Past work design research has emphasized a set of task-focused work characteristics. More recently, scholars have called for a broader focus on socially oriented work design features (Morgeson & Campion, 2003; Parker & Wall, 1998). Although this call has been answered both empirically (Morgeson & Humphrey, 2006) and theoretically (Grant, 2007), there are many other relationally oriented aspects of the work environment likely to be important for work design and employee outcomes. This includes the nature of the relationship between leaders and followers. The quality of the relationship between leaders and followers has been shown to be related to numerous affective and behavioral outcomes (Gerstner & Day, 1997; Ilies, Nahrgang, & Morgeson, 2007). Yet, we are unaware of any research linking leader-member exchange (LMX) to work design. This is unfortunate because the role taking, role making, and role routinization stages that characterize the development of leader-member relationships are likely to have significant implications for a role’s work characteristics, in part because the testing episodes that result in high or low quality relationships will tend to lead to more positive (or negative) work characteristics. In turn, work characteristics are expected to be related to work outcomes such as satisfaction, task performance, and organizational citizenship behavior. We seek to explore these two possibilities across a wide range of work characteristics. We empirically examine these issues in a field sample of 311 full-time workers who hold a variety of different jobs. Job incumbents completed the Work Design Questionnaire (WDQ; Morgeson & Humphrey, 2006), which measures 18 work characteristics and job satisfaction. Supervisors provided judgments of job incumbent task and citizenship performance. Both sources provided ratings of LMX. As shown in our results, both incumbent- and supervisory-rated LMX is significantly related to numerous work characteristics, particularly the task and knowledge characteristics. This provides support for the idea that more positive leader-member relationships are related to higher levels of work characteristics. The work characteristics, in turn, are frequently related to satisfaction, task performance, and organizational citizenship behavior. Implications of these results for work design research and theory will be discussed.

Keywords: work design, relationships, leader-member exchange, leadership, followers

Towards a theory of collaborative work design

CORDERY, J. (University of Western Australia)

The scope of work design theory has recently been expanded to incorporate aspects of task, job and role content that derive from the social context within which work is performed (Humphrey, Nahrgang & Morgeson, 2007). Work characteristics that arise from tasks and activities involving interaction with others have been identified as playing a significant role in determining employee behavior, affect and well-being (Grant & Parker, 2009). In the main, theory and research in this area have focused on relational characteristics of jobs and roles as they are enacted and experienced by employees. Much of contemporary service work is collaborative in nature, however, with customers engaged in performing key tasks and activities interdependently with those performed by employees, as co-producers of service outcomes. The increasing frequency of such boundary-spanning collaborative work has significant implications for work design research and practice. In the first instance, it points to the need to consider how properties of tasks and activities that customers engage in as part of such collaborations affect their behavior and attitudes. Second, it opens up the possibility for research into the nature and effectiveness of collaborative work designs at

537 Symposia
both dyadic and group levels, where membership of those collaborating units includes both employees and non-employees. In this paper, I document the rise of collaborative co-production work in service organizations, and present a theoretical framework designed to guide future research into collaborative work designs. This model identifies inputs at the individual, dyadic and group level that are likely to influence a range of effectiveness outcomes for this type of work.

Keywords: work design, work characteristics, well-being, relational characteristics, collaborative co-production work

Job Crafting: A further exploration of the construct and its relationship to job design and goal choice

UNSWORTH, K. (University of Western Australia)

