state). Participants responded to the color (Experiment 1) or to the vertical, upright/upside-down orientation (Experiment 2) by pressing a left or right key. They had to ignore the torches’ horizontal orientation and functional state. In Experiment 1, a corresponding Simon-like effect was observed, irrespective of the functional state, between the position of the tool goal-directed portion and the position of the response. In Experiment 2, a corresponding affordance effect was found between the position of the tool handle and the position of the response. However, this effect was evident only in the active-state and was absent in the passive-state condition. Tools can be coded as a function of their goal-directed tip and thus interpreted as “pointing to a direction”, similar to arrow symbols. This only occurs if simple perceptual processing is performed, as for the color discrimination task. On the other hand, affordances (and the coding of tools as a function of their graspable portion) seem to depend on detailed processing of shape, as for the vertical discrimination task. Furthermore, they are selectively activated if the functional meaning of tools is highlighted, providing evidence that they consist of specific motor simulations of appropriate grasp-to-use actions directed towards the handle.

Keywords: Simon-like effect, spatial stimuli, functional affordance effect, motor behavior, reach-to-grasp action

Situational and gender consistency of risk-taking behavior in daily life
MORIIUMI, S. (Osaka University), USUI, S. (Osaka University)

Although there are many studies about the situational consistency of risk-taking behavior, in Japan, few studies have such behavior in numerous situations in daily life. Many studies suggest that men take more risks than women, but we cannot simply conclude that is true because some studies suggest the opposite result. Thus, the aim of the present study is to test whether risk-taking behavior is consistent across several situations, and to identify situations in which no gender difference is suggested. We generated 50 items governing risk-taking behavior in daily life. These 50 items were categorized into five situations (traffic, health, financial, social, and crime prevention). One hundred and ninety-seven undergraduate and graduate students (119 male, 77 female, and 1 unclear) assessed these items on a five-point scale. To test the consistency of risk-taking behavior in daily life, the mean rating of each situation was calculated and the correlation was analyzed. Results indicated significant relations across situations, but the degree of the relations differed. In particular, the relation between traffic and health categories was weak. Furthermore, independent t tests demonstrated that men take more risks than women in health, financial and crime prevention situations, but differences in traffic and social categories were not significant. One-way analysis of variance (ANOVA) indicated that the risks in health and crime prevention situations were easier taken among the five situations. Although risk-taking behavior is consistent across several situations in daily life, relations between those situations were not necessarily strong. Other factors may thus influence risk-taking behavior as well as the situation. Furthermore, there was no significant gender difference in social and traffic situations. Many previous studies indicated that men take more risks than women, but in reality, this is not so simple. In addition to these suggestions, the result of ANOVA may indicate that the costs related to health and criminal risk are underestimated in daily life. Therefore, further studies are needed to verify the factors that affect situational and gender differences of risk-taking behavior in daily life and the related risk assessment.

Keywords: risk taking, daily life, situational consistency, gender

SHIM, S.H. (Chung-Ang University), LEE, J-H. (Chung-Ang University)

Social anxiety disorder (SAD) has negatively biased processing of social information. Especially individuals diagnosed with SAD have been found to selectively attend to negative faces and other threatening social stimuli. SAD studies indicate that high-social anxiety individuals (HSAs) show more attentional bias especially toward angry faces (threat-related cues) relative to neutral and happy faces than low-social anxiety individuals (LSAs). Moreover, visual search task studies show that anxious individuals identify angry faces faster than happy faces. Studies have shown that motivational or affective stimuli can influence perception. These studies have proposed that negatively loaded stimuli loom larger than positively loaded or neutral stimuli, suggesting that negatively loaded stimuli are more attentionally demanding or motivationally salient compared to positive and neutral stimuli. Therefore, we hypothesize that HSAs will perceive threat-related stimuli (angry facial expressions) as larger than positive (happy facial expression) and neutral stimuli of the same size. Participants will be screened and divided into 2 groups (HSAs, LSAs) using the Social Avoidance and Distress Scale (SADS) and the Beck Depression Inventory (BDI). Before and after the task, participants will complete the State–Trait Anxiety Inventory–State Form. Three emotional facial stimuli (angry, happy, neutral) in three different ellipse sizes will be presented randomly in pairs. All participants will be asked to attend to a fixation cross for 500 ms at the start of each trial. They will then be presented with a pair of stimuli for 2000 ms and decide whether one is larger or the same, as quickly and accurately as possible, by pressing a key on a keyboard. After the task, participants will evaluate the emotional facial stimuli by rating their emotional valence (-2 (very unpleasant) to +2 (very pleasant)) and arousal levels. As this study is currently in progress, we predict that HSAs will have lower perceptual sensitivity and
will perceive angry facial stimuli as larger than neutral and happy facial stimuli compared to LSAs. These results would suggest that perception sensitivity in social anxiety is affected by the processing of threat-related information.

Social comparison orientation of college athletes and the relationship with sport trait anxiety

CHU, Y. (Beijing Sport University)

The purpose of this study is to investigate the status of social comparison among college athletes, and analyze its relationship with sport trait anxiety. A convenience sampling method was adopted to collect data, and the participants were 260 college student athletes and 60 undergraduate students from Beijing. The social comparison was examined by Social Comparison Scale, and the sports competition anxiety was measured by Sports Competition Anxiety Test. Results are as follows: (1) There is no significant difference between college athletes and the ordinary university students in social comparison orientation, however, (2) Social comparison orientation in female college students athletes is significantly higher than that of males; (3) There is no significant difference in social comparison orientation between athletes of the collective project and the individual project; (4) Social comparison of performance-based projects athletes is significantly higher than that of confrontational items. (5) Social comparison orientation is positively correlated with sports competition anxiety. There is no significant difference for social comparison orientation between college athletes and ordinary undergraduate students; Female college athletes showed more social comparison orientation than that of males. Social comparison orientation is positively correlated with sports competition anxiety, and it could predict sports competition anxiety.

Keywords: social comparison, athletes, sport trait anxiety, sports competition anxiety, social comparison orientation

Social-psychological model of brand-communications

BROVKINA, Y. (State University of Management)

The formation and approbation of the social-psychological model, corresponds to modern tendencies of the brand communication development. The efficient brand-communication concept is systematized within the said model. The methods applied in the course of this research were a questionnaire poll, expert interviewing and discourse analysis. Within the model, the brand-communication is represented as a three-dimensional one, the axes of which are the brand image, personal sense and conventional sense. The brand-communication model levels are disposed on the basis of the efficiency principle. At the first (lowest) level of the brand-communication model the image of the brand plays the most important part. The other two are less significant compared to it. The level brand communication model is linear. At the second level, the value (component) of the personal sense arises, together with the image, while the conventional sense is insignificant. At the third level, together with the image and the personal sense, the conventional sense, formed in the personal and group communication and under the influence of the mass communication, is enhanced. The brand-communication efficiency is increased, going from the lower to the upper level. The units (empiric referents) are the arguments, which are distributed through the model axes. The conventional sense is formed under the influence of the explicit arguments, the personal sense is formed under the influence of the implicit arguments, and the brand image is formed under the influence of the sum of all arguments. Brand-communications are special types of social communications, which can be represented as a three-level structure model. The social-psychological model suggested is the instrument to study the brand-communications efficiency.

Keywords: brand-communication, social-psychological model, brand image, personal sense, conventional sense
Sociometric analysis of groups in schools

BARRASA, A. (University of Zaragoza), LACUESTA, R. (University of Zaragoza), JIMENEZ, T. (University of Zaragoza), MARTIN-ALBO, J. (University of Zaragoza)

Sociometric tests have become a very used instrument in different social areas; computer programs developed up until now scarcely exploited all its possibilities because these programs only analyze a limited number of indexes (generally related to elections, rejections and indifferences). The program of software described in this paper considerably extends the previous calculations, adding values and indexes related to perceptions (of elections and of rejections) and to group contexts (group structure and relation subject-group), and it likewise allows elaborate different graphics (sociometric distance and sociograms of election, rejection, and perception of election and of rejection).

Keywords: sociometric analysis, schools, election, rejections, software

Some factors affecting psychological adjustment and wellbeing of Indian gay and bisexual youths

PAREKH, S. (Shri.M.M.G.Women’s College), PAREKH, S. (Shri M.M. Ghodasara Arts & Commerce College-Junagadh.), PANCHAL, D. (Gujarat University)

Homosexuality and homosexual behaviors are still considered unnatural, inhuman, unethical and a punishable offence under the law. Various forms of homophobia towards homosexual activities also exist. The present study investigated which factors/variables were related to the psychological adjustment and wellbeing of gay and bisexual youths in India. A total of 136 gay and bisexual youths participated in this study and were aged between 16 to 26 years, with a mean age of 20.8 years. In terms of education, 13.97% participants completed primary education, 16.91% completed secondary education, 35.29% completed high school and higher secondary education, and 33.82% completed college education. In total, 25.74% of participants were reared in and/or resided in rural areas (i.e., villages and small towns), while 74.26% participants were from urban areas. A special 49 item Interview Schedule was developed for this research. As a part of this structured interview, the participants were also requested to evaluate their feeling about their sexual orientation from extremely unhappy and unsatisfied to extremely happy and satisfied, their feeling of psychological well-being from extremely displeased to extremely pleased, and their feeling of psychological strength from lot of psychological problems and extremely weak and unadjusted to no psychological problems and extremely strong and adjusted. Participants were also requested to clearly select the options regarding ‘who knows your homosexuality/bisexuality’ or ‘to whom you have disclosed your homosexuality/bisexuality’. The results showed that those gay and bisexual youths with higher education, residing in urban area, having memberships in gay organizations, and having disclosed their homosexual and bisexual orientation to others have more positive gay and bisexual identity and more positive psychological adjustment compared to those with lower education, residing in rural areas, having no memberships in gay organizations and not having disclosed their homosexual and bisexual orientation to others. Therefore, the level of education, the area of residence, the membership in gay organizations and self-disclosure of gay and bisexual orientation are related to the psychological adjustment and wellbeing of the Indian gay and bisexual youths.

Sport, general health and marital satisfaction: Between athletes and non athletes

GHOLAMI, M. (Islamic Azad University), NIKKHU, M. (Azad University Tehran)

Health is one of the most important issues in the world, even physically and psychologically. Nowadays people seek special ways to keep their health and of course to promote it, including using drugs, good nutrition, healthy life style etcetera. The purpose of this study is to consider the role of sport and exercise on health
and marital relationships. Our sample contains 120 individuals aged between 30 to 45 years, who were divided into the two groups of athlete and non athlete. They were asked to fill out the General Health Questionnaire (GHQ), and Marital Satisfaction Inventory. Analysis was prepared using SPSS. Outcomes demonstrate that athletes have less anxiety, depression, dysfunction in social positions and physical symptoms in comparison to non athletes (p = 0.01). There was no difference in marital satisfaction between two groups. In comparison, athletes have better conditions in all of the items in GHQ and also males had a higher healthy physical condition than females. Sport improves the satisfaction of the relationship but not to a significant measure.

Keywords: general health questionnaire, marital satisfaction, sport, physical health, exercise

Stratified person-job match for effective online career development

Work and life satisfaction depends significantly on the extent to which individuals find opportunities to act out their abilities, needs, values, interests, personality traits and self-concepts. A successful career requires three crucial elements: 1) Knowledge about oneself; 2) the knowledge of the challenges and chances of various professions/jobs; and 3) a stratified person-job match on the principle of best and most effective fit. The evaluation of an online career development portal is presented (N=43,287) that is based on these principles. For every participant the online self-assessment of abilities, personality, interests, values and learning styles is matched with the characteristic patterns of approximately 1,000 jobs (based on the O*NET® content model). This allows a three-step process (according to Gati, 2006) including: 1) pre-screening and a shortlist of potential jobs; 2) in-depth exploration of options; and 3) choice of option with direct online application or booking of required training.

Keywords: job satisfaction, success, career development, personality, learning strategies

Stress and well-being in first year students of psychology

BLIUMAS, R. (Vilnius University), BULOTAITE, L. (Vilnius University), POČIUTE, B. (Vilnius University)

The first year at university is a challenge for students due to the new teaching methods, new requirements, new environment, and increased independence. In 2009 the Department of General Psychology of Vilnius University began a longitudinal study. In the first part of this study we analysed psychological well-being of first year students of psychology. The main purpose of the research was to identify the main factors, influencing the psychological well-being of students and clarify peculiarities of students stress. 76 first year students of psychology (62 female and 14 male, mean age = 19.08 years) participated in this study. Specially designed questionnaires using Likert scales intended to reveal different aspects of stress, Ryff’s scales of psychological well-being was also used in the research. The results of study, as expected, showed a significant relation between stress and psychological well-being of first year students. We identify the most stressful areas of student’s life. Relatively high level of stress in first year students, also peculiarities of their psychological well-being was linked with necessity to adapt to the new learning and living environment.

Keywords: university, psychological well-being, university students, psychology, stress

Stress increases fatigue in dental students, while fatigue in turn increases their worry about developing musculoskeletal problems

SCHÉLE, I. (Umeå University), HEDMAN, L. (Umeå University)

The understanding of university students, especially in programs with clinical practice, is not covered by classical educational psychology and will benefit from a work-environment approach. In this study, we hypothesized that perceived stress (PS) would increase the students’ weariness in their neck and shoulders (Weary neck), as well as their Fatigue (feeling fatigued in a way that limits what you manage to
do after school hours). PS was expected to be influenced by ergonomic factors, such as assistance and the possibility to adjust and organize the clinical workplace when treating patients (Ergonomics), and students’ worries about developing musculoskeletal problems (Worry). A web-survey was distributed to all (850) Swedish dental students of which 50 percent answered the survey, a percentage in line with corresponding Swedish surveys. A Structural Equation Modeling (SEM) analysis was conducted on the data (Chi-square = 448.519; df = 228; p = .000; Normed Chi-square = 1.967; RMSEA = .055). Our analysis shows that Ergonomics influences PS (men = -.25; women = -.34) as well as Fatigue (men = .41; women = .44). Fatigue increases Weary neck directly (men = .47; women = .42), as well as indirectly by influencing Worry (men = .49; women = .67) which in turn influences Weary neck (men = .31; women = .29). None of the gender differences were significant. Dental students’ weariness in neck and shoulders is clearly related to both psyche and soma. However, dental students’ worries about developing musculoskeletal problems seems to be based on their feelings of fatigue and only indirectly by their perceived stress. This indicates that both male and female students are already bodily, as well as mentally, aware of the strain their chosen profession puts on their physique.

Keywords: perceived stress, ergonomics, fatigue, worry, structural equation modeling

Stress management training: A good treatment for anxiety, but not for hypertension

Sanz, J. (Complutense University of Madrid), Espinosa, R. (Complutense University of Madrid), Magán, I. (Complutense University of Madrid), García-Vera, M. P. (Complutense University of Madrid)

Psychological treatments for hypertension have at best received mixed support from empirical studies and expert panels. The aim of this study was to examine the effects of stress management training (SMT) on clinic, ambulatory and self-measured blood pressure (BP) measures, and also on psychological measures (anxiety, depression, anger, and stress). Preliminary results were obtained from a controlled trial examining SMT for hypertension. Twenty patients with essential hypertension were randomly assigned to a treatment group and treated with an individual program based on relaxation and problem-solving training (n = 12), or to a waiting list control group (n = 8). At pretreatment and post-treatment (8 weeks) stages, six clinic, 24 self-measured and 65 24-hour ambulatory Blood Pressure (BP) readings were obtained in all patients. At both stages, all patients completed questionnaires assessing anxiety [the Beck Anxiety Inventory (BAI) and the anxiety subscale of the Hospital Anxiety and Depression Scale (HADS-A)], depression [a short form of the Beck Depression Inventory-II, BDI-II], trait anger (the trait anger subscale of the State-Trait Anger Expression Inventory-2, STAXI-2), and stress (the short version of the Survey of Recent Life Experiences, SRLE). Time and group interaction effects were examined using 2x2 repeated measure ANOVAs and, when significant, pre-post Wilcoxon signed-rank tests were calculated for each group. Results indicated that the mean scores for anxiety, as measured by the BAI and the HADS-A, were significantly decreased after the SMT program in the treatment group as compared to the control group (time-group interaction effects were significant with p = .027 and .005, respectively). No similar effects were observed for clinic, ambulatory or self-measured BP measures, or for depression and stress measures (all time-group interaction effects were not significant with p > .05). The time-group interaction was also significant for trait anger (p = .028), but it reflected an increase in STAXI-2 scores in the control group. Results do not support the efficacy of STM for reducing BP, but support its efficacy for reducing anxiety, and suggest that STM could be a complementary therapy to an efficacious antihypertensive therapy for patients with hypertension who report a great deal of negative emotions.

Keywords: hypertension, stress management, anxiety, depression, anger
Study and comparison of the relationship between learning styles and the educational performance in 3rd grade female students of the government and top government high schools, Kashmar, Iran

MANSOUR, L. (University of Shahid Beheshti), ALAMBOURI, F. (University of Shahid Beheshti), ETEMAD, S. (University of Western Australia)

This research has been conducted to compare the relationship between the learning styles and the educational performance of 3rd grade female students of government and top government high schools in Kashmar, Iran. For this purpose, 250 female 3rd grade high school students (150 from government schools and 100 from top government schools) were randomly selected by adopting the taxonomic cluster method. Learning methods (objective experience, contemplative observation, abstract thought and active testing) and learning styles (homogeneous, heterogeneous, comparative and attractor) were assessed using Kelps questionnaire. Dortaj’s educational performance questionnaire was also applied to study self-efficiency, emotional effects, programming, lack of controlling consequence, and motive. The collected data was analyzed using the following statistical methods: comparative correlation, Khido’s statistical test, multivariate variance analysis and LSD pursuing test. The results suggest that only programming and lack of controlling consequence are meaningfully inter-related with learning style among characteristics of educational performance. The difference between the two groups studied was significant, and learning style in top government schools was mostly heterogeneous, whereas it was comparative in ordinary schools. No meaningful relationship was observed between the educational performance of students in government schools and top government schools. The findings revealed that learning styles of students in the fields of math, experimental science and humanities were heterogeneous, attractor and comparative respectively, and the difference in terms of self-efficiency among these three fields was meaningful, but no difference was observed in comparison with other characteristics of educational performance.

Keywords: learning strategies, educational performance, female students, learning methods, Iran

Supervisors' behavior inhibiting trust in the expertise and trustworthiness that subordinates have in supervisors

FUJIWARA, I. (Kansai University), TAKAGI, O. (Kansai University)

In the workplace, the improvement of productivity, to say nothing of group maintenance, are common goals. It is important that the instruction system based on the divide of work between supervisor and subordinate functions well for the improvement of productivity in the workplace. However, there are power differences caused by differences of position and authority between supervisor and subordinate. The power differences influence the process of both supervisor and subordinate in creating a relationship where both can trust each other, and we believe there are differences between the process of a supervisor trusting a subordinate and the process of a subordinate trusting a supervisor. To look at trust from the viewpoint of expertise and trustworthiness, firstly, we examined supervisors’ behavior promoting trust that subordinates have in supervisors in order to understand how they create mutual trust in the relationship between supervisor and subordinate where power differences exist. In the present research, we examined their inhibiting factors. We adopted a semi-structured interview method, asking employees questions such as “do you think you cannot trust the supervisor’s expertise or trustworthiness based on the supervisor’s behavior?”, and “do you think supervisors cannot trust you based on behavior in expertise or trustworthiness?”. We classified the obtained remarks into respective categories. As a result, firstly to describe the behavior inhibiting trust in trustworthiness that subordinates have in supervisors, the remarks were classified into nine categories and a few labels. To describe their expertise, they were classified into four categories and a few labels. On the other hand, to describe the behavior inhibiting trust in trustworthiness that subordinates think supervisors have in them, the remarks were classified into one category and a few labels, and
to describe their expertise, they were classified into five categories and a few labels. We discuss the contents of supervisors’ behavior inhibiting trust that subordinates have in supervisors. However, as there are promotion factors, we need to discuss each original or common factor.

Keywords: supervisors, trustworthiness, subordinate, power difference, expertise

**Surviving the role of religious orientation in mental health and happiness in seniles**

HOMAYOUNI, A. (Islamic Azad University)

Religious orientation can be understood in terms of two dimensions: extrinsic religiosity and intrinsic religiosity. Those with an “intrinsic religious” orientation dedicated their life to God or a higher power and reported they were less afraid of death and experienced greater feelings of well-being, happiness and mental health than people who fit into the “extrinsic religious” category of using religion for external ends, such as a way to make friends or increase community social standing. Eighty senile people aged between 50-70 years were randomly selected and Allport’s religious orientation scale (AROS), Argyle’s happiness inventory (AHI) and General Health Questionnaire (GHQ) were administered to them. Pearson correlations were used for analyzing the data. Findings showed that there is a negative and significant correlation between intrinsic religious orientation and components of mental illness, positive and significant correlation between extrinsic religious orientation and components of mental illness, negative and significant correlation between components of mental illness and happiness. In seeking of satisfaction and happiness of in life people choose some ways. One of the most ways is being religious and religious orientation. In religious orientation, people with intrinsic religious orientation tend to have internal value and a personal relationship with God and this attitude makes them hopeful in life and makes them happy in every time of life. People with extrinsic religious orientation tend to be religious for getting the situation and prestige and social confirmation. When they do not reach their goals they are disappointed especially in during the aging period and get depressed.

Keywords: religion, attitudes, happiness, mental illness, depression

**Survive in the other battlefields: Can at-risk children be more resilient on certain developmental domains?**

SUNG, M-J. (Chaoyang University of Technology)

This study examined two questions that Luthar, Cicchetti, and Becker (2000) suggested to the future research of resilience. The first question is when multiple outcomes are assessed, whether these should be examined separately or somehow integrated? The second question is when multiple outcomes are considered separately, are some of these accorded more importance than others as the most critical indicators of resilience? This study is part of an ongoing project that aims to assess risk and protective factors for preschool children adjustment. The final sample consisted of 827 children, 68.2% were boys, and the age range was 1.82 -7.90 (M = 5.59, SD = .99). We used the Children’s School Readiness Scale (CSRS) as the measure of children’s developmental outcomes, and used the Children’s Developmental Risk Factors Checklist (CDRFC) to identify the children’s risk factors in development. The CSRS has 7 subscales; the Cronbach’s alphas range from .84 to .92. The CDRFC has 3 subscales, which are Individual Characteristics, Parenting Processes, and Environmental Context. The Kuder-Richardson 20 coefficients of each subscale are .73, .63 and .77. First, we used hierarchical cluster analysis to see what kinds of combinations of developmental outcomes are more sensible. According to this solution, we created five composite scores. Then we used risk and development as two dimensions to separate children into four groups; resilient, vulnerable, maladjusted, and normal. When multiple outcomes were examined, some separate domains had more children classified into the resilient group, the integrated domain. On the other hand, there still existed some domains which had more children classified into the vulnerable group. Finally, we estimated the odds
ratios of high-risk to low-risk children on multiple developmental domains. Most integrated domains have higher odds ratios (2.24-6.01, $M=4.82$) than separated domains (1.99-5.28, $M=3.34$). To conclude, the current study also provides evidence that children’s resilience can be seen in many different situations, they could be individual domains, or could also be combinations of some domains. In future studies, more models about children’ resilience should be considered and examined by using multiple developmental outcomes in both separated and integrated ways.

**Teacher and non-teacher perceptions of relative secondary teacher status**

WALL, G. (University of Canterbury)

The aim of this study was to determine the status cues used by teachers and non-teachers to make judgments about the relative status of secondary teachers. The paper is comprised of three studies. In the first and second studies, secondary teachers generated and rated the status cues used to make judgments about the relative status of their teaching colleagues. In the third study, a group of teacher and non-teacher participants were presented with vignettes in which four status indicators were systematically manipulated. Half of the questionnaires used a masculine pronoun to describe the hypothetical teacher, and half used a feminine pronoun. Significant main effects were found between each of the four status indicators, with each of the high status indicators (eg. Own office) being rated as higher status than its low status partner (eg. Shared office). There were differences in the perceived status of each of these indicators between teacher’s ratings and non-teacher’s ratings. A number of two-way interactions between the four indicators were found, with teachers having one high status and one low status indicator often being rated as having lower status than teachers with two low status indicators. There were no significant differences in status whether the hypothetical teacher was described as male or female. In was found that both teachers and non-teachers use a number of cues to make judgments about the status of individual secondary teachers. Teachers and non-teachers differ in their perceptions of how much status each indicator confers on an individual, but agree in their perceptions of what constitutes high and low status on each indicator. Future research should focus on whether teachers provided with high status opportunities, eg. their own office, feel a corresponding increase in status, or whether these indicators only continue to confer status as long as they remain a scarce resource.

**Keywords:** secondary school, status, vignettes, teachers

**Teachers’ responses to children with and without the label “ADHD”**

OHAN, J.L. (Queensland University of Technology), VISSER, T. (University of Queensland)

This project aimed to examine whether elementary-school teachers’ perceptions, emotions, and behaviors differed for children with inattention and hyperactivity-impulsivity as a function of whether or not they are labeled as having “ADHD.” The secondary question addressed in this study was the contributions of teachers’ professional backgrounds in predicting the extent to which they were influenced by the presence versus absence of an “ADHD” label (i.e., showed a “label bias”). Thirty-four teachers rated their emotional and behavioural reactions towards vignettes describing children who met attention-deficit/hyperactivity disorder (ADHD) symptom criteria that included or did not include the label “ADHD.” Vignettes labeled with “ADHD” elicited more negative emotions, less confidence in working with the child, and increased perceptions of the child’s impairment, but also increased participants’ willingness to help professionals implement treatment interventions. We also examined whether teachers’ experience teaching students with ADHD and/or teachers’ training specific to ADHD predicted the degree of bias shown to vignettes that included an “ADHD” label. Although little effect of experience was found, training specific to ADHD reduced label bias. Our findings point to a significant impact of the ADHD diagnostic label on teachers’ reactions. Given that negative
first-impressions are resistant to change, introducing this label at the start of a school year might be cause for concern. Finally, that training specific to ADHD reduced much of this bias indicates that in-service ADHD training may help alleviate some of the negative perceptions that are engendered by the label of “ADHD.”

Testing for measurement equivalence of IPIP across online and paper-and-pencil surveys

ROWINSKI, T. (Cardinal Stefan Wyszyski University), CIECIUCH, J. (University of Finance and Management)

Recently, online surveys have become more popular where a lot of psychological investigations are based on questionnaires now implemented in online surveys. Researchers are used to prepare paper-and-pencil version for online conditions. But there is implicit assumption, that these two versions – offline and online – are equivalent. An equivalence of these two version scale is a sine qua non condition of comparing results from two sources of data collecting and including new results into scientific knowledge. This assumption needs to be empirically verified. 1118 participants completed paper-and-pencil versions and online surveys on a special website. A short version of IPIP questionnaire is taken from Goldberg’s International Personality Items Pool, which corresponds to FFM. This is a 120-items version with five scales and 30 subscales. For all calculation we have used AMOS 17 software. Measurement equivalence was provided in a framework of multigroup confirmatory factor analysis. This procedure was used for each dimension of personality measurement: extraversion, neuroticism, agreeableness, consciousness and intellect. The results support the hypothesis that more deeply invariance measuring did not allow the researcher to take into account assumption about equivalence. The MGFCA measure invariance of IPIP scale at three levels (configural, metric and scalar), where each of them are supposed to meet some rigid value. During the analysis some items need to be exchanged to prepare an invariant version of IPIP questionnaire – in short version. The procedure of invariance measure allows the researcher to build scales that can be use online and offline version as well.

Keywords: online surveys, paper-and-pencil surveys, IPIP questionnaire, personality measurement

Testing of decision-making in field hockey: A comparison of static and dynamic screen versions

SPITTLE, M. (Deakin University), EVANS, S. (Victoria University), PAYNE, W. (University of Ballarat)

In team sports, such as hockey, quick and accurate decision-making is vital, so being able to accurately test decision-making is important. If a decision-making test is to be effectively used in sport, it is important that the test is valid and reliable, can distinguish between expert and non-expert players, and can be completed relatively quickly. Dynamic video sequences take more time to complete than static screen captures, but may be more ecologically valid. Therefore, the aims of this study were to develop a screen based test of decision making in hockey and compare the validity and reliability of a static and dynamic version of the test. This is the first study to directly compare static and dynamic presentation stimulus on a screen based test. Video-footage was used to create 80 test items that were assessed for content validity by a panel of coaches, which allowed the number of test items to be reduced to 50. The screen-based tests were then completed by 210 participants with an average age 20.45 +/- 4.75 years from various sports and levels of hockey. Item difficulty, item –to-total correlation, and a between group comparison of scores for experienced and inexperienced hockey players to determine item-difficulty were used to reduce the number of items for each test from 50 to 25 items. Test-re-test reliability of the final 25 items was also assessed by having some participants complete the tests again 1 week later. The dynamic test was able to adequately discriminate between experience levels, \(F(1, 208)=17.15, \eta^2 = .076, p < .001\), and appeared to be somewhat internally consistent (\(\alpha = .59\)). The static test was able to adequately discriminate...
between experience levels $F(1, 208)= 32.26$, $\eta^2 = .134$, $p < .001$, and appeared to be somewhat internally consistent ($\alpha = .63$). To conclude, the tests had good discrimination, good test re-test reliability, and acceptable internal consistency, however, the static presentation displayed fractionally better psychometric properties than the dynamic presentation. This is in contrast to the expectation that dynamic presentation would provide more ecologically valid testing. More research is needed on the applied use of decision-making tests in sport.

Thai youth's perception on sustainable development: A case study of Muay Thai

AKKAPOO, A. (Bureau of Sport Science, Office of Sports and Recreation Department), YUVANONT, P. (Sripatum University)

Muay Thai, or Thai boxing, has been the Thai people’s favorite form of martial arts throughout the nation’s history. Practice was aimed either to win over the enemy or to self defend. Muay Thai training became a popular and, in certain sense, compulsory sport, leading to the establishment of an amateur association of Muay Thai more than hundred years ago. The global community has been gaining popularity; Muay Thai became a favorite martial art worldwide. However, since the sport is fighting based, the parents of Thai youth then discouraged their children from engaging in such a violent activity on the assumption of a negative attitude towards Muay Thai. Actually, this mentality was based on the belief that Muay Thai is a necessary art for good livelihood for the poor, i.e. Muay Thai is a bread winning job of children from poor families in about the same manner as in other countries, but on the apprehension that their children would be at risk of serious injury or death. While Muay Thai as a martial art proved to be Thailand’s valuable heritage, all the negative beliefs should not be held by Thai youth. Muay Thai might be taking a down turn in the near future. Compared with the international fighting sports, however, it was found that Muay Thai in perception of the new generation seem to lack clear development directions. In understanding the real perception of Thai youth towards Muay Thai, we proposed a vision for the sustainable development of Muay Thai. The research was to investigate the attitude and perception of the Thai youth towards Muay Thai, and to find ways to make it a professional sustainable sport for Thailand.

The affective consequences of working with others: Social interaction as an antecedent of affect at work

MINBASHIAN, A. (University of New South Wales), BECKMANN, N. (University of New South Wales), WOOD, R. (Melbourne Business School)

In recent years, theory on affect in the workplace has increasingly focused on the factors that account for within-person fluctuations in affective experience. The present study examines the impact of workplace interactions on affect at work, the psychological processes through which workplace interactions influence momentary affect and individual differences in the extent to which this relationship occurs. The participants were 185 managers from five large Australian companies. Participants completed a three-week experience sampling activity in which they responded to short questionnaires on handheld computers up to five times each workday. The items sought information about the people they were interacting with, the tasks they were completing and their affective states at the time of the signal. The data were analysed using hierarchical linear modeling. The results indicate that the typical individual experiences higher levels of both positive affect and negative affect when interacting with others compared to when working alone. These effects are accentuated when the individual is interacting with a supervisor compared to interactions that do not involve a supervisor. Furthermore, these effects are largely mediated by perceptions of the tasks people work on either individually or with others. Workplace interactions account for a significant amount of the fluctuations in positive affect and negative affect that occurs at work. We discuss the implications of our findings for theories of workplace affect. We also consider...
how our results relate to issues about the
dimensionality of affective experiences.

Keywords: working with others, social interaction, affect, workplace interactions, affective consequences

The antecedents and outcomes of creativity measured by Abbreviated Torrance Test for Adults (ATTA)

PENG, L. (Peking University), PENG, L. (Peking University)

This study attempted to examine the antecedents and outcomes of creativity measured by the Abbreviated Torrance Test for Adults (ATTA). Five Factor Model of personality (FFM) was presented as an antecedent, and supervisor’s rating of employee innovation behavior was tested as an outcome. This is the first time measuring individuals’ creativity by using a test in a field study. Our goal was to investigate if FFM could influence an individual’s creativity and innovation behavior, and whether creativity could predict employee innovation behavior. The study was conducted in a field setting. Participants were employees from the research and development department of a Chinese organization. Employees first finished the ATTA in a limited time, then filled out a questionnaire that included items measuring big five factors of personality and demographic information. On a separate rating form, each employee’s supervisor rated the employee’s innovation behavior. The results of ATTA were scored in three different dimensions: fluency, flexibility, and originality. The five dimensions of FFM, that is, extraversion, agreeableness, conscientiousness, emotional stability, and openness, were also scored independently. Correlation analysis revealed that both agreeableness and openness had significant positive correlations with fluency, flexibility, and originality (p < .05) they also had significant positive correlations with supervisor’s ratings of innovation behavior (p < .05). Conscientiousness had significant positive correlations with fluency and flexibility (p < .05). In addition, emotional stability exposed a significant positive correlation with fluency (p < .05). The originality in ATTA correlated with supervisor’s rating of innovation behavior significantly in a positive direction (p < .05). The present study shows that personality can predict creativity and creativity can in turn predict innovation behavior. Although creativity and innovation are believed to be cognitive activity, the personality seems to play a role in influencing these cognitive activities.

Keywords: big five model of personality, creativity, innovation, emotional stability, originality

The appeasement behaviors in social transgressions: The functions of emotional expressions and the moderator of emotional intelligence

SASAKI, M. (Meiji University)

This experimental study investigated the functions of emotional expressions to examine how anger disturbs reconciliations, and how embarrassment facilitates reconciliations, in social transgressions. We explore emotional intelligence as a moderator of the psychological processes involved in social transgressions. In Experiment 1, 120 participants, non-students, ranging from the thirties to the fifties, viewed DVD images, in which we improved the situations of social transgression as well as the transgressors’ emotional expressions. The factorial design was emotion 2 (anger/embarrassment) x stimulus person 2 (male/female) x scenario 2 (workplace/neighborhood), which equated to 8 conditions. Two stimulus persons (male and female) are shown in the DVD images. Each DVD-condition offers two scenarios; one shows the social transgression in a workplace (male/female), and the other in the neighborhood (female/male; vice versa). The participants were assigned to a particular DVD-condition and asked to view the scenes repeatedly. Then, they firstly rated the stimulus person’s emotions and secondly self-rated their motivation for appeasing or punishing the stimulus person. Experiment 1 indicated that the social transgressors’ expressions of embarrassment facilitated the decoder’s reconciliation, and also indicated that the expressions of anger facilitate the decoder’s avoidance to the expresser. The results suggested that emotional expressions in social transgressors repair or deteriorate the stressful
relations of the dyads, that is to say, there can be seen appeasement behaviors in social transgressions. As we are interested in individual differences in appeasement behaviors, we designed Experiment 2 in order to elucidate certain kinds of emotional intelligences as moderators in the appeasement process. Experiment 2 was conducted using the same scenarios of Experiment 1, to which emotional intelligence was now added. We hypothesized that emotional intelligence moderated the appeasement behaviors in the social transgressions. The results will be discussed in this congress.

Keywords: social transgressions, anger, embarrassment, emotional intelligence

The application of psycho-social theory in the process of treating a delinquent girl

RAHEB, G. (Welfare and Rehabilitation University)

There are various factors that affect a juvenile's psycho-social health and create abnormal behaviors. In this case study, is a fourteen year old girl, who has abandoned her family, uses drugs, has attempted to commit suicide, experienced several incidences of self harming, given up schooling, and who has several sexual relationships. Her treatment process starts in multiphase. The aim of this study is to use the psycho-social methods for treating. This study is a case study that uses all of the following dimensions of social, psycho, family and physiologic. The treatment was based on recognizing the problem and patient and the careful recognition and definition of abnormal behavior. The method was based on methods of change and improvements, and when applied, aims at illuminating undesirable behaviors and creating desirable behaviors. Other methods have been used as well; direct and indirect methods, protective and guide techniques, cognition treatment based on self ordering and problem solving methods. These optimistic results have made an improvement to the family's status; to welcome the young girl. By illuminating abnormal behavior and logical thinking in lieu of impulsive behavior, eventually, an optimum role was achieved.

Keywords: psycho-social treatment, abnormal behaviour, impulsivity, logical thinking, females

The association of rumination and spiritual well-being with depressive symptoms among adults: The applicability of resiliency models

HEARN, K. (University of Ballarat)

Depression is a significant mental health problem for Australian adults, particularly women. Throughout the literature, rumination has been identified as a cognitive risk factor for the experience of depression and spiritual well-being has been recognised as a protective factor. This study examined the applicability of the direct effects models, and the compensatory, the risk-protective, and the protective-protective models of resiliency, for the prediction of depressive symptoms from the risk factor, rumination, and the protective factors of existential and religious well-being. A sample of 330 adults aged between 18 and 65 years, including 178 women and 152 men (M Age = 35.72, SD = 13.80), completed the Centre for Epidemiologic Studies–Depression Scale, the Ruminative Thought Style Questionnaire and the Spiritual Well-Being Scale. Results indicated that when existential well-being was the protective factor, the compensatory model was supported for both women and men. In contrast, when religious well-being was the protective factor, the compensatory model was supported for women only. Results also supported the protective-protective model for women only, with the relationship between rumination and depressive symptoms generally weakening as the number of protective factors increased. Results implied that rumination was a risk factor for depressive symptoms. Further, interventions aimed at increasing existential well-being may be beneficial for men, whereas interventions aimed at increasing both existential well-being and religious well-being may be beneficial for women.

Keywords: depression, resilience, cognitive risk factors, rumination, spirituality
The clinical application of reminiscence for suicidal older adults

MCCARTHY, B. (McCarthy Psychology Services), BHAR, S. (Swinburne University of Technology), BROWN, G. (University of Pennsylvania)

Older adults have a higher suicide rate than any other segment of the population in many countries, including the United States of America and Australia. The design of effective suicide prevention strategies for older adults hinges on the identification and treatment of specific risk factors. Hopelessness, suicidal ideation and depression are risk factors for suicide in the elderly (Beck, Kovacs, & Weissman, 1975; Brown, Beck, Steer, & Grisham, 2000a). While cognitive behavioural therapy (CBT) is efficacious for treating depression in older adults (Scogin, Welsh, Hanson, Stump, & Coates, 2005), significant proportions of these patients continue to report high levels of hopelessness (Szanto, Reynolds, Conwell, Begley, & Houck, 1998) or suicidal ideation (Bruce, Ten Have, Reynolds, Katz, Schulberg, Mulsant, Brown, McAvay, Pearson, & Alexopoulos, 2004) post-treatment. Techniques that encourage older adults to reminisce about their past mastery experiences have been found to improve well-being (Bohlmeijer, Smit, & Cuijpers, 2003), and therefore, may help reduce hopelessness and suicidal ideation beyond the effects of more traditional interventions offered through CBT protocols. However these techniques have received less research attention and little is known about their clinical efficacy for hopelessness and suicidal ideation. Even less is understood about ways of incorporating reminiscence based techniques into a CBT framework. This paper explores the efficacy and application of such techniques in a randomized control trial of CBT with suicidal older men.

Keywords: older people, suicide intervention strategies, suicidal ideation, well-being, mastery experiences

The coherence of moral thinking from a developmental perspective

LIN, H.T. (Fo-Guang University), LIN, W. Y. (Chung-Yuan Christian University), WANG, J.W. (Fo-Guang University)

The implicit assumption of Piaget’s and Kohlberg’s cognitive developmental theory is the development of cognitive coherence (equilibrium between internal cognitive structure and external environmental world) via resolution of cognitive conflict. The purpose of the present research is to investigate whether the global coherence of moral thinking is increased by age. The author utilized four moral situations to evaluate the subjects’ responses to two contradictive arguments concerning behavior of stealing, cheating, cheating in an exam, breaking a promise. The correlation of the two responses indicated the degree of coherence. Since the material should be developed differently for younger children and older subjects, the author designed two studies to study two age groups; Study 1 for elementary school children, Study 2 for older subjects. Study 1 showed that sixth graders’ moral judgment is more coherent than third graders’ except the “Breaking a Promise Story”. Study 2 showed that college students’ moral judgment is more coherent than sixth graders’ degree of coherence except “Breaking a Promise Story” as well. Taking study 1 and study 2 into account, coherence of moral thinking is increased by age which supports the implication by Piaget and Kohlberg’s theoretical hypothesis. Because Study 1 and Study 2’s used the “direct-transparent test” method which may induce the awareness of the conflict of the two arguments and hence decrease the age differences in judgments, Study 3 used a “direct-subtle test” to test the effect of the obviousness of conflict. Study 3 showed that the “direct-subtle test” is more sensitive than the direct-transparent test from a developmental perspective. This indicates that people that have a higher ability to detect contradiction may be involved in the development of the coherence of moral thinking.

Keywords: Piaget, Kohlberg, developmental psychology, cognitive coherence

The comparison between the factor of paired personality trait terms by the reaction times and the questionnaire: Attempt by extroversion and emotional stability scales
MATSUDA, K. (Bunkyo-Gakuin University), SATO, E. (Tokyo-Fuji University)

It was hypothesized that reaction times (RT) to personality trait terms would change with the personality traits. The selective reaction time was analyzed, and the personality factor was extracted that was the reaction times for paired personality trait terms (ICAP2008, Berlin). We aim to try that correspondence with the personality factor from reaction times and the questionnaire scale scores. There were individual differences of the autonomous nervous system in the study of neurosis tendency (Eysenck, 1967). We examined RT for 8 terms in each session. There were 4 extraversion-introversion paired terms and 4 nerves-toughness paired terms. The paired personality terms were shown to the participants’ right and left on the computer display, and it was selected to respond to them pushing a right and left reaction key. The selected key and reaction time were recorded. Participants also answered paired terms questionnaire which used the reaction time measurement with a five stage rating. Those reaction times were converted into z-scores for each participant, the extroversion and toughness were subtracted in the plus, and introversion and nerves were in the minus. The factor analysis was done by using the z-score. The result of the questionnaire arranged the reversal item and did the factor analysis. Each factor analysis was independently done. The result of the factorial analysis showed that two factors had been extracted from both reaction time and the questionnaire. Both factor structures were almost corresponding, with the first factors showing the extroversion and both the second factors showing the emotional stability. The factor score of the factor by reaction time and the factor by the questionnaire were requested respectively. The correlation coefficient of the factor by reaction time and the factor by the questionnaire was requested from these factor scores. Both the correlation coefficient of the first factor was \( r = 0.876 \), and the second factor was \( r = 0.719 \). The absolute values of the correlation coefficient between the factors that do not correspond were from 0.040 to 0.173. This result clarified that the comparison of paired terms by selective reaction time showed the result similar to the measurement according to the rating scale from our experiment. In addition, the reaction time shortened when the conviction level to personality trait term was high, and was shown to be longer in the opposite case. As a result, the personality measurement that used reaction time was better than the rating by the questionnaire.

**Keywords:** reaction time, personality traits, extraversion, introversion, emotional stability

### The construct validity of the two factor model of psychopathy

DOUGLAS, H. (The University of Newcastle)

Psychopathy has been conceptualised as consisting of two separate but related constructs (Karpman, 1948). The first is primary psychopathy, consisting of untruthful, selfish and callous behaviours. Secondary psychopathy is proposed to consist of emotional disorder, primarily in the form of impulsivity. The aim of the current study was to determine the construct validity of the two factor model of psychopathy. Personality questionnaires including the Five Factor Model, The Diagnostic and Statistical Manual (DSM; APA, 1994) defined personality disorders as measured by the Hogan Development Survey (Hogan & Hogan, 2001), and the Levenson Self-Report Psychopathy scale (Levenson, Kiehl & Fitzpatrick, 1995) were administered to 241 first year psychology students. Principal Components Analysis revealed that the two components of psychopathy were loading onto separate components. Primary psychopathy loaded with low empathy and agreeableness, whereas secondary psychopathy shared loadings with neuroticism and borderline personality traits. It was concluded that the current results provide evidence for the construct validity of a two factor model of Psychopathy.

**Keywords:** primary psychopathy, secondary psychopathy, construct validity, two factor model

### The coping styles of Japanese host families in cross-cultural contact with international students: Identifying a typology on the basis of the AUC-GS learning model
This research explores the coping styles of Japanese host families in intercultural contact situations with international students. The previous literature regarding intercultural psychology of the Japanese focused on the effectiveness of mastery of western style communication skills. The present study identifies the typology of coping styles by Japanese hosts to determine their intercultural communication styles. Semi-structured interviews were conducted with 20 Japanese host families who have hosted international students in local communities. The collected narratives were analyzed qualitatively in terms of culture “Awareness, Understanding and Coping”, using the framework of the AUC-GS learning model. The informants were examined with regard to whether they noticed the existence of cultural differences, understood the occurring mechanisms of cross-cultural problems, and successfully coped with those problems. The informants were divided into six categories. The type traditionally considered legitimate in theories of intercultural psychology was found to be the most common with its goal overcoming intercultural conflicts. This type was then divided into 3 sub-types according to the developmental conditions of their coping strategies, which suggested a developmental model for hosts’ coping ability, progressively creating cross-cultural understanding. Besides this legitimate type, new categories of host type were found, one of which was paying attention to advantages and attractiveness of international exchange with positively oriented recognition while lacking the analytical perspectives on culture differences. Another new type found was the host conducting the de-categorization coping style with the denial of culture differences. The host families coping styles of Japanese host families in intercultural contact were not categorized into the type traditionally considered ideal and legitimate. The present study suggests that both types of intercultural communication styles that focus on culture differences and that defocus them are equally effective for Japanese hosts. The educational implications of self-generated intercultural communication skills by hosts and their possible applications are discussed.

Keywords: coping styles, Japanese, cross-cultural contact, international students, AUC-GS Learning Model

The correlation between character strengths and happiness of Bugis people

WINANTI, P. (University of Indonesia)

The aim of this research was to produce a description about happiness and character strengths of the Bugis people of Indonesia, including their signature strengths. Furthermore, this research aimed to find the correlation between character strengths and happiness of the Bugis people and seeking the strength of each character’s contribution to happiness. The participants were 225 Bugis adults, ranging from 18 to 55 years of age. The researcher constructed an instrument for measuring happiness and modified a VIA-IS instrument for measuring character strengths. To determine participants happiness and character strengths, participants completed the questionnaire given by the researcher. The results indicate that the majority of participants have a high level of happiness and character strengths. The signature strengths of the Bugis people are gratitude, kindness, citizenship, fairness and integrity. This research also found significant correlation between character strengths and happiness of the Bugis people - character strengths gave 32.9% of the contribution to happiness. Among those, love, love of learning and curiosity gave significant contributions. It is concluded that there is an association between character strengths and happiness of the Bugis people.

Keywords: character strengths, happiness, Bugis people, Indonesia

The correlation between the ADL level of elderly care facility residents and their water intake

JOH, H. (Kobe University)

In this research, our first purpose is to examine the correlation between activities of daily living (ADL) level and water intake by investigating the living condition of the residents who live in...
elderly care facilities. The secondary purpose is to clarify the influence of their water intake on their subjective health (how lively they are) and the objective health viewed from their caretakers to propose better living conditions with improved ADL level. We had requested a survey concerning the living conditions of residents in five special nursing homes and one general nursing home for the elderly (six nursing homes in total) in Kobe City. The respondents to the survey were the 439 residents in all the facilities. Out of the 439, we got answers from 404 (89 males and 315 females) residents. We discovered that a lower ADL level tends to be the result of a residents’ physical well-being, such as their walking ability and presence of illness, based on our observation of their ADL level, as well as subjective and objective health views in relation to their water intake. Especially, we found a correlation between water intake and excretion ability, recognition level, independence level and subjective health view on one’s personal health, and it was made clear that the amount of water intake in the day is one important cause in determining an individual’s ADL level. In this study, the results showed that it is necessary to grasp and reexamine living conditions which may be associated with a decrease in ADL level; especially, it is important to control residents’ water intake during periods of fracture and illness. As being bedridden results in a decline in the person’s psychosomatic functions, and reduced water intake causes a decrease in their ADL level, water intake and its management may be most important for improvements in living, better ADL and quality of life.

The development of the concept of death among Japanese young children

TSUJIMOTO, T. (Osaka University), NAKAYA, M. (Nagoya University)

The primary focus of this study was to examine the acquisition process of the death concept with regard to humans and animals among Japanese young children. In order to examine the degree to which children understand the concept of death, researchers have specified four death characteristics. The death characteristics that have been used for research studies include “finality”, “irreversibility”, “universality”, and “causality”. Although studies have found few consistent conclusions in regards to what age children acquired these death concepts, many have demonstrated that children acquire the concept of death by the age of 10 in Western countries. This study evaluated the acquisition of these concepts in Japanese children. In this study of Japanese children, 117 subjects aged 3-6 years old were interviewed individually about the four death concepts with regard to humans and animals. The scale items and score calculations were developed using the DDCQ (Development of Death Concept Questionnaire, Smilansky, 1987) as a reference. First, the study determined which type of death (human or animal) was easier to conceptualize. The results suggest that the conceptualization of death in animals is easier than in humans. The finality, irreversibility and universality death characteristics were easier to conceptualize in animals, while causality was conceptualized similarly in both humans and animals. The study then examined the effect of age on the conceptualization of death, which found a significant difference in both humans and animals. Specifically, age differences precipitated a significant effect on the conceptualization of irreversibility, universality and causality in human death as well as universality and finality in animal death. The results of the study suggest that children acquire the concept of death in animals more easily than in humans. It is assumed that children are more frequently exposed to the concept of animal death (e.g. pets) than human death. While it was found that the conceptualization of death was nearly completed by the age of 4 or 5, there is still the assumption that the irreversibility characteristic of death can be conceptualized by the age of 3 or 4.

Keywords: death, children, development of Death Concept Questionnaire

The development of the face audience communication fear scale for Chinese college students

ZHIFEI, S. (Guizhou Normal University), HONHLI, W. (Guizhou Normal University)
The objectives of this study was to develop the Face Audience Communication Fear Scale for Chinese college Students according to the actual background of the Chinese college students, and to examine the reliability and validity of the Face-Audience Communication Fear Scale (FACFS). The first sample consisted of 349 students from education and non-education universities for items analysis. One part of the second sample, with 619 college students, was for confirmatory factor analysis (CFA); and the other part for cross-validity analysis. The third sample was for test-retest reliability. Exploratory and confirmatory factor analysis were used to develop and evaluate the structure of the scale. Results showed that the FACFS has four factors: lecture fear, social communication fear, group communication fear, and the ability of coping with fear. The CFA showed the fitness of the high order factor of the scale: CMIN/df = 1.692, GFI = 0.916, IFI = 0.940, NNFI = 0.930, CFI = 0.939, and RMSEA = 0.047. Cronbach’s Alpha coefficient was 0.903, and the test-retest reliability was 0.88. To conclude, factor analytic studies showed that the structure of the FACFS was reasonable. The internal consistency, test-retest reliability, content validity, construct validity of the FACFS entirely were in accord to psychometric demands.

Keywords: Face Audience Communication Fear Scale, Chinese students, reliability, validity, scale development

The difference between Japanese men’s and women’s evaluations of the “food selection criteria”

OKANO(ASAKAWA), M. (Bunkyo University), OKANO, M. (Bunkyo University)

Asakawa and Okano (2009) studied food selection criteria and derived the following five dimensions: (1) mood, (2) safety, health, and nutrition, (3) convenience, (4) weight control, (5) price. In this research, the reliability of the five dimensions of “food selection criteria” is investigated first. Next, the difference between males’ and females’ evaluation of the five dimensions is examined. The 36-item questionnaire survey about food selection criteria was completed by 116 female students and 115 male students. Based on Asakawa and Okano (2009), we made a five-factor model and analyzed it with Structural Equation Modeling (SEM). In addition, Multiple Group Analysis was carried out to compare the estimations of the five dimensions between males and females. Analysis of the five factor model produced the following scores of the fit index: GFI = 0.939, AGFI = 0.915, CFI = 0.948, RMSEA = 0.056, AIC = 317.022. Having demonstrated its reliability, we decided to adopt this model. To conclude, through Multiple Group Analysis, the differences in estimation of the five dimensions between males and females were confirmed, revealing a difference in only the “weight control” dimension. The female students considered the “weight control” dimension more important than did male students.

Keywords: food selection criteria, reliability, gender, structural equation modeling, multiple group analysis

The difference of compromise process according to suggested stimulus(occupations) in the career decision making situation of Korean youths

YI, J. (Seoul National University), KIM, K. H. (Seoul National University), KIM, J. H. (Seoul National University)

The object of this study is to analyze the compromise factor preference in terms of a change in the combinations of the factors. Gottfredson and her colleagues have suggested the ‘sex type’ of occupation is the most important factor (most hard to compromise) compared to ‘prestige’ and ‘interest’ in career decision process. However, Kim(2009) produced different results from the Korean subjects, in which interest is the most important factor compared to prestige and sex-type. In this study, a hypothesis was examined: The job options given to the subjects will make the differences. If the job options contain an occupation with extremely male (or female) type, this will make different result compared to the case with no extreme sex type. For this purpose, this study used a web-based career decision program developed by Kim and Kim (in print). Three different kinds of job options were given to the subjects: Situation 1, occupations considered...
with strong sex types are included in the decision making options (E.g., nurse as extremely female; aircraft pilot as extremely male). In Situation 2, occupations considered with strong sex type characteristics are not included. Situation 3 provides randomly selected occupations regardless of their sex types. One hundred and sixty-two subjects participated in the study, and they are middle and high school students in South Korea. The major finding is as follow: In Situation 1, the female students consider sex type as most important, however, same results did not appear in the Situation 2 and 3. In contrast, the male students consider interest most important in the Situation 1, 2, and 3. Compromising is one of the main aspects in the career decision process and the combination of job options is an important factor related to the compromising preference. There seems a gender difference in terms of compromising factors in career decision-making. However, the study did not tell where the gender difference came from.

Keywords: career, decision making, gender differences, occupation

The difference of decision making pattern in Iowa Gambling Task between Japanese pathological gamblers and Japanese university students

KIDO, M. (Kwansei Gakuin University), SHIMAZAKI, T. (Kwansei Gakuin University)

Pathological gambling (PG) is persistent and recurrent maladaptive gambling behavior that disrupts personal, family, or vocational pursuits. Decision making deficits also play an important role in the definition of PG. However, there are no empirical studies about decision making processes of pathological gamblers in Japan. Therefore this study compares decision making processes of pathological gamblers with normal controls using the Iowa Gambling Task (IGT). In this study we administered IGT to PG group (n = 8) and normal control group (n = 30). PG group was consisted of Gamblers Anonymous (GA) members, which is a mutual aid organization of PG, and the normal control group consisted of Japanese university students. In the IGT, participants had to choose between 4 decks of cards and had to make 100 card choices. The 4 decks consisted of 2 disadvantageous decks (high-risk, high-return decks) and 2 advantageous decks (low-risk, low-return decks). We used a computerized version of IGT as described in Bechara, Tranel, & Damasio (2000). We subdivided the 100 card choices into 5 blocks of 20 cards each. And we counted the number of choices from disadvantageous decks and advantageous decks for each block. We then calculated the net score to derive the total number of choices of advantageous decks from disadvantageous decks for each blocks. As the task progressed, the normal control group gradually shifted their preference towards advantageous decks and away from the disadvantageous decks, as reflected by the shift in the net scores towards positive. Similarly, the PG group shifted their preference towards advantageous decks, but they chose more cards from the disadvantageous desks by and large. In addition some of the members of PG group failed to demonstrate this shift in behavior. In this research, the possibility was proved that IGT can recreate the distinctive feature of decision making patterns of Japanese pathological gamblers. Therefore, future research will investigate the factor of changing decision making patterns of pathological gamblers to develop the method of intervention for PG patients.

The differential efficacy of virtual reality exposure in the treatment of chronic agoraphobia

PEÑATE, W. (University of La Laguna), PITTI, C.T. (Canary Service of Health), VILLALVERDE, M.L. (University of La Laguna), BETHENCOURT, J.M. (University of La Laguna), DE LA FUENTE, J. (University Hospital La Candelaria), PERESTELO, L. (Canary Service of Health), GRACIA, R. (Canary Islands University Hospital)

This paper presents data about the differential findings of two intervention programs in the treatment of patients with chronic agoraphobia disorder: traditional psychological therapy and the use of virtual reality. The traditional therapy consists of the use of expositive techniques with cognitive restructuring (cognitive behavior...
therapy; CBT). The treatment with virtual reality (VRT) consists of exposing patients to phobic scenarios constructed in a virtual reality, as part of expositive procedures. Patients were also treated with psychoactive drugs (venlafaxine or paroxetine). Patients were treated in the psychiatry service of Hospital Universitario de Canarias. Sixty patients received 11 individual psychotherapy sessions (30 CBT group, and 30 VRT group). Sessions 1, 2, and 3 were similar for both the CBT and VRT group. In the VRT group, sessions 4 to 11 consisted of an exposing procedure to phobic stimuli, presented by virtual reality. The CBT group was trained in the use of exposition to different phobic stimuli. Both groups were treated with cognitive restructuring to deal with pathological thoughts (non-adaptive coping strategies), and were motivated to use in vivo self-exposure. Patients were assessed three times: pre-treatment, post-treatment and a six month follow-up. Results were analysed according to different measures of level of anxiety and the use of coping strategies. Results showed that both treatment programs were efficient. Also, data suggest a better clinical efficiency of VRT with chronic agoraphobic patients, not related to the type of drugs used. These findings are discussed in relation to the development of new technological approaches to mental health.

Keywords: agoraphobia, virtual reality, cognitive behavior therapy, differential efficacy, cognitive restructuring

The dimensions of newcomers’ adjustment and its relation with other variables in the background of China motherland

LIUZHAN, J. (Huazhong Norm University)

The aim of this study was to explore the concept of newcomers and research the relationships between antecedent variables and their outcomes. The methodology employed on 345 newcomers included a literature review, questionnaire survey, exploratory factor analysis, confirmatory factor analysis and structural equation modeling. The fit indices of newcomer adjustment for the theoretical model was $X^2 = 143.37$, $df = 62$, RESEA = .062, CFI = .918, GFI = .937, NFI = .866, PNFI = .689, NNFI = .897 and AIC = 201.37. There were three structures identified for newcomer adjustment, which were role clarity, self-efficacy, and social acceptance. In conclusion, the collective versus individual tactics, and serial versus disjunctive tactics, have significant relationships with the two dimensions of newcomer adjustment of role clarity and self-efficacy. Newcomer adjustment has positive relationships with work satisfaction and job performance, and casts a negative effect on the individuals’ quit intentions.

Keywords: newcomers, adjustment, structural equation modeling, China

The ecology of perception of safety in urban environment: The case of the city of Rome

BILOTTA, E. (University of Rome - Sapienza), BONAIUTO, M. (Sapienza), BONNES, M. (Sapienza)

The Cumulative Risk Model (Evans, 2003; Evans, 2004; Evans & Marcynyszyn, 2004) is a model traditionally applied to developmental issues and is proposed here for the first time in relation to the analysis of safety and fear of crime in the city of Rome. The aim of the study is to clarify some of the dynamics existing between perception of safety, fear of crime and social/physical factors. 550 residents of three neighborhoods of Rome (safe, unsafe, and neither safe or unsafe) participated to the study. The instrument comprised a self-administered questionnaire with a first section containing social, environmental, and safety questions and the second containing well being questions and sociodemographic information. Each risk factor (taken out from the responses of the residents) was defined dichotomously (0/1) on the basis of statistical or theoretical criteria. Cumulative risk was defined as the simple, unweighted sum of fourteen risk factors (Evans 2003). Results confirmed the cumulative negative effects of multiple risk factors on perception of insecurity/fear of crime and on well being/satisfaction with life. In particular, it is shown that as the number of risk factors rise, perception of insecurity and fear of crime increase, while well being and satisfaction with life decrease. The present data showed that, consistently with the literature of developmental psychology (Greenberg, Lengua, Coie &
Pinderhughes, 1999; Evans & Marcynyszyn, 2004), exposure to a small number of risk factors does not lead to strong negative consequences for the person, but as the number of risk factors rises, the negative consequences increase. Traditional approaches to safety may underestimate the negative effects of a large number of risk factors on safety, since they are usually focused on a small number of factors. On the other hand, analyzing a large number of risk factors acting together may help to get closer to the daily experience of a resident in terms of perception of insecurity/fear of crime, and to capture the “ecology” of safety in the city.

Keywords: cumulative risk model, crime, Rome, safety, well-being

The effect of "pupils' safety map": How the map based on Photo Projective Method increases the safety awareness

OKAMOTO, T. (Kwansei Gakuin University)

This study aimed to examine the effects of the “Safety Map of the Pupils' Commute” for the increase of parents’ safety awareness. The map was made with the unique method; Photo Projective Method (PPM) which was developed by Noda (1988). PPM is a new technique based on a projective method which captures subjects’ perceived environments by photographs. Thus, the method helps us understand the individual’s internal mental world. We have already revealed the differences of children’s safety awareness from the adults’ one with this method (e.g. Okamoto, Hayashi, & Fujihara, 2008, 2009). However, we have not measured the effect of the map on safety awareness. Thus in this research, we investigated to what extent their parents increase their awareness of the safety by using the map based on PPM. Firstly, we asked 27 children (6-12 years old) and 30 mothers to take any photos of hazard points or anxious areas for the children during their school commute. Secondly, we developed the Safety Map based on this evidence and our findings (Okamoto, et.al., 2008, 2009), and distributed it to 285 pupils and their parents. Thereafter, we asked them to discuss the safety with their family. The map includes road information, photos, types of hazards, and comments for the safety. In addition, we also distributed questionnaires of safety awareness twice - before and after distributing the map to their parents. The result shows that the usability, needs and the veracity of the map is high, and parents’ safety awareness of the children’s safety is increased by joining in the map making process. Using the PPM, creating and distributing the map of safety for the children shows that the importance of the map is high. In addition, the result also shows the applicability of PPM to the situations which are hard for the subjects to verbalize.

The effect of “green exercise” on state stress and anxiety

MACKAY, G. (University of Canberra)

This study explored the effects of green exercise on state stress and state anxiety, and the role played by intensity, duration, and degree of greenness. A quasi-experimental design was implemented, with 101 participants from a variety of pre-existing outdoor exercise groups from the Australian Capital Territory completing pre- and post-exercise questionnaires. Results indicated a significant reduction in participants’ levels of state stress (d = .38) and state anxiety (d = .51) following green exercise. Reductions in state stress and anxiety were evident in the majority of green exercise groups. The intensity and duration of green exercise did not significantly affect changes in state stress or anxiety. The degree of perceived greenness of the exercise was associated with greater reductions in state anxiety. Green exercise has important implications for economic and mental health benefits, along with health policy and urban planning.

Keywords: green exercise, state stress, state anxiety, health policy, mental health

The effect of aquariums on the interest of older adults

GASSHO, A. (Gifu University), SHUZO, O. (Gifu University), NORIMI, N. (Seikoukai Med. Corp.),
KEISHIRO, Y. (GEX Co. Ltd.), AKIRA, O. (Chubu Gakuin University)

It is becoming popular for aquariums to be placed in the rooms of some hospitals and nursing homes to relax or cheer the patients. However, the effects of aquariums have not been clarified to date. In this study, we discussed whether the visual aquarium (VA) and real aquarium (RA) attract the interest of older adults. We placed VA and RA on the lounge of a retirement home and an adult day care center in Gifu city. NEC Uo-Hakkei with a 25 inch monitor was used as the VA. The RA was almost the same size as the VA. Each aquarium consisted of the same kinds of tropical fishes and plants. For the first 4 weeks the VA was placed in the home/center, and for the next 8 weeks, the RA was placed in the home/center. In the retirement home, behaviors of the residents in the morning (6:00~8:00) and in the evening (17:00~19:00) was recorded through security cameras. In the adult day care center the behaviors of the visitors were recorded during a lunch break (12:30~13:30) by 4 observers. In the retirement home, significantly more residents approached the VA and RA or gazed at them in the mornings of the first week. However, in the VA condition, the number of residents approaching the aquarium or gazing at them decreased rapidly in the evenings of the first week. In the RA condition, on the other hand, the number of residents was maintained for 8 weeks, except for some days. In the adult day care center, significantly more visitors approached the RA. However, in the VA condition, the number of visitors was not increased as in the RA condition. These results showed that the RA and the VA can attract the interest of older adults. Although they lost interest as time passed, the RA seems to have the effect of attracting interest continuously relative to the VA.

The effect of cognitive enhancement training programmes in older adults: An ERP study

LIMBRICK, K. (University of Tasmania), SUMMERS, J. (University of Tasmania), MARTIN, F. (University of Tasmania)

Normal ageing is often associated with progressive losses in a number of abilities, primarily executive control processes and cognitive functions involving memory. The current study examined the effectiveness of the Active Cognitive Enhancement (ACE) programme on source memory. ERP measurements were used to examine differences in brain activity in older adults, during a source memory task, before and after completion of the cognitive training programme. The ACE programme was developed for individuals aged 55 to 80 years of age, and focuses on enhancing a range of cognitive abilities including memory, attention and concentration, speed of processing, and problem solving. Fifty-eight participants were assigned to either the ACE training or control group. ACE participants were tested on the source memory task while EEG recordings were taken prior to and immediately following completion of the 10 week cognitive training programme. Controls were tested twice, 10 weeks apart. The source memory task involved a study phase in which participants were instructed to learn 20 visually presented words, as well as the colour of the font (red or blue). The test phase involved 40 words (20 old and 20 new), and participants indicated whether the word displayed had been presented in the study phase, and if so, what colour it had originally been presented in. After the completion of the ACE programme participants had significantly more correct responses on the source memory task. Analysis of the EEG data indicated pre-post differences in brain activity in the right frontal area in both the early (400-800ms post stimuli) and late (600-1200ms post stimuli) time windows, as well as along the midline in the early time window. In these areas, there was a significant increase in positivity of the mean amplitudes post-programme, which could be seen as being representative of increased recruitment in these brain areas. These findings indicate that the ACE program produced significant improvements in source memory capabilities in a group of older adults. The EEG results suggest that the improved source memory may be linked to increased recruitment of frontal brain areas in the right hemisphere.
The effect of computer use on social interaction and academic performance of Pakistani adolescents

KAUSAR, R. (University of the Punjab), SALEEM, F. (University of the Punjab)

The present study was conducted to examine the effect of computer use on social interaction and academic performance of adolescents. It was hypothesized that: there is a relationship between computer use and social interaction and there is a relationship between computer use and academic performance. A sample of 200 adolescents was selected from the private sector schools in Lahore, Pakistan. A demographic information questionnaire and a questionnaire for social interaction and technology use were used for assessment. Data was analyzed using descriptive statistic, correlation, and t-test analyses. The results indicated that there is a significant negative relationship between computer use and social interaction whereas there is no relationship between computer use and academic performance. Excessive computer use does not affect academic performance of adolescents but it adversely affects social relationships of adolescents.

Keywords: adolescent social relationships, computer use, academic performance, social interaction, technology use

The effect of continuous warning signals on a visual task

TAKECHI, N. (Osaka University), USUI, S. (Osaka University)

This study was conducted to investigate the effect of continuous auditory warning signals on a visual task. In two experiments, participants performed tracking tasks with or without an audio stimulus (AS). We manipulated three factors, “validity,” “length of AS (length),” and “instruction”. In the validity factor, responses could be “valid” (the tracking target (target) and AS were on the same side), “invalid” (the target and AS were on opposite sides), and “no-audio” (without AS). Validity refers to the relationship between the location of the AS presented and that of the target presented or the target’s direction of movement. Lengths were set to 4, 7, or 10 seconds to investigate the effect of continuously presenting the AS. Instruction was made to investigate whether participants respond to the AS, and it was constructed by “irrelevant” and “cue”. In the irrelevant condition, targets and AS were presented from the same side 50% of the time. In the cue condition, the target and AS were likely to be presented from the same side. We measured the reaction time and keeping time (amount of time in which participants continue tracking the target). An analysis of variance (ANOVA) was performed on the three factors described above. In Experiment 1, participants responded more rapidly in the valid condition than in the invalid condition and reacted the most slowly in the no-audio condition. By contrast, in Experiment 2, participants responded more rapidly in the irrelevant condition than in the cue condition. In both conditions, the keeping time under the valid condition was longer than that under the invalid condition when an AS was the cue. However, there was no difference under the irrelevant condition. The direction in which the target was moving had no effect. These results suggest that the relationship between the continuous AS and the visual task affect the visual task performance, when the AS is a cue of the visual task. At the same time, the direction of the target’s movement has no effect. The locations of audio and visual stimuli presented must therefore be considered when designing working spaces where people are presented audio signals.

Keywords: auditory warning signals, visual task, audio stimulus, visual task, working spaces

The effect of Dohsa-hou (a Japanese body-movement psychotherapy) for pain management on hemodialysis patient’s life style

HARAMAKI, Y. (This study aimed to clarify the effect of Dohsa-hou (Japanese original body-movement psychotherapy) on the hemodialysis patient’s life style involving pain management. The case study was a 63 year old female who had been receiving dialysis treatment for 33 years, and had
chronic pain throughout her whole body for a long time. The researcher applied Dohsa-hou 3 times a month. Three categories were measured to verify the effect of Dohsa-hou: 1) an understanding/relieving of her chronic pain (pain care); 2) the functional improvement of her life; and 3) the motivation improvement of her self-care. The effects were: 1) an understanding/relieving of chronic pain, her pains were an excessive pain reaction by experience, and it became clear that relieving by the relaxation through applying the Dohsa-hou; 2) through Dohsa-hou, her life styles, which were rigid and strained herself to housekeeping when there was chronic pain were recognized, and it became clear that her mental styles were changed to not straining oneself, loosening is mastered, and it comes to build the life style of a rest by Dohsa-hou; and 3) the effect of Dohsa-hou which raised her motivation to self care was indicated by tackling chronic pain using Dohsa-hou tasks at her house, and taking medicine for chronic pain for the purpose of preventing the chronic pain. Dohsa-hou is an original Japanese psychotherapy which approaches the mental state through improvement of body movement. This case study indicated that the effect of Dohsa-hou was relieving for chronic pain, her life styles, and increasing self care ability (including pain management).

**Keywords:** pain management, Dohsa-hou, Japanese original body-movement psychotherapy, chronic pain, life style

### The effect of emotional labor on stress and job satisfaction in call-centre agents: Modifying role of self-efficacy

TRIPATHI, N. (Indian Institute of Technology Guwahati), KUMAR, N. (Indian Institute of Technology Guwahati)

The present study investigates the effect of emotional labor on stress and job satisfaction in call centre agents. Furthermore, the role of self-efficacy as a moderator has also been examined. The sample included 269 call centre agents from seven call centers, located in New Delhi and in the vicinity. Standardized measures of emotional labor, perceived stress, job satisfaction and self-efficacy were administered. Cronbach’s Alpha of all the measures varied from moderate to high. Direct relationships indicated that (a) only one dimension of emotional labor (i.e. surface acting) was positively related to perceived stress \( (r = .13, p < .05) \), (b) surface acting dimension of emotional labor was negatively correlated with extrinsic-intrinsic dimension of job satisfaction \( (r = -.13, p < .05) \), whereas frequency with deep acting dimension of emotional labor was positively correlated with one dimension of job satisfaction, i.e. social-intrinsic \( (r = .15, p < .01) \). Further, stepwise regression analysis revealed that (a) among the dimensions of emotional labor, two dimensions (surface acting and frequency with deep acting) turned out as significant predictors \( (\beta = .17, p < .01; \beta = -.13, p < .05) \) of perceived stress, whereas in the case of job satisfaction significant predictors were frequency with deep acting \( (\beta = .36, p < .00) \), variety with deep acting \( (\beta = -.27, p < .00) \), and surface acting \( (\beta = -.18, p < .00) \). In order to analyze the moderating effect of self-efficacy, sample was divided into high and low self-efficacy groups using median score. Results revealed that one dimension of emotional labor (surface acting) predicted perceived stress \( (\beta = .31, p < .00) \) and two dimensions of job satisfaction (social-intrinsic and extrinsic-intrinsic) \( (\beta = -.22, p < .01; \beta = -.28, p < .00) \) for the high self-efficacy group but not for the low self-efficacy group. Another dimension of emotional labor (frequency with deep acting) also predicted perceived stress \( (\beta = -.21, p < .05) \) but only for the high-self efficacy group. These results indicate that employees with high self-efficacy are likely to have more negative effects of stress, especially when they are engaged in surface acting.