The construct of job crafting (“the physical and cognitive changes individuals make in the task and relational boundaries of their work”) has gained widespread attention since its conception by Wrzesniewski and Dutton (2001). However, very little work has been done to further explore the construct and how it might work. In this paper, I suggest that job crafting is a form of self-regulation. This repositioning of job crafting allows us to: 1) identify a much broader range of job crafting strategies than those suggested by Wrzesniewski and Dutton (2001); 2) draw upon a literature that has identified some of the mechanisms and processes involved in affecting motivation and performance; and 3) examine how it interacts with job design. Based on control theory (Carver & Scheier, 1981), I suggest that job crafting is most likely to occur when there is a discrepancy between the task (performance) and personal higher-order goals (goal). Feedback from job crafting efforts will provide information as to the current level of discrepancy and, unlike current theorizing, I suggest that when the discrepancy is sufficiently reduced then job crafting will stop. Furthermore, based on Bandura (1986), I suggest that one’s self-efficacy to make changes will be a key factor – when an individual has low self-efficacy (due either to other individual characteristics or the situation they are in), then they are unlikely to produce changes. To date, there is little understanding about how job crafting increases meaning, however, using the self-regulation literature we can draw upon research on goal choice and goal hierarchy. I suggest that job crafting strengthens the relationships between lower-order task goals and higher-order personal goals. Finally, I suggest a more sophisticated model of the relationships between job crafting and job design by separating behavioural job crafting (actually making changes to the job) and cognitive job crafting (thinking about the job differently). Most importantly, I suggest that cognitive job crafting will affect perceived job design but that, in contrast to behavioural job crafting and previous theorising, will not be reciprocally affected by the design of the job.

Keywords: job design, self-regulation, motivation, performance, control theory

Multilevel approaches to stress management: Trading off certainty with impact

MORRISON, D. (University of Western Australia)

When considering stress intervention strategies within organisational settings a variety of options are available to practitioners including job redesign, clarification of role relationships, developing coping skills, and employee assistance in terms of medical or psychotherapeutic treatment. It seems that many organisations focus on some but not all of the above when seeking to ameliorate the effects of exposure to stress. The most commonly used interventions appear to address stress in the work place at the individual level as opposed to assuming a broader perspective that incorporates organisational change of some sort. The question often asked is which approach is likely to be the most effective given that in one way or another all approaches are expensive. Evidence from a series of studies is presented which suggests that changes at the job level in objective job characteristics will have a modest but highly predictable outcome. The vast majority of variance in the stress experience is found at the individual level. Approaches to dealing with stress at work at the individual
level, such as skill development, improved selection and delivery of employee assistance, are more varied and less predictable in their impact perhaps because they interact with contextual variables. The stress experience seems largely to rely on individual perceptions of self and context and it is argued in this paper, therefore that it seems likely the biggest gains will be found with management/supervisor training in impression management of the context as well as employee perceptions of their work situation.

Keywords: stress management, job redesign, role relationships, coping skills, individual level

**Quality of life in the span of development in intercontinental perspective**

Chair(s): FRESE, M (IAAP Department of Psychology University of Giessen)

Discussant(s): SINGH, A P. (Govt. M.L. B. Girls P.G. College Bhopal M.P.)

Globalization is leading the world to become one unit. The different continents are no longer a barrier to development. This is also encouraging the citizens of developing countries to move towards developed countries and as a result the problems associated with migrants are emerging. Transitional traumas and adjustment affect mental health in both positive and negative ways. This symposium will focus on the quality of life of the Indian population in terms of life span, development, and the intercontinental perspective. In this symposium the research paper represents a study based on longitudinal case studies about patient gender and life span development stages: adolescents, adults, senior adults, old aged. Data analyses consisted of correlational and comparative qualitative and quantitative analytical methods. Two papers focus on dual continental aspects while the other three focus on the status of women, cancer patients and community living older people in reference to quality of life. The key learning objectives are to understand the impact of Quality of life on different stages of life span development, to analyze the impact of migration on Quality of life, to analyze the impact of dual Continental living on Quality of life on different populations, to analyze the impact of community living on Quality of life in old aged multicultural populations, and to understand the importance of subjective Quality of life parameters in the Asian/Indian culture and mental health.