**Keywords:** emotional labour, stress, job satisfaction, call centre, self-efficacy

### The effect of grateful messages and descriptive norms in deterring deviant behavior: An experimental study on deterring deviance from trash-disposal rules

YUO, S. (Nagoya University), YOSHIDA, T. (Nagoya University)

Expressing gratitude reinforces prosocial behavior (McCullough, 2001). This study examines whether statements of gratitude on posters can be effective in deterring deviant behavior, especially deviance from trash-disposal rules in Japan. Messages like “Thank
you for following the disposal rules” expresses gratitude and should, therefore, induce reciprocity (McAdams & Bauer, 2004). By showing appreciation for cooperation beforehand, one expects people to oblige by refraining from careless disposal. Others’ behavior (descriptive norm) may, however, cause grateful messages to have a boomerang effect. Using the focus theory of normative conduct (Cialdini et al., 1991), we predicted that grateful messages would be more effective than neutral messages when the descriptive norm is consistent with the message (injunctive norm) owing to reciprocity. It would fail, however, when the descriptive norm is inconsistent with the injunctive norm, because the message would be unrealistic, thereby causing dissonance. Further, we predicted that people are inclined toward obeying rules when the two norms are consistent, regardless of the message type. The experiment was a 2 (grateful versus neutral message) × 2 (consistent versus inconsistent norm) between-subjects design. Participants (226 Japanese undergraduates) were given a small tea carton and a plastic straw each and instructed to dispose them in trash cans after drinking. The descriptive norm was manipulated by discarding some trash by following the rule (norm consistent) and some by not following the rule (norm inconsistent). Either message was printed around the cans. We scored the subjects’ mode of disposal along 3 criteria, such as disposing the carton and the straw as combustible and incombustible garbage respectively. The ANOVA results indicated that participants followed the disposal rule when the two norms were consistent rather than inconsistent. However, there was no significant interaction between message type and norm. Contrary to our assumption, participants were not affected by message type. Observers reported that participants seemed to dispose of trash without reading the message. Therefore, results might indicate a strong influence of other people and not the messages, a finding congruent with previous research (e.g., Cialdini, 2003). Future studies should use more visually perceptible messages in order to exert the required influence.

**Keywords:** gratitude, normative conduct, trash-disposal, Japan

**The effect of leader’s emotional intelligence on subordinate’s organizational commitment and job satisfaction: Focused on mediating effect of leader’s behavior**

TAK, J. (Kwangwoon University), KYOUNG, E. (Kwangwoon University)

The purpose of this study was to investigate the relationship between the leader’s Emotional Intelligence (EI) and the leader’s behavior, and the mediating effect of the leader’s behavior between the leader’s EI and the subordinates organizational commitment and job satisfaction. This study also examined the moderating effect of an organization’s career development and education support on the relationship between the leader’s behavior and the subordinate’s attitudes. Data were collected from 251 workers in various companies in Korea. The results of this study showed that the leader’s EI positively related to the leader’s coaching behavior, consideration behavior and visionary behavior. Coaching behavior, consideration behavior, and visionary behavior were positively related to the subordinate’s organizational commitment and job satisfaction. The leader’s coaching behavior, consideration behavior, and visionary behavior mediated the relationship between the leader’s EI and subordinate's organizational commitment and job satisfaction. Finally, an organization’s career development and education support moderated the relationship between the leader’s coaching behavior, consideration behavior, visionary behavior and subordinate’s attitudes. The leader’s coaching, consideration, and visionary behaviors mediate the relationship between the leader’s emotional intelligence and the subordinate’s organizational commitment and job satisfaction.

**Keywords:** emotional intelligence, leadership behaviour, job satisfaction, organisational commitment

**The effect of mothers’ emotion traits on that of high school and university students in Japan: A study within the framework of the cognitive appraisal theory**

YAMAUCHI, H. (Nagoya University)

---
This study aimed to investigate the effects of mothers’ emotion traits - defined as “the tendency of the individual to experience a particular emotion with frequency in his or her day-to-day life” - on students’ emotion traits. A further aim was to examine the mechanism that underlies this effect, and the cognitive appraisal theory (e.g., Lazarus, 1991) was applied. The theory assumes that emotions are elicited by the appraisal of the relationship between an event and the self (i.e., event -> appraisal -> emotion). The Subjects comprised 97 high school students and 110 university students, and their mothers, numbering 207. The students and their mothers were instructed to complete the same questionnaire, which comprised a scale that could measure their emotion traits and appraisal styles. The scale contained 14 short stories describing interpersonal situations. Subjects were asked to rate (1) anger and sadness and (2) typical appraisals, that they would feel in a given situation on a 3-point scale. The main results were that (a) the anger/sadness appraisals were strongly associated with the anger/sadness traits in both students and mothers; (b) no direct relationship between students’ and mothers’ anger/sadness traits was found; and (c) the students’ anger/sadness appraisals were regressed on their mothers’ anger/sadness appraisals. The fact that an association was found between the appraisal styles and emotion traits is congruent with the cognitive appraisal theory. However, intergenerational transmission of emotion traits, a phenomenon suggested by earlier research, was not found. On the contrary, the appraisal style was found to transmit from mothers to students. The result implies that mothers’ appraisal styles affect adolescents’ emotion traits by using the latter’s appraisal styles as an intermediary. The results could be interpreted two ways. First, the transmission of emotion traits’ is limited to infants since the subjects of most of the advanced research in this field involved infants. Second, developmental changes affect the result. In infancy, emotions may be elicited in processes that do not involve cognitive appraisal. With development, emotions that need cognitive appraisal may increase, and thus, the nature of the effect that mothers have on adolescents may also change.

Keywords: emotion traits, mothers, students, cognitive appraisal theory, appraisal style

The effect of optokinetic stimulation on pseudoneglect in a virtual environment

CHO, A. (Chung-Ang University), LEE, J-H. (Chung-Ang University)

Hemispatial neglect is the impaired or lost ability to detect or react to sensory stimuli presented in the hemispace contralateral to the lesioned cerebral hemisphere. Healthy individuals also show a small leftward bias known as ‘pseudoneglect’. Although visual scanning training (VST) has been successful in treating neglect, it has some drawbacks. Optokinetic stimulation (OKS) is a visual display of numerous stimuli all moving coherently to the neglected side, and is a technique that makes up for the weaknesses of VST. In this study, we applied OKS to a virtual environment which allows control of the participant’s visual field and also increases immersiveness of the stimuli. Another advantage is that it is easier to generalize the treatment to daily life because the treatment stimuli uses a background of typical city streets, thus participants can experience a realistic treatment environment. The purpose of this study is to test the effect of this new OKS program for hemispatial neglect by examining its effectiveness on pseudoneglect. Participants will be neurologically healthy, right-handed people. Prior to the treatment, a baseline level will be assessed using a line-bisection task and an erase task on paper and on a screen. Participants will receive leftward- and rightward-OKS treatment in a virtual environment at slow, medium, and fast speeds, at random. After each rightward and leftward session, participants will receive a line-bisection test and an erase test. Treatment will be conducted using the GDS Side View Neglect program, which we created for OKS treatment in a virtual environment, presented using a see-through head mounted display with a head motion-tracking device. As this is a study in progress, we predict that participants will show a correction of their leftward bias after the fast-speed rightward-OKS compared to the other speeds, while leftward-OKS will induce an increased leftward bias. Also, completion speeds of the erase task will be reduced after rightward-OKS, but not after leftward-OKS. This study will examine the influence of OKS in a virtual environment, and the expected results may
provide a valuable treatment method for hemispatial neglect patients.

**Keywords:** hemispatial neglect, visual scanning training (VST), optokinetic stimulation (OKS), virtual environment

**The effect of positive and negative leading post-event information on eyewitness memory within participants**

NABATA, Y. (Hokkaido University), NAKA, M. (Hokkaido University)

Studies often examine the effect of post-event information on eyewitness memory by providing participants with only misleading post-event information. However, the effect of post-event information has not been examined by providing participants with positive leading (PL) post-event information. PL post-event information might influence eyewitness memory in a similar positive way as negative leading (NL) post-event information negatively affects it. This study investigated the effect of post-event information within participants by providing them with correct (PL) and incorrect (NL) post-event information. Twenty-four undergraduates were presented a three-minute movie followed by one of three versions of a narrative about the events in the movie. Each narrative contained four correct (e.g., ‘An old and a young man were fishing in a river.’), four incorrect (e.g., ‘An old and a young man were fishing in a lake.’) and four neutral (e.g., ‘An old and a young man were fishing.’) statements that were counterbalanced across the three versions of the narrative. Afterwards the participants were asked to answer a cued recall test concerning the events. Questions about events that had received PL post-event information were not answered more frequently correctly (81%) than questions about events that had received neutral post-event information (73%), which suggested that participants did not use the correct information that was given in the narrative. Both kinds of questions were, however, answered more often correctly than questions about events that had received NL post-event information (55%), indicating that participants frequently failed to ignore the misleading post-event information. Participants did not make use of the PL post-event information, but they failed to ignore the NL post-event information. The difference between the performance on the questions that had received PL or neutral post-event information might become significant with more participants, but the effect of NL post-event information would probably remain larger than the effect of PL post-event information. There were correct, incorrect and neutral statements concerning each event in the study, so the results were not affected by the saliency of the events. The accuracy of the post-event information might, however, have influenced the results. Because the correct statement and the witnessed event are congruent, participants are not required to make any changes to their eyewitness account, whereas they have to decide whether to make adjustments when their account and the incorrect statement are incongruent.

**Keywords:** post-event information, eyewitness accounts, negative leading post-event information, positive leading post-event information, witness

**The effect of receiving help on self-esteem and face in different relational contexts**

WEI, C.F. (Taipei Municipal University of Education), LIN, S.Y. (Chung Yuan Christian University)

Previous research confirmed that receiving help might be perceived as self-threatening (Ames et al., 2004; Fisher et al., 1982; Nadler & Fisher, 1986). According to the self-evaluation-maintenance model, receiving help from a significant other on an ego-relevant task can be threatening to one’s self-esteem. In Chinese Confucian culture, there are strong positive duties among inside-family members (Wei, 2001). It is inferred that role obligation moderates the relationship between receiving help and self-esteem threat. The research design was a 2×2 between-subject factorial design. A self-developed scenario questionnaire was used to measure the dependent variables. The independent variables were closeness of relationship (inside- vs. outside- family relationships) and power distance of relationship (vertical vs. horizontal relationships) between the helper and the recipient. The dependent variables were self-esteem, face perception, and
the degree of indebtedness the recipient felt after receiving help. One hundred and sixty two college students participated in the study (105 females and 57 males) and the average age was 19.75 years. Receiving help from outside-family members made individuals feel lower self-esteem, face perception, and indebtedness than when helped by inside-family members. Receiving help from high-status persons in vertical relationships resulted in lower self-esteem, face perception, and indebtedness than when helped by equal-status persons in horizontal relationships. Self-esteem threat for receiving help was reduced in inside-family or vertical relationships because of role obligation.

Keywords: help, self-esteem, role obligation, face perception, indebtedness

The effect of relationship with parents on other-oriented achievement motivation

ITO, T. (Gakushuin University)

In self-determination theory, autonomy has an important role on achievement motivation. But to fulfill expectations of significant others was reported frequently by Japanese people as a motive for achievement. Ito (2003) distinguished other-oriented achievement motivation as this motive from self-oriented achievement motivation. The purpose of this study is to examine the effect of the relationship with parents on acquiring other-oriented achievement motivation. 84 undergraduate students were subjected to both the questionnaire survey and the semi-structural interview. This questionnaire was about the attitude to self-and other-oriented achievement motivation. In the interview, they were asked what expectation their parents had to them and whether they had experiences of conflict with their parents, when they were in junior and senior high school. The expectations of parents were classified by five categories (respect for will of children, average grade, specific expectation, high grade, and low or no expectation). In the result of factor analysis of the questionnaire, six sub-scales (e.g. positive attitude to other-oriented achievement motivation) were formed. An ANOVA on these sub-scales showed that undergraduate students whose parents had specific expectations or high expectations were likely to have other-oriented achievement motivation than undergraduate students whose parents had little or no expectation. And it was shown that undergraduate students whose parents had had specific expectations had negative attitudes but undergraduate students whose parents had had high expectations had positive attitudes to self-oriented achievement motivation. It seems that the content of expectations of parents has an important role on the nature of children's achievement motivation. Acquiring other-oriented motivation is encouraged by an appropriate relationship with parents.

Keywords: self-determination theory, achievement, parents, expectations, attitudes

The effect of rice deprivation on rice craving and rice-eating frequency in Japanese people

KOMATSU, S. (Doshisha University), DAN, I. (National Agriculture and Food Research Organization), AOYAMA, K. (Doshisha University)

Food cravings are defined as an intense desire to consume a particular food or food type that is difficult to resist. Various studies found that in Western countries chocolate is a food particularly craved. In contrast, Japanese people most frequently experience craving for rice. Rice craving was not related with voluntary restriction of rice but with involuntary restriction of rice. The objectives of this study were to experimentally investigate whether rice deprivation produces rice craving, how the periods of rice deprivation influence rice craving, and whether rice deprivation increases rice-eating frequency after deprivation periods. Participants were 51 undergraduate students. They were divided into one-day deprivation condition, three-day deprivation condition, or no deprivation condition. Participants in the deprivation conditions were instructed not to eat plain rice (including sushi, onigiri, and donburi) for one or three days. They were allowed to eat rice prepared as part of a meal, such as fried rice and pilaf. For one week, they maintained a food diary and assessed nightly how often they experienced a craving for rice during that day. Participants in the one-day
deprivation condition and three-day deprivation condition showed an increase in rice craving during deprivation periods. There was no significant difference in rice craving between the first day in the one-day deprivation condition and the third day in the three-day deprivation condition. On the first deprivation day, participants in the one-day deprivation condition tended to experience more craving for rice than participants in the three-day deprivation condition. However the difference was not statistically significant. Participants did not, however, increase rice-eating frequency after the deprivation period, compared with the pre-deprivation conditions. This result showed that rice deprivation produced rice craving. Interestingly, the frequency of rice craving was irrespective of how long they were deprived of rice. Increased rice craving does not necessarily lead to overeating of rice. Thus, in the future, we need to examine whether eating rice results in a decrease in rice craving.

Keywords: food craving, rice, deprivation

The effect of self-concept on stress coping and mental health, evidence from female students in a Chinese university

LIU, C. (Harbin Normal University)

The aim of this study was to measure the effect of self-concept on stress coping and mental health, with particular focus on female students from a Chinese university; and to provide empirical guidance in improving psychological health for female university students. A questionnaire, targeted to 1070 current female students enrolled in an Arts Faculty of a university in Harbin China, was conducted in June, 2009. Informed on the nature of the study, and agreed to cooperate, subjects were given questionnaires and asked to complete these during lecture time. The questionnaire incorporates the following factors: self-concept scale, self-esteem scale, stress coping scale, state-trait anxiety inventory and self-rating depression scale. Two groups are defined as ‘only-child’ and ‘not-only child’. All the above mentioned factors were examined across the two groups. Relationships between self-concept and the rest of the factors were examined by variance analysis. Regression analysis was used to quantify the impact of self-concept on stress coping and mental health. The scores on the factors of self-concept and self-esteem were found to be significantly higher for the ‘only-child’ group than those for the ‘not-only child’ group. No significant difference was observed between the two groups in terms of the stress coping, depression and anxiety. The probabilities of depression are as follows, 0.25 for the ‘only-child’ group, 0.37 for the ‘not-only child’ group, and 0.31 for the overall participants. Self-concept and other psychological factors were found to be significantly correlated. A positive correlation was found between the scores of self-concept or self-esteem and the scores of stress coping, and a negative correlation was observed between the scores of self-concept or self-esteem and the scores for anxiety or depression. The study indicates a relatively high rate of depression among the female university students surveyed. Positive self-concept can not only enhance the self-esteem and promote the behaviors of effective stress coping, but also decrease the rate of anxiety and depression. As a result, psychological health is improved.

Keywords: self-concept, stress coping, mental health, females, university students

The effect of sleep deprivation and recovery on subjective appetite and cravings: A pilot study

HEATH, G. (Centre for Sleep Research, University of South Australia), SARGENT, C. (University of South Australia), DORRIEN, J. (University of South Australia), PATERSON, J. (University of South Australia), BIernaUX, R. (University of South Australia), DADDS, J. (University of South Australia)

A growing body of epidemiological studies has demonstrated a link between obesity and sleep deprivation. Laboratory studies suggest self perceived hunger and cravings for calorie rich foods increase following sleep deprivation; however, these factors have not been examined during subsequent recovery following sleep deprivation. The aim of the current study was to examine appetite and food cravings in healthy adults following moderate sleep deprivation with two different recovery conditions. Six males and five females (age: mean±SD, 23.8±4.7 yr)
were allocated to one of three conditions each commencing with a baseline night and ending with an ad libitum sleep. Experimental conditions consisted of one night of sleep deprivation followed by either 6 x 6-h or 6 x 9-h sleep opportunities. The control condition consisted of 7 x 9-h sleep opportunities. Subjective hunger and food cravings were assessed at regular intervals during wake periods using visual analogue scales and a brief questionnaire, respectively. Food cravings were split into four categories: sweet carbohydrate/fat (e.g. chocolate), savory carbohydrate (e.g. potato chips), protein (e.g. meats) and carbohydrate (e.g. potato). Changes in self perceived hunger and food cravings across time and between conditions were analysed using repeated measures ANOVA. There was a significant effect of condition for hunger such that the experimental conditions reported significantly lower levels of subjective hunger than the control condition ($p<0.01$). No significant effects across time or between conditions were found for food cravings. In contrast to previous studies, there was no difference in self perceived hunger or cravings following sleep deprivation. There are two possible explanations for these findings. Firstly, although this study included females there were unequal gender balances within conditions, such that the control condition contained more males than females. Females have a lower daily energy requirement than males and this could account for the difference in hunger ratings across the conditions. Secondly, previous studies have restricted participants from eating during the day of testing. This may influence self perceived hunger and cravings for calorie rich foods. This pilot study raises a number of methodological issues that should be considered in future research.

Keywords: sleep problems, hunger, obesity, food craving, appetite

The effect of social environmental factors on the adaptation process after social exclusion

YANAGISAWA, K. (Hiroshima University), TERADA, M. (Hiroshima University), ISOBE, C. (Hiroshima University), URA, M. (Hiroshima University)

Eisenberger et al. (2003) found that social exclusion accentuates social distress, not only under explicit social exclusion conditions (i.e. individuals were prevented by other players from participating in a social activity: ESE) but also under implicit social exclusion conditions (i.e. individuals were unable to join other players in a social activity because of extenuating circumstances: ISE). However, self-regulation of this distress occurred only under the ESE condition. On the basis of these results, it can be proposed that although ISE included only the estimation process of impact resulting from social exclusion, ESE included also the regulation process of the impact. On the other hand, it has been found that some social environmental factors have negative or positive impacts on a series of treatment processes of social distress. Previous research revealed that availability of social support moderates the impact of social distress, and high-maintenance interactions have negative effects on self-regulation of social distress. Therefore, the present study examined what influence processes exist between these social environmental factors and the impact of ISE and ESE. In particular, we focus on the daily high-maintenance interactions with family members and friends, and the support of family or peers. University freshmen ($n = 56$) individually participated in a laboratory experiment that ostensibly used instant messaging through a computer network. They participated in all of three experimental conditions (i.e. ISE, Inclusion and ESE). Before and following each experimental manipulation, participants rated their current level of need satisfaction as an index of social distress. Results of path analyses showed that greater peer (not family) support predicts lower social distress in ISE conditions, but not in ESE conditions. In contrast, the results showed that a higher frequency of high-maintenance interactions with family member or friends predicts greater social distress in ESE conditions, but not in ISE conditions. Taken together, we discuss the effects of each social environmental factor on the adaptation process after social exclusion. The results of the present experiment suggest that social support and high-maintenance interaction probably have different impacts at different times in a series of adaptation processes.

The effect of the 'shoe size' hierarchy in judgments of teacher status

WALL, G. (University of Canterbury)

To aim of this study was to determine whether the age of students taught has an effect on the perceived status of teachers. A group of 80 teachers and non-teachers rated the status of a list of different occupations that included three different teaching roles: early childhood educator, primary teacher and secondary teacher. Both groups rated secondary teachers as having the highest status, followed by primary teachers, and finally early childhood educators. Non-teachers rated each of the three teaching roles as higher status than teachers, however non-teachers tended to be more generous than teachers in their status ratings overall. This finding indicates that perceived teacher status is affected by the relative ‘shoe-size’ of the students that they teach. Specifically, the younger the child, the lower the perceived status of those who teach them.

Keywords: perceived status, teachers, shoe-size hierarchy

The effect of the attribution for academic achievement on academic expectancy and performance: A meta-analysis

HSU, C.S. (Chang-Jung Christian University)

This study investigated the impact of the attribution for academic outcome on academic expectancy and performance by means of meta-analysis. This meta-analysis was based on a self-attribution theory and explanatory style, and presented the outcome of a pilot study. Computerized database searches, manual searches in several journals, and reference list searches were conducted. Criteria were set up to identify usable studies in this meta-analysis. A 95% confidence interval estimate was performed to examine the significance of the average of effect sizes (d). Twenty four studies were collected, including 14,190 participants, which provided 83 and 29 effect sizes respectively for achievement performance and academic expectancy. With regard to positive academic events: (a) the attribution of ability and effort was significantly predictive of academic achievement (d=.67 and .54 respectively); (b) the attribution of ability and effort was significantly predictive of academic expectancy (d=1.11 and .91, respectively); (c) the attributions of stable and unstable factors were both significantly predictive of academic achievement (d=.45 and .40, respectively); (d) the attributions of stable and unstable factors were both significantly predictive of academic expectancy (d=.59 and .66, respectively); (e) the internal locus of control was significantly predictive of academic and performance and expectancy (d=.58 and 1.01, respectively); (f) the attributions of controllable and uncontrollable factors were both significantly predictive of academic performance (d=.31 and .10, respectively); (g) the attributions of controllable and uncontrollable factors were both significantly predictive of academic expectancy (d=.59 and .66, respectively); (h) the attribution of positive events to stable, internal, and controllable factors could contribute to academic performance and expectancy. The predictive power of the attribution of unstable or uncontrollable factors was less but significantly positive. This was a pilot study and more studies will be collected in order to verify the above results.

The effect of the leadership styles on the perceived organizational support: The moderating role of implicit misattribution

ZHOU, M. (National University of Defense Technology; Peking University), WANG, L. (Peking University), ZHANG, J. (Peking University)

Leadership styles such as transactional leadership and transformational leadership can exert an influence on perceived organizational
support. However, an empirical study we reported has revealed that the aforementioned impact is moderated by employee implicit misattribution. This research can help us understand how leadership styles impact on staff. Particularly, the study of implicit misattribution can keep the real result from being suspected and from misgiving the staff. We measured Implicit Misattribution by the Implicit Association Test (IAT). In the IAT, the concept words included the words expressing success and those not expressing success; the attributive words included the words expressing external attributes and the ones expressing internal attributes. Meanwhile, participants were required to complete the scales including dimensions of leadership styles and perceived organizational support. Preliminary results showed that the relationship between transformational leadership and perceived organizational support is positive, and the relationship between transactional leadership and perceived organizational support is negative. Implicit Misattribution plays a moderating role in the relationship between leadership style and perceived organizational support. For those with external attribution, the positive relationship between transformational leadership and perceived organizational support was stronger, and the negative relationship between transactional leadership and perceived organizational support was stronger. For those with internal attribution, both positive and negative relationships were weaker. Quantitatively testing Implicit Misattribution is a challenge. Based on the above results, we expect that leadership styles can affect perceived organizational support in a certain pattern, depending on employee implicit misattribution.

The effect of the type of median strip on drivers’ subjective sense of speed

HWANG, B.K. (Chungbuk National University), OH, J.S. (Chungbuk National University), PARK, S.J. (Chungbuk National University)

As many have admitted, the design based on human factors is an important factor for safety as well as the improvement of safety-facilities. The original purpose of median strips was to prevent veering vehicles, as with the center-line invention, however, the type of median strip has an influence on drivers’ subjective sense of speed. When it comes to visual information, Edge Rate and Global Optic Flow are the most influential parts that affect drivers’ subjective sense of speed. We have tried to determine whether there is a difference depending on the type of median strip. Sixty participants who had a driver’s license attended the study. The test conditions were forms of concrete and guardrail and pavement markings and we used a simulation program which was developed to describe a real traffic situation, with three types of median strip. The participants were asked to push the button when they sensed each speed—60km/h, 80km/h and 100km/h—and the responses measured. All conditions were repeated randomly. The condition of guardrail had the fastest sense of speed among all condition. As the one way ANOVA result showed, there was a significant difference when participants responded at 60km/h (F=3.69, p<.05). Moreover, there were significant differences when participants responded at both 80km/h (F=3.69, p<.05) and 100km/h (F=3.39, p<.05). This study showed that the types of median strip have an influence on drivers’ subjective sense of speed. Therefore, we conclude that designers should develop the median strip according to drivers’ subjective sense of speed and the effect of median strips, making more effective safety-facilities on the road. We also need to consider other factors that affect drivers’ subjective sense of speed, such as road environment.

Keywords: driving, median strips, sense of speed, visual information, speed

The effect of work orientation and identification within organizations of separation prevention

ENAMI, J. (Hiroshima University), URA, M. (Hiroshima University), ISOBE, C. (Hiroshima University), ORIMO, H. (SDA, Inc.)

While employees’ job change and separation rates have been increasing due to the worsening employment environment because of recession, companies have strived to secure excellent...
human resources. This is a common problem throughout the world. In Japan, 66% of companies answered "securing excellent human resources" as an issue for their personnel policy (Nissei report 2008). Shein (1978) proposed that for career planning and career development, activities aiming to increase employees' involvement is important. In this study we examined the effect of employees' work orientation and identification to the companies of their intention for job change and in-company career vision. We predicted that employees' levels of identification to their organization mediate the relationship between their work orientation and job change and career vision. In this study work orientation was divided into two categories, "goal-accomplishment orientation," and "human relationship orientation". Furthermore, we classified identification into three categories, which were identification to the company itself, division, and superiors and colleagues. The participants were 219 people including general employees and management levels. Survey forms were collected by mail. The survey content was as follows; (1) measure of orientation for work, (2) identification, (3) job change intention, and (4) in-company career vision. Path analyses were conducted respectively for rank and file employee and management levels. The results showed that "human relationship orientation" directly predicted higher career vision in the rank and file level ($\beta=.23$, $p<.01$). Also, both "goal-accomplishment orientation" and "human relationship orientation" were completely mediated by identification to the company to predict lower job change intention ($\beta=-.34$, $p<.001$). On the other, for management level employees, “goal-accomplishment orientation” was partially mediated by identification to their superiors and colleagues to predict their lower job change intention ($\beta=-.29$, $p<.01$). Taken together, for rank and file level employees, the higher the work orientation, the higher their organization level identification suppresses their job change. However, for management level employees, personal level rather than organization level identification plays the role of mediation. These results suggest that mediation processes between work orientation and job change differ by job class.

The effectiveness comparison of existential-humanistic group therapy for self-esteem development of male prisoners in central prison of Mashhad

HASSANABADI, H.

Since self-esteem has a central role in crime as well as prisoners' behaviour. On the other hand, according to literature, the existential-humanistic therapies can influence self-esteem, so the aim of this research was to examine the effect of existential-humanistic group therapy (EHGT) on developing self-esteem among the male prisoners in the central prison of Mashhad (Iran). This study was based on pretest-posttest control group design. 24 inmates were randomly located at two intervention and control groups. Only the first group received a 15 session course of EHGT. Both two groups were tested by Rogers self-esteem inventory, before, after and one month after therapy termination. In comparison to control group, results showed that the intervention group self-esteem was developed meaningfully during post and follow-up period, i.e. EHGT can help to reduce prisoners' personality weaknesses. Nevertheless there are different factors which affect inmates’ self-esteem and are out of our control. This finding not only is useful to forensic therapists but also for other practitioners such as family and school counsellors.

Keywords: self-esteem, crime, prisoners, existential-humanistic therapies

The effectiveness of a positive parenting program and mental health of mothers of children with attention deficit/hyperactive disorder

MOUSAVI, R. (Shahed University), JAFARI, B.

The current research examined the effectiveness of a Positive Parenting Program on mothers of 4-12 year-old children with attention deficit/hyperactive disorder. The study used pre and post-test method with a control group. In a quasi-experimental study, mothers of 20
children with attention deficit/hyperactivity disorder were selected from two university-affiliated health institutes and randomly allocated into Experimental and Control groups. The experimental group sustained an 8 session instruction of the Positive Parenting Program. The subjects were assessed by a General Health Questionnaire at 3 time-points (before and after treatment and follow up). The data was analyzed by Multivariate Covariance Analysis. The findings showed that the program caused significant mental health improvements in the experimental group compared to the control group mothers. Thus, in conclusion, the Positive Parenting Program was effective for improving mothers’ mental health with children with attention deficit/hyperactive disorder. Therefore, it is recommended this method should be used for mothers of such children.

**Keywords:** positive parenting, mental health, Attention Deficit Hyperactivity Disorder

The effectiveness of stress management and active listening training for Japanese workers

KANO, R. (University of Tezukayama Graduate School), MORISHITA, T. (University of Tezukayama Graduate School)

Managing mental health problems in workplaces is becoming a serious issue in Japan. The ministry of Labor (the present ministry of Health, Labor and Welfare) has established guidelines for promoting mental health in work places in 2000, aimed at encouraging each organization to develop and practice their own mental health programs. In the guidelines, it is recommended that workers should know how to manage stress by themselves. The present study was undertaken to examine the effect of stress management and active listening training. Active listening is the listening skill based on the “Three basic therapist conditions” suggested by Rogers. Participants were 95 Japanese workers in their third year after entering the company, ranging in age from 20 to 27 years (M=24.3, SD=1.3). The training was given in September 2009. The Active Listening Attitude Scale (ALAS) and Brief Job Stress Questionnaire (BJSQ) were completed by participants before training and one month after the training. Thirty one males (M=24.9 years old) and 34 females (M=23.7 years old) without serious life event experiences before filling out post-questionnaires, were used for further analysis. The scores of pre- and post-training were compared using a paired t-test. There was a significant difference in ALAS scores between pre-training and post-training (36.7(SD=5.9) for pre-, 38.5(SD=5.5) for post-, t=2.415, df=64, p<.05). There were significant differences in two subscales of BJSQ in males: the score for “amount of psychological load of work” increased after the training (5.0(SD=1.6)for pre-, 5.7(SD=1.6) for post-, t=2.469, df=30, p<.05). “Stress of interpersonal relationships in the workplace” was also increased after training (8.7(SD=2.0) for pre-, 9.3(SD=2.0) for post-, t=2.039, df=30, p<.05). Higher scores for these indices indicate lower degrees of stress. We conclude that these results revealed that our training is highly effective for younger workers to improve listening skills to manage stress of interpersonal relationships in the workplace.

**Keywords:** stress management, active listening training, Japanese, mental health problems, workplace

The effects of emotional intelligence on facial expression and identity recognition

KOMATSU, S. (Kyushu University), HAKODA, Y. (Kyushu University)

Emotional intelligence (EI) refers to competencies in processing and managing emotion. We examined the relationship between EI and recognition of facial expression or facial identity by using a selective attention task. We hypothesized that high EI relates to superior recognition for facial expression in particular. Participants were asked to recognize the expression or identity of faces while irrelevant dimensions of identity or expression were held or varied. Participants then completed scales for EI. Results showed that EI correlated significantly with expression recognition in the case that facial identity is held. However under condition of varied identity, correlations between EI and expression recognition were weak or not significant. Also, correlations between EI and identity recognition were weak.
or not significant. These results suggest that relationships between EI and facial expression recognition varied with facial identities.

Keywords: emotional intelligence, facial expression, identity, emotions, expression recognition

The effects of general-self-efficacy on causal attribution and coping behavior in negative interpersonal situations

NOGUCHI, Y. (Gakushuin University)

The purpose of this study was to see whether general-self-efficacy (GSE) would affect causal attribution and coping behavior in negative interpersonal situations. GSE is one aspect of self-efficacy which has an influence on long-time performance and general behavior tendency. Miyake (2000) found that men with high GSE tended to fail more on the test to internal and controllable causes than those with low GSE. In addition, high GSE men and women adopted more active coping behavior. However, the effects of GSE on attribution in interpersonal situation have not been clear. Considering that negative interpersonal events have a great impact on our mental health, there is a need to examine the influence of GSE on causal attribution and coping behavior in interpersonal situations. There were two specific hypotheses. First, people with high GSE would attribute negative personal events to more internal and controllable causes than those with low GSE (hypothesis 1). Second, high GSE individuals would adopt more positive coping behavior than those with low GSE (hypothesis 2). To test these hypotheses, two negative interpersonal events were described. One event was quarreling with a close friend (situation A) and the other was an awkward silence at a party (situation B). Participants were asked to imagine themselves being faced with the events, and to rate the likelihood of six probable causes and how important they were for them. Furthermore, they completed Interpersonal Stress-Coping Inventory and GSE scales. Ratings of causal attribution in each of the situations were analyzed separately, with significant differences found only in situation B. Contrary to hypothesis 1, people with low GSE tended to attribute negative interpersonal events more to internal causes than those with high GSE. This result may be interpreted as individuals with high GSE making causal attribution in a self-protected manner. The hypothesis concerning coping strategies (hypothesis 2) was supported, as it was found that high GSE individuals adopted more positive coping strategies than those with low GSE.

Keywords: general-self-efficacy, causal attribution, coping strategies, interpersonal situations, general behavior tendency

The effects of give-or-take frame, receiver’s expectation, and amount of money on repeated dictator game

HORNG, R.-Y. (National Chiao Tung University), PENG, S.-Y. (National Chiao Tung University)

The purpose of the study was to examine the “give or take” frame, the receiver’s expectation, and the amount of money on repeated dictator game. One hundred and sixty-one participants were randomly assigned to frame (give, take, neutral) by receiver’s expectation (expectation vs. no expectation) conditions to work on four dictator games with a large or small sum of money. Frame and receiver’s expectation were between-subject variables manipulated by the linguistic cues and rules of the game in the cover story. Amount of money and practice were two within-subject variables. The dependent variable of the study was the ratio of money the dictator allotted to the anonymous receiver. Results showed that the most significant factor affecting dictator’s decision was the amount of money to be distributed. Participants became more greedy (giving less) when the amount of money involved was larger. Give-or-take frame might evoke the social exchange schema and thus slightly increased the generosity of the participants in the dictator game when compared to the neutral condition. But the effect was limited to the second game with the giving frame, and disappeared in the remaining games. Participants who were told that the receivers of the money were waiting for their decisions would allot significantly less money to the other party unbeknown to them in the first game. But this effect disappeared in the remaining games. Individual differences may be the dominant factor affecting people’s decision
in dictator game. Factors such as frame or receiver’s expectation affect decisions in dictator game only temporarily. The finding that people giving less when knowing that the others are waiting for the outcome of their decision is quite intriguing and needs further clarification in the future study.

Keywords: give or take frame, receiver expectation, dictator game, money

The effects of integrated after-school career counseling program on students’ career maturity: A case study of Loei Home After-school Program, Thailand

SEEDAGULRIT, S. (Loei Rajabhat University), SEEDAGULRIT, M. (Loeipittayakom School)

The aim of this study was to compare the pretest and posttest scores on the career maturity of an experimental group, and to compare the posttest scores on career maturity between the experimental group and the control group. The samples were 9th grade students. They were randomly assigned to an experimental group or control group. Each group comprised of 8 students. The experimental group participated in the integrated after-school career counseling program conducted by the researcher. The instrument used for data collection was the career maturity inventory (Crites, 1978). Data was analyzed to obtain a mean, standard deviation and t-test. The results indicated that, compared to a control group, students who participated in the integrated after-school career counseling program improved their career maturity. The integrated after-school career counseling program is an effective way to enhance the after-school program and focus on the needs of high-risk students and help them develop the decisional attitude and competencies that increase readiness to deal with career-choice tasks and facilitate behavioral responses that meet these tasks.

The effects of orexin-1 receptor antagonism on alcohol self-administration and relapse behaviour in rats

KRIVDIC, B.K. (Howard Florey Institute), DUNCAN, J.R. (Florey Neurosciences Institute), FRANCIS, A.J.P. (RMIT University), KRSTEW, E. (Florey Neurosciences Institute), LAWRENCE, A.J. (Florey Neurosciences Institute and the Centre for Neuroscience, University of Melbourne)

Increasing evidence suggests that the environment and reinforcement play a key role in the motivation to consume alcohol and the propensity for relapse. The orexin system in the brain has been implicated as part of the neurobiological mechanism(s) driving these behaviours. The current study aimed to (1) investigate whether the selective orexin-1 receptor antagonist SB-334867 could reduce the motivation to self-administer alcohol and (2) examine cue-induced alcohol-seeking following prolonged abstinence in alcohol-preferring (IP) rats. Intra-peritoneal injections of SB-334867 or vehicle were administered prior to operant sessions under fixed ratio (n = 20) and progressive ratio (n = 18) schedules of reinforcement. Rats were then withdrawn from alcohol for 7, 14, 28 or 56 days, following which they were allowed to respond in the presence of alcohol-related cues but in the absence of reward. Results indicated that SB-334867 attenuated volitional alcohol self-administration and alcohol break points. Furthermore, rats displayed robust cue-induced alcohol seeking following all periods of abstinence and SB-334867 attenuated this response in rats abstinent for 14 days. The results further implicate orexin in the modulation of the rewarding effects of alcohol and the salience of alcohol-related cues.