**A comparative study on quality of life of Asian adolescents, adults and senior adults living as us citizens**
PATEL, G. (YAI - National Institute for People with Disabilities New York City)

An “age relevant” concept of development (Baer, 1970) focuses not on the age at which a particular experience occurred but rather the point in sequence that the experience occurred. A significant role for life span developmental intervention lies in the identification of ageism and internalized age related norms. There is no single, universally accepted definition of Quality of Life (QOL; Lauer, 1999). The World Health Organization definition, for example, focuses on the subjective perspective (EHOQOL Group 1993), whereas other constructs are broader and include objective indicators of health, housing, and other material circumstances. According to recent reviews (Lauer, 1999), most researchers believe that both subjective and objective information is necessary to understand QOL. With such concerns in mind, this study was designed to investigate the relationship between QOL across three different stages of life span development (adolescent, adult and senior adult). The sample consisted of 30 randomly selected individuals of Asian background (15 Male, 15 Female) who were residents of the US and held US citizenship. Within this sample there were 10 adolescents (five male and five female) aged between 13 and 18 years, 10 Adults (five male and five female) aged between 21 and 28 years, and 10 Senior Adults (five male and five female) aged between 58 and 65 years. A QOL Scale, which was developed from Lehman’s QOL scale (Olive et al., 1997), is a researcher-led questionnaire enquiring about objective life circumstances and subjective life satisfaction in nine domains — work/education, leisure, religion, finances, living situation, legal/safety, family relations, social relations and health — and it includes subjective ratings of overall well-being. The subjective satisfaction ratings were recorded on a seven point Likert scale (‘delighted - terrible’). The study found a significant difference between QOL and age groups. The difference was observed among males and females in the Senior Adult group. A two way interaction also indicated this difference. The study concluded that there is a difference in the level of subjective QOL and age groups. That is, the Asian senior adults who migrated from their native countries later in life reflects low subjective QOL as compared to other groups who migrated at early age. Asian adolescents who are born in the US demonstrate a higher level of QOL at the objective level.

Keywords: age, quality of life, well-being, adolescents, senior adult

Quality of life in the span of development: Case study on dual continental perspective

SHARMA, A. (Multi linguistic Specialist South Eling), TYAGI, (Govt. M.L.B. Girls P.G. College Bhopal M.P.)

Development is not usually explained as an empirical term (Reese & Overton, 1970), however, on occasion it is (Kaplan, 1983). Many times what happens across the life span is what constitutes development. The concept of development centers on the value based notion of improvement. According to the life span perspective, development is a life-long, interactive, multidimensional, multidirectional, culturally, and historically embedded process that shows plasticity, involves both gain and losses and is a multidisciplinary field of study (Sugarman, 2001). Quality of life has been interpreted in many different ways, for example, it has been interpreted as satisfaction (Summers, 1976), happiness (Esterling, 1978), psychological wellbeing (Andrews & Withey, 1978), and degree of fulfillment of important goals (Frish, 1989). In Positive Psychology, the scientifically unwieldy notion of happiness is broken down into further quantifiable aspects: positive emotion (the pleasant life), engagement (engaged life), and purpose (meaningful life) (Seligman, 2008). In spite of globalization there is demarcation between developed and developing countries in terms of physical, social, cultural and psychological environments. India is the amalgamation of different cultures, geography, economic status, changing values, gender discrimination, and rapid change where as European and Western continents have gender equality, modernity, comfortable life styles and discipline. Since last century, a lot of internal pressures have affected the quality of life, wellbeing and mental health of Indian citizens who have moved out of the country. The aim of present study was to analyze the quality of
life across the span of development of an Indian individual in the dual-continental perspective. The methodology involved the analysis of a longitudinal case study of an Indian female (aged 56 years) who was a resident of London for the past 30 years after migrating from India at the age of 25 as a single female, who lead a positive and high quality life. The case study focuses on the psychological phenomenology of an Indian female and the factors which contributed to positive living were analyzed. The results show that a positive attitude, social and economical security, self regulation, locus of control, job satisfaction, disciplined life style, and happiness contributed to positive living. The analyses of case study show that according to the dual continental perspective, the physical quality of life is high in the European continent but psychological wellbeing is high in the native continent. In conclusion, this case can be applied to dual citizenship so that positive life and living can be enhanced.

Keywords: quality of life, development, positive psychology, dual continental perspective, India

Life skills for quality of life at old age: Need for community well-being

SINGH, A. P. (Govt. M.L. B. Girls P.PG. College Bhopal M.P.)

Ageing is virtually a universal phenomenon. The world community seems to have become increasingly aware of the multifarious issues that surround old age. This concern is attributed to the increasing number of older people in the population and its consequential demands for health, mental health, and care. Quality of life is a holistic concept. Quality of life is defined by WHO as an individual’s perception of his/her position in life in the context of culture and values system and in relation to their goals, expectations, standards, and concerns (WHO QOL group, 1995). UNICEF defines “life skill” as the psychosocial and interpersonal competencies in a person that enable him/her to deal effectively with the demands and challenges of everyday life. The impotence of a ‘healthy community’ has been recognized as an emergent field of research to understand the linkages between human survival, the ecosystem and wellbeing. The concept of wellbeing has been defined as the state of being healthy, happy or prosperous. Community wellbeing is an emerging concept that needs exploration through empirical research to understand the indicators of wellbeing, empathy, understanding, security, and psychosocial conformity by living together in a social community. The present study focuses on exploring life skills which enhance quality of life among older people who are living in a small community and to see whether this leads to community wellbeing and a positive life. The sample consisted of 50 male and female participants (aged 70 to 80 years) who were randomly selected from Aasara old age home (multicultural) in Bhopal M.P. India. A life skill questionnaire was developed and administered to find out the correlation between life skills and quality of life. The two way interaction between gender and age reflected a significant difference in the type of life skills and quality of life. It was found that positive life skills enhance quality of life and quality of life contributes to community wellbeing.

Keywords: quality of life, community wellbeing, life skills, age, older people

Cancer patients’ perceptions about their quality of life: a qualitative exploration

MEHROTRA, A (Indian Institute of Technology Kanpur, Kanpur, U.P.)

Research on the psychosocial aspects of cancer patients has concentrated on their quality of life. The present work attempts to understand aspects of patients’ quality of life through their stories. The main idea behind this work was to understand how patients’ stories reflect their lives and to gain an understanding of the changing patterns, whether they are personal, professional, physical, psychological, emotional or financial. Narratives were collected from cancer patients. Narrative analysis was done to extract themes related to patients’ perceptions of their life and their relation with their quality of life. It was found that patients’ perceptions of their disease severity affected their life experiences. Patients’ quality of life was also influenced by the effects of cancer treatment. At the personal level, patients’ quality of life gets affected through their physical
appearance, will-power, mood, preferences and thoughts. At a broader level, the quality of patients’ relationship with their family members is also affected. In people affected by cancer, social, emotional, instrumental and psychological support enhances their well-being and quality of life. Another reason for the impact of disease on patients’ experiences is rooted in financial matters. In India, most people are not insured for their health which puts them under major stress. Religious and spiritual thoughts were prevalent in all the narratives. During their illness, patients tended to rely more on religious beliefs and fate. Patients applied religious beliefs to make their thoughts more positive in order to reduce the negative impact of illness on their well-being. It was also observed that patients were willing to share their experiences. Sharing could be one medium to make a person’s psychological and emotional quality of life better. Disease not only affects patients’ present life, it also affects their future perspective. This was also reflected in their narratives. Patients also expressed their views regarding the role of information and their communication pattern with medical experts in order to reduce their stress levels and thereby enhancing their overall quality of life. The results have important implications for counselling cancer patients about their psychosocial issues and concerns.