Keywords: Orexin, alcohol-seeking, alcohol, reward, rats

The effects of package design of mineral water on the content evaluation

MAEDA, H. (Kobe Shinwa Women’s University)

The purpose of this study was to examine the effect of brand (package design) on the evaluation of taste using mineral water. A 2
(content: mineral water versus tap water) × 2 (package design: national brand of mineral water versus “tap water”) experimental design was employed, and the research was conducted on a total of 55 participants. In order to judge the quality of the water, 6 items (7-point scale) were used. The main findings were that, in the content of the bottle, “mineral water” was evaluated higher than “tap water”, and in package design, “mineral water” also increased the evaluation of quality. These results suggest that not only objective quality of water but also brand (package design) affects the consumers’ perceived quality.

Keywords: package design, mineral water, content evaluation, brand, consumers

The effects of personal interaction on seeking information about crime prevention measures

ARAII, T. (University of Tsukuba), YOSHIDA, F. (University of Tsukuba)

Prior study has suggested that close relationships among neighborhood residents reduced violent crime victimization risks, but the mechanism for this has not been clearly investigated. One theoretical hypothesis is that personal interactions with others in neighborhood promote an individual’s willingness to seek further information about crime prevention. Thus, this study attempted to identify the effects of personal interaction with others on a person’s willingness to prevent crime and on an incentive to seek information about crime prevention measures. In a web-based survey conducted in Japan, mothers (N = 1040) with three to 12 year old children were asked to complete a questionnaire that measured the amount of personal interactions with others in their neighborhoods (i.e., the breadth of their social network and the frequency of conversation with others), her willingness to prevent crime, and the frequency of seeking information about crime prevention measures on the Internet. Structural equation modeling gave the following results: (1) Overall, a wide social network increased the frequency of conversations about children’s safety with neighbors, and such conversations encouraged mothers to seek information about crime prevention by making them realize their own responsibility in crime prevention and increasing their willingness to cooperate with neighbors.; (2) However, for some mothers, such conversations increased their willingness to defer crime problems to the police and government, and that decreased their incentive to seek information about crime prevention; and (3) When a wide social network increased the frequency of conversations about news contents, such conversations indirectly decreased information-seeking through a willingness to defer crime problem solving to the police and government. In sum, the results indicated that personal interaction with others had significant effects for mothers of young children to seek information about crime prevention measures. But these effects depended on types of willingness being aroused (i.e. a realization of the individual’s own responsibility in crime prevention, the individual’s willingness to cooperate with neighbors, and the individual’s willingness to defer crime problem solving to the police and government).

Keywords: personal interaction, crime prevention, information seeking, Japan, social networks

The effects of reading the picture books and the video picture books on the children’s understanding of the stories

TOGO, E. (Tokyo Future University), ISO, Y. (Tokyo Future University), TSUBOI, H. (Tokyo Future University)

Reading picture books to children is the important educational activity for child daycare and parenting. Recently, the video picture books are being used as a similar teaching material. The meaning of the picture books and the video picture books has been discussed a lot at many occasions in the past, however, it has not been clarified that what kind of influences these picture books and video picture books actually give to children’s understanding of stories. In addition, it also has not clarified that there is any effect difference by group size such as style of one to one, a small group, or a big size group, when the picture books or the video picture books are read. The effects of the picture books and the video picture books of children’s
understanding of book stories by group size, age, and material was studied in this research. The subjects were three year old (N=49), four year old (N=60), five year old (N=71) kindergarten children. The effects were measured using content of the story scales. Reading a picture story one-to-one was more effective in three year old children, and both reading a picture story and a video picture story were effective in five year old children. For reading a video picture story by the large group situation, the higher scores of the story understanding were at the beginning and the ending contents of a story. According to this result, we suggested that we should have enough time to start to read and to finish reading the story.

The effects of self efficacy on the outcome of a group cognitive-behavioral intervention including self-monitoring method

TAYAMA, J. (Nagasaki University), NISHIURA, K. (Miyagi Gakuin Women's University), HAMAGUCHI, T. (Saitama Prefectural University), TOMIIE, T. (University of Hokkaido)

The purpose of this study was to investigate whether degrees of self efficacy (SE) are associated with physical activities or psychological factors after self-monitoring intervention. The subjects found in this study consisted of 49 female college students. We put the subjects in three groups, according to ones degree of SE: high SE group, middle SE group and low SE group. We conducted an intervention study using group cognitive behavioral intervention including the self-monitoring method. We performed a psychological assessment in order to examine SE, self esteem and stress responses, while also applying experimental protocol in the pre, intervention and post period stages. ANOVA of exercise volume disclosed significant group x period interaction. The significant period effect was disclosed in exercise volume and total energy expenditure. In the post period, low SE group showed a significantly lower exercise volume than high SE group. Low SE group had a significantly lower exercise volume, total energy expenditure and step counts in the post period compared in the intervention period. In conclusion, after we applied group cognitive behavioral interventions including the self-monitoring method, we discovered that high SE promoted the habituation of exercise while also inhibiting the risk of rebound. Apathy was decreased in only the subjects categorized with low SE using group cognitive behavioral intervention including the self-monitoring method.

Keywords: self-esteem, self-efficacy, self-monitoring, cognitive behavioural therapy, physical activity

The effects of the breath-training program on reducing the stress-symptoms of the CHD patients

SRISAYEKTI, W. (Padjadjaran University), FARDIANI, (Padjadjaran University)

This study intended to determine whether the Indonesian traditional breath-training program 'Merpati Putih' had therapeutic aspects for patients with coronary heart disease (CHD). The aim was to find out whether the training could reduce the stress-symptoms of the CHD patients in Bandung, Indonesia. The study was a continuation of the empirical findings reported by the members of the organization of the ‘Merpati Putih’. 20 clinically stable CHD patients (determined by the doctor), 10 males and 10 females, 40-60 years old (M = 50.1; SD = 4.8) participated in this study. They were diagnosed with CHD with artery coronary stenosis > 75% in at least one coronary artery, recommended by cardiologists for regular medical treatment whether or not they had received percutaneous coronary interventions (PCI) or a coronary artery bypass graft (CABG). The study consisted of 13 sessions, twice a week, two hours per session. Interrupted time-series with multiple replications design (Cook & Campbell, 1979) was applied. The stress symptoms were measured by the adapted questionnaire (Severin, 2002), and a sphygmomanometer was used for blood pressure, and manual measurement with a stop watch for heart beat. Results showed that the breath-training program reduced the stress-symptoms (questionnaire $\chi^2 = 225.878$, $p = .05$; blood pressure $\chi^2 = 154.224$, $p = .05$; heart beat
The effects of the timing of judges’ instructions on the verdicts of jurors

ARAKAWA, A. (Nagoya University), KAWANO, N. (Nagoya University)

Since 2009 Japan has been using the Saiban–in system where six lay jurors must cooperate with three professional judges to determine and explain a verdict. However, some reports have shown that Japanese lay people tend to nullify the law in specific situations including, importantly, cases involving contested criminal responsibility. Because judges’ instructions seem to play important roles in preventing nullification by juries, it is important to identify instructions that are effective in this regard. The current study examined the effects of the timing of a judge’s instructions regarding responsibility on the verdict reached by a jury. Sixty seven undergraduates participated in the experimental scenario, and participants completed questionnaires after reading a scenario which involved a murder case where the defendant pleaded “not guilty by reason of insanity.” Respondents were asked to: (1) choose between “guilty” or “not guilty by reason of insanity”; (2) explain the reasoning behind their answer to item (1); (3) rate the confidence in their verdict on a 5-point Likert scale; and (4) explain the lack of confidence in their verdict, if appropriate. Participants were assigned to one of the condition of (a) instruction-preceded (the judge’s instructions about legal responsibility preceded presentation of the scenario) or (b) scenario-preceded (the presentation of the scenario preceded the judge’s instructions about legal responsibility). Forty-one participants reached a verdict of guilty and 21 chose the other option. The rate of favoring “not guilty by reason of insanity” was lower under the instruction-preceded condition than under the scenario-preceded condition ($\chi^2(1) = 2.882, .05 < p < .10$). On the other hand, no significant difference between the groups with respect to participants’ subjective certainty was found. These results suggest that the timing of judges’ instructions affects the verdict reached by jurors. More specifically, instructions underscoring legal responsibility led jurors to uphold the law when such instructions preceded the scenario.

Keywords: judges, jurors, verdict, judge’s instructions, Japan

The effects of variations in placing diagrams within items of a Japanese language reading test

YASUNAGA, K. (Nagoya University), ISHII, H. (Nagoya University)

The purpose of this study was to examine if the manner of presentation affects item difficulty in a Japanese language reading test. Study 1 identified items with low difficulty and discrimination. Study 2 examined whether the way in which the diagram is presented affects item difficulty and discrimination in the test. In this study, item difficulty was the proportion of correct, not the mean of item response theory. In study 1, junior high school students in South Korea ($N=232$) were administered a translated version of the Gunma Prefecture Achievement Test. In addition, the data of Gunma Prefecture Achievement Test administered in 2006 was studied. In Study 2, students in Japanese junior high school ($N=778$) were assigned to one of test O ($N=250$), test N1 ($N=170$), test N2 ($N=180$) and test N3 ($N=178$) groups. Students had 50 minutes to answer. The researcher rated based on the answer rubric. In study 1, item difficulty and item discrimination of this test were analyzed. The results showed an item showed low difficulty and discrimination when it featured a diagram composed of two blank spaces presented by two words which were reversed of the original order in the text, and accompanied by a hint alongside these spaces (O). In study 2, therefore, the effects of placing blanks and hint placements were examined, composing four distinct versions: test O, test N1, test N2 and test N3. Test N1 featured a diagram.
composed of two blank spaces presented by two words which were altered in presentation order, and accompanied by a hint underneath these spaces. Test N2 was composed of two blank spaces presented in the same order as in the original text with the hint alongside them, while test N3 had it underneath. It was found that N2 and N3 were high in both difficulty and discrimination. Item difficulty increased more than 0.2 points. It was observed that item difficulty and discrimination was high when two blank spaces were placed in order of text. It was concluded that the manner in which the diagram is placed affects item difficulty and discrimination on testing.

The enrichment of the Theory of Zone of Proximal Development from the affective dimension

LU, J. (Shanghai Normal University)

Vygotsky, the founder of the psychology science in the Soviet Union, pinpointed the theory of “Zone of Proximal Development”, which refers to the “Distance between the actual developmental level as determined by independent problem solving and the level of potential development as determined through problem solving under adult guidance or in collaboration with more capable peers” (Vygotsky). Vygotsky insisted that the difficulty of teaching contents should be within the Zone of Proximal Development. However, it only remains the focus on the domain of cognition. How to trigger students’ motivation to jump seems lacking in evidence in Vygotsky’s research. In this case, based upon Vygotsky’s theory etcetera, we put forward the Affective Teaching Strategy – the Strategy of Exceeding Expectations, which aims to not only spark the students’ interest but also provide them with an impetus to their learning. The strategy has two kernels, which are that the stimuli beyond expectation can trigger surprise, and the surprise can be transformed into interests. The strategy was conducted in the form of field experiments. The subjects of the experiment were two classes of students in Senior High One. A mathematics teacher gave lessons to the controlled class with traditional methods, while giving the experimental class the Teaching Strategy of Exceeding Expectations. When the math teacher presented a new lesson, he asked an unexpected question. “If I have news to release, but every one only has two minutes to tell another two students spontaneously, and you can tell no one else. Suppose there are 600,000 people in this area, how fast can the news be spread all over?” Three minutes later, the teacher unveiled the answer, “only forty minutes!” All the students felt astonished, since then the teacher began the new lesson “Sum of Geometric Progression”. The experiment verified that it is possible to exert the Strategy of Exceeding Expectation in mathematics teaching by furnishing the texts with affection. Furthermore, it was also testified that the Strategy of Exceeding Expectation in math teaching functions as the regulator to students’ learning sets, the improver of their cognitive learning as well as the teaching effects. Vygotsky’s theory of “Zone of Proximal Development” elaborated the reasons that teaching should be within the Zone of Proximal Development from the cognitive dimension. As we proposed, the conditions of teaching should be within the Zone of Proximal Development from the affective dimension, which can trigger the students’ desire for “jumping to reach”. Since then we put forward the corresponding Affective Teaching Strategy - Strategy of Exceeding Expectations which combined cognition with emotion to solve the problem of “promoting students’ initiative by teaching”.

The experience of children unexpected loss: A case study

MUNTEANU, (The Medical Centre of Diagnosis and Treatment)

Unexpected loss appears as a result of an unanticipated event, for which it is impossible to prepare in advance. The case study takes into consideration the loss and suffering aspects of brothers and the unique nature of this suffering. It underlines that every child reacts to pain in his own manner, even if they are part of the same family, have suffered the same psycho trauma
and have had bad news given to both of them at the same time. The paper presents the emotional answer of brothers that have suffered a loss, the young brother death. Family drawing was used as a diagnosis and therapeutic child approach. From the psycho diagnosis point of view, it was the right approach to better know the family structure, the existence of guilt feeling and the trauma impact on the child. Therapeutically, the drawing was a provocative technique for starting a guided dialogue towards self-consciousness and improvement. The family drawing procedure was an efficient diagnosis and psychotherapeutic method for the disclosure of unexpected loss experience and child suffering. The loss experience was different for the two brothers: for one of them, the black clothes were associated with death and suggested a certain separation from someone close, the other one felt responsible for the accident (“If I stayed home, he didn’t fall down”) and still waiting for the brother return. The obtained results allowed the parents to know the real feelings of their children, their place within the family and the relationships between the family members. Each painful experience is unique. Loss experience is different from one child to another, even if they belong to the same family and were the witnesses of the same trauma. Using psycho-diagnosis method, the family drawing procedure was useful in revealing the feelings of loss and the expectations regarding the event. The psychotherapeutic approach must be individual, as well as intra-family group. Children must be listened and helped during the whole suffering process, supported during their emotional recovery. The body fights against illness, with or without pills. Love and constant affection within the family heal the deepest wounds.

The factors which reduce the effects of the enlighten education on date domestic violence for high school students

YOSHITAKE, K. (Nagasaki Junshin Catholic University), YOSHITAKE, Y. (Kyushu University), FUJIWARA, T. (Naagsaki Junshin University), FUJIWARA, H. (NPO Eco check Network Japan)

Recently, domestic violence (DV) has become one of the big social problems in Japan. Especially Date DV, that is DV in an unmarried couple, has been paid attention to, because it effects young people and starts during junior high school days. Study 1 investigated the effects of enlighten education of Date DV on high school students and the factors that block the effects. Study 2 investigated its effectiveness for University students who have, or had, steadies (i.e., a steady relationship). In study 1, the subjects are 2402 high school students (727 boys and 1647 girls, 28 unidentified). After the enlighten education, a questionnaire was completed. Before the enlighten education, 74% of them did not know about Date DV. After the education, 89% of them perceived physical violence as Date DV, 94% of them perceived mental violence as Date DV, and 84% of them perceived restriction as Date DV. This showed the effects of this enlighten education. But 20% of them who have, or had, steadies (n=1268) perceived restriction as positive, even after the enlighten education. They agreed to the opinion that being restricted in seeing their friends by their steadies is not bad because it is caused by their steadies’ love. Those who did some Date DV perceived mental violence as a form of DV less than those who did not (t = 5.53, df = 928, p < .01), and those who had performed mental violence also perceived it as a form of DV, less than those who had not (t = 6.45, df = 918, p < .01). For restriction, the same results were shown. This suggested the tendency to tolerate Date DV in youth, with their steady, and with some experiences of DV. In study 2, the subjects are university students (108 women). The questionnaire consisted of five cases of Date DV: checking partner’s cellular phone, restriction of their behavior, mental violence, physical violence and sexual violence. It was investigated which cases they regard as examples of Date DV and whether they can reject, or not, Date DV in these cases. This study showed a difficulty in saying ‘No’ in serious violence cases, even though they perceived the case as a form of DV. The importance of early education has been suggested.

Keywords: date domestic violence, enlighten education, young people
The father-child relationship in childhood and family structure in late adolescence

KATSURADA, E. (Kwansei Gakuin University), NAKAMI, H. (Kyoto Bunkyo University)

The aim of this study was to examine the association between the father-child relationship in childhood and family structure in late adolescence. Fifty-eight university students participated in the study. Their average age was 20.6 years. To assess family structure the participants were administered the Family System Test (FAST; Gehring, 1993), which is a figure placement technique focusing on family cohesion and hierarchy. Our previous study using this instrument among Japanese university students indicated that family cohesion was perceived explicitly but family hierarchy was not. Therefore, we changed the size of the original blocks so that family hierarchy would be expressed more explicitly in a Japanese sample. The Scale of Psychological Presence of Father (SPPF; Matsunaka & Miura, 2006) was used to assess the participants’ relationship with their fathers in childhood. The SPPF consisted of 5 subscales; positive views of his/her father, discipline, father-child communication, protection and recognition, and family communication. The internal consistencies of these subscales were relatively high (α=.72-.82). The results of the FAST indicated that 19 people were categorized as a ‘Balanced’ type, 19 as ‘Liable-balanced,’ and 20 as ‘Unbalanced’ types. ANOVA was conducted with 3 types of family structure as an independent variable and the SPPF subscale scores as dependent variables. Significant differences were found only on the subscales of ‘positive views of his/her father’ and ‘protection and recognition.’ The means and standard deviations of subscale scores in each type were as follows: ‘Balanced,’ 24.16 (SD 4.18); ‘Liable-balanced,’ 20.05 (SD 4.12); ‘Unbalanced,’ 21.65 (SD 4.60); for the score of ‘positive views of a father,’ F(2,55) = 4.38, p < .05, and 10.53 (1.74), 8.32 (2.03), 8.45 (2.68), respectively for the score of ‘protection and recognition,’ F(2,55) = 6.08, p < .01. The results showed that students categorized as a ‘Balanced’ type had significantly higher scores on the subscales of ‘positive views of his/her father’ and ‘protection and recognition’ than did those of ‘Liable-balanced’ and ‘Unbalanced’ types. These results suggest that the positive father-child relationship in childhood could be the base of the university students’ perception of family structure.

Keywords: father-child relationship, family structure, adolescence, family cohesion, hierarchy

The flow experience in the scope of consumption and the study of its correlates

PALACÍ, F. (Spanish National University for Distance Education), SALCEDO, A. (Instituto de Consumo de Castilla la Mancha), RUIZ, M. (Spanish National University for Distance Education), GARCES, J., LÓPERZ-ARAUJO, B. (Spanish National University for Distance Education)

During the last years the flow achieved a leading role in studies performed on the labor psychology field. Starting with the Moneta and Csikszentmihalyi definition (1996), whereby flow is an extremely enjoyable optimal experience, we established the first goal of this work to apply the flow concept beyond the scope of labor reaching the consumption domain. Thereby, the flow scale developed by Rodríguez, Aguilar, Cifre and Salanova (2003) was adapted to the consumption scenario from a sample of 450 subjects proving its performance for both products and services. The second goal of this work was to determine, for those cases of consumption in which the application of this scale seems to be valid, which other variables the flow is related to involving our experiences of consumption in both traditional and internet shopping. Our outcomes reveal that it is appropriate to use the flow scale in the consumption scope of products but not on services. Furthermore, considering the product sample, the flow keeps significant relationships among the variables dealing with attraction made by shopping stimulus, tending to impulsive purchasing with positive effect in both traditional and internet shopping. The values relationship between both consumption scenarios is very similar. In conclusion, we revised the theoretical implications of the present study and propose future research about the flow experience in the consumption experience.
The impact of aphasia on couples’ communication

CROTEAU, C. (Universite de Montreal), BARIL, G. (Lucie-Bruneau Rehabilitation Center), LE DORZE, G. (Universite de Montreal)

Aphasia, a neurological language disorder, may affect conjugal life. Limited information is available on the impact of aphasia on the couples’ communication. Nevertheless, it is an important aspect to study because it may help to improve intervention with couples living with aphasia. The aim of the present research is to document each member of couples’ perception of the consequences of aphasia on couple’s communication. Nine French speaking couples with one member having chronic aphasia of different types and levels of severity participated in the study. The eighteen participants were met individually in a semi-structured interview in order to gain information on their perception of their communication. The interviews were audiotaped and transcribed. A qualitative analyse was realised. Excerpts of interviews pertaining to communication were selected. These excerpts were resumed with a descriptor, coded and grouped within themes. Five themes emerged from the analysis: appreciation of communication, frequency and length of conversations, topics, types of communicator (initiator of conversation and participator in discussion), feelings and reactions associated to communication. The participants mentioned that the communication was positive before aphasia and that it is now fair or difficult. After the onset of aphasia, conversations are less frequent and the topics are restrained or limited. Many interviewees reported that the communication style from both members of the couple has changed and that the person with aphasia is a less active participant. Difficulty in managing emotions, for both partners, was associated to communication. In addition, some spouses reported that they refrain themselves from initiating discussion on specific topics in order to maintain a positive relationship with the person with aphasia. These results give us a comprehensive view of the communicative consequences of aphasia. They are useful in orienting interventions that consider the needs of couples living with aphasia.

Keywords: aphasia, communication, couples, communication, emotions

The impact of applying case method of teacher’s math teaching problem solving ability

LIU, P.Y. (National Dong Hwa University), SHENG, Y.C. (Miaoli County Pan-Tau Elementary School), HENG-CHANG, J.L. (National Taiwan Normal University)

Sophisticated math epistemological belief, constructive pedagogical content knowledge, and teaching problem-solving capability are considered building foundations of a math expert teacher. The researchers adopted a qualitative analysis method to explore how the teaching case method originated teacher professional development program influenced teachers’ epistemological belief, pedagogical content knowledge, and problem-solving capability and students’ math achievement. The first part of the research was a teacher professional development seminar for 3 math teachers of the learning community group. Discussion materials include: 1. required pedagogical content knowledge in math teaching such as general teaching knowledge, subject content knowledge, learner and learning knowledge, and 2. epistemological belief and problem-solving capability that were obtained from content analysis of three real teaching cases designed based on textbook. In the second part, qualitative analysis method was applied to collect and analyze data gathered from a longitude classroom observation, interview, and reflection journal. The results showed that with construction of situational learning environment and a learning community, the teachers build up a strong connection between teaching theory and practice and fostered critical thinking and problem solving capability. When teachers gained sufficient pedagogical content knowledge and became expert teachers, they were more likely to improve students’ math problem-solving capability. Also, the researchers demonstrated that a research combining teacher, textbook, and classroom could generate...
research results that could be generalized to improving classroom teaching quality.

The impact of communication strategy on forgiveness in different relational contexts: The mediation effect of intent attribution

HSU, N. Y. (Taipei Municipal University of Education), WEI, C. F. (Taipei Municipal University of Education), CHEN, S. W. (National Tsing Hua University)

The purpose of this study was to examine the effect of communication strategy (telling truth, lying, or concealing) on the emotional response and coping of the receiver in different relational contexts (sibling, friends or couple). Previous research showed that people lied less to close others, such as spouse and family (DePaulo and Kashy, 1998). Although lying has a detrimental effect on family relationships, it would be more acceptable in outside-family relationships because lying to family members might violate one’s role obligation, and then resulted in harsh critics (Hsu, Wei, and Chen, 2009). Therefore, telling the truth to a sibling is more acceptable than to friends or spouse, but lying or concealing to sibling is less desirable. Self-oriented communication leads to negative consequences more than other-oriented communication. The study used a 3×3 between-subjects design. Self-designed scenario questionnaire was used to measure the mediating variables and dependent variables. The independent variables were the communications strategy (telling truth, lying, or concealing) and relationship (sibling, friends or couple). The dependent variables were the emotional responses, forgiveness, and future relationship. The intent attribution was the mediator. College students participated in this study. The result showed that the both communication strategy and relationship influenced the evaluation of the communicators and maintenance of future relationships. Though lying was rated worse than concealing or honesty, it was even worse to lie to sibling than to friends or spouse. Self-oriented communication leads to less desirable evaluations than other-oriented communication.

Honesty was regarded as one of the role obligations in family relationships. Therefore, lying to family members violated role obligation, which hazards future interaction.

Keywords: communication strategy, relational context, lying, role obligation, other-oriented communication

The impact of expectation sources on indebtedness

CHIU, L.T. (Chung Yuan Christian University), WEI, C.F. (Taipei Municipal University of Education), CHEN, S.W. (National Tsing Hua University)

This study aimed to understand Chinese college students in the pursuit of expectations from different sources (oneself, parents), of their life goals after failure and the mediation effect of indebtedness between expectation and behavior intention. Questionnaires were used for the pre-test results, using a structural equation analysis model to explore the structure equation model of life goals, indebtedness, and behavior intention. Two hundred and fifty undergraduates from Chung Yuan Christian University served as participants. When an individual did not attain the goal of high self-expectations, they tended to have strong indebtedness to themselves. On the contrary, when they failed at the goal with high expectations of parents, they felt indebtedness to parents. Furthermore, indebtedness becomes the predictor of subsequent behavior. As the participants felt more indebtedness, they would persist in pursuing the life goals. The source of expectation corresponded to the target of indebtedness and indebtedness served as the motivation for pursuing life goals.

Keywords: expectation source, indebtedness, Chinese students, life goals, motivation

The impact of intensive behavioural treatment on children with autism

KHUSHABI, K. (University of Welfare and Rehabilitation Sciences), HOSSEINI, S. B. (Azad University)
The current study examined an intensive behavioral intervention based on the applied behavioral analysis-Lovaas model, for children with autistic spectrum disorders. The sample consisted of 21 children (18 males, three females) aged between 3.1 and 9 years ($M = 5.7$, $SD = 1.6$). There were 17 children with autism, three with Asperger’s syndrome and one with childhood disintegrative disorder. All the children met DSM-IV criteria for the relevant disorder. The children have received one to one treatment by trained trainers, four hours a day, six days per week, for a five-month period. The children and their parents underwent multimodal assessment captured on video, at intake, end of each month of treatment, and at a two-month follow-up. As part of the assessment, the parents were asked to fill in the Autism Treatment Evaluation Checklist. The results indicated that verbal and nonverbal communication skills, sociability, sensory and cognitive awareness, attention and concentration, and physical health were significantly enhanced in the sample. Thus, intensive behavioural treatment would produce significant and durable gains for young children with autism spectrum disorder.

Keywords: Autism spectrum disorder, children, intensive behavioural treatment, Asperger’s syndrome, Autism treatment evaluation list

The impact of intensive behavioural treatment on children with autism

KHUSHABI, K. (Rehabilitation University), POURETEMAD, H. (Shahid Beheshty), HOSSEINI, S.B. (Azad University)

The current study examined an intensive behavioural intervention based on the applied behavioural analysis-Lovaas model for children with autism spectrum disorder. The sample consisted of 21 children (18 male and 3 female) aged between 3.1 and 9 years ($mean=5.7$, $SD=1.6$). There were 17 children with autism, 3 with Asperger’s syndrome and 1 with childhood disintegrative disorder. All children met the DSM-IV criteria for the relevant disorder. The children received one on one treatment by trained trainers, 4 hours a day and 6 days per week for a five-month period. The children and their parents underwent multimodal assessment captured on video, at intake, end of each month of treatment, and at a two-month follow-up. As part of the assessment, the parents were asked to fill in the Autism Treatment Evaluation Checklist. The results indicated that verbal and nonverbal communication skills, sociability, sensory and cognitive awareness, attention and concentration, and physical health were significantly enhanced in the sample. Thus, intensive behavioural treatment would produce significant and durable gains for young children with autism spectrum disorder.

The impact of morning recovery on task and contextual performance: The addition of an objective measure of performance

STEELE, A. (University of Western Australia), WOOD, E. (University of Western Australia), MORRISON, D. (University of Western Australia)

This study examined the utility of morning recovery as a predictor of self-reported task performance, contextual performance and perceived workload, and sought to advance the literature on recovery and performance through the introduction of an objective measure of task performance. Twenty four university students completed a general survey at the commencement of their participation within the study, and then two daily surveys and a cognitive task over the course of one week. Hierarchical linear modeling showed recovery to be positively related to personal initiative above the contribution of person-level and day-level control variables. The hypothesized relationships between recovery and measures of task performance failed to be supported. These findings suggest that feeling recovered in the mornings is not only a pleasurable experience for the individual but may have repercussions for some aspects of work-related task and contextual performance throughout that day.

Keywords: recovery, task performance, contextual performance, workload, objective measure
The impact of nutrition intervention programmes on the cognitive development of pupils in early childhood centres in select communities in northern Nigeria

KATO, R. (Kaduna Polytechnic), OHIDAH, E. (Kaduna Polytechnic), LAWAL KONTAGORA, H. (Kaduna Polytechnic)

The importance of nutrition in cognitive development is established in the literature. Relatively higher levels of poverty in northern Nigeria have necessitated the initiation of a number of intervention programs by government, local and international non-governmental organisations and donor agencies. The aim of this paper is to assess the impact of nutrition intervention programs in Nigeria by measuring the direction of differences in the cognitive development of children in three UNICEF intervention communities and three non-intervention communities. It is expected that the null hypotheses will not be upheld, and pupils from the non-participant (control) communities will perform poorer on the tasks and have poorer nutrition statuses than those from the participant communities across the board. Three hundred male and female pupils of early childhood centres in three focal and three non-focal communities in Kaduna State of Northern Nigeria will constitute the study sample. Anthropometric measures will be used to determine the nutrition status of both groups of respondents, while cognitive development will be measured using tests developed by the researchers. Multivariate and descriptive analysis will be applied to the data. The implications of the findings for further intervention will be discussed and appropriate recommendations will then be made to the communities, government and other stakeholders.

Keywords: nutrition, nutrition, cognitive development, early childhood, Nigeria

The influence of biological and non-biological subjects in premises on children’s deductive reasoning

TENG, J. (CYCU), TENG, W. C. (Chung Cheng University), LIN, H. T. (Chung Cheng University)

One of the major preoccupations of the theory of mental models is that human reasoning could be shaped by past experience. Human reasoning ability would be influenced not only by formats but also by contexts of conditionals. This research will investigate the influence of the subjects of conditionals biological or non-biological, on children’s reasoning performance. The subjects are first graders in northern Taiwan. A group test was conducted. The results demonstrated that the correction rate of reasoning in conditions with biological subjects were significantly higher than those with non-biological ones in modus ponens. The results also suggested that children have better performance on conditional reasoning when they have more background knowledge relevant to the premise. In addition, a clear response set of the preference of “uncertain” choice was found. This reaction shows a significant discrepancy from most of the published studies. However, due to the fact that the relationship between antecedent and consequent in the conditionals with a biological subject is always real in experience while the relationship in the conditionals with non-biological subject is not, the results deserve further clarification. Therefore, the present research is of value in looking into young children’s reasoning process.

Keywords: child psychology, reasoning, past experience, children

The influence of co-worker relationships on person-organisation misfit

COOPER-THOMAS, H. (University of Auckland)

This paper will explore the association between co-worker relationships and individual perceptions of person-organisation misfit. Person-organisation fit research has tended to focus on fit as a positive construct, and research to date has been primarily quantitative, investigating antecedents and consequences of fit. This literature has shown that social factors are positively associated with fit. Our research is novel in looking at misfit, and focuses on how interactions with co-workers influence individual
employees to the point where these employees feel that they are a misfit. While perceptions of misfit may be rarer than perceptions of fit, the implications of feeling that one does not belong may be more severe. The research comprises a literature review and qualitative data analyses. Our findings confirm that co-worker relationships are key influences on perceptions of person-organization misfit. Feelings of not belonging can be based on differences on socio-demographic and personality variables, but it is through communication between colleagues that these differences become actualised. The consequences of misfit are grave, and include severely reduced wellbeing. Employees who feel that they are misfits are prevented from contributing to their full potential, and the consequences are negative for these employees and for their employing organizations. Although misfit was perceived from interactions, the basis often seemed to be personality or demographic differences. Given the increasing diversity of workforces globally, misfit may be on the increase. Hence, there are ethical and practical imperatives for improving co-worker relations and hence reducing the likelihood that employees will feel like misfits.

The influence of performance feedback on task performance under pressure

YAMANAKA, S. (Nagoya University)

Task performance is often impaired when pressure to perform (e.g., competition, audience-induced pressure) is salient. This study investigated whether performance under pressure may be influenced by the perception of success or failure during the performance. It was hypothesized that subjective arousal evoked by the perception of failure during task performance would impair cognitive task performance, whereas the perception of success would not evoke subjective arousal and would not impair performance. A 2 (feedback: success/failure) by 3 (block: pre-block/post 1-block/post 2-block) design experiment was conducted on undergraduates. Participants performed a n-back task (a representative working memory task) in front of the experimenter, who monitored their performance. Participants were told that each block comprised 24 trials and that their task performance in each block would be compared with that of other students. They were also told that they would get an extra incentive depending on their ranking. They received performance feedback of either progressive success or progressive failure after blocks 1 and 2. Subjective estimates of arousal for each block were also collected alongside performance measure, upon completion of task performance. The ANOVA revealed that the success group experienced low arousal and a low error rate in blocks 2 and 3. In contrast, the perception of failure resulted in higher error rates and arousal estimates in block 2. For block 1 (before feedback), there was no difference in the error rate between the success and failure groups. A correlation analysis revealed no correlation between the error rate and the performance anxiety assessed before the performance. These findings suggest that task performance under pressure may be influenced by the perception of failure or success during performance. The perception of failure evokes subjective arousal and impairs the cognitive task performance. Moreover, task performance was observed to be affected by the cognition of the situation. The social implications of this research are discussed.

The influence of self-focused attention on blushing in high- and low-blushing propensity individuals

KIM, K. (Chung-Ang University)

Although blushing is a common emotional response, most people consider blushing undesirable, and often try to stop or conceal it. Some individuals experience so much distress from blushing that they sometimes even develop a blushing phobia or social phobia because of it. According to a cognitive model of fear of blushing, belief to be blushing is assumed to give rise to negative and dysfunctional beliefs regarding the costs of blushing. The anticipation of these costs causes fear, and this fear of
Electronic Poster Presentations

**Abstracts of the 27th International Congress of Applied Psychology**

**blushing leads to increased self-focused attention. Finally, this increased self-focused attention leads to a quicker and more sensitive detection of small temperature differences (increase), thus leading to an enhanced or even exaggerated sensation of blushing. The purpose of the present study is to investigate the influence of self-focused attention in individuals with high- and low-blushing propensities using an in vivo approach. Participants will be screened using the Blushing Propensity Scale (BPS) and the Self-Focused Attention scale (SFA), and they will be divided into 4 groups: 1) high BPS – high SFA group; 2) high BPS – low SFA group; 3) low BPS – high SFA group; and 4) low BPS – low SFA group. Prior to the task, baseline levels of skin temperature will be assessed (baseline). Participants will then be asked to engage in a 5 minute conversation with two unknown confederates (social task). After the conversation task, participants will have a recovery period of 1.5 minutes (recovery). Blushing will be measured using a thermal imaging camera and a subjective questionnaire. [Study in progress] We predict that high BPS individuals will represent considerably higher levels of facial temperature in the high SFA groups compared to the low SFA groups, while low BPS individuals will show no significant differences across the two SFA groups. This is an empirical study to examine the influence of self-focused attention within the fear of blushing mechanism. The present findings may provide valuable information to assist in the development of possible treatment solutions to help individuals with a strong fear of blushing.**

**The influence of self-related task and frame on risky decision making**

**DU, X. (Shandong Normal University), ZHAO, S. (Shandong Normal University)**

Since the “framing effects” was presented by Kahneman and Tversky in 1979 as an important issue in risky decision making, many studies have confirmed its existence. However, there are also some studies which have not found this. Thus some researchers suggest that there are some factors, such as individual traits and task context that affect framing effects. In this study, we examined whether, in risky decision making, self-related task affects framing effects. We used typical “Stock Problem” as the experimental material. The stock issue was described in the frame of positive and negative. Participants (n=113) rated the level they approved of two projects on a 6-point scale. The experiment was 2×2 between-subjects design. The independent variables were self-related task (self-related vs. non self-related) and frame (positive vs. negative). The data was analysed by 2×2 ANOVA. The results showed that the main effect of frame was significant (p<0.05). Participants responding to negatively framed options (M=3.90) made more risky decisions than participants responding to positively framed options (M=3.40) and the main effect of self-related task was significant (p<0.05). Participants responding to non self-related options (M=3.88) made more risky decisions than participants responding to self-related options (M=3.42). Two-way interaction effect between frame and self-related task was also significant (p<0.05). Further simple effect analysis showed that in the non self-related task, participants responding to negatively framed options (M=4.38) made more risky decisions than participants responding to positively framed options (M=3.43), and there was no difference in self-related task. The study concluded that self-related task influenced framing effects. We suggest that in the self-related task, people were using in-depth processing, so the framing effects disappeared.