**Keywords:** cancer, quality of life, narrative analysis, religious beliefs, stress

### The quality of life and depression among working and non-working women

**SHRIVASTAVA, M.** (Govt. M.L.B.Girls P.G. College Bhopal, M.P)

Quality of life is the product of the interplay between social, health, economic and environmental conditions which affects human and social development (Ontario Social Development Council, 1997). In India, quality of life is the most neglected aspect at the social as well as government level. Unfortunately, in India, attention has been given only to the physical health of women and children in terms of mortality and morbidity and less attention given to mental health and quality of life. Due to changes in the psychosocial and economical environment in India, women have started seeking employment. However, this is leading to deterioration in the areas of physical health and mental health. Depression is the most unrecognized illness among children and women in urban India especially among house wives (Singh, 2007). The present study aims to explore the correlation between quality of life and depression among working and non-working women in the sub-metro region of India. The sample consisted of 70 women (35 working and 35 non-working) aged between 35 and 40 years. Participants were randomly selected from Bhopal and were from an average economical background. The Zung depression rating scale was selected to assess depression. The quality of life questionnaire was developed to study the correlation between depression and quality of life among women. The Zung depression rating scale was administered on 70 working and nonworking women. The quality of life questionnaire was used to assess the level of QOL. The correlation was analyzed and a significant difference was found between the quality of life and depression among working and non-working women of average economic status in India. The quality of life of working women was found to be better than the non-working women. The economical condition and mental health of working women was also found to be better when compared to non-working women. The level of depression was low in working women compared to non-working women but work stress was found in some working women.

**Keywords:** quality of life, depression, India, women, employment
Racism, power and reconciliation: Listening to indigenous voices

Chair(s): BRETHERTON, D. (Australian Centre for Peace and Conflict Studies)

This symposium consists of five papers which explore processes of reconciliation. The first paper reviews research into the current state of the relationships between Indigenous and non-Indigenous Australians and provides a background to understanding the need to repair and heal relationships. The second paper describes similar studies in Chile and uses a narrative approach to understand how Mapuche people cope with racism and discrimination. The third paper gives a conceptual overview of reconciliation processes, and analyzes the importance of structural factors and power inequalities. The fourth paper then brings our attention back to Australia and explores indigenous views of the impact of the Prime Minister’s apology. The final presentation is by an Indigenous person, who will describe her work in conflict resolution and peace building in remote Aboriginal communities in the Northern Territory of Australia and examine how current government policy impacts on her work. The key objectives of this symposium are to listen to Indigenous voices and to contextualize reconciliation processes in Australia and other parts of the world. The symposium will raise some reflective questions about the political role of psychologists and psychological research. Are psychologists removed from political events? Or are we located within the dynamics of power? An important feature of this symposium is the exploration of methods of psychological research which are sensitive to the power dynamics inherent in research and create spaces in which indigenous and minority voices can be heard.

Relationships between Indigenous and non-Indigenous Australians

MELLOR, D. (Deakin University)

To provide a background into the current state of the relationship between indigenous and non-indigenous Australians. This paper discusses four phases in the construction of the Australian nation as it is today, in terms of the Indigenous experience: invasion and dispossession, forced assimilation, striving for self-determination, and the expectation of reconciliation. The need to resolve the current impasse is exemplified by data drawn from our studies on racism as it is experienced by Indigenous Australians, and a discussion of how it impacts on the lives of this population. It is concluded that further work needs to be done at a political level to improve the lived experiences of Indigenous Australians and to repair the relationship between Indigenous and non-Indigenous people. The possible role of psychological theory and psychologists in this endeavor will be discussed.

Keywords: indigenous Australians, racism, dispossession, forced assimilation, reconciliation

Cultural factors that enhance self-esteem and ethnic reaffirmation among Mapuches in Chile

MERINO, M. E. (Universidad Catolica de Temuco)