**Keywords:** self-related task, risky decision making, framing effect, frame, decision making

**The influence of the type of reasoning tasks on children’s performance**

**LANG, H. Y. (CYCU), LIN, W. Y. (Chung Cheng University), LIN, H. T. (Chung Cheng University)**

The major purpose of the present study was to examine the influence of the type of reasoning tasks (oral, word cards and pictures) on children’s performance and try to clarify the hypothesis that memory had a effect on children’s performance from previous studies. We constructed two conditional sentences, each sentence contained 4 conditional formats (MP,
DA, AC, MT) and presented orally, word cards and pictures. The research design was a between-subject factorial design. Participants were 32 students in the first grade of elementary school (18 boys, 14 girls) and randomly assigned to three groups. The results showed that the influence of the type of reasoning tasks on children’s performance were not significantly different. Word cards and pictures used do not promote children’s performance by helping to remember. Children’s performance of reasoning tasks showed that children have better reaction in DA and AC than the others, the pattern is not consistent with previous studies. In MP when the reasoning task was in word cards or pictures, the reactions were worse than the other, and the difference between oral and word cards were significant. Three of these findings worth summarizing: first, maybe the children’s reasoning performance are not correlated with short memory ability. Second, over half the participants chose the “maybe” answer in all the conditional formats. An explanation for this is that they present a strong response set. Finally, there is small number of participants in this research; therefore we need to increase the number in the future. Future research should clarify the correlation with memory ability, reasoning ability and finding out that what made the difference on children’s performance.

Keywords: memory, performance, reasoning, personality

The investigation of personality disorders within mental patients using temperament and character

ZAREAN, M. (University of Social Welfare and Rehabilitation Sciences), ZAREAN, Z. (University of Tehran), BAHRAMI EHSAN, H. (University of Tehran), GHORBANI, N. (University of Tehran)

This study was carried out to investigate the relationship between seven personality dimensions and personality disorders among mental out-patients. A sample of 97 psychological outpatients (43 female and 54 male) were asked to complete the Temperament and Character Inventory and MCMI Inventories. Results showed low persistence and self-directedness within many of the personality disorders. Also, personality dimensions of TCI can significantly predict 28 to 66 percent of personality disorder variance. The maximum and minimum amount of prediction was related to avoidant and sadistic personality disorders, respectively. Finally, the results of canonical correlation analysis indicated that avoidance, impulsivity, pessimism, and insensitivity are common properties among personality dimensions and personality disorders.

Keywords: mental illness, personality disorder, personality

The KYT’s effect to safe culture of the hospital organization: Qualitative analysis to the cognition of administrative nurses

HOSOKAWA, K. (Sanyo Gakuen University), HYODO, Y. (Okayama University), TANAKA, K. (Okayama University)

This case study used a semi-structured interview survey to reveal the affect of the KYT, a form of risk prediction training, on the organization of culture. The KYT was the cognitive training for increasing risk sensitivity for the hospital workers. After the hospitals took KYT into their medical safety programs, the safe cultures were expected to be developed. Informants were five administrative nurses of hospital “A”. They described the changes which they noticed after the KYT operation according to three levels: (1) the personal level, (2) the team level, and (3) the administration level. The KJ method was used for analysis. This survey obtained approval of the ethics committee in the Hospital “A”. The informants reported the following changes in the Hospital: the conveyance, confirmation and explanation of nurses became more accurate; administrators were more aware about their responsibility to safety; attitudes of nurses in conferences became more active; information was more shared and the amount of communication increased in the teams; procedures of treatments were shown in clearer ways, like making a manual; and awareness of medical safety was enhanced in the hospital. It is suggested that the safety level of the hospital was improved in three levels: (1) behavior and consciousness in individuals; (2) habit and atmosphere of teams; and (3) system and norm in the organization. The KYT affected not only
individuals, but also the organization. This study suggests that the three layered model of the KYT is effective in developing a safe culture, which mutually affects individuals, teams and the whole organization.

Keywords: risk prediction training, safety, KYT, hospitals, medical safety

The leadership effectiveness of multiple leaders: How do they effectively guide their team?

HOKAURA, C. (Hiroshima University), SAKATA, K. (Hiroshima university), HAYASE, R. (Okayama University)

Whereas many groups have formal or appointed sub-leaders other than their formal leaders, researchers have focused on the effectiveness of a single leader with a few exceptions (Kouguichi et al., 2002; Mehra et al., 2006). We examined how leadership behavior by a leader (L) and sub-leader (SL) is effective for the group. Leadership behavior was measured using the framework of PM theory (Misumi, 1985), which measures a leader’s degree of task-performance behavior (hereinafter called P) and group maintenance behavior (hereinafter called M). It has been proven that a high P and high M leadership style (i.e., PM style) is most effective. Our first hypothesis is that when leaders and sub-leaders have good relationships, complementary leadership style by the leader and sub-leader (i.e., P-L & M-SL, M-L & P-SL) will be equally effective as the perfect leadership style (i.e., PM-L & PM-SL). Our second hypothesis is that the complementary leadership style, especially the combination of M leader and P sub-leader, will be more effective than the opposite one. 209 nurses (140 women, 60 men, 9 no response) rated senior (L) and sub-senior nursing officers (SL), on points of PM leadership, social power, leadership effectiveness and others. As a result of ANOVA, complementary leadership style was seen to have a high effect on the reduction of leaders’ mental and work burdens, and leadership effectiveness corresponded to perfect style rather than the same leadership style. In addition, the P-L & M-SL combination was rated as being higher in leadership effectiveness than the M-L & P-SL system. Our study showed the effectiveness of complementary leadership style. However, contrary to Hypothesis 2, P-L & M-SL style was evaluated higher than M-L & P-SL. We put forth a number of possible explanations. The effective complementary style may be a result of the good relationship between the leader and sub-leader. Alternatively, the M sub-leader might have improved the relationship between the P leader and followers and raised general leadership effectiveness. Also, because leaders have high legitimate power over sub-leaders, followers may accept P type leadership and alter their own styles to suit the leader.

The manpower profile and researchers’ work motivation of government research projects in Taiwan

LIU, H.W. (National Central University), YANG, C.C. (Fu Jen Catholic University), SHIA, B.C. (Fu Jen Catholic University)

The first aim of this research was to determine the manpower profile of government research projects by researchers’ demographic characteristics in difference disciplines, and to analyze the potential manpower profile based on applying a databank and a survey. The second aim was to determine the hygiene factors and motivators of researchers committing to work. A databank analysis and a questionnaire survey were used in this study. Two databanks in the Taiwanese government were used, one is the high education manpower profile from the Ministry of Education, and the other is applying project dataset from the National Science Council. Eleven year, 1997~2008, data is included in the study. Researchers who work for university and research institutions made up the sample and 7,002 subjects were collected. The response rate was 43.40%. Motivations with 21 items were developed from the study based on interviews and literature, with measurement by five-points Likert scales. A paired T-test and descriptive statistics were used in the study. The results showed that despite the intention and actually doing research projects, male researchers are the major manpower. In processing projects, there are almost 4 times more males than
females; however, females are only one and half of males. Researchers who work in public universities are the major manpower of projects. We also found the hygiene factors and motivators of researchers are almost the same as reported in Hersberg’s research. The hygiene factors are procedure and safe needs. The motivators are resources, social, self-esteem, and self-actualized needs. The only difference from Hersberg is that getting resources is one of the motivators of researchers when they decide to commit to research projects. Hygiene factors vary by age. Safety to the elder ones and simple procedure to the younger ones are not hygiene factors. No sex role effect was found in the project review system; however, there is intuition effect. Therefore, female researchers and researchers who work in private institutions are the big potential manpower for the Taiwanese government research projects. This study empirically tested and found the hygiene factors and motivators of researchers.

Keywords: manpower profile, government research projects, motivation, hygiene factors, Taiwan

The meaning of therapists’ personality variables and their therapeutic style in constructing relation with schizophrenia patients

SAWICKA, M. (Institute of Psychiatry and Neurology)

The aim of this research was the evaluation of constructed therapeutic relations with schizophrenic patients dependent on therapists’ personal attributes and working style. 30 psychiatrists and 150 patients took part in an examination. The patients were assessed using the Dual Questionnaire form of the Therapist – Patient Relation, judging approval, professionalism, uncertainty, dominance, rejecting in the psychiatrist attitude (M. Stark). The psychiatrists were assessed using the Therapeutic Style Questionnaire: instructional, expressive, engagement, attentional, operative (H. F. Alvarez). Personality variables were evaluated on the basis of: The Satisfaction with Life Scale (E. Diener); Courtauld Emotional Control Scale (M. Watson); Generalized Self-Efficacy Scale (R. Schwarzer); and the Life Orientation Test (M.F. Schieier). With a view of establishing which variables were explaining the therapeutic relations in schizophrenia, a method of stepping multiple regression was used, in which explained variables were taken from variables describing the therapeutic relations in the Dual Questionnaire Form. Received results show that the variables explaining the attitude of the schizophrenic to the psychotherapist were: psychiatrist’s approval, explained 13% of the variance through the following configuration of variables: quality of life of the psychiatrist, dealing with anger and the length of the cooperation. The psychiatrist’s professionalism explained 21% of variances: his quality of life, attentional styles of the work and the length of the cooperation; the psychiatrist’s uncertainty explained 16%: psychiatrist’s quality of life and time of the cooperation. They explain the dominance of the psychiatrist in 12%: life orientation and the length of the cooperation. They explain rejection in 20%: psychiatrist’s self-control over his anger, his quality of life, and time of the cooperation. Received results show that the factors explaining the attitude of the schizophrenics to the therapists, are the variables describing the personal dimension of the psychiatrists treating them. An important factor underlined in the majority of the analyses was a dimension of the length of the cooperation with the psychiatrist. This variable showed that the longer the patient was cooperating with one therapist a chance of creating the effective therapeutic relation was all the greater.

Keywords: therapist-patient relation, schizophrenia, cooperation

The measurement of harmful group activities as the member’s abuses in cultic and terroristic groups

NISHIDA, K. (University of Shizuoka)

The Group Health Scale (GHS) was developed for measuring harmful group activities which subtly abuse the members physically and psychologically. The scale consists of four dimensions, which measure the group characteristics of totalistic group identity, deprivation of private life, sealing critics, and absolute compliance. They are confirmed
harmful activities on the base of democratic human rights by administrating some preliminary surveys on normative beliefs of group activities in Japan, Spain, and United States. Now, we checked out the degrees of some harmful group activities in Japan. Former members (N = 340) of a variety of social groups in Japan rated group activities which they experienced. Around half of the participants had belonged to some controversial groups and the remaining participants had not belonged to these kinds of groups. The questionnaire administered included not only the GHS, but also the items for rating their subjective abusive levels to their belonged groups. It was clearly shown that the mean score on the GHS for the participants who had not belonged to any controversial groups was low (M = 65, SD = 24), but the score for the participants who had belonged to the groups was quite high (M = 185, SD = 40) comparatively, and the latter’s subjective evaluation of their abusive experiences were higher than the former. It was also shown by the analysis of the sub scales, that the former members of controversial groups rated higher scores on each of the four sub scales. It was suggested that some controversial group activities were harmful because they were very abusive psychologically, and because individuals were regarding their group activities as the only path of virtue, even though irrelevant people were troubled. It was also suggested that the unhealthy group had the characteristics of forcing totalistic identity, deprivation of private free life, sealing any criticism by the members as well as their irrelevant people, and requesting the member’s absolute compliance to their authority.

Keywords: harmful group activities, physical abuse, psychological abuse, Japan

The moral, the majority, and the minority: The interplay of moral and descriptive norms in the context of volunteerism

SMITH, M. (University of Queensland), MASSER, B. (University of Queensland)

The present research had three focal aims: (a) To identify potential targets for interventions aimed at encouraging volunteer participation, (b) extend the moral norm literature by experimentally manipulating a moral norm using priming techniques, and (c) provide greater insight into normative influence processes by determining whether conformity to descriptive norms depends on whether one has been primed with a moral norm. Prior to the main study, a pilot study demonstrated the construct and discriminant validity of a novel prime designed to activate a moral norm for volunteering. In the main study, 229 university students were randomly assigned to a moral norm prime or control condition (moral norm manipulation) and subsequently informed that either a majority or minority of university students volunteer (descriptive norm manipulation). Intentions to volunteer were then assessed. Priming participants with a moral norm for volunteering strengthened their intentions to volunteer. Moral and descriptive norms also interacted to influence volunteer intentions. Specifically, control participants had stronger intentions to volunteer when informed that a majority as opposed to a minority of university students volunteer. In contrast, primed participants’ intentions to volunteer did not differ according to the prevalence of volunteering. This research provides evidence for the causal impact of moral and descriptive norms on intentions to volunteer. Evidence that moral norms moderate the relationship between descriptive norms and intentions to volunteer provides insight into the boundary conditions of normative influence and highlights the importance of considering the main and interactive effects of situational factors in the context of volunteerism. Findings also possess important applied implications as they suggest interventions aimed at encouraging volunteer participation could profit from targeting moral and descriptive norms.

Keywords: volunteer participation, moral norms, volunteer intentions, descriptive norms, conformity

The power of written emotional expression on psycho-physiological health

GARGYA, S. (Delhi University)
The present research examined the effect of written emotional expression on participant's psychological health—affect [Positive Affect (PA) and Negative Affect (NA)], and cognition [components of the Impact of Event Scale (IES) i.e. intrusions, hyper arousal and avoidance, narrative analysis] and physiological health [Heart-rate (HR), Blood-pressure (systolic SBP) and (diastolic DBP)], and physical health (symptoms, perceived and general health). Ten participants were randomly assigned to each of three conditions- Trauma Condition, Happy Condition and Neutral Condition (n = 30). Each participant wrote for three days consecutively, and a follow up was taken after two months. Pre and post measures of writing were taken on affect using the Positive and Negative Affect Schedule (PANAS), cognition via the Impact of Event Scale revised (IES), and narrative content. Physiological arousal was assessed by recording Heart Rate and Blood Pressure, while physical symptoms and health were assessed using the SMU- health Questionnaire. Findings revealed significant short term affect changes across all the three conditions. The happy condition induced a significant reduction in heart-rate, health problems and symptoms. The trauma condition induced an elevated heart rate, and reduced health problems. The neutral condition also showed significant improvements in health problems. Narratives in the trauma condition had greater usage of negative emotion words while narratives in the happy condition had more positive emotion words. These findings have been discussed in light of cognitive processing and confrontation – inhibition theory to understand the possible mechanism underlying health. All three conditions however showed significant improvements in long term symptoms and health problems. Hence, expressive writing does reap physical health benefits. Therefore it can be concluded that writing is an effective intervention to improve one’s health.

The prevalence of ADHD in primary school students in Tehran

KHUSHABI, K. (University of Welfare and Rehabilitation Sciences), HOSSEINI, S. B. (Islamic Azad University), FARZADFAR, Z. (Shahid Beheshty University)

Attention Deficit Hyperactivity Disorder (ADHD) is characterized by a developmental disorder involving inappropriate poor attention span or age-inappropriate features of hyperactivity and impulsivity and/or both. In order to assess the prevalence of children with ADHD in Tehran, a sample of 2667 children including both males and females aged between 7 to 12 years were selected by a two-stage method sampling among a grid of sectors of 19 different educational areas by stratified random sampling. We tested the rate of ADHD in the considered children based on two questionnaires of Conners Parent and Teacher Rating Scales (CPRS and CTRS) and semi-structured interviews. According to the recent studies, it is possible to describe the rate of ADHD prevalence based on the CPRS and CTRS questionnaires and semi-structured interviews among the primary school children in Tehran (aged between 7 to 12 years of age) within a range of 3% to 6%. These mentioned findings are somewhat similar to the announced statistics of the American Psychiatric Association (APA; 2003).

Keywords: Attention Deficit Hyperactivity Disorder, developmental disorders, inappropriate poor attention, hyperactivity, impulsivity

The processes of intercultural communication

NAKATA, S. (Sophia University)

The purpose of this study was to investigate the intercultural communication and development of self in childhood. Twenty four preschool children aged 3-5 years completed an interview, which was conducted individually using pictures and photographs. Pictures and photographs of daily life in Japan and the United States were used. The results showed the processes of cross-cultural awareness. When an infant saw the picture, the photograph, and the story, they infant understood the culture of Japan and the United States. After seeing the picture and the photograph, the infant who had seen a video concretely understood the message of the video.
We clarified that the method of the infants maintaining the interpersonal relationship was understood by eyes and expressions as: 1) cross-cultural experiences and understandings; 2) cross-cultural communication; 3) interactive activities for intercultural understanding; 4) expression in intercultural communication; 5) cross-cultural training; 6) intercultural communication in the process of misunderstanding; 7) the processes of cross-cultural awareness and its effect on learning; and 8) cross-cultural understanding and communication.

### The projective method of the measurement for the fear of crime of children

HARADA, A. (Koshien Junior College), KAGEMURA, Y. (Koshien University)

The aim of this study is to measure fear and risk perception of crime of children by a projective and experimental method. The experiment for which 32 children, who were 10 and 11 years old, constructed a desirable town to live in was submitted. On the sheet that a virtual town area including their home was printed, the participants arranged the cards that the elements of a town were painted, for example, school, house, hospital, parking, bank and so on. After the construction was finished, they were asked where they got the fear and risk perception of crime. The following figure shows the sample of the result of a virtual town. The result suggested the relation between a position of home and a location of the fear and risk perception of crime. It was suggested that what children said was strongly led by influences of teachers or parents. This method is effective for children. It is difficult to ask children if they feel the fear of crime directly. The measurement of this study uses an indirect method and the psychological burden for children is small.

**Keywords:** fear of crime, children, risk perception

### The proposal of commissioner(a) from family school – C.F.E.: A strategy for conflict resolution and the construction of democratic practices from a Latin American perspective

The paper presents the experience of a working diagnostic and research done on building the proposal of Commissioner(a) of Family School – C. F. E. Educational Institution Paulo VI Palmira Municipality, Department of Valle del Cauca, Colombia, South America. This paper sets out the seven key elements for the underlying, legal, pedagogic, didactic, recreational and strategies for the construction of knowledge; partner-community; inter institutional; foundations for the construction of democratic practices and elements from the projection of Public Policies. The strategy of C.F.E, in the pedagogical context which also integrates various aspects, must be understood as a mechanism of initiating conflict mediation and the construction of democratic practices. Now, in such educational institution, i.e. The Commissioners of Family School students from the first grade to the eleventh grade, who through a mechanism of choice are elected to support the process of reporting, processing and mediation of conflicts occurred in the school, based on the situations dealt with in the table: Minor Conflicts and Major Conflict. The paper proposes a discussion for conflict resolution strategies developed in Latin American countries: Colombia, México, Venezuela, Peru, Chile and Argentina. It is based on a working methodology and qualitative research through observation, focus groups, group work, case studies and workshops of imagery and representations among others. The research results show the verification and construction of strategies for conflict resolution and prevention of situations that violate the rights in children and adolescents in educational institutions.

The pros and cons of avoidance goals: How neuroticism influences the effects of avoidance goals on performance, flow and well-being

OERTIG, D. (University of Zurich), SCHÜLER, J. (University of Zurich), SCHNEBELLE, J. (University of Zurich), BRANDSTÄTTER, V. (University of Zurich)

Previous research has shown that avoidance goals are associated with several negative outcomes. We hypothesized that avoidance goals can also have positive effects under certain circumstances. We assumed that individuals high in neuroticism benefit from avoidance goals in the short term, whereas they suffer from such goals in the long-run. Three studies investigated whether neuroticism moderates the effect of avoidance goals on performance, flow and well-being. In study 1 (N = 30), an experimental study in the lab, employees were randomly assigned to an approach or avoidance goal group while working on an in-basket exercise. Study 2 (N = 283) examined the students’ academic approach and avoidance goals during a semester. In study 3 (N = 102) we gathered experimental as well as cross-sectional data. On the one hand students were randomly assigned to an approach or avoidance goal instruction while writing a creative story in the classroom (study 3a). On the other hand we measured students’ dispositional goal orientation at school (study 3b). We also assessed neuroticism in all of the studies. The results of the experimental studies showed that the interaction between neuroticism and experimental manipulation significantly predicts the performance in the in-basket exercise (study 1) as well as the flow-experience when writing a creative story (study 3a). Participants high in neuroticism performed better and experienced more flow when receiving an avoidance goal instruction. Individuals low in neuroticism however benefited more from an approach goal instruction. As expected, the results of the longitudinal and cross-sectional studies (study 2 and 3b) showed that participants high in neuroticism who pursued a lot of avoidance goals or with a dispositional avoidance goal orientation reported the lowest well-being and dispositional flow-experience at school. These findings extend previous research by demonstrating that neuroticism moderates the effects of avoidance goals on positive outcomes. Implications for theoretical and practical concerns are discussed.

The prostitution and commercial sexual exploitation of children and adolescents: A clear path for trafficking in persons, from Latin American routes

VIAFARA SANDOVAL, H. (Foundation for the Improvement of the Management and Education for Democracy (FUNDAGEPAD))

There is an increasingly close relationship between prostitution and the commercial sexual exploitation of children and adolescents. This practice clearly links previous and established links with the population minority – in both cases men and women, who are becoming more explicit. From the findings it can be said that we are currently witnessing a market of the body, inscribed in practices that are by no means fixed, namely, in places set for this. The status of place here changes since so-called prostitution that is located to the subject or subject vendor of service in a particular place – street, reserved, bar, choreography, etc. Today it is made mobile, i.e., the place is not the most important, but the people offering the service (prostitute, fufurúfa, prepayment, man) are subject not static, because the offer easily agency from a classified but runs in another space, or are advertised on the web and materialize anywhere from one country or outside it. The "territories" for the trade of the body have suffered mutations. Now, the recognition of the activity – from the tracks and findings – allow daring to rise such that here is configured a kind of industry or company that is well organized, which also makes use of technological resources such as in any other organization. This paper proposes a reflection that commits empirical findings of several Latin American nations: Colombia, Mexico, Venezuela, Peru, Chile, Argentina and Brazil. A qualitative research methodology through observation, interviews, and focus
groups, in addition to queries using newspaper classifieds and websites, etc, is used.

Keywords: prostitution, sexual exploitation, children, people trafficking, Latin American

The psychological impact of deployment in a clinical sample of Australian military

CAMPBELL, J. (James Cook University), JACKSON, T. (James Cook University)

A large number of studies have shown psychological effects in military personnel serving on deployments. This study evaluated differences in symptom acuity between Australian Defence Force (ADF) personnel who had been deployed compared to non-deployed; and those on warlike missions compared to peacekeeping missions. Exposure to life threatening combat as an independent predictor of psychological disorder, and the influence of incongruent Rules of Engagement on outcomes was assessed. A clinical database of 1600 current and former ADF personnel, serving post-Vietnam War, was analysed. Participants had completed self report measures of depression, anxiety, stress and alcohol use upon initial presentation at a local counselling agency. The participants were categorised into one of two exclusive groups, either Deployed or Non-deployed. The Deployed participants were further classified into warlike or peacekeeping mission types. Further, cases were selected on the basis of their deployment to specific zones of conflict where Rules of Engagement (ROE) were either congruent or incongruent. The Specific Conflicts chosen were Iraq/Afghanistan, representing congruent warlike deployments, the Solomons/ Bougainville representing congruent peacekeeping, and Somalia/ Rwanda representing incongruent peacekeeping. Analysis indicated that there were no effects for deployment by itself on depression, anxiety or alcohol use, but where combat was experienced, stress levels were higher. Peacekeepers reported more anxiety than those on warlike deployments. Where there was incongruence between Rules of Engagement and deployment experiences higher levels of anxiety and stress were reported. Peacekeepers on missions with congruent ROE had less risky alcohol use than those on congruent warlike or incongruent peacekeeping missions. The finding that peacekeeping is as disturbing as warlike deployments and that incongruent Rules of Engagement influence psychological outcomes has implications regarding recruitment, training and deployment preparation for ADF personnel.

Keywords: military deployment, Australian Defence Force, psychological impact, rules of engagement, peacekeeping

The psychology of teaching netball and cricket to persons with an intellectual disability

YOUNG, J. (Victoria University), BROWNE, A. (Victoria University)

This presentation reviews a netball and cricket program for persons with an intellectual disability and, in doing so, highlights key principles associated with successfully coaching this special population of athlete. Twenty (12 female and 8 male) Victoria University First Year Education students delivered a 12-week series of sessions to 26 persons (8 female and 18 male aged 16 – 26 years) with an intellectual disability (predominantly persons with autism and downs syndrome). The first 6 weeks of the sessions focused on netball and the second half on cricket. At the completion of the two blocks of sessions, Victoria University students were asked to evaluate their experiences. A series of inductive content analyses was conducted to analyse the data. The data analyses revealed a range of factors associated with successful coaching including: (a) focus on an athlete’s abilities; (b) adapt to ensure inclusive for all; (c) take an individual approach to plan a fun, challenging and safe lesson and (e) attend to one’s communication skills (e.g., provide lots of visual demonstrations and embrace infectious smiles, positive encouragement and feedback). In further findings, coaching cricket was found to be more challenging than coaching netball in that the former required additional modifications to keep athletes involved and engaged at all times. The program’s findings are consistent with general coaching principles (e.g., Martens, 2004). As such, the program’s findings re-enforce the notion that ‘coaching is coaching’ - irrespective of the targeted group, key principles relating to of the importance of
Teaching evaluation provides feedback to teachers. Previous research has focused on teachers’ profession and teaching strategies, while ignoring the role of students’ learning goals. It is inferred that the relationship between teachers’ characteristics and teaching evaluations vary with students’ achievement goals. Participants were college students in Northern Taiwan. A self-report inventory was used to measure students’ achievement goals and their evaluation of teachers. Participants were asked to rate one teacher of a compulsory course in teaching skills, academic demand, knowledge acquisition, and performance criterion. Learning goals were divided into learning vs. performance goals. This study showed that students who pursued performance goals prefer teachers with lenient performance criterion and low academic demand, but students with learning goals tended to like teachers having good teaching skills and being helpful in knowledge acquisition. Students’ evaluations of teachers were influenced by teachers’ characteristics and their own achievement goals. Therefore, poor teaching skills would not always lead to low teaching evaluation. The fit between students and teachers is the crucial determinant of teachers’ evaluations.

Keywords: teaching, students, evaluation, feedback, learning goals

The relationship between college students’ negative self-thinking, self-esteem and mental health in Chinese’s culture

CHENG, S. (Hangzhou Normal University and Chinese Psychological Society), CUI, Q. (Chinese Psychological Society)

Using experimental and test methods, we selected 201 college students (101 male, 100 female) to complete the Implicit Association Test, the Self-Esteem Scale, the Habit Index of Negative Self-Thinking, the Automatic Thoughts Questionnaire and SCL-90. We explored the relationship between college students’ negative self-thinking, self-esteem and mental health in Chinese culture. The results showed that there is a significantly positive correlation between habitual negative self-thinking and cognitive
content negative self-thinking, and habitual negative self-thinking and cognitive content negative self-thinking have a more significant gender difference in males than females. It was found that students have a strong implicit self-esteem, and implicit self-esteem and explicit self-esteem are relatively independent, with no significant gender differences, and male mental health has a more significant gender difference in females than males. Also, habitual negative self-thinking and cognitive content negative self-thinking, respectively correlated statistically significantly with explicit self-esteem, but were not correlated with implicit self-esteem; habitual negative self-thinking contributed to the prediction of self-esteem was statistically significant. Habitual negative self-thinking and cognitive content negative self-thinking contributed to mental health and were both statistically significant; habitual negative self-thinking accounts for variance in mental health over and above cognitive content negative self-thinking. Furthermore, males’ explicit self-esteem correlated statistically significantly with mental health, whereas females were not significant; the correlations between implicit self-esteem and mental health were not significant. The effect of negative self-thinking on mental health is not mediated by explicit self-esteem.

Keywords: Chinese culture, negative self-thinking habit, self-esteem, mental health, gender

The relationship between driving workload and drivers’ human factor

SONG, H.H. (Chungbuk National University), OH, J.S. (Chungbuk National University), YUN, B.Y. (Chungbuk National University)

Excessive workload has mainly been referred to as the state such that an operator cannot perform a task any further due to a lack of resources. As drivers are also operators who perform tasks, drivers could be affected by excessive workload. We are concerned that excessive workload could affect the drivers' resources that are needed for driving; hence there exists the possibility that excessive workload could cause a serious traffic accident. Therefore, we examined which human factors are related to drivers’ subjective workload, by means of the following instruments: Driving Behavior Determinants, Driving Confidence Level Questionnaire, and "NASA-TLX." The participants were 215 drivers (159 males, 53 females) with an average age of 33 and average driving experience of 8 years, who responded to all three questionnaires. The Driving Behavior Determinants and the Driving Confidence Level Questionnaire are widely regarded as appropriate tools for determining drivers' characteristics. Furthermore, several studies have verified that these tools measure the factors that affect driving behaviors such as speeding. The NASA-TLX is known as a self-assessment tool for measuring subjective workload. We performed a correlation analysis on the results of the Driving Behavior Determinants and Driving Confidence Level Questionnaire, and the drivers’ subjective workload level, as assessed by the NASA-TLX. The correlation analysis revealed that "Lack of Interpersonal Adaptability" \( r = .219, p < .01 \), "Situational Anxiety" \( r = .248, p < .01 \), and "Insensibility" \( r = .364, p < .01 \) showed significant correlations with high levels of the driver's subjective workload. "Unsafe Driving" did not show any significant relationship to high workload, but it suggested a tendency toward correlation \( r = .135, p < .05 \). This study aimed to provide a theoretical understanding of driving workload and discovered that some human factors relate to workload. It is suggested that these results could assist drivers and researchers to develop ways to better manage driving workload.

Keywords: driving workload, driving, human factors, driving confidence, excessive workload

The relationship between emotional intelligence and depression and adjustment in light of gender variables among Sultan Qaboos university students

SULAIMAN, S. (Sultan Qaboos University)

This study aimed to investigate the relationship between emotional intelligence and depression and adjustment in light of gender variables among Sultan Qaboos university students. A sample of 323 students answered questions on emotional intelligence, Beck depression
inventory and adjustment scales. A t-test was used to discover the differences between males and females on emotional intelligence means (high, low), and upon means of depression and adjustment. Results show that the mean of emotional intelligence of all students of the sample was in the high level, and there was also a significant effect for gender on the level of emotional intelligence in favor of females. Results show a negative relationship between emotional intelligence and depression, while on the other hand there is a positive relationship between emotional intelligence and adjustment. Results also reveal a significant effect in means of depression symptoms due to the level of emotional intelligence for males and females in favor of those who have low levels of emotional intelligence. On the same track, results show a significant effect in means of adjustment due to the level of emotional intelligence for males and females in favor of those who have high levels of emotional intelligence.

Keywords: emotional intelligence, depression, adjustment, gender variables, university students

The relationship between learning strategies, study difficulty and help-seeking needs in college students

WU, P. Y. (National Changhua University of Education), LIN, S. D. (Department of Guidance and Counseling, National Changhua University of Education(NCUE))

In this study, we construct a structural questionnaire, to survey that which learning strategies are more correlated with undergraduates’ satisfactory about their study. And we also investigate which factors are correlated with their interest in getting help from counseling. 3,032 undergraduates completed a survey including Learning Strategies Scale, Study Difficult Scale, and a self-rating question (with Likert’s 5 point scale) about their satisfaction of their study. They also answered how they had resolved their study difficult before, and their interest in attending counseling activities in the future. There are 21 departments, which belong to seven colleges, including education, science, arts, technology and vocational education, management, social science and physical education, and engineering. The results indicate learning strategies, study difficulty, study satisfaction, help-seeking behaviors (before), and the need of counseling activities have high significant correlation. The more help-seeking behaviors they had used before, the more satisfaction they feel about their academic performance now ($r=135$, $p<.001$), they also feel lower level of study difficulty($r=-.261$, $p<.001$), higher usage of learning strategies($r=.497$, $p<.001$), and less need to get help($r=-.049$, $p<.05$). T-test, ANOVA, regression, and path analysis also had interesting finding. To improve college students’ academic performance and to give the sufficient counseling resources, learning strategies and help-seeking behaviors are very important factors. Research results are discussed and given suggestions in the background of education and counseling.

Keywords: satisfaction, undergraduate students, help-seeking, study, academic performance

The relationship between national and psychological identity and psychological well-being among Shahed and non-Shahed students

MOUSAVI, R. (Shahed University), ROSHAN, R. (Shahed University)

The aim of the present study was to investigate the relationship between different aspects of identity (religion, national and psychological) and psychological well-being among Shahed (the group of students who have lost their father in war) and non-Shahed (group of students with a living father) students. The statistical universe consisted of the students of Tehran universities with a sample of 1000 cases (500 Shahed and 500 non-Shahed) who were selected by stratified random sampling. Psychological well-being scale, religious and national identity scale, and revised identity style questionnaires were used as the research devices. The data were analyzed by correlation and Fisher Z. The results of the study indicated that there is a significant positive correlation between psychological well-being sub-scales and religious and national identity, except that the relationship between strict religious identity and happiness and optimistic sub-scales. Information identity style, normative identity style and commitment have
positive correlation with psychological well-being sub-scales; this is while the diffuse/avoidant identity style showed a negative correlation with all the psychological well-being sub-scales. The relationship between religious identity and psychological well-being was not significant in Shahed and non-Shahed groups. In the non-Shahed group the relationship between Iranian patriotic identity and positive relations with others were stronger than for the Shahed group; the difference between Shahed and non-Shahed groups was significant only in the relationship between information style and life satisfaction. Attention to religious factors can be helpful and useful to increase psychological well-being, and psychological and national identity of students.

The relationship between organizational climate and occupational health

ANDRADE, N. (Catholic University of Brasilia), RABELO NEIVA, E., EMANUELE DA CRUZ DIAS RIBEIRO, P.

This study aims to investigate the relationship between organizational climate in a company's Information Technology’s Structure, and health indicators of the workforce. To collect the data, we used a modified version of the Assessment of Organizational Climate by Moos (1986), composed of 90 items, that has been applied and validated in Brazil by Günther and Puente-Palacios (1993) which aims to evaluate the dimensions of personal relationship with subscales of involvement, cohesion and support, personal development with subscales of autonomy, orientation, size, pressure maintenance and change, and with subscales of clarity, control and comfort. The second instrument was the fourth scale Inventory of Work and Risk of disease - ITRA, composed of 29 items dealing with social pathologies associated with the organization of work, health and the risk of disease, developed and validated by Mendes (2007). The instruments were administered in two sessions with an interval of one week each, in a sample of 123 professionals working in the company. The participants' responses were coded and data processed electronically using the BioEstat 5.0. The Moos Inventory revealed that the results were moderate when analyzing personal relationship dimensions, personal development, maintenance and changes that employees identify themselves moderately with the institution. The data obtained from the ITRA showed satisfactory aspects to physical and social health and moderate psychological health. The relationship between the results of the surveys by Moos and the ITRA showed that thirteen items were significantly correlated to one or more dimensions of social climate in organizations, indicating the need to evaluate in greater depth issues that can influence the organizational climate and health of the worker. In conclusion, the results presented are related to the perceptions of people regarding their work environment, and how they feel in the organization. Management strategies to improve quality of work life can be developed in the company, to evaluate these issues and act on them. This leads to consideration of the importance of establishing changes in the climate of the organization, particularly in aspects that have been shown to correlate with health, which can be extended to physical and social components.

Keywords: organisational climate, health, quality of work life

The relationship between personality traits and depression among active and non-active elderly females of Tehran

ASLANKHANI, M.A. (Shahid Beheshti University), SHAMS, A. (Shahid Beheshti University), SHAMSIPOUR, P. (Shahid Beheshti University)

The purpose of this study was to examine the relationship between personality traits and depression among active and non-active elderly females of Tehran. Subjects consisted of 188 elderly females (94 actives and 94 non-actives) between the ages of 63-82 years, who were selected from an available population in the city of Tehran. Three instruments were used including: 1) demographic questionnaire, 2) Beck depression questionnaire and 3) NEO personality traits questionnaire. Data were collected and analyzed using descriptive statistics and
inferential statistics such as mean, standard deviation, Pearson correlation coefficient and Enter multi variant regression. Findings revealed there is a significant correlation between personality traits of neuroticism, extroversion, openness and conscientiousness with depression in active subjects, and openness and conscientiousness with depression in non-active ones. Findings also showed that there is a linear relationship with openness and extroversion variants in the active population and conscientiousness variants in non-active subjects. On the bases of these findings, being physically active can improve positive personality traits such as extroversion and openness and decrease depression in elderly females of Tehran. In addition, we can predict depression changes from the amount of physical activity and personality traits in the population under study.

Keywords: personality traits, depression, elderly people

The relationship between positive moods, personal resources and mental health

WANG, Z. (Shaanxi Normal University)

Fredrickson’s (1998, 2001) broaden-and-build theory of positive emotion holds that people’s daily experiences of positive moods compound over time to build a variety of consequential personal resources. To date, prospective correlational studies have shown that people who experience or express positive moods more than others show increases over time in optimism and tranquility (Fredrickson, Tugade, Waugh, & Larkin, 2003), ego-resilience (Cohn, Fredrickson, Brown, Mikels, & Conway, 2008), mental health (Stein, Folkman, Trabasso, & Richards, 1997), and the quality of their close relationships (Gable, Gonzaga, & Strachman, 2006; Waugh & Fredrickson, 2006). However few studies explored the relationship between positive moods, personal resources, and mental health. This study extends previous research by proposing and testing a model that examines the relationship between positive moods, personal resources, and mental health. We hypothesized that positive moods increase mental health by improving personal resources, namely, ego-resilience, interpersonal trust, and coping style. Positive and Negative Affect Schedule (PANAS; Watson et al., 1988), The Ego-Resilience Scale (J. Block & Kremen, 1996), Trust Inventory, Coping Style Inventory, and SCL-90 scale were administered to 667 undergraduates. There were 311 males, and 356 females. Mean Age was 20.3 years. The result of this study indicated that positive moods correlated with personal resources (ego-resilience, interpersonal trust, and coping style) positively, and positive moods, personal resources correlated with score SCL-90 negatively. The path analysis (SEM) showed that positive moods predicted mental health directly; the path coefficient of positive moods to mental health was significant. Positive moods predicted ego-resilience, interpersonal trust, and coping style directly; the path coefficient of positive moods to the ego-resilience, interpersonal trust, and coping style were significant. Ego-resilience, interpersonal trust, and coping style predicted mental health directly; the path coefficient of ego-resilience, interpersonal trust, and coping style to mental health was significant. The results suggested that positive moods influenced mental health directly, and positive moods influenced mental health indirectly through ego-resilience, interpersonal trust, and coping style processes.

Keywords: positive emotion, optimism, tranquility, quality of close relationships, personal resources

The relationship between resilience and work motivation of Japanese nursery teachers

SHIMIZU, M. (Tezukayama University), MORI, T. (Hiroshima University)

The topics of resilience and motivation have been usually investigated separately, the first in the area of health psychology, and the second in the area of learning psychology. Consequently, the relationship between them is not well-known. The purpose of this study was to examine their relationship by using a population of Japanese nursery teachers. Two analytical scales were used. The resilience scale (Mori and others, 2007), which we had devised previously for university students, contained 4 factors: (1) an ‘I Am’ factor, which examined self-
understanding or self-esteem; (2) an 'I Have' factor, which examined social support from others; (3) an 'I Can' factor, which examined the reliability of one’s own capacity or ability; and (4) an 'I Will / I Do' factor, which examined future, or present, customary behaviour. The work motivation scale was derived from Farnet and others (2008) and revised for Japanese nursery teachers. It examined 5 types of motivation for 6 work tasks. The motivation types were based on self-determination theory (Deci and Ryan, 1985, 2002; Ryan and Deci, 2000) and were: (1) intrinsic motivation; (2) identified regulation; (3) introjected regulation; (4) external regulation; and (5) motivation. The work tasks, derived from Japanese guidelines for nursery teaching, were: (1) Planning nursery teaching and care; (2) Interacting directly with children; (3) Describing the work log or children’s personal records; (4) Management of the whole centre (ex., clearance, cleaning, or safety check); (5) Evaluating nursery teaching and care; and (6) Adapting to parents. The questionnaire was answered by 3325 Japanese nursery teachers. The more resilient teachers had a significantly higher motivation than other teachers. But this significance did not occur with external regulation of the 'I Have' and 'I Can' factors for some work tasks, or with external regulation of the 'I Am' and 'I Will' factors for the other work tasks. The relationship between work motivation and resilience depends on the factors of resilience, type of motivation, and work tasks.

Keywords: resilience, motivation, work task, nursery teachers, Japan

The relationship between self-consciousness goal focus, match-efficacy and choking of collegiate basketball players

LU, G. (Beijing Sport University), QIQI, W. (Beijing Sport University)

The term “choking” is used to describe athletes’ performance decrease under pressure. The psychological mechanism and influencing factors of choking are one of the hot topics in sport psychology. This research was conducted to study the relationship between self-consciousness goal focus match-efficacy and choking. Forty collegiate basketball players participated in this 8-week study, which employed a longitudinal design under no, low and high pressure. The subjects were measured for their level of self-consciousness goal focus and match-efficacy in the second week. The previous research has testified to the reliability and validity of these scales. The results showed that the choking index is highly positively related to self-consciousness, gently and positively related to goal focus, and gently and negatively related to match-efficacy. However, regression analysis showed that only public self-consciousness and private self-consciousness could predict the level of choking, and they could completely explain 61.5% of the variance of the choking index. Both the private-consciousness and the public consciousness were effective predictors of choking index. Choking was related to self-consciousness goal focus and match efficacy.

Keywords: sport psychology, match-efficacy, goal focus, choking, athletes

The relationship between time management disposition and self-monitoring of Chinese middle school students

CHI, L. (Beijing Sport University), ZHOU, X. (Beijing Sport University), YE, H. (Beijing Sport University)

This research attempted to reveal the relationship between time management disposition and self-monitoring of Chinese adolescents. Three hundred and thirty one Chinese middle school students (166 junior students, 165 senior students) were selected, and asked to fill in a Self-Monitoring Scale (Snyder, 1974) and Adolescence Time Management Disposition Scale (ATMDS, Huang & Zhang, 2001). ATMDS consist of three subscales: the sense of time value, the sense of time control and the sense of time efficacy. Subjects were divided into two groups, high self-monitoring group (H group) and low self-monitoring group (L group). The results show that significant differences exist between the H group and L group on sense of time value and sense of time control and the sense of time efficacy. Subjects were divided into two groups, high self-monitoring group (H group) and low self-monitoring group (L group). The results show that significant differences exist between the H group and L group on sense of time value and sense of time control and the sense of time efficacy. Subjects were divided into two groups, high self-monitoring group (H group) and low self-monitoring group (L group). The results show that significant differences exist between the H group and L group on sense of time value and sense of time control and the sense of time efficacy. Subjects were divided into two groups, high self-monitoring group (H group) and low self-monitoring group (L group). The results show that significant differences exist between the H group and L group on sense of time value and sense of time control and the sense of time efficacy. Subjects were divided into two groups, high self-monitoring group (H group) and low self-monitoring group (L group). The results show that significant differences exist between the H group and L group on sense of time value and sense of time control and the sense of time efficacy. Subjects were divided into two groups, high self-monitoring group (H group) and low self-monitoring group (L group). The results show that significant differences exist between the H group and L group on sense of time value and sense of time control and the sense of time efficacy. Subjects were divided into two groups, high self-monitoring group (H group) and low self-monitoring group (L group). The results show that significant differences exist between the H group and L group on sense of time value and sense of time control and the sense of time efficacy. Subjects were divided into two groups, high self-monitoring group (H group) and low self-monitoring group (L group). The results show that significant differences exist between the H group and L group on sense of time value and sense of time control and the sense of time efficacy. Subjects were divided into two groups, high self-monitoring group (H group) and low self-monitoring group (L group). The results show that significant differences exist between the H group and L group on sense of time value and sense of time control and the sense of time efficacy. Subjects were divided into two groups, high self-monitoring group (H group) and low self-monitoring group (L group). The results show that significant differences exist between the H group and L group on sense of time value and sense of time control and the sense of time efficacy. Subjects were divided into two groups, high self-monitoring group (H group) and low self-monitoring group (L group). The results show that significant differences exist between the H group and L group on sense of time value and sense of time control and the sense of time efficacy. Subjects were divided into two groups, high self-monitoring group (H group) and low self-monitoring group (L group). The results show that significant differences exist between the H group and L group on sense of time value and sense of time control and the sense of time efficacy. Subjects were divided into two groups, high self-monitoring group (H group) and low self-monitoring group (L group). The results show that significant differences exist between the H group and L group on sense of time value and sense of time control and the sense of time efficacy. Subjects were divided into two groups, high self-monitoring group (H group) and low self-monitoring group (L group). The results show that significant differences exist between the H group and L group on sense of time value and sense of time control and the sense of time efficacy. Subjects were divided into two groups, high self-monitoring group (H group) and low self-monitoring group (L group). The results show that significant differences exist between the H group and L group on sense of time value and sense of time control and the sense of time efficacy. Subjects were divided into two groups, high self-monitoring group (H group) and low self-monitoring group (L group). The results show that significant differences exist between the H group and L group on sense of time value and sense of time control and the sense of time efficacy. Subjects were divided into two groups, high self-monitoring group (H group) and low self-monitoring group (L group). The results show that significant differences exist between the H group and L group on sense of time value and sense of time control and the sense of time efficacy. Subjects were divided into two groups, high self-monitoring group (H group) and low self-monitoring group (L group). The results show that significant differences exist between the H group and L group on sense of time value and sense of time control and the sense of time efficacy. Subjects were divided into two groups, high self-monitoring group (H group) and low self-monitoring group (L group). The results show that significant differences exist between the H group and L group on sense of time value and sense of time control and the sense of time efficacy. Subjects were divided into two groups, high self-monitoring group (H group) and low self-monitoring group (L group). The results show that significant differences exist between the H group and L group on sense of time value and sense of time control and the sense of time efficacy. Subjects were divided into two groups, high self-monitoring group (H group) and low self-monitoring group (L group). The results show that significant differences exist between the H group and L group on sense of time value and sense of time control and the sense of time efficacy.
No significant differences were found between male and female students on all three subscales, but significant differences existed between junior and senior students. The scores of junior students were higher than senior students on sense of time value, \( F(1,329) = 4.227, p < .05; F(1,329) = 5.802, p < .05; F(1,329) = 9.472, p < .01 \). The conclusions drawn from this study are that significant differences on time management disposition are found between different levels of self-monitoring, and significant differences exist between junior and senior school students on all three subscales. There were also no significant differences between male and female middle school students.

The relationship of gender role with mental health and its components in employed women

ALI AK BARI DEHKORDI, M. (Payame Noor University), SHOKRKON, H. (Payame Noor University), HASSANZADEH, P. (Payame Noor University)

In the present study, the relationship of gender role (masculinity and femininity) and mental health was investigated in employed women. To serve this purpose, a sample consisting of 500 employed women in administrations, organizations and administrative companies of Tehran city were selected randomly. All subjects answered to all items of Goldberg’s (1972) General Health Questionnaire (GHO) and Bem’s (1981) sex role inventory (short form). To analyze data statistically, Pearson’s correlation coefficient and multivariate regression were used. The results of the research indicated that femininity and masculinity have a positive correlation with each other. Femininity has also negative correlations with mental health, anxiety, dysfunction and depression; but has no correlation with somatic signs. Masculinity has negative correlation with mental health and dysfunction; and has no correlation with somatic signs, anxiety and depression. In addition, the results of regression analysis showed that masculinity has no significant role in explanation of mental health and its components. The results of this research showed that employed women are high in bout of gender role (masculinity-femininity), also, more study and research must be done regarding gender role in Iran.

Keywords: gender roles, mental health, employed women

The relationship of job involvement with promotion opportunity, supervisor satisfaction, participation in decision making and internal motivation

Job involvement and its benefits are prompted by a rise from both personality and individuals characteristics and organizational context, job design and supervisor’s behavior. The purpose of this research is investigations of the relationship of job involvement with some of these predictor variables such as promotion opportunity, supervisor satisfaction, participation in decision making and employee's internal motivation. The research hypothesis is defined as a signification relation between job attachment and these four variables. In order to obtaining research purposes, 272 men and 4700 of women satisfaction universe selected form public organization by simple random sampling. Subjects respond to Kanungo's job involvement questionnaire (1982), promotion opportunity scale (Balfour & Wechsler, 1996), supervisor satisfaction scale (Smith, Kendal & Hulin, 1969), participation in decision making scale (Balfour & Wechsler, 1996), and internal motivation (Balfour & Wechsler, 1996). Data was analyzed using stepwise regression analyses. Regression analysis’s proposed just one model that includes participation in decision making and job attachment has 0/038 percent common variance. Although pervious research indicated that a combination of personality factors (locus of control, achievement need, internal motivation) and organizational factors (supervisory style, organizational climate,
compensational trend) influence job involvement, the current study’s findings were not consistent with previous research. This issue implies that effective factors in job involvement according to organizational context and cultural contest can be very different.

**Keywords:** job attachment, promotion, supervisor satisfaction, decision making, internal motivation

### The relationships among parents’ autonomous motivation, motivational supports, and children’s autonomous motivation

ITO, T. (Aichi University of Education)

The purpose of this study was to examine relationships among the mother’s and the father’s autonomous motivation, motivational supports, and the child’s autonomous motivation. Four motivational support variables—autonomy support, involvement, academic support, and warmth—were hypothesized to mediate between parents’ and children’s autonomous motivation. In addition, this research explored whether there were some differences between the mother’s and the father’s models. Japanese university students ($N=284$) in grade 1 through to grade 4 (i.e. from 18 to 22 years old) completed questionnaires regarding their parents and themselves in high school. The autonomous motivation scale was based on the Self-Determination Theory (SDT). Four subscale scores of autonomous motivation were combined to form a relative autonomy index (RAI). These subscales were external, introjected, identified, and intrinsic. Simplex structures were confirmed by correlation analyses. The item formats of autonomy support, involvement and warmth are similar to those of Robbins (1994) and Sakurai (2003). The academic support scale assessed parents’ promotion of self-regulated learning (Zimmerman & Schunk, 2001). Structural equation modeling indicated that parents’ autonomous motivations were positively associated with warmth, autonomy support, and academic support. The warmth was positively related to autonomy support, involvement, and academic support. Furthermore, there were significant paths to children’s motivation from autonomy support. On the other hand, relations between parents’ involvement and academic support, and children’s autonomous motivation were not significant. Direct paths from parents’ autonomous motivations to children’s motivation were significant. The results of both the mother’s and the father’s models were almost the same. To conclude, in the previous research, there were relatively few studies that examined precisely the mediated processes between parents’ and children’s autonomous motivation. The present study suggests that the parents’ warmth is the most important mediating factor in both mother’s and father’s models. When parents with warmth are academic and autonomous, supportive and involved, their children are most likely to internalize the regulation of their learning. In future research, it will be necessary to examine how parents support children and how the children become autonomous in a longitudinal study from childhood through adolescence.

### The relationships between cultural-self concepts and the different types of implicit preference

SHIOMURA, K. (Iwate Prefectural University)

Recently, the cultural-self concepts have needed re-thinking and are discussed here in a new perspective. The present study investigated the relationships between cultural-self concepts and two types of implicit self-esteem. The implicit preferences of Japanese university students were measured by the Go/No-go Association Task (GNAT) technique, which is one of the derivative types of the Implicit Association Test (IAT). Seventy-six Japanese university students (32 males and 44 females) participated in both GNAT tasks and explicit self-rating questionnaires on cultural-self concepts and self-esteem. Participants took both the Self versus Best Friend GNAT task, and the Self versus general Other GNAT task so that two kinds of implicit self-esteem, Self-Best Friend GNAT effect (implicit preference for Self over Best Friend) and Self-general Other GNAT effect (implicit preference for Self over general Other).
were calculated. Statistical analyses were performed to determine whether some types of cultural-self concepts and explicit self-esteem can be predictive of this difference score of GNAT effects. The regression analysis for all participants showed no significant predictor. On the other hand, in the respective analyses for male and female participants, only the collectivism scale was a significant predictor among some self-related scales for males. The results showed that for Japanese the function of the collectivism is different for males and females. There is a three-way interactional relationship among implicit self-esteem discrepancy for Best Friend and general Other as the Other category, the collectivism that has been considered as a distinctive property in Japanese culture, and the gender differences.

Keywords: cultural-self concepts, implicit preference, self-esteem, collectivism, Japan

The repeating natural disaster and PTSD of survivors

FUJIMORI, T. (Yokohama National University), OMORI, T.

The research of repeating disaster survivors’ mental health has been done little in Japan. The exception is Tetsushi Omori’s survey on the mental health of Tsubota district’s residents after the eruption of Miyake-island in Tokyo (in print). The eruption at Miyake-island in July, 2000 was a volcanological rarity, and it has been emitting volcanic gas in a wide area of the island. The repeated emissions of volcanic gas have been covering a large area of the island, even after 9 years following the eruption, and it exceeds the safety and environmental standards in many parts of the island. According to the Omori’s research, survivor’s mental health of repeating disaster after 7 years, using GHQ28; an abbreviated version of GHQ (General Health Questionnaire) 28, 63.6% of the disaster survivors were found to be in the high risk category. The research clearly shows the influence of the repeating disaster on the survivors’ mental health. GHQ has been used for research relating to natural disasters; for example, Ohta et al.’s (1995) research of the volcanic eruption of Mt. Unzen, Fujimori and Fujimori’s (1995) research of the Hokkaido Nanseioki Earthquake, and Tanaka and Takagi’s (1997) research of the Hanshin-Awaji Great Earthquake. Each research assessed the mental health of non-recurring disaster’s survivors using GHQ. The mental health of Miyake-island’s residents, who live under the stress of repeating disaster, needs to be examined, focusing on post traumatic stress disorder (PTSD) as well. This research updates and further examines the Miyake-island’s residents’ mental health following Omori’s research in 2007. The study was performed from September 2nd to October 2nd, 2009. We surveyed the residents of Tsubota district of Miyake village in Tokyo over the age of 20 who had witnessed the eruption in 2000. The questionnaire use was the IES-R (Impact Event Scale- Revised) which informs and measures sex, age, demographic characteristic of occupation, stress event, and PTSD. The IES-R was translated into Japanese by Asukai, of The Tokyo Institute of Psychiatry, and his joint researchers with the permission of the original authors (Weiss & Marmar, 1997). The questionnaires were distributed and collected by the researcher and the volunteers by visiting the Tsubota district of Miyake village. The survey response was 215, and the rate was 75.3%. The survey respondents were composed of 99 males (46.0%) and 116 females (54.0%). Their ages varied between 20 to 88, and the average of the respondents was 64.4 years (SD=13.8). The occupations of the respondents were unemployed (27.4%) and farming (23.7%). These occupied half the number of respondents’ occupations. Additional occupations included; civil servants (6.0%), construction industry (5.6%) accommodations (5.1%), shops (4.7%) and restaurants (4.2%) adjoined by the little difference. It is pointed out by Kato and Iwai (2000) that the cut-off point to judge whether the symptoms indicate PTSD is the IES-R standard score of 24 points or more. When the ratio of PTSD in the present study was calculated according to this standard, 27.6% of the survivors were found to indicate PTSD. Next, the PTSD group and non PTSD group were examined to show characterizing factors in their differences. When the χ² test was performed to examine differences in gender, the ratio of PTSD women (36.2%) was significantly higher than men (17.1%) (p < .01). In relation to age, notable differences were shown (p < .001). The group of participants above 65 years of age (40.9%) scored a higher ratio of PTSD than the
group of participants under 65 years of age (13.3%). In relation to their occupations, the residents who had undesirable job situations (32.8%) showed significantly higher signs of PTSD than the residents who had desirable job situations (16.4%) ($p < .05$). In relation to the stress event, the residents who held concerns over the influence of volcanic gas on health (34.0%) compared to the residents who did not (14.1%), showed a higher ratio of PTSD ($p < .01$). The residents who had concerns about wearing gas masks and gas warning systems (34.3%) compared to the ones who did not (16.0%) also showed a higher ratio of PTSD. As a result of the survey on the residents who continue living under the stress of the repeating disaster, 27.6% showed an indication of PTSD. In the prior research (DSM-IV, 1994), the lifetime prevalence (of PTSD) was shown to be between $1 \sim 14\%$, and the numerical value that had been obtained in the present study was high. The study suggests that living under the influence of repeated harmful volcanic gas, the survivors’ mental health is continuously jeopardized, and the damage to their mental health caused by the repeating disaster became visible through chronic symptoms. In relation to gender, females showed more indications of mental damage. In relation to age, the older generation group showed more signs of PTSD. As for the relation with occupation, the residents who had undesirable job situations showed symptoms of PTSD. The above results concur with the results of previous research. Conclusively, the enhancement of social support, such as mental care and recovering employment, are necessary for those who show symptoms of PTSD.

The repeating natural disaster and the mental health of the survivors

OMORI, T. (Yokohama National University), FUJIMORI, T. (Yokohama National University)

Traditionally in the study of the mental health of disaster survivors, the disaster itself is a non-recurring event. However, in the case of the disaster survivors of Miyake Island there is a rare study of an on-going process of the island’s residents trying to adapt to recurring natural disaster as part of their lives. On a February day in 2005, the residents of Miyake Island returned to their homes after an absence of more than 4 years following the volcanic eruption in 2000. However, even 9 years after the eruption, at the time of this research, the majority of the area of Miyake Island was still covered with poisonous gas. The readings of the gas still exceeded the standard thickness for volcanic gas based on the Environmental Law. Residents of Tsubota district on Miyake Island were still working on recovery and reconstruction under the environmental stress at the time of the research. It is this paper’s goal to determine how the mental health of disaster survivors in the Tsubota district is influenced by the recurring disasters. The research focused on following two points: 1) determining the mental health status of the residents after 9 years of the disaster using GHQ28; and 2) making clear the causations that relate to high-risk people. As a result of the research, extraordinarily high scores of high-risk people were found, according to GHQ28, exceeding by more than 4 times the score of the average population in Japan. Moreover, using multivariate logistic analysis, concerns by the residents such as not being able to go home, unemployment, and work conditions were identified as the main risk factors in this case.

The revoicing as educational discourse strategy

ONODA, R. (Tokyo Gakugei University), TONEGAWA, A. (Tokyo Gakugei University), UEBUCHI, H. (Tokyo Gakugei University)

This study had two purposes. The first purpose was to explore how teacher’s “revoicing” (O’Connor & Michaels, 1996) were used to control classroom discourse. The second purpose was to investigate the effects of revoicing on children. A moral class was selected for observation. In this context, teacher made an effort to elicit the children’s own opinion. Therefore, multiple utterances of the children appeared in the morals class. In an elementary school fourth grade classroom, morals classes were observed for 4 hours. The observational
records were sorted based on Mehan’s IRE structure (Mehan, 1979). Furthermore, teacher’s and children’s utterances were analyzed quantitatively by categories and qualitatively by contents. The roles of revoicing in the process of composing class were analyzed by focusing on the number of utterances per minute. In addition, the opinions of the children were recorded by reaction-papers. The categorical analysis showed that revoicing was functionally divided into two types. One was “initiative revoicing” which deepened the contents of children’s utterances. The other was “responsive revoicing” which meant simple response. The correlational analysis showed that teacher’s revoicing were correlated with the children’s utterances ($r=0.45$). In addition, teacher’s initiative utterances were negatively correlated with the number of revoicing ($r=-0.28$). The contents of reaction-papers showed that children’s opinions were strongly biased toward certain categories. The qualitative analysis suggested that teacher effectively used “initiative revoicing” and “responsive revoicing” to control classroom discourse. The quantitative analysis suggested that teacher applied children’s utterances to configure class by using revoicing instead of initiative utterances. On the contrary, contents of the reaction-papers suggested one possibility. It was that children implicitly recognized the teacher’s orientation, so multiple utterances of children might be constrained in classroom discourse.

The role of driving behavior determinants in detecting reckless drivers

OH, J.S. (Chungbuk National University), SONG, H.H. (Chungbuk National University), LEE, S.C. (Chungbuk National University)

This research examined driving behavior determinants (DBD), which reflect the characteristics and attitudes of drivers who are involved in reckless driving. Ways of improving studies and making practical use of the DBD concept are also suggested. Recent related research on the concept of DBD and its needs for improvement was reviewed in the first instance.

Lee (1990) first suggested the concept of driving behavior determinants. This theory explains that drivers’ personal and socio-cultural factors indirectly affect their behavior, but DBD (e.g., risk sensitivity and law abidance) created by drivers’ personal and socio-cultural factors, directly affect the drivers’ behavior. The researchers who conducted the first illustrative study (Kim, Oh, and Lee, 2006) insisted that DBD consist of risk sensitivity, law-abidance, and situational adaptability. Lee and Oh’s (2007a) follow-up study found that risk sensitivity and law-abidance are correlated with violations such as speeding and drunk driving, and situational adaptability is correlated with failure to cope in certain traffic scenarios. Upon further analysis, Lee and Oh (2007b) found situational adaptability was divided into two factors; personal-relational adaptability and physical-situational adaptability, and problems in personal-relational adaptability explained drivers’ speeding and distractibility. However, Oh and Lee (2007) claimed that there were no differences between DBD levels of reckless drivers and normal drivers, finding only differences in DBD factors effect sizes. This weakness was explained as a limitation of the self-reporting system they used, and the researchers suggested that a standardization procedure would solve this problem. The existence of DBD and its effects on reckless driving have been verified by various studies. DBD sub-factors, however, cannot be considered as established yet. Also, certain steps are needed in order to use DBD for the detection of reckless drivers and creation of education programs for them. First, as many human factors as possible (e.g., anger and introversion) have to be considered, so that many different kinds of reckless behavior can be predicted. Second, we need a standardization procedure for scoring DBD, to protect objectivity, which may even make accident prediction possible. To address these weaknesses further studies, with large sample sizes and even inter-cultural sample groups, are needed.

The role of intrinsic motivation in the relationship between justice perception and organizational effectiveness

LEE, Y. J. (Ajou University), PARK, J. (Ajou University), KIM, D.Y. (Ajou University)

Contingent employees in South Korea are typically associated with the staffing company, which originally recruited them and provides their wages and manages their opportunity for promotion, and are also associated with the assigned company, where they actually work. While contingent employees work in the assigned company, they are likely to be surrounded by full time workers, who earn more and have a more permanent job within that organization, and through a process of comparison, may feel discouraged in their work, resulting in lower levels of organizational effectiveness. Because of such potential problems, organizations need to develop management skills to cater for contingent employees specifically (Belous, 1989). Justice perception, which is associated with motivation, was expected to be an important factor to enhance organizational effectiveness of the assigned company. First, we seek to investigate whether the relationship between distributive justice perception and organizational effectiveness (e.g., job satisfaction, organizational commitment, and turnover intention) is mediated by motivation itself. Second, we attempt to examine the possible mediating effects of intrinsic motivation in the relationship between justice perception and organizational effectiveness, respectively. Lastly, we aim to test whether the relationship between justice perception and turnover intention is mediated by intrinsic motivation. Three hundred currently contingently employed workers (131 females, Age M=31.97, SD=7.39) completed measures of distributive perception, extrinsic and intrinsic motivation, two measures of organizational effectiveness, comprising of job satisfaction and organizational commitment, and a measure of turnover intention. The results showed a reliable mediating effect of intrinsic motivation in the relations between distributive justice and organizational effectiveness (i.e., job satisfaction, organizational commitment, and turnover intention). Our research suggests that for contingent employees, it is important for staffing companies to create environmental conditions which could encourage their distributive justice perception toward the staffing company as well as their internal motivation in order to produce better performance in the field. It is helpful for the contingent workers to communicate with each other. The effect of extrinsic motivation also implies that if employees perceive fair treatment from the staffing company, both assigned and staffing companies could influence extrinsic motivations to increase organization effectiveness.

The role of oxytocin: A review

RANKIN, J. (University of the West of Scotland)

The aim of this paper is to provide a critical review of the role of oxytocin. Oxytocin is a neuropeptide hormone produced in the hypothalamus, stored in, and released from, the posterior pituitary gland (neurohypophysis). Secretion of oxytocin is a neuro-endocrine response. The actions of oxytocin are mediated by specific, high affinity oxytocin receptors. Oxytocin is a very interesting hormone that has both peripheral (hormonal) actions, and actions in the brain and central nervous system. This presentation will provide a critical review of evidence to date and highlight relevant areas emerging that will be of interest to psychologists. Briefly, its peripheral actions are as follows. Oxytocin is best known for its role in female reproduction. It is released in large amounts during parturition resulting in uterine contraction. This facilitates the birth process, control of bleeding and involution of the uterus. Oxytocin has a key role in the ejection of milk from the breast during lactation (let down reflex). Furthermore, oxytocin may be involved in sexual response in humans. The relationship between oxytocin and sexual response remains unclear. Meanwhile, its actions on the central nervous systems are as follows. Once secreted, oxytocin cannot re-enter the brain because of the blood-brain barrier. Instead, the behavioural effects of oxytocin are thought to reflect release
from centrally projecting oxytocin neurons, different from those that project to the pituitary gland, or which are collaterals from them. Oxytocin has been implicated in non-social behaviours such as pain perception, anxiety learning and feeding. More recently there has been increasing interest in the role oxytocin may play in other behaviours such as social memory and attachment, sexual and maternal behaviour, aggression, human bonding and trust. It has been suggested that oxytocin expression may be involved in human disorders characterized by aberrant social interactions, such as autism and schizophrenia. The trust-inducing property of oxytocin may emerge as a controversial topic. It has been suggested that the trust-inducing properties of oxytocin may help those who suffer from social anxieties and mood disorders while there is another school of thought that this potent hormone has the potential for misuse in the wrong hands.

The role of phonological information in bilingual processing: Multimodal interaction in word perception

KIM, D.H. (Chung-Ang University), LEE, J.H. (Chung-Ang University)

Recent studies on visual word recognition have found that bilinguals nonselectively activate lexical information regarding both of their known languages when reading text. However, the mechanisms involved in this process have not been fully identified. Many previous studies have tried to explain this phenomenon using the phonological mediation hypothesis. According to this hypothesis, phonological information of both languages activate automatically by spell-sound correspondence during the initial phase of bilingual processing. To examine this hypothesis, previous studies have used priming tasks where bilinguals were presented with visual language in short stimulus onset asynchrony (SOA). Priming tasks, however, are limited to testing phonological activation indirectly through visual word processing. The best way to examine phonological activation of visual words is to present visual words and auditory words spontaneously. If a bilingual’s visual word recognition is mediated by phonology, it should be affected by auditory words. To test this hypothesis we designed a multimodal phonological decision task. In this task, participants have to decide whether a spontaneously presented visual word and auditory word pair is phonologically different or the same. Forty Korean-English bilinguals will participate in this experiment. They will be randomly assigned to either the Long-SOA (1500ms) group or the Short-SOA (130ms) group, and each SOA group will be exposed to four types of stimuli pairs: 1) Same-meaning Same-language; 2) Same-meaning Different-language; 3) Different-meaning Same-language; and 4) Different-meaning Different-language. Eighty word pairs will be randomly presented [Study in progress]. In the Short-SOA group, mean reaction times for the Same-meaning Different-language word pairs will be significantly slower than the for the other conditions, and error rates will also be significantly higher than in the other conditions. These expected results will indicate that phonological representations generated from words in one language can activate words in another language, and is consistent with previous studies of phonology in bilingual word recognition. They will also indicate that a multimodal task can be useful for phonological activation in bilingual processing.

The role of positive/negative experiences of interpersonal interaction and goal achievement on social self-regulation

HARADA, C. (Nagoya University), TSUCHIYA, K. (Nagoya University), YOSHIDA, T. (Nagoya University)

Social Self-Regulation (SSR) has been defined as the ability to inhibit or assert the self depending on internal and external needs in a social setting when there is discrepancy between desire, intention, and current perception (Harada, Yoshizawa, & Yoshida, 2008). Previous studies have clarified that the effect of SSR on antisocial behaviors is stronger than the temperament
facets of self-regulation (behavioral inhibition/approach system, effortful control). Although the SSR is supposed to be built through interpersonal interaction and goal achievement in adolescence, few studies have examined the factor to improve SSR directly. In the present study, we aim to explore whether the positive/negative experiences of interpersonal interaction and goal achievement could be a factor to improve SSR. A total of 166 undergraduates were instructed to recall their middle-to-late adolescence (from junior high school to college). The self-regulation ability during junior high school years and current SSR ability was assessed using the Social Self-Regulation scale consisting of self-assertiveness, patience, and emotion/desire inhibition. The positive/negative experiences during high school years were assessed by a scale measuring interpersonal interaction and goal achievement experiences. The results of structural equation modeling revealed that positive experiences of goal achievement promote all three facets of SSR; self-assertiveness, patience, and emotion/desire inhibition. Additionally, experiences overcoming negative interpersonal conflict promoted self-assertiveness. The results were supporting Arnett’s (2008) claim that the interpersonal interaction in broader circumstances promotes socialization in adolescence. These results indicate that the experiences of goal achievement contribute to self-regulation success in social settings by promoting SSR ability. Moreover, it is revealed that not only positive experiences but also negative experiences contribute to improving an aspect of SSR if the individual had overcome them. The features that highlight SSR compared to other self-regulation abilities are discussed. Future research could benefit from adopting a longitudinal and participant-observation based approach.

Keywords: social self-regulation, goal achievement, interpersonal factors, negative experience, positive experience

The role of psychological climate in an occupational stress and coping process: A transactional model

BUTTERWORTH, T. (University of New South Wales)

In this study, Psychological Climate (PCT) is examined using Lazarus and Folkman's (1984) theoretical framework of transactional stress and coping. The first aim was to establish the components of the stress and coping process that would be affected by a person's perceived work environment (i.e. PCT). Secondly, this study aimed to determine if a general model could be produced that parsimoniously reflected the impact of a person's perceived work environment on his/her stress and coping process in the workplace. Paper- and web-based surveys were completed by 196 participants who were employed in various occupations. Respondents were required to be employed on a part-time or full-time basis for at least six months. Participants identified the most stressful situation they were currently experiencing at work and appraised the threat and level of control they had over the situation. Coping strategies and psychological stress levels were evaluated at a 2-4 week follow up. Path analysis through structural equation modeling successfully identified and validated the Transactional Stress and Climate (TSC) model. The TSC model shows the importance of a person's perception of his/her work environment on the experience of stressful encounters at work. The TSC model suggests that when a person evaluates his/her work environment as being psychologically safe (high PCT), stressful encounters at work are appraised as less threatening and more controllable. The TSC model also suggests that psychologically safe work environments are associated with lower levels of psychological stress 2-4 weeks later. This research shows the importance of employee perceptions of work environment (PCT) when evaluating stress and coping processes in the workplace.

Keywords: psychological climate, transactional, coping strategies, occupational stress

The role of team goal setting and team leadership as predictors of the team competency

IKEDA, H. (St. Thomas University), FURUKAWA, H. (Kyushu University)

So far, team ability has been discussed in terms of the properties of teamwork among members,
such as mutual understanding, communication, cooperation, and so on. Recent work teams are expected to be successful not only in sustaining good outcomes within the team, but also in adapting teams to changing task environments. Therefore, different kinds of teamwork are needed for sustaining and adapting, respectively. Taking these things into consideration, we proposed a new concept of ‘team competency’ which represents the properties of teamwork from sustaining (lower level) to adapting (higher level). In this study we explored the facilitative effects of team goal setting (performance goal, learning goal) and team leadership (empowerment, information sharing) upon team competency. Team goal setting and team leadership, respectively, would facilitate mainly lower level and high level of team competency. Thirty teams (146 persons) from 2 different Japanese companies participated in this study. Participants were asked questions pertaining to team goal setting (performance goal and learning goal setting), team leadership, and team competency. Before aggregating the individual-level scores to obtain the team level score, the viability of this procedure was examined statistically. Indexes of RWG and ICC were examined and verified. The results of hierarchical multiple regression analysis revealed that setting team performance and learning goal had a significant relationship with cohesion and mutual understanding, which represent lower levels of team competency. In contrast, a higher level of team competency was determined by setting a team learning goal, but not by team performance goals. Further, empowerment by the team leader had significant positive effects on higher levels of team competency, on creative thinking, autonomous innovation, as well as lower levels of team competency of cohesion, and mutual buck-up. This study suggested that two types of team goals have different effects on team competency. Team performance goal setting enhanced cohesiveness and mutual understanding among members, whereas team learning goal setting had a positive impact on team adaptation and innovation. Furthermore, the results suggest that empowerment by a team leader provides basic and necessary conditions for enhancing team competency.

### The role of working memory in third grade children’s process of mental abacus calculation

**HONG, L.** (Mental Health Education Association), **WANG, H.** (Mental Health Education Association)

The aim of this study was to investigate the specific temporary storage roles played by visuo-spatial sketchpad subcomponents in the process of mental abacus calculation of children. A 2×3×2 mixed design was adopted to examine the performance between trained children and untrained ones, finishing mental arithmetic under three conditions which were control, concurrent articulatory suppression, and concurrent hand tapping. Results showed that the visuo-spatial sketch pad only produced an interference effect on the trained children’s reaction time and accuracy. To conclude, the visuo-spatial sketch pad was much more responsible for temporary storage aspects of mental abacus calculation.

**Keywords:** temporary storage, visuo-spatial sketchpad, mental abacus calculation, children

### The role of writing about the same trauma or writing different traumas in an emotional disclosure procedure

**PEÑATE, W.** (University of La Laguna), **PITTI, C.T.** (Tasmania del Pino Sedeño ), **CHICO, J.** (University of La Laguna), **BETHENCOURT, J.M.** (University of La Laguna)

The present paper is inserted into the studies on the effectiveness of the emotional disclosure of traumas and highly stressful events. Specifically, it studied the role on mental and physical health of writing on the same trauma or different traumas. Sixty students of psychology grade were assigned to three experimental conditions: 1) to write three consecutive days on the same trauma; 2) to write about different traumas; or 3) to write on trivial affairs. As dependent variables, the positive and negative effect, the level of symptoms of post-traumatic stress disorder, the level of depression and the self-
reported level of health, were assessed. Measurements were carried out session by session, and two months later. The results indicated that the negative affect diminished and the positive affect was increased, session by session. Two months later, both symptoms of post-traumatic stress and physical health were significantly diminished for the group that wrote on the same trauma, in comparison with the other two groups. The depression level also diminished, both for the group that wrote on the same trauma, and for that which wrote on different traumas. Although the model of cognitive exposure has greater support, the results are discussed according to the need for a new and more extended explanatory model.

Keywords: writing, trauma, emotional disclosure, post-traumatic stress disorder, depression

The role of Zhong Yong in group decision making

ZHANG, C. (Ajou University), PARK, J. (Ajou University), KIM, D-Y. (Ajou University)

Examining a South Korean sample, a recent study reported that the risk decisions of South Koreans were facilitated by group situations, with gender compositions of male, female and mixed groups (Park & Kim, under review). This is because a diffusion of responsibility is a pre-established social norm in South Korea. However, one may not be able to generalize that the group facilitation effects observed in South Koreans would also manifest in Chinese. That is because Chinese put a higher value than South Koreans on ‘Zhong Yong’, which encourages moderation and avoidance of extremes within groups by combining divergent decisions among group members. The present study aims to show that the risk decisions of Chinese would not be facilitated by group situations due to Zhong Yong, regardless of gender composition. 284 participants (155 females; Age: M = 20.9, SD =1.41) were randomly assigned to male only, female only, and mixed gender experimental groups, or to a separate control group for each gender. In the pre-test, each participant completed the Choice Dilemma Questionnaire (CDQ; Kogan & Wallach, 1964) assessing risk decisions. Then in the manipulation period, experimental group participants conducted a group discussion (n=4) for 10 minutes, with the aim of reaching a group consensus on a new, but identical copy of the CDQ. Control group participants took a break for 10 minutes. Throughout the following analyses, South Korean data were reproduced with permission. Unlike South Koreans, risk decisions of Chinese were not facilitated by group situations regardless of gender composition. To demonstrate whether the observation results from Zhong Yong, difference scores were calculated by averaging the lowest and highest CDQ scores at pre-test among group members. Comparison of this score to the group CDQ scores revealed no significant differences in all of the three experimental groups, indicating the possibility that group decisions reflected a compromise between individual opinions. However, a similar examination of South Korean scores yielded significant differences in all experimental groups, indicating no effect of Zhong Yong. Despite the fact that both countries share collectivist values, the data suggest that Zhong Yong could play a critical role in distinguishing the group decision-making processes of Chinese and South Koreans.

Keywords: group decision-making, Chinese, South Koreans, Zhong-Yong

The sexual differences of coping behavior in situations arousing "anger" emotion in university students

TANAKA, C. (Gakushuin University)

Human behaviors and cognitions are often influenced by emotions. Especially, ‘anger’ leads to irrational judgments and aggressive behavior, and then these may be the causes of criminal or social maladjustment behaviors. This study used some scenarios depicting provocations from one’s friend which aroused anger, and investigated what kinds of behavior occurred and whether there were any sexual differences. A total of 111 undergraduate university students (males = 48, females = 63) completed the questionnaire. The scenarios depicting provocations had three levels of the friend’s reputation: compared with participants, the friend’s reputation is (1) high; (2) equal; (3) low (levels of reputation, between-participants). The
scenarios also had two situations: a friend demonstrated the provocation to you where (1) another person was not around you; (2) someone was around you (situations, within-participants). After reading two of six scenarios, students were asked for their degree of anger. Next, the participants were asked to rate 34 behaviors according to the degree they wanted to perform it. The scale had five points (1 = extremely unlikely – 5 = extremely likely). An ANOVA, involving 2(sex) × 2(situations) × 3(levels of reputations), revealed a significant main effect of situations for the degree of affect (F (1,105) = 31.72, p < .01). Factor analysis was conducted for 34 behaviors and then 6 factors were identified: (1) verbal aggressive behavior, (2) direct aggressive behavior, (3) indirect aggressive behavior, (4) time-latent aggressive behavior, (5) fear and (6) escape. The results of the analysis found a significant main effect of situations (F (1,103) = 11.205, p < .01) and sex (F (1,103) = 4.771, p < .05) on direct aggressive behavior. The interaction effect between situation and sex in time-latent aggressive behavior was significant (F (1,103) = 6.48, p < .05). Finally, the analysis detected a significant main effect of sex in fear (F (1,104) = 26.70, p < .01). This study suggested that people felt anger most strongly when they were exposed to the provocation by other person in a group situation, regardless of their sex and friend’s reputation. Sexual differences were found; females tended not to present aggressive behaviors in group situations. Additionally, a sensitivity of ‘fear’ in females was found.

Keywords: anger, behaviour, gender, provocation

The source of motivation for next trial among business people

TSUMAGARI, Y. (Kyushu University), FURUKAWA, H. (Kyushu University)

This study focused on the motivational function of reflection on past experience.

Markman (2003) argued that there are two contrasting reflections. The first is “Reflective processing,” whereby the present standing is almost ideal. The second is “Evaluative processing,” whereby the present standing is far from an ideal one. The previous study showed that people who engage in evaluative processing have higher motivation and improve their performance (Markman et al., 2008). However, they did not distinguish among experiences people reflected, success or failure. As for this, another study (Gilbar & Hevroni, 2007) reported that people with evaluative processing of failure suffer depression and lose their motivation to try the next task. We aimed to reconcile these findings by discriminating the experiences people reflect in terms of success and failure. We examined the effect of reflective and evaluative processing upon motivation for the next trial. Two hundred and fifty nine business people were asked to complete a series of questionnaires, asking how they reflect on their successful and failed experiences, respectively, in daily work life. They were also asked how much motivation they have for the next trial after success and failure. The main results were: (1) people who engage in evaluative processing of their failures tend to have higher motivation for the next trial after success and failure; (2) people who engage in reflective processing of their successes tend to have higher motivation for the next trial after success and failure; and (3) among people who engage in evaluative processing of their failures, motivation is higher for those who engage in reflective processing of success more often. These results suggest that evaluative processing of failure, as Markman (2008) proved, and reflective processing of success, lead to improved motivation for the next trial. Reflective processing on success may be necessary in order to prevent motivation decline by the evaluative processing of failure.

Keywords: motivation, reflection, past experience, success, failure

The study of brain/behavioral systems as predictors of personality types A & D

DAVOUDI, I. (Shahid Chamran University of Ahvaz), SAFIKHANI, A. (Shahid Chamran University of Ahvaz)

This study was carried out to investigate components of Behavioral Systems including, behavioral activation (approach and active avoidance), behavioral inhibition (extinction and passive avoidance) & fight-flight (fight and flight)
systems as predictors of personality type A & D in Shahid Chamran university postgraduate students. The sample consisted of 273 students who were selected by stratified random sampling method. The Persian form of Gary-Wilson Personality Questionnaire (Wilson, Barrett & Gray, 1989), Type A Questionnaire (Najarian, Macvandi, Dabbagh & Nikfar, 1996), and Type D Scale-14 (DS14) (Denollet, 1998) were administered to all subjects. To analyze the data in this study, regression analysis was used. The results of this study, showed that among all of the components of brain/behavioral systems, extinction ($\beta=0.26$, $p<0.001$) and passive avoidance ($\beta=0.24$, $p=0.001$) can predict type D significantly. On the other hand, fight ($\beta=0.16$, $p=0.004$) and approach ($\beta=0.16$, $p=0.01$) can predict type A significantly. These findings suggest that type A and type D are distinct structures. The implications for theoretical development are discussed.

Keywords: personality type A, personality type D, Gary-Wilson Personality Questionnaire, regression analysis, behavioral systems

The study of educational expectations, filial piety and willingness to attend cram schooling of Taiwanese senior high school students

PENG, Y.C. (Taipei Municipal University of Education), WEI, C.F. (Taipei Municipal University of Education), CHEN, S.W. (National Tsing Hua University)

The purpose of this study was to explore the relationship between educational expectations, filial piety and willingness to attend cram schooling. Academic performance is the most important role obligation of children and adolescents to their family. Students may go to cram school out of their own choice or parents’ demand. Therefore, filial piety also contributes to the drive for academic achievement. A questionnaire was used to investigate educational expectations among senior high school students and their parents, students’ filial piety belief, and their willingness to attend cram schooling. Two hundred high school students served as participants. Both student’s and parental educational expectations could predict willingness to attend cram schooling. Filial piety of reciprocity was positively correlated to willingness to attend cram schooling. Students went to cram school not only to achieve good grades, but also to fulfill parents’ educational expectations for them. Academic achievement helped children fulfill their role obligation to parents.

Keywords: education experience, filial piety, cram schooling, academic achievement, role obligation

The study on difference of aspect on burnout syndrome and depression

KISHI, T. (Toho University), YAMADA, Y. (Toho University)

Some studies have showed that there is a moderate correlation between burnout and depression, although psychologists have taken different approaches to each of these mental problems. We investigated the different aspects of burnout and depression in hospital nurses. Participants were 503 staff nurses (30 males and 473 females) who worked in a university hospital in Japan. They were asked to answer a questionnaire included demographic items, MBI-GS Japanese version, and CES-D Japanese version. Both of psychological scales were computed for each subscale. Exhaustion score and cynicism score were moderately correlated with somatic score and depressive affect score. Professional efficacy score was moderately correlated with positive affect score. But, any MBI-GS subscales score were not correlated with interpersonal relations score. Physical symptoms and feelings of fatigue are common aspects in burnout syndrome and depression. However, interpersonal relations are depression specific, and not included in burnout syndrome.

Keywords: burnout, depression, nurses, MBI-GS Japanese version, CES-D Japanese version

The synergy and utility of proactive coping and positive reframing on negative affect

HODGE, D. (York University), GREENGLASS, E. (York University)
Major life events can cause significant stress, even if those events are considered positive. A crucial factor determining experienced stress is coping strategy used, which impacts both practical and psychological outcomes. Proactive coping is a forward-looking coping strategy, which promotes engagement with challenging situations and is associated with reduced worry, stress, and perceived threat. The goal of the present study was to explore the relationship between the psychological reframing of life events, either positive or negative, the degree to which proactive coping was used to deal with these events, and negative psychological outcomes. Data were collected from 472 undergraduate students at a large Canadian university in an internet experiment. Participants were asked to think of a personally significant positive or negative event, and then to write about it from a positive perspective (focusing on benefits) or a negative one (focusing on harm), creating four experimental conditions. Participants were assessed on three dependent variables, negative affect, depression, and perceived threat associated with the event. Regression analyses were conducted in which predictors were event, perspective, proactive coping, and their interactions. Results of the regression analyses showed significant interactions between proactive coping and perspective on measures of negative affect, depression, and threat. Higher levels of proactive coping predicted to lower levels of depression, negative affect, and threat, but only when participants focused on positive aspects of the event. These results demonstrate the moderating role of proactive coping in dealing with feelings associated with significant life events. When individuals use high levels of proactive coping and focus on the benefits of a recalled life event, the experience of deleterious affect is attenuated following recollection. These results have practical and theoretical implications for psychological functioning. In particular, they illustrate the link between positive thinking and proactive coping as well as their synergy in promoting adaptive functioning.

Keywords: proactive coping, positive reframing, stress, positive thinking, life events

The variance trend by personality of the reaction time: Personality traits of extraversion-introversion, nerves-toughness

SATO, E. (Tokyo Fuji University), MATSUDA, K. (Bunkyo Gakuin University)

In this study we measured reaction times (RT) to personality trait terms and examined RT as the quantitative indicator to determine whether the personality trait terms match the participant’s personality. For this purpose we examined the relationship between personality traits and RT to personality trait terms. It was hypothesized that reaction times to personality trait terms would change with the personality traits in this study. This experiment measured RT to personality trait terms as on the two axes of extraversion and emotional stability. In the simple response session, participants responded to personality trait terms as stimuli on a computer. In a personality self-rating session, participants valuated whether personality trait terms matched to themselves or not by pushing a circle mark or divorced mark. Finally, participants executed “scale construction of a Big Five personality inventory“. The participants were 40 university and graduate students aged 20–30 years. For the sake of examining RT to personality trait terms, we divided and examined four models, raw data, personality valuation time (Dander’s model), the increasing rate of reaction time, and the increasing rate of personality valuation time. The raw data did not show a relationship between personality traits and the RT to personality trait terms. By personality valuation time, it was found that the RT of the extroversion and emotionally unstable was longer than personality valuation time and quite variable SD. Two-way ANOVA revealed that a main effect was found for emotional stability by the increasing rate of personality valuation time ($F(1,1261)=16.52, p<.01$). A main effect was found for extraversion scores by the increasing rate of reaction time ($F(1,1261)=21.09, p<.01$) and the increasing rate of personality valuation time ($F(1,1261)=20.48, p<.01$). This experiment suggested that the RT of the participants with high emotional stability scores was continued by a constant reaction in two sessions, but as their own personality valuation increased many times, reaction times were quite variable. It is suggested that the participants with high
Extraversion scores had quite variable reaction times to stimulus terms and personality valuation. It was difficult to examine experimentally the relationship between personality traits and reaction times to personality trait terms. However, this result suggests that RT would be able to show personality traits as behavioral evidence.

Keywords: reaction time, personality traits, extraversion, introversion, emotional stability

The Virtual Errands Task (EVET): An experimental study of the complexities of everyday cognition

Trawley, S. (University of Edinburgh), Law, A. (Liverpool John Moores University), Logie, R. (University of Edinburgh)

What cognitive processes are important for multitasking? An influential model of multitasking performance (Burgess et al., 2000) predicts specific relationships between three latent cognitive constructs: planning, retrospective and prospective memory (PM). However, the role of planning was not well supported by the cognitive data. The study aim was to create a virtual analogue of the Multiple Errands Task (Shallice & Burgess, 1991), and apply that data to the Burgess et al. model. In addition to the measures used to support the original model, we included individual difference measures of spatial and verbal working memory span, planning, retrospective and prospective memory. The Virtual Errands Task (EVET) requires participants to attempt eight location based errands in a four storey virtual building (e.g., collect computer from room G4). The virtual building was created using the Valve Hammer Editor, a 3D map creation program provided with the computer game Half-Life 2. 157 participants (95 females, 62 males – overall mean age 19.6yrs) learned the errand list to criterion and made a plan before starting the test. Individual difference measures assessed retrospective and working memory capacity (spatial and verbal), planning ability and PM. Multiple regression analysis showed that independent measures of spatial working memory span, planning ability and retrospective memory were significant predictors of EVET performance. Results are supportive of accounts that argue for domain-specific working memory processes, and highlight a role for spatial working memory capacity in multitasking. The role of planning and retrospective memory in multitasking was supported in this dataset and is in line with the Burgess et al. model. However, data are in disagreement over the importance of prospective memory (as indexed by independent measure of PM).

Keywords: virtual errands task, cognition, multitasking, working memory, prospective memory

Thinking biases in searching for explanation: Plausibility effect and local coherence

Lin, W-Y. (Chung Yuan Christian University), Wang, J-W. (Fo Guang University), Cheng, C-M. (Fo Guang University)

The authors hypothesized that behind the Post hoc Explanation Bias, people may emphasize the plausibility of every individual explanation rather than the existence of alternative explanations. This in turn generated the second hypothesis that the attention to plausibility may lead such individuals to the neglect the contradiction of existing explanations and induce local coherence. Two experiments were designed to test these hypotheses. In Experiment 1, four stories with unusual events were used. Participants (228 college students) were asked to indicate to what degree they thought the explanation presented after each story was acceptable. The experiment employed a 3 (one, two, or three alternative explanations mentioned) x 2 (with or without a personal explanation) independent sample factorial design. In Experiment 2, the researchers devised two contradictory statements plausible in individual contexts so as to test if participants (284 college students) would accept these two conflicting statements equally as predicted by the local coherence hypothesis. Two target stories with different task forms were utilized. Participants were asked to evaluate the probability that an explanation was true (Statement A) in one story and the feasibility (how likely it will work in practice) of a suggestion (Statement A') in the other. Two target stories were adequately separated by four
filling stories. In addition, the first story in Experiment 2 was designed to have three versions: a control version (possible explanatory statement), a prediction version (predictive statement), and an explanation version (post hoc explanation). The results of Experiment 1 are consistent with the plausibility hypothesis: (1) participants demonstrated less acceptance of the explanation offered if he had his own explanation; (2) the number of alternative explanations had no effect on participants’ acceptance of the particular explanation offered. The result of Experiment 2 evidently supports the local coherence hypothesis. Also, a significant positive correlation was found between the participants’ response to each version of the first story and their response to the second story, as predicted. Thus, to conclude, both plausibility effects and local coherence hypotheses, which are supposed to be the mental mechanism of Post hoc Explanation Bias, were supported by the data from the two experiments conducted.

Keywords: post hoc explanation bias, plausibility effect, local coherence

Time elapsing since cessation of cannabis use: Implications for visuospatial memory performance

MURPHY, P. (Edge Hill University), ERWIN, P. (Edge Hill University), FISK, J. (University of Central Lancashire), MACIVER, L. (Edge Hill University), YANULEVIT, K. (Edge Hill University), KEANE, E. (Edge Hill University), LARKIN, D. (Edge Hill University), MONTGOMERY, C. (Edge Hill University), WAREING, M. (Edge Hill University)

Previous studies have shown cannabis use to be related to impaired performance on some cognitive tasks, including those drawing upon visuospatial memory. However, whilst evidence now exists for a withdrawal syndrome following the use of this drug, relatively few studies have examined the relationship between the time elapsing since cannabis use was ceased and cognitive performance level. The neurotoxic properties of cannabis make this an important question. The present study examines this relationship with regard to visuospatial memory span. Visuospatial memory span was measured for 58 abstinent cannabis users (mean age 23.0 years, SD = 3.8 years) using a computer generated grid task. Measures of IQ, mood, substance use history, and demographic characteristics were also obtained. Use of cannabis within 7 days of testing was an exclusion criterion for the study except where the toxicological analysis of urine samples showed samples to be negative for cannabis and other illegal drugs. The independent variable was based on estimated time since last cannabis use (range of 3 to 4,377 days) divided into quartile groups with cut offs at 14, 65, and 615 days. The groups did not differ in lifetime cannabis consumption, or in age for the onset of alcohol and cannabis use, respectively. Significant inter-group effects for background variables were only found for age and Ravens matrices Set E scores. Mean visuospatial memory span progressively improved across the first three quartiles, but the fourth quartile showed the poorest span scores. Whilst a one-way ANOVA showed no significant effect for span scores, simple contrasts showed the fourth quartile to have performed significantly worse than the third. This contrast remained significant when age and Set E scores were controlled as covariates. There appears to be no immediate explanation from substance use or background variables for the reversal in visuospatial memory performance found in the fourth quartile group. Longitudinal or prospective methodology is required for the further investigation of this effect. The employment of battery measures testing a range of cognitive abilities would also be desirable.

Keywords: cannabis, visuospatial memory, abstinence

To appoint problem-solving subtest quota on marriage adjustment of male and female married students in Islamic Azad University (Iran)

SEIRAFI, M. (Islamic Azad University), SABET, M. (Islamic Azad University, Roodehen Branch), HAKAMI, M. (Islamic Azad University)

The aim of this research was to: (1) Appoint the quota of each one of the problem-solving subtests (controlling, creativity and self-confidence) to explain marriage adjustment variance; (2) review of relationship between
gender and marriage adjustment, and (3) review of relationship between gender and problem-solving pieces. This study is under the applied research category and is a correlation study. Out of all students of Islamic Azad University–Roodehen Branch (Iran), 180 male and female married students based on "Morgan" table were selected as a sample for the research. The research tools were "Spanner" marriage adjustment test and "Kedidi" problem-solving scale; and the data were analyzed using multi variable regression. Problem-solving subtests explain almost 1%8 of joint variance between problem-solving and marriage adjustment. There is a negative significant correlation between marriage adjustment and Controlling; and for each unit of standard deviation on Controlling, 0.175 SD would be changed on marriage adjustment. There is a positive significant correlation between marriage adjustment and Creativity and self-confidence and for each unit of standard deviation on creativity and self-confidence, 22% and 19% SD changed on marriage adjustment respectively. Moreover, there is no significant correlation between gender with marriage adjustment and Problem-solving pieces. Problem-solving subtests along with age, social status, level of education, role of gender, number of children, marriage duration, can be one of the effective factors on marriage adjustment; and to increase marriage adjustment some solutions can be made by problem-solving skill training.

Keywords: problem-solving, marriage, creativity, self-confidence, controlling

To learn or not to learn, that is a question: Understanding the low-achieving secondary students in secondary vocational education of mainland China

LAN, Y. (Hong Kong University)

While much is known about the achievement of high ability Chinese students, much less research has focused on their lower ability peers. This poster reports the first study of examining the interrelationships of approaches to learning, academic self-concept, and locus of control and their associations in influencing low-achieving secondary vocational education (SVE) students’ academic achievement. In particular, this study served as a prerequisite to develop appropriate intervention programs to improve SVE students’ academic achievement and assist in their successful secondary vocational employment and development. A quantitative study, the self-descriptive questionnaire (SDQ), learning process questionnaire (LPQ), and internal-external locus of control scale were administered in a 45-minute regular class to all the participants (N =310). Students’ academic achievement data were obtained from the school-based tests files. Path analyses were run to analyze collected data. Path coefficients from academic self-concept to students’ academic achievement and to both deep and achieving learning approaches were substantially positive (p < .01). However, the coefficients from locus of control, both achieving and deep learning approaches to academic achievement were statistically insignificant (and close to zero). This study identified the likely major role of academic self-concept in affecting 1) low-achieving secondary vocational students’ academic achievement, and 2) achieving and deep learning approaches, two approaches that may positively interact with each other to produce high quality learning directly. In particular, the results indicated that intervention programs designed to enhance academic self-concept of secondary vocational students may lead to improved achievement and facilitate their achieving and deep level learning approaches to gain more desirable academic outcomes consistently.

Keywords: learning, academic self-concept, secondary vocational education

Transition in relationships between Hansen Disease sanatorium residents and their hometown families

NUMAYAMA, H. (Sendai Shirayuri Women's College), FUKUSHIMA, T. (Iwaki Meisei University), KIKUSHI, T. (Tohoku Univ.)

Hansen’s Disease (HD) is an infection caused by Mycobacterium leprae. This bacillus has the capacity to invade the skin and peripheral nerves, but it is of low pathogenicity and symptoms rarely appear even in those infected. Chemotherapeutic drugs such as Promin have been found to cure the disease. In Japan, HD
sufferers were compulsorily segregated to remote sanatoriums by national policy until 1996 long after a curative method had been established in the 1950s. Most current residents were obliged to live a life in which freedom of movement, career choice, marriage, etc. were legally restricted for over fifty years. They were not free to return home and their family relationships were also restricted because their hometown families had also suffered serious discrimination. This research examines the transition in the relationships between the residents and their hometown families since entering sanatorium until now, as part of applied psychological analyses of the lives of HD sanatorium residents recognized as a social issue in Japan. We adapted a personal interview method. We conducted interviews on 7 residents (age over 70s). We composed seven chronologies of every resident’s transition using their autobiographies as necessary. The analysis of chronologies showed the following four points. (1) Although the transition process showed two patterns, the relationships were generally characterized by “unidirectionality,” that is, one-way communication from their families to the residents. (2) One pattern is the process from “unidirectionality” through “breakdown” to “reunion,” and the other is the process from “unidirectionality” to “acknowledgement inside the family” without “breakdown.” (3) The transition to “breakdown” was triggered by their parents’ death or their siblings’ marriage, and the transition to “reunion” or “acknowledgement” was triggered by social trends regarding the abolishment of the national segregation policy. (4) Both “unidirectionality” and “breakdown” were designed to protect their hometown families. These results suggest that changes both in social surroundings and in family composition are mainly involved in the transition of relationships mentioned above between HD sanatorium residents and their hometown families.

Keywords: Hansen’s Disease (HD), relationships, sanatorium residents, family, transition

Transport psychology and road traffic safety in Poland

BAK-GAJDA, D. (Motor Transport Institute), BAK, J. (Motor Transport Institute)

Psychological tests for drivers have been introduced in Poland by law as an element of preventive action to enhance traffic safety. The aim of the tests is to eliminate those drivers whose psychical condition may influence their behaviour in an improper and dangerous way. Polish law includes the obligation of psychological tests for professional drivers and for drivers who break the traffic law (collecting demerit points), driving under the influence of alcohol, as well as driving instructors and examiners. Psychological tests for drivers verify their predisposition and driving skills, in particular: psychomotor ability, mental ability, and personality. The methodology (i.e. measures of relevant traits in traffic safety) of psychological tests for drivers will be presented. Specific instruments verify psychomotor abilities: reaction time, distance judgment, speed judgment, night and dusk vision, sensitivity to dazzling, visual and motion coordination. Specific paper questionnaires verify mental abilities, personality and temperament traits: intelligence, attention, memory. Driving a car is a task which demands particular competencies including: knowledge, skills and specific mental features. Every driver should posses: knowledge about traffic regulations, vehicle handling, etc, practical skills of driving a vehicle, prediction of traffic situations and, what is especially important, and self-diagnosis ability. This skill determines whether driving style chosen by the driver will be safe. In Poland, the authorities are also looking for the best solutions. Drivers’ psychological tests attempt to be one of them, through helping drivers in recognizing the proper and safe way of coping with different situations on the road. Traffic psychologists in Poland cooperate in drivers’ education and reeducation programs as well as road safety campaigns. In this respect, the role of transport psychology is to educate young drivers, adults and older road traffic users about safe behaviour in various traffic conditions.

Keywords: psychological testing, Poland, traffic safety, predisposition, driving skills

Traumatic brain injury and secondary psychosis
The relationship between psychotic symptoms and traumatic brain injury (TBI) is unclear, with an estimated prevalence ranging from 0.7% to 9.8%. This dual diagnosis results in significant patient distress and disability, and can complicate broader aspects of rehabilitation. Despite this, our understanding of psychosis following TBI (PFTBI) is poor. Twenty-four papers on PFTBI were reviewed. Studies show a highly variable range of psychosis onset, progression and course. Existing clinical, neurocognitive and localisation data suggested the absence of negative symptoms as a potential diagnostic distinction for PFTBI, revealed common deficiencies in language, verbal memory and verbal learning, and a higher prevalence of frontal and temporal (both left and right) lesions. However, substantial and potentially confounding methodological weaknesses were inherent in the majority of this research. Conceptualisations of the precise relationship between psychosis and TBI, and features of PFTBI, are premature until the considerable methodological limitations shown in the existing literature are addressed in comprehensive and standardised research. We anticipate initiating the first comprehensive investigation of clinical and cognitive/neuropsychological symptoms in PFTBI. Symptom trends that are distinctive of psychosis secondary to TBI may indicate the potential for a separate diagnostic category. Identification of potential risk factors may aid the detection of those at a higher risk for psychosis and allow management strategies to be implemented early, prior to the onset of advanced symptoms.

Keywords: traumatic brain injury, secondary psychosis, psychosis, rehabilitation, risk factors

Understanding the psychological reasons behind microblogging

QIU, L. (Nanyang Technological University), HO, J. H. (Nanyang Technological University)

Microblogging has recently become a new form of communication that is rapidly changing everyone’s life. Through services such as Twitter, millions of people can broadcast short messages to their followers via instant messaging, SMS, or web interfaces. However, few studies have been conducted to understand why people want to microblog. In this study, we aim to understand the psychological motivation behind microblogging. We hypothesize that one is more likely to microblog when one has existential anxiety. We recruited 60 undergraduates and randomly assigned them to the control group and experimental group. Existential anxiety was manipulated using the terror management theory where the experimental group was asked to write a short essay about death, whereas the control group was asked to write about dental pain. Then participants were introduced to Twitter and given an account to post a message. They were told that they could use Twitter anytime during the study. The experimenter then told the participant to wait for the next task and left the room. The participant was left alone in the room for three minutes. This was to give participants opportunities to tweet if they want. Then the experimenter asked the participant to perform another two trivial tasks each with a three-minute break afterwards. One task was to slot 20 pictures into 20 envelopes and the other task was to sort the envelopes into three trays according to their colors. During the 3-min break, the experiment posted tweets (such as “helping my friend with her work” “feeling pretty random right now”) from an account that the participant was following. This was to give participants opportunities to tweet if they want. After the two trivial tasks, we collected all the tweets generated by the participant during the study and ended the study. Our results showed that the experimental group produced significantly more tweets than the control group. This research is the first empirical study that employed a between-subjects design to understand the psychological motivation behind microblogging. Results suggest that people are more likely to microblog when they have existential anxiety.

Keywords: microblogging, communication, existential anxiety, terror management theory, psychological motivation
**Understanding the social consequences of microblogging**

QIU, L. (Nanyang Technological University), KA-YEE LEUNG, A. (Singapore Management University), TANG, N. (Nanyang Technological University)

Microblogging has recently become a new form of communication that is rapidly changing everyone’s life. Through services such as Twitter, millions of people can broadcast short messages to their followers via instant messaging, SMS, or web interfaces. However, few studies have been conducted to understand the impact of these emerging phenomena. In this study, we seek to understand the social consequences of microblogging. Further, we want to examine which aspects of microblogging are related to the consequences. We recruited 120 undergraduates and randomly assigned them to one of four groups (29 to 31 participants in each group). Each group was asked to perform a microblogging task at least once a day for a month. The tweet-only group was asked to tweet without reading others’ tweets (they did not follow others). The tweet-and-read group was required to post a tweet and read others’ tweets (they followed each other). The read-undergrad-only group read the tweets generated by the tweet-only group. The read-nonundergrad-only group read tweets from a pre-selected group of non-undergrad twitter users. We created these groups to understand the consequences of different aspects of microblogging (i.e. regular read-and-tweet, tweet-only, read tweets from people in the same community, and read tweets from people outside one’s own community). Participants completed a battery of surveys (including PANAS, subjective well-being, loneliness, communication, and peer attachment scales) before and after the microblogging treatment. Our results showed that after one month, the tweet-and-read group had a higher level of positive affect (measured by PANAS) than the other groups. The tweet-only group, on the other hand, considered themselves having better communication and relationship with their friends (measured by subscales of the Inventory of Parent and Peer Attachment) than the other groups. This research is the first empirical study that employed a between-subjects design to systematically understand the social consequences of microblogging. Results suggest that both writing and reading microblogs are needed to improve one’s affective state. More interestingly, simply writing microblogs is sufficient to make one perceive or experience better communication and relationship with others.

**Keywords:** blogging, affect, social consequences, communication

**Upper body reach posture and trajectories prediction in three-dimensional workshop**

LU, G. (Beijing Sport University), MOWEI, S. (Zhejiang University)

Upper body reach posture and trajectories prediction has been one of the focus topics in the field of Human Factors. The existing predictive methods, however, should be improved in prediction accuracy, the attainment of natural posture or trajectories and the real time of a prediction. The present study has adopted new perspectives in this field. In the first, the right arm and torso were specified as an eleven-degrees-of freedom kinematic linkage according to the human body’s physiological features. Secondly, the workplace was divided equally into 600 regions. Thirdly, based on real-time longitudinal data collected through three-dimensional motion capture system during the period of the right hand reaching 600 targets in the workplace, the fitting-curve method and the kernel function which stems from self-organization map theory were introduced to predict upper body reach posture and trajectories. The prediction was made in three conditions, namely pointing the target button by natural speed Research ⅰ, pointing buttons by high speed Research ⅱ and pushing the target button by natural speed Research ⅲ. On the basis of those results, an upper body reach posture and trajectories prediction computer system was established. This system can be used in the simulation of upper body motion in computer three-dimensional human modeling, and also in ergonomic design evaluation. It was concluded that different parts of the right arm play different roles during the reach motion period; even the actions in different degrees-of-
freedom of the same articulation are distinct. Reach posture and trajectories mainly depend on the target position, however they are also affected by the motion speed and control type. The approach which integrates the workspace, curving fitting method and kernel functions can be used in upper body reach posture and trajectories prediction, and can also be introduced into modeling the motion of other body parts. The established upper body reach posture and trajectories prediction computer system can satisfy the ergonomic design and evaluation due to its accuracy, naturalness and real-time prediction.

Using unimodal and bimodal congruence effects to assess neural connectivity in individuals with mild autistic traits

TAYLOR, L. (University of Western Australia), MAYBERY, M. (University of Western Australia)

The aim of the project was to examine the assertion that the cognitive profile of autism can be attributed to impaired neural connectivity between distant brain regions. Participants were undergraduate students, selected for either high or low scores on the Autism Spectrum Quotient (AQ). The study employed (a) a bimodal discrimination condition in which participants classified visual stimuli as either high or low on the screen, while instructed to ignore concurrently presented high and low pitched tones, and (b) a unimodal discrimination condition in which participants classified stimuli as high or low on the screen, while instructed to ignore arrow-heads attached to the critical visual stimulus elements. A congruence effect for the bimodal condition (that is, faster response times for high positioned lines paired with high pitched auditory tones or low positioned lines paired with low pitched tones, relative to the alternative stimulus pairings) should reflect long-range neural connectivity, whereas such an effect for the unimodal condition (that is, faster response times for arrows pointing up positioned high on the screen, or arrows pointing down positioned low on the screen, relative to alternative pairings) should involve short-range neural connections. High and Low AQ groups showed a similar magnitude of congruence effect in both the unimodal and bimodal conditions of the discrimination task. Three alternative explanations of the results are: (1) Neural underconnectivity is not a pervasive feature of the autistic brain; rather, it is specific to particular neural regions (for example, the frontal lobes). Thus, limitations of underconnectivity may be more pronounced when tasks involve integrating information between the frontal lobes and other neural regions; (2) Greater symptom severity is related to more extensive underconnectivity in individuals with autism, with individuals with high-functioning autism less affected by neural underconnectivity; and (3) The ‘fractionable’ behavioural traits in autism are underpinned by distinct and potentially separable neurological mechanisms.

Keywords: Autism Spectrum Quotient, cognitive profile of autism, neural connectivity, discrimination task, fractionable behavioural traits

Validation of the anger rumination scale

BESHARAT, M.A. (University of Tehran)

Anger rumination is an inevitable and repetitive cognitive process which occurs during anger experience, continues after anger experience, and increases the duration of anger. Anger rumination has been associated with a wide range of psychological disorders, especially emotional disturbances. The main purpose of this study was to examine the reliability and validity of the Anger Rumination Scale (ARS). Three hundred and eighty four students from the University of Tehran (211 females, 173 males) were included in this study. All participants were asked to complete the ARS, the Tehran Multidimensional Anger Scale (TMAS), and the Mental Health Inventory (MHI). Test-retest reliability and internal consistency of the ARS were evidenced at satisfactory levels. Content validity of the ARS was calculated according to Kendall’s coefficients of concordance for ARS subscales including Angry Afterthoughts, Thoughts of Revenge, Angry Memories, and Understanding of Causes as well as ARS total score. All Kendall’s coefficients of
concordance were statistically significant. The convergent and discriminant validity of the ARS were supported by an expected pattern of correlations between the ARS and the measures of trait-anger, state-anger and, anger-in, anger-out, anger-control in, anger-control out, psychological well-being, and psychological distress. It was concluded that the ARS is a reliable and valid scale for measuring anger rumination.

Keywords: Anger Rumination Scale (ARS), validity, reliability

Validity of computer-assisted health assessment of elderly adults using visual analogue scales and face scales

KIMURA, T. (MOA Health Science Foundation), TSUDA, Y. (MOA Health Science Foundation), UCHIDA, S. (MOA Health Science Foundation), EBOSHIDA, A. (Hiroshima University Graduate School of Biomedical Sciences), YAMAOKA, K. (MOA Health Science Foundation)

Aims of this study were to compare personal computer (PC) administered versions of the visual analogue scale (VAS) and the face scale (FS) and to verify the validity of these scales for use with elderly adults. PC versions of VAS, FS, and the Japanese version of the Perceived Stress Scale (JPSS) were developed. The VAS and FS comprise 3 items: (1) generic quality of life (QOL), (2) health status, and (3) stress. In 2006, 293 participants (105 males and 188 females; 180 younger adults under 60 years of age and 99 older adults) completed the PC versions of VAS, FS and the JPSS, as well as the paper-and-pencil versions of VAS, FS, and the 8-Item Short-Form Health Survey (SF-8). The older group had higher generic QOL and lower stress scores. In the younger group, all correlation coefficients between VAS and FS were over 0.6, whereas in the older group, they were under 0.5 with the exception of health status. In the younger group, correlation coefficients between the JPSS and stress items of VAS and FS; and between the mental component summary (MCS) of the SF-8 and stress items were over 0.5, whereas in the older group, the stress item of VAS was only weakly correlated with the JPSS and not significantly correlated with the MCS. In the case of younger adults, the PC versions of VAS and FS were strongly correlated with paper-and-pencil versions and therefore, computer-assisted data collection was valid for this group. The results for elderly people, however, suggest that the PC versions of VAS and FS did not have sufficient validity, especially with regard to the stress items. Moreover, the conceptual validity of the scales could not be verified. It is suggested that further investigations are needed to improve the PC scales for aged respondents and to develop better explanations for them.

Keywords: Visual analogue scale (VAS), face scale, validity, elderly people, computers

Validity of the basic assumption underlying the comparison question technique (CQT)

HAN, Y.H. (Chungbuk National University), PARK, K. (Chungbuk National University)

Comparison Question Technique (CQT) is based on the basic assumption that psychophysiological responses vary depending on whether the subject receives a relevant or a comparison question and whether the subject is motivated to tell a lie or the truth. One of the major criticisms against CQT to detect lies is that even an innocent subject would show great physiological reactions to a relevant question as compared to the reactions to a comparison question. "Pretest interview" is purported to condition the subject's psychological state that may insure the assumed physiological reactions upon receiving the respective questions given in the main test. The present study examined whether the pretest interview helps achieve its assumed purpose of accelerating innocent subjects' physiological reactions to a comparison question. Subjects were instructed to complete a computer maze game within a predetermined time and were promised a substantial amount of money upon succeeding and abiding by all rules. After the game was completed, the experimenter accused the subject of cheating while playing the game and suggested they take a polygraph test in order to receive the promised...
money. The subjects in the experimental group were subjected to a standard pretest interview for CQT before taking the main polygraph test examined by an expert. The subjects in the control group were subjected to a modified pretest interview. The subjects also rated the amount of pressure felt while answering the relevant and comparison questions given during the test. The subjects in the experimental group showed greater physiological reactions to the comparison question than to the relevant question and felt higher pressure by the comparison question than by the relevant question. On the other hand, the subjects in the control group did not significantly differ between the comparison and relevant question. Thus, the standard pretest interview for the CQT was effective in accelerating innocent subjects’ physiological reactions to the comparison question relative to his/her reactions to the relevant question. This result supports the assumption that, in CQT tests, after the standard pretest interview, innocent subjects would experience more emotional arousal by a comparison question than by a relevant question.

Keywords: comparison question technique, physiological reactions, pretest interview, polygraph test, relevant question

Validity of the Global competence inventory: Ipsative method

TAK, J. (Kwangwoon University), CHO, E. H. (Kwangwoon University), KIM, C. M. (POSCO Research Institute), SONG, C. (KAIST)

This study was intended to examine the validity of the Global Competence Inventory developed using an ipsative method. The preliminary global competence inventory had 18 competencies and 20 items for each competence, making the total of items 360. The inventory was administered to 89 employees working in a global company in Korea and asked them to rate the importance of each item in working overseas. Half of them had overseas working experience. They were asked to select the most appropriate item as well as the least appropriate item for themselves. These employees consisted of four different groups separated by overseas experience as well as the level of performance appraisal scores. The inventory scores were compared to the performance appraisal scores. The results showed that generally, means for each of the 18 competencies were different across four different groups, suggesting that the ipsative method reduces faking effect. Also, the results showed that the high performance group with overseas working experience had higher scores in task-related competencies such as decision making, creativity, leadership, and passion whereas they had lower scores in relation-related competencies such as acceptance of different culture, negotiation, and consilience. These results appear to support criterion-related validity of the Global Competence Inventory. The Global Competence Inventory has criterion-related validity. Also the ipsative method appears to reduce faking effect.

Keywords: faking, global competence, overseas working, ipsative method

Verbalizing the model’s performance in microcounseling: Facilitation of the acquisition of counseling skills by the use of modeling

KAWAGOSHI, H. (Doshisha University), SUGIWAKA, H. (Doshisha University)

Microcounseling is a method for training in counseling skills. Training of microcounseling consists of instruction, modeling, exercise, and feedback. The aim of this study was to investigate the effect of verbalizing the model’s performance in modeling. Paraphrasing, one of the micro skills was used to index the acquisition of counseling skills. It was expected that verbalization of the model’s behavior would improve the acquisition of counseling skills compared with no verbalization. Thirty-five undergraduate students were randomly
assigned to either the verbalization group \( n=18 \) or the non-verbalization control group \( n=17 \). The pre, post, and follow-up (one week from post test) tests were performed in order to examine the variation of paraphrasing scores. Modeling was practiced after the pre test. In modeling, participants of the verbalization group were asked to report the contents of the model’s behavior. Participants of the control group observed the model’s performance without verbalization. The scores of paraphrasing for each group in pre, post, and follow-up tests were calculated. From the pre test to the post test, both groups obtained the performance gain. However, the verbalization group showed a higher performance gain than the control group. The verbalization group performance remained at the same level from the post test to the follow-up test. The control group showed performance loss from the post test to the follow-up test, although the follow-up test score was higher than the pre test score. These findings suggest that verbalization of the model’s performance improves the acquisition and the maintenance of the counseling skills. The conclusion of this study is that verbalizing the model’s performance in microcounseling modeling promotes more effective acquisition of the counseling skills.

**Viewers’ impressions of internet advertisements: An analysis of viewer perception toward the advertising of green tea beverages**

OKANO, M. (Bunkyo University), OKANO, M. (Bunkyo University)

In recent years, the internet has become immensely popular and internet advertising is increasing drastically. However, internet advertising is still at a stage where it is difficult to acquire systematic information on the kind of expressions that are effective for advertising on the internet. This study aimed to clarify the advertising approach on the internet that is highly effective, by conducting an audience rating survey in a natural setting of web browsing. Eighty five participants were asked to evaluate the advertisement homepages of three Japanese green tea beverages. Specifically, the participants were asked to browse through the individual websites built for advertising the three brands, then they were asked to write an essay on their impression about the websites in 100 characters and rate the attractiveness of the advertisement and the purchase intention on 7-point scales. Text mining was performed to extract the frequency distribution of the “main words” from the free-description responses. Some of the commonly used nouns were “game,” “materials,” “trivia,” “quiz,” “tea leaves,” “simplicity,” “top pages,” “green,” and “characters.” Furthermore, correspondence analysis revealed the relationship of these “main words” and the degree to which the participants had a favorable impression of, and were attracted to, the homepages. In the free-description answers, the participants described the contents of the websites using many words like “game” and “quiz,” which they considered to be the characteristic features of the interactive media. It is believed that these features influenced the degree to which the participants had a favorable impression of, and were attracted to, the websites.

**Violence risk assessment: A prospective study in Taiwan**

TAM, W.C. (Chung Yuan Christian University), SHIAH, Y.J. (Kaohsiung Medical University)

One of the important topics in forensic psychology is the violent behavior of persons with mental disorders. Violence risk assessment is helpful in court sentencing or discharge of psychiatric inpatients. In 2005, a new violence risk assessment instrument called the Classification of Violence Risk (COVR) was published in the United States. The goal of this study is to investigate the utilization of the COVR and the predictors of violence of psychiatric patients in Taiwan. Sixty eight psychiatric inpatients were recruited from northern Taiwan, and the COVR and Brief Psychiatric Rating Scale (BPRS) were administered to each participant. The participants and their collaterals were interviewed at the 10th and 20th week after discharge, collecting data on the violent
behavior of the participants. Results indicated that the COVR possessed good inter-rater reliability (kappa = .932~.974), but its validity was not supported significantly in statistics. When age, sex, number of hospitalizations, BPRS score, and Global Assessment of Functioning (GAF) score were controlled, it was statistically significant that patients with schizophrenia had more violent acts compared to those with mood disorders. Results seemed to support the hypothesis that patients with psychotic disorders were more violent than those with mood disorders. However, as the sample size was small, more research is needed to clarify the validity of using the COVR in Taiwan. In addition, future research might investigate the comparison of violence between patients with bipolar disorders and depressive disorders.

Keywords: violence, classification of violence risk, forensic psychology, psychotic disorders, mood disorders

Virtual aquarium could not substitute for a real one

SHUZO, O. (Gifu University), AKIRA, G. (Gifu University), NORIMI, N.

The recent progress in digital electric devices has been remarkable. This trend has been also exceptional in interior goods which make our life soothing and cheerful. A virtual aquarium (VA) was one of such goods developed for this purpose. However, it has not been clarified if a VA can substitute for a real aquarium (RA). The purpose of this research was to determine whether a VA has the same effect as a RA or not. A NEC Uo-Hyakkei, with a 25 inch Braun-tube monitor was used as a VA. The content of presentation comprised of 6 angelfish, 15 false raminose tetras and some types of plants. The presenting (viewable) face, however, was only in front. The RA was almost the same size (26 inches) as the VA, but the content of the RA could be observed through three faces. The content of the RA comprised of 5 white angelfish, 3 siamese algae-eaters, 3 otoconclus and some types of plants. Either aquarium was placed in the corridor by an entrance of a classroom. Subjects were 34 students of a lecture class at this room. One of the aquariums was exhibited in turn and the schedule was as follows: none (phase I: 4 weeks), VA (II: 4 weeks), RA (III: 4 weeks) and VA (IV: 2 weeks). The behaviors of the subjects were monitored through security camera and analyzed for their concerns toward both aquariums. The number of students casting their eyes on the aquarium, and their stopping times in front of the aquarium, were used as indexes for representing their concern towards the aquariums. In the first week of phase II, introducing VA firstly, both indexes showed very high scores. But, as the presentation passed for four weeks, both numbers decreased. In contrast in phase III, first high scores continued to the end. This high concern with the RA, however, did not continue with VA in phase IV. These results showed that although VA attracted the students’ eyes on first encounter, the attraction faded soon. In contrast, RA continued to attract them till the end of the phase. These findings might show that a VA is not a substitute for a RA.

Visual guidance and expertise motor response in spinning baton catching

Takahashi, M. (Tokyo Institute of Technology), IDA, H. (Kanagawa Institute of Technology), ISHII, M. (Tokyo Institute of Technology)

The aim of this preliminary study was to examine the difference between motor response and visual cues of experts and novices. Baton twirling is a sport that requires years of training for manipulation of the baton. It is expected that spinning baton catching requires the accurate motor control of hand movement guided by the visual cues of baton trajectory. The motor and perceptual response of baton catching, especially when baton is spinning, should be different from that of ball catching (Takahashi et al., in press). Takahashi et al. (2007) reported that experts in baton twirling visual search behavior gaze on the center region of baton. Former studies on motor learning showed that reaction time for specific tasks are gradually changed by practice (Schmidt, 1991). This study focused on comparing the motor and perceptual response time among experts and novices. Two expert baton twirler and two novices participated this study. Tasks were to catch the
baton in an imaginary circle (perpendicular = 50 cm) with their right hand. A baton was thrown with spin by one expert baton twirler to participants (distance = 4 m) in their sagittal plane. The tasks were repeated until the number of successful catches had reached 10 trials per each participant. Their catching hand movements and the baton flight were measured by using 3D auto motion analysis system (Motion Analysis Inc., Santa Rosa, CA) with six cameras at 180 Hz. Their eye movements were monitored during the execution of each task, by using an eye tracking system (EMR-8, nac, Japan). Their response time of initial hand and gaze on the center region of baton were analyzed by using collected data. The response time of eye and hand movement of experts were 326.9 ± 128.2 and 421.3 ± 93.2 ms, respectively. Those of novices were 171.1 ± 155.1 and 26.1 ± 97.5 ms, respectively. More analysis is now in progress (the number of individuals for both expert and novice groups has been increased to 10). In the presentation, the stability in expertise motor and perceptual response in baton catching will be discussed.

Keywords: motor response, visual cues, experts, novices, baton twirling

Visuospatial memory in preclinical Huntington's disease

FRICK, A. (Karolinska Institutet), WAHLIN, A. (Stockholm University), GRAFF, C. (Karolinska Institutet), BYRNE, G. (University of Queensland), ROBINS WAHLIN, T. (Karolinska Institutet)

Detecting possible preclinical manifestations of Huntington's disease (HD) is still a controversial issue. Manifest HD has been associated with impairment in visuospatial memory. However, it is still unknown how nonverbal memory is affected in the preclinical phase of HD. The aim of this study is to study visuospatial memory in preclinical HD. Participants (n=70) were recruited through a predictive testing program for HD. The number of CAG repeats in the expanded allele and current age were entered into a regression equation to calculate Predicted Years To Onset (PYTO) of HD. Based on genetic information and median split of PYTO, three groups were formed: carriers with less than 12 years to disease onset (PYTO<12); carriers with 12 or more years to disease onset (PYTO≥12); and noncarriers (NONCARRIERS). Three neuropsychological tests were used to examine visuospatial ability and memory: Rey-Osterrieth Complex Figure Test, copy and recall after three minutes; Corsi Block-tapping Test; and an experimental spatial test where the participants had to memorize the position of 20 objects in a room and relocate them after two minutes delay. All three tests were administered to all participants individually, in the same order. The PYTO<12 group located significantly fewer objects correctly on the spatial test and scored significantly lower on the Corsi Block-tapping Test than the NONCARRIERS group, indicating spatial deficits. No significant differences were found on the Rey Complex Figure Test, or between the PYTO<12 and the PYTO≥12 groups or the PYTO≥12 and the NONCARRIERS groups . The present results suggest that visuospatial episodic memory and working memory are impaired in the preclinical phase of HD before appearance of motor symptoms and diagnosis. These impairments are associated with visual-spatial and three-dimensional object location, but not with visual object cognition, in the carriers with less than 12 estimated years to disease onset. The results suggest not only early dysfunctions in the dorsal caudate nucleus and the putamen, but also in cortico-striatal circuits between the striatum, prefrontal cortex, and parietal lobe.

Keywords: Huntington’s disease, visuospatial memory, nonverbal memory, preclinical Huntington’s disease, motor symptoms

What keeps from taking active behaviors in environmental issues in their daily life in Japan?

YOSHITAKE, K. (Nagasaki Junshin Catholic University), YOSHITAKE, Y. (Kyushu University), YOSHITAKE, K. (Nagasaki Junshin University), FUJIWARA, T. (Nagasaki Junshin University), FUJIWARA, H. (NPO Eco check Network Japan)

Environmental problems are now universal, and the youth need to think of it as their own problem, and do anything practical, themselves, for their world and for their future. Therefore, it is more important to have a sense of public-spirit and we-feelings, but the Cabinet Office in
Japan (2009) suggested that in a questionnaire, individuals in the age of twenties have a strong orientation toward individualism. This study investigated the public spirit, group consciousness and some attitudes about social issues and environmental problems, et cetera. and analyzed what keeps the youth from showing positive behaviors in environmental issues. The subjects are 101 university students, and the method used was a questionnaire. The main factors considered are public spirit, concern about social issues, crisis perception about environmental problems, subjective effectiveness to do ecological movement by oneself, and ecology behaviors in seven areas.

The results are as follows. University students’ group consciousness in their community is low, but ones in their country and world, and their public spirits are high. 95% of them have some concerns about today’s environmental problem. In crisis perception, 86.1% perceive these as pressing matters and 81.2% perceive it as getting serious. Those with low concerns about social issues generally have lower concerns about environmental issues than those with high social concern ($t = 2.78, df = 99, p < .01$). Those with low concerns about environmental issues have a lower crisis perception of environmental issues ($t = 2.32, df = 92, p < .05$) and feel more helpless in performing ecological behaviors by oneself ($t = 3.16, df = 89, p < .01$) than those with high environmental concerns. Those with low environmental concerns do not take more positive action across seven environmental areas, than those with high environmental concerns ($F = 7.98, df = 1.98, p < .01$). When separating the trash they act positively, but in wearing warm or cool clothes without using air conditioners, they don’t act positively.

To conclude, the difference of ecology behaviors in private and public spaces was investigated. The effects of the way of setting up spaces was suggested. Ideas for everyone to urge positive actions in environmental issues was discussed using the described data.

Keywords: ecology behaviors, environmental issues, public spirit, group consciousness, Japanese

What makes children suggestible?
Examining the relative contributions of linguistic, pragmatic, metacognitive and social/contextual factors

This study aimed to examine the impact of and interactions between linguistic, metacognitive, pragmatic and social/contextual factors, on suggestibility in child eyewitnesses. 112 early elementary school children completed the Video Suggestibility Scale for Children (Scullin & Ceci, 2001), in which misleading questions about a video they had viewed previously were asked, and then repeated following either positive or mild negative feedback. A fresh set of questions were then asked and repeated in the same manner. Children were also tested on pragmatic ability, language ability (syntactic and semantic) and metacognitive ability (calibration of confidence judgments), as well as memory for the video (free recall). While all pragmatic measures showed developmental trends, they did not all appear to tap a single underlying competence. This was reflected in the correlations between the measures, in particular in the correlations between the pragmatic measures and responses to the repeated questions vignettes. The newly developed measures showed good internal consistency and proved engaging to the children. Implications for forensic contexts are discussed. In regards to yielding to initial questions, after controlling for age, lower yielding was associated with both higher language ability (in the second set of questions), and superior calibration performance. Neither pragmatic ability nor memory trace strength (free recall) predicted yielding. In regards to shifting to repeat questions, contrary to expectation, better language ability was associated with more frequent shifting. As expected, better calibration was associated with less shifting, at least in the first set of questions, and there was a borderline negative association between pragmatic ability and shifting. Strength of memory trace did not predict shifting. Although negative feedback elicited markedly more shifting than positive feedback, it did not impact on the association between individual difference factors and shifting. There were no significant interactions between predictors. The results provide some evidence that individual differences in children’s pragmatic, language and metacognitive abilities.
can provide protection from suggestibility. Although pragmatic ability did not appear to protect children from yielding to misleading questions, it was associated with decreased vulnerability to shifting when those questions were repeated. By contrast, greater general language competence was associated with reduced vulnerability to yielding, but increased vulnerability to shifting. Superior calibration was associated with reduction in both yielding and shifting. Memory trace strength showed no predictive power. Importantly, we found no evidence that metacognitive, memorial and social factors interacted to influence suggestibility, and no evidence of age differences in the effect of these factors on suggestibility. Forensic implications are considered.

Keywords: child eyewitnesses, meta-cognition, language, suggestibility, pragmatic ability

What protects migrant children from social maladjustment in China

YIBING, YU (Anhui Agricultural University), YING, Y. (Beijing Normal University)

Migration is a complex experience for rural children who have to move with their parents to the city in China. Many researchers indicated that migrant children have negative consequences in their mean level of psychosocial development compared to their urban partners. Positive adjustment in migration children has received relatively little attention. Therefore, this paper aims to reveal the positive adjustment and key protective factors for migrant children. In this research, 693 migrant children are contrasted with 345 urban students. Three domains of social adjustment (including behavioral, academic and real-life satisfaction variables), and prospective protective factors (such as personal and parental variables) have been examined with self-administered questionnaires. Based on the literature review, the author operationally defined “positive adjustment” as having higher scores in social adjustment variables than that of contrasted urban partners in each domain. The results indicated that nearly half of the migrant children have positive developmental results in at least one domain, and at least a quarter of the target participants are well adjusted in each domain. Logistic regression revealed that personal mastery is the common key protective factor in all domains and that there are specific protective factors associated with different domains. So, this result argued that the migrant children are not a risk population as a whole. There are domain-universal and domain-specific protective factors in social adjustment.

Keywords: migrants, children's adjustment, psychosocial development, personal mastery, protective factors for migrant children

What romance stories tell us about love?
A content analysis on couple intimacy in popular Chinese romance novels

CHAO, W. (National Taipei University of Education)

Research studies have indicated the impact of reading romance novels on people’s expectations of relationships, gender roles, and beliefs on intimacy. This study examined what messages romance stories convey on intimacy. Content analyses were conducted on the texts of four representative Chinese romance novels by a popular Chinese romance novelist Qiong-Yao. Four aspects of intimacy were examined in the novel characters’ intimate interactions: the bonding process between couples, intimate conflicts and their resolution strategies, gender roles and their beliefs about love. Results show (1) not only his/her appearance, but also if he/she treats your family members properly and considerably, can touch a lover’s heart; (2) Conflict resolutions between couples are often initiated by others (e.g., parents); (3) Conflicts are often dissolved in dramatic, mystical processes, in which both couples participate passively and contribute little; (4) Gender roles are predictably stereotyped, more so on male characters than on females; (5) Themes of many stories convey a belief of karma (predictable results due to external, uncontrollable causes, regardless the intimate process per se), leading to a passive attitude toward intimacy management. Messages abstracted from romance novels can motivate readers toward external, unstable attribution in intimate relationships. Applications of these popular romance cultural messages for gender education and couple counseling are proposed.
Keywords: romance novel, intimacy, couples therapy, gender roles, conflict resolution

What’s the ideal leader? Managers’ visions in three different European countries

PELLERGRINI, M. (IIIT, Mexico), SCARATTI, G. (Cattolica University of Milano), PAPPALARDO, P. (University of Padova), TRONCHET, S. (University of Verona)

Following the previous research titled “The Effectiveness of Leadership - the feedback of direct report subordinates as an element of comparison and improvement for the manager” (Pellegrini M. et al.) presented in the recent international congress of Berlin 20-25 July 2008, we decided to delve into this topic by analyzing all data at our disposal. The aim of this research (in a cross-country prospective) is to explore, in great detail, the perceptions of managers concerning what they recognize as the ideal leadership style. The sample consists of a group of 600 European workers and their 100 managers, working in 42 European companies in various sectors (industry, distribution, energy, finance, service, and food). The survey instrument is an on-line questionnaire (126 items) on Leadership-style Grid feedback 360° (Blake and Mouton - Managerial Grid Model). The main focus is on managers and their ideal vision of the most effective leadership style, with comparisons in three different cultural contexts (Italy, Germany and Czech Republic). Analysis of data, by using the non-parametrical method Kruskal Wallis, highlights significant differences between the three groups on the perception of the ideal leadership style, in particular on 9.9 style ($\chi^2(2) = 7.123; p < 0.05$ Post hoc analysis p global = 0.05/3 = 0.017; Bonferroni’s correction). We notice that the ideal leader for German managers is oriented towards 9.9 style (mr(D) = 59.59), more than Italian managers’ ideal (mr(I) = 50.13) and Czech managers’ ideal (mr(CZ)= 41.73). We can highlight, in addition, significant differences on 9.1 style ($\chi^2(2) = 14.744; p < 0.01$ Post hoc analysis p global = 0.01/3 = 0.003 Bonferroni’s correction) as the ideal leader for Italian managers (mr(I) = 60.47) is more results-oriented than the ideal leader for German managers (mr(D) = 40.34). We can also highlight that the ideal leader for Czech managers (mr(CZ) = 60.71) differs from the German ideal (mr(D) = 44.71) on 5.5 style ($\chi^2(2) = 12.428; p <0.01$ Post hoc analysis p global = 0.01/3 = 0.003 Bonferroni’s correction). Last of all, European managers (German in particular) are ideally 9.9 oriented (M-Italian = 85.33; M-German = 89.94; M- Czech = 77.65). Italian managers have a concept of the ideal leader being a little more oriented to results and control of their employees (9.1 style). The Ideal leader for Czech managers has a preference for compromise and balance (5.5 style).

Why do individuals who score high on psychopathic traits fail to respond appropriately to cues of distress in others?

MARETTI, C. (University of New South Wales), KEMP, R. (University of New South Wales), DADDS, M.

Individuals with psychopathic tendencies (namely those who score high on callous-unemotional traits) fail to respond appropriately to signs of distress in others (e.g. sad and fearful faces) and this is thought to contribute to the high levels of aggression in these individuals. However, the underlying mechanisms of this deficit remain unclear. We aim to determine if this failure is due to an inability to recognise signs of distress or whether these sign are recognised but do not lead to an inhibition of aggression (i.e. the Violence Inhibition Mechanism is dysfunctional). Participants compete in a competitive computer game against a simulated opponent. During the game, the participant has the opportunity to blast their opponent with a loud noise, the intensity of which provides a measure of aggression. This paradigm is used to study the effect of expressions of fear on the level of aggression displayed. Based on previous research, it is hypothesised that individuals with psychopathic tendencies will not be inhibited in their aggressive behaviour in condition 1, however in condition 2, the increase in the salience of the opponents distress will lead to a reduction in aggressive behaviour. Preliminary results will be reported. We anticipate that increasing the
salience of the opponent’s distress leads to an inhibition of aggressive behaviour in individuals with psychopathic tendencies, suggesting a deficit in the attention and processing of emotional cues in their environment. However, if participants fail to respond to signs of fear, this suggests that the Violence Inhibition Mechanism is dysfunctional. The findings of this research will clarify why it is that psychopathic individuals fail to respond appropriately to signs of distress in others. Further this research will test some of the predictions made by a widely cited model of aggressive behaviour in psychopathic individuals, The Violence Inhibition Mechanism Model. The implications of this research will be applicable to intervention strategies tailored for this subset of the population, such as training these individuals to focus on and be more alert to the emotional signals of others.

**Why migrant workers want to leave? The importance of industrial work adaptation**

CHEN, S. (Peking University), WANG, L. (Peking University), YANG, Q. (Peking University), LIN, W. (Peking University), KONG, H. (Luxottica Group), YU, Z. (Luxottica Group)

Most industrial workers in China’s manufacturing industry come from rural areas, and high turnover rate of these migrant workers has seriously impacted organizational performance. Based on the person-environment fit theory, we believe that whether migrant workers adapt to repetitive and intensive work in mass production (industrial work adaptation) is one of the crucial factors leading to turnover intention. In order to empirically measure this effect, we developed the Industrial Work Adaptation Scale (IWAS). We conducted two studies. In study 1, we generated 16 scale items from the existing literature on person-environment fit, industrialization and related constructs. The scale was administered to 582 migrant workers of a large manufacturing company located in southern China. Study 2 tested the scale using a new sample and tried to determine the mechanism between industrial work adaptation and turnover, which is supposed to be job burnout. In study 1, we conducted exploratory factor analysis and confirmatory factor analysis, which resulted in a 7-item scale. IWAS was demonstrated to have acceptable psychometric properties; evidence of convergent, discriminant, and incremental validity was provided. IWAS was strongly related with job satisfaction, organizational commitment, organizational justice, perceived supervisor support and in particular, turnover intention. Study 2 further validated the psychometric properties of IWAS. Industrial work adaptation predicted turnover intention ($β = -0.072$, $p < .01$), and especially burnout ($β = -0.041$, $p < .01$), which mediated the relationship between industrial work adaptation and turnover intention ($ΔR^2 = 0.088$, $p < .01$). Overall, the present studies suggest that the Industrial Work Adaptation Scale is a reliable and valid measure. These studies expand the comprehensiveness of the current research on high turnover rates of industrial workers. Theoretical implications of the IWAS are discussed.

**Will you be my child again?’ The meaning of giving birth to another child to parents who lost their child in a traumatic accident**

CHEN, S-F. (Department of Psychology and Counseling), LIN, Y.C. (Jing Chuan Child Safety Foundation)

The aim of this study was to explore the grief adjusting process of parents who lost their child in a traumatic accident, and how they construe the birth of a newborn child. Authors of this research worked with 3 pairs of parents with kindergarten children who died in a car accident in Taiwan in 1999. The parents were traced for ten years worth of relevant documents including news reports, working records, field notes of social workers, and interviews of these parents, in order to conduct a qualitative analysis of each case study. Results revealed that (a) giving birth to another child was often construed as an attempt to “get the lost child back” by these
parents, with or without planning the birth; (2) the newborn comforted these parents by engaging them with child bearing and having hope again for its future, nevertheless its effect on mitigating parent’s grief varied between and within families; and (3) parents show apparent transference and over-protection parenting toward the newborn. To conclude, (1) these parents can benefit from other’s empathic acceptance for their attempt to give birth to another child; (2) reflecting on their grief process can facilitate adjustment of these parents; and (3) it is a useful reminder for these parents to be aware of their parenting, in order to avoid over protection of their newborn child.

Women and stress: Psychoneuroimmunology and the role of vitamin supplementation

OLIVER-BAXTER, J. (University of Adelaide), WHITFORD, H. (Cancer Council Australia), TURNBALL, D. (University of Adelaide), OLVER, I. (Cancer Council Australia), CHAMBERS, A. (Flinders University)

A possible mechanism linking chronic stress, immune dysfunction, and disease has been termed the Oxidative Model, referring to the oxidative imbalance of cells associated with antioxidant status and psychological distress. The current study applies this model to determine whether taking supplements targeted at people experiencing chronic stress can prevent the depletion of nutrients required for effective immune function. Improvements in psychological and physiological wellbeing were explored using a Randomised Control Trial (RCT) including a supplement designed to decrease the physical impact of stress (active) and a placebo group (control). A sample of 60 general population women experiencing chronic psychological distress was employed. Psychological parameters included distress, coping styles, anger expression, loneliness, anger expression, family relations, and the State-Trait Personality Inventory. Based on previous research, biochemical parameters included 5’-eectonucleotidase (NT), Homocysteine (HCY), Tissue Ascorbate (VITC), and C - Reactive Protein (CRP). Specific to this study, biomarkers Cholesterol (CHOL), Total Antioxidant Status (TAS), Lipid Oxidation (LO), Folate (FOLATE), Vitamin B12 (VITB12), and inflammatory cytokines (IL-1β, IL-5, IL-6, IFN-γ, TNF-α, TNF-β, and IL-10) were also assessed. Allocation to the active group was linked to significantly increased FOLATE ($p = .000, \eta^2 = .27$) and VITB12 ($p = .01, \eta^2 = .16$) levels. A Wilcoxon Signed Rank Test revealed a statistically significant decrease in inflammatory cytokine levels in the active group: IL-1 ($p = .01, \eta^2 = .40$), TNF-α ($p = .02, \eta^2 = .40$) and TNF-β ($p = .003, \eta^2 = .42$). Improvements in physiological status for NT ($p = .02, \eta^2 = .14$) and HCY ($p = .01, \eta^2 = .16$) were observed for all participants across the trial. Conversely an increase in LO ($p = .003, \eta^2 = .18$) was seen. Exposure to vitamins at times of psychological distress did not conclusively improve physiological or psychological wellbeing by the mechanisms proposed by the Oxidative Model. However levels of inflammation decreased for those randomized to the active group. Future research using this model would benefit from employing a more homogenous chronic stress sample, improved sensitivity, and/or specificity of a screening tool for psychological distress. More research into therapeutic levels of nutrient supplementation is required.

Women’s conflicted views towards gender roles in contemporary Japanese society

NAMEDA, A. (Ritsumeikan University)

In recent years, while an increasing number of people tend to show a desire to take part in performing both paid work and household work, in reality men spend most of their time in paid work and women mainly spend time in both paid work and household work. This situation shows that there is a gap between their views and practices in dividing family work. In order to understand how people’s expressed views are not practiced, the purpose of the present study was to grasp how people view the gender roles. Semi-structured interviews with three unmarried women with no prior work
experience were conducted to gain data. The interviews started by asking the question “What do you think gender equality is?”, and asked the participants about their experiences and views in terms of gender issues and of the roles in their family. The discussion in the interviews was about their individual experience of gender, the division of family work for the parents, the views towards roles in their own future family and general views to gender issue in society. Results from the analysed text data was that there were multiple voices that were not necessarily consistent each other in and across contexts, even in the one participant. The voice representing the hope of being with their children conflicted with the voice representing their view of busy paid work, for example. In addition, while in the context of their own family work or society, the participants tend to express the disagreement with the pattern of gender roles dictating that “men have paid work and women do household work”, the gender division of family work for parents was normal and likely to be comfortable for them. Considering the fact that each participant had both of experiences or views supporting gender roles and not supporting gender roles, it is thought that the participants possibly make decisions for either following the gender roles or not following gender roles.

Work and home demands and satisfaction: A work-life balance model

MUSCALU BRATESCU, I.C. (Nagoya University), MATSUMOTO, M. (Nagoya University), ATSUKO, K. (Nagoya University)

In achieving satisfaction with work and home life, work-life balance strategies are used. The aim of this study was to test a work life balance model using the data drawn from Romanian office workers and structural equation modeling. We assumed that the condition of high work, respectively home demands, would be associated with low levels of control over work, respectively job demands and low perceived work and home social support, satisfaction with work, respectively home and work life balance become low. The data is to be collected from approximately 200 respondents. When work life balance is low (low satisfaction with balance and low work-life balance skills), anxiety and depression levels are probably increasing. Low work, respectively home control over tasks and low work, respectively home perceived social support probably associates positively with low levels of using work-home adaptive strategies and low satisfaction with work and home. We assume that control and social support from work and home, together with work-home adaptive boundary strategies, enhance work, respectively home satisfaction that, in their turn enhance the formation of work-life balance skill, which associates negatively with low levels of general mental health. All hypotheses will be tested using quantitative methods. The questionnaires are validated using the parallel blind technique. The snowball technique is used as sampling method. Half of the sample will receive the set of questions regarding work (demands, control, support, satisfaction) to complete first; the other half will receive the set of items measuring home (demands, control, support, satisfaction). These findings will be discussed in relation to the formulation of a work-life balance model of work and home demands and satisfaction.

Work motivation and desirable and undesirable personality traits according to Indian students and employees

MATHEW, T. (Bond University), HICKS, R. (Bond University), BAHR, M. (Bond University)

The last few years have seen a salient increase in trade relations between Australia and India (Hebbani, 2008). India is Australia’s fastest growing major export market and investments between Australia and India are also increasing (Rudd, 2008). India is a lucrative market as it has a growing middle class of 300 million people with a growing purchasing power of approximately 85 billion Australian dollars (Harcourt, 2007). As trade relations between Australia and India are on the rise, understanding what motivates Indians and what they consider desirable and undesirable personality characteristics will provide a
competitive edge to organizations in Australia looking to enter the Indian market. In order to gain a richer and better understanding of what motivates Indian students and employees and what according to them are desirable and undesirable personality characteristics, semi-structured interviews were conducted. The interviews were recorded on a voice recorder and later transcribed into text. The interviews were then content analyzed. Results revealed that Indian students were motivated to study for their future careers and family expectations, whereas Indian employees were motivated at work by several factors such as money for survival and to provide for their families. Some of the personality characteristics considered desirable by Indian employees were conscientiousness and humility, whereas Indian students thought being friendly and respectful of teachers were desirable characteristics. Some of the personality characteristics considered undesirable by Indian employees were being political and arrogance, whereas the students felt that some of the undesirable characteristics were laziness and disobedience. It is hoped the findings of the present study will have practical implications for both Australian organizations in India and Indian organizations in terms of selection, training, development and compensation.

Working memory capacity and individual differences in empathy

YOSHIDA, A. (Tohoku Fukushi University)

What is the origin of individual differences in empathic concern? Although the theoretical importance of empathy has long been recognized, the origins of these individual differences were largely unknown. In this study, we investigated the effect of working memory capacity (WMC) on individual differences in empathy. A Japanese version of the Reading Span Test (Osaka and Osaka, 1994) was administered to 24 female university students. Participants were then asked to complete the Sakurai’s (1988) Japanese version of the Interpersonal Reactivity Index (Davis, 1983), the Basic Social Skills Inventory (Horike, 1994) and the Social Skills Inventory (Kikuchi, 1995). The IRI scale consisted of four subscales: perspective-taking, fantasy, empathic concern, and personal distress. Also, the SSI scale consisted of three subscales: encoding, decoding and control. The results revealed that the individuals low in WMC had significantly higher perspective-taking scores than the high-WMC participants ($p < .01$). We also found no significant coefficient of correlation between skills and empathy for the low-WMC participants. Turning to the individuals high in WMC, we found a negative coefficient of correlation between reading skill and empathic concern ($r = -.584$), and a negative coefficient of correlation between encoding skill and individual distress ($r = -.796$). These findings suggest that people who are deficient in working memory capacity may have difficulty distinguishing self from others in empathic situations, and that working memory capacity functions as a moderator of the relationship between skills and empathy.