The aim of this paper is report on the findings of a study conducted with Mapuche adults from Temuco and Santiago in Chile, with a particular focus on the effectiveness of some cultural strategies utilized by Mapuches to cope with discrimination and to enhance self esteem and ethnic reaffirmation. In this qualitative study 100 Mapuches from Temuco (50) and Santiago (50) with ages ranging between 23 and 78 years ($M = 47.2$, $SD = 14.1$) and representative of low, lower middle and middle socioeconomic status were interviewed. The method used was discourse analysis through life story oral narrations. The analyses found that experiences of discrimination may generate positive and negative psychosocial long-term effects. Among the positive effects is the development of self-esteem and ethnic affirmation acquired through a family and community strategy of teaching children and adolescents to face discrimination positively. This effect was reported by half of the sample and participants identified the latter period of adolescence to
Abstracts of the 27th International Congress of Applied Psychology

be the key developmental stage for such positive outcomes to be triggered. However negative long-term psychosocial effects such as negation of ethnic identity and acceptance of inferiority were also reported by around one quarter of participants. This study has shown that a substantial proportion of Mapuches in Chile exhibit resilience to discriminatory stressors due to the use of coping strategies that, on the one hand protect them against the negative effects of discrimination, and on the other, trigger an increase of self-esteem and ethnic reaffirmation.

Keywords: discrimination, self-esteem, ethnic reaffirmation, adolescence, coping strategies

Power and reconciliation

TINT, B. (Portland University)

This paper will explore the theoretical implications of power relationships within the reconciliation process. The paper is conceptual but will use case study material to illustrate theoretical points. Many societies worldwide have suffered long term conflicts that have divided nations, groups and communities of people. Most conflicts today are not interstate conflicts between sovereign nations, but between communities that often live together in co-existence. This includes Jewish Israelis and Palestinians, Hutus and Tutsis in Rwanda, Tamil and Sinhalese in Sri Lanka, Blacks and Whites in South Africa and Native communities and White U.S. Americans, Canadians and Australians. In many of these contexts there have been processes of reconciliation that have attempted to address the wounds of the past while simultaneously forging a better future. As scholars and practitioners in peace and conflict resolution, we must be mindful of ways in which attempts at reconciliation can re-stimulate injuries of the past, particularly those that are rooted in hegemony and abuses of relational, structural, political and economic power. This paper will explore the theoretical implications of power relationships within the reconciliation process. The paper will reflect on a number of questions. In whose best interest is it to "reconcile" - if, when and how? What are appropriate processes that include both a reconciliation focus but also address the power differentials that exist not only in the past, but in the present as well? What are the challenges and responsibilities of those on differing sides of the power relationship? This paper will be grounded in both theoretical constructs surrounding these issues as well as anecdotal case studies informing these questions.

Keywords: power relationships, reconciliation, conflict resolution

Themes in Australian reconciliation: What comes after sorry?

BALVIN, N. (University of Queensland)

The aim of this study was to examine Aboriginal Australians’ experiences and perspectives on the Parliamentary apology to the Stolen Generations (February 2008) and their ideas regarding the next steps in Indigenous and non-Indigenous reconciliation, while also adding to the theoretical body of knowledge regarding apologies and reconciliation. In particular, the research aimed to understand the impact of the apology on Indigenous Australians and whether their perceptions of the relationship with non-Indigenous Australians have changed since the apology. 34 (19 females and 15 males) Aboriginal Australians from urban (Melbourne, Adelaide, Brisbane) and rural/remote (Ipswich, Broome, Darwin and Yirrkala) parts of Australia participated in semi-structured interviews examining the apology, forgiveness, and the next steps needed for reconciliation. The interviews were approximately 30-60 minutes long and used an elicitive interview style, which allowed for the introduction of new themes. Participants were recruited either by direct approach by the interviewer or via a “snowball” sampling method, where another Indigenous Australian passed the researchers’ contact details to potential participants. Participants were reimbursed for their time. The interview data was analysed using the qualitative software package NVivo. Preliminary findings were shared with Indigenous Australians and their feedback shaped the final results. The views of Indigenous Australians on the apology varied. Some believed it provided empty words without actions, while others thought it was a unifying experience that acknowledged Indigenous Australians and their history. Daily
experiences of post-apology life were categorised into themes of understanding, accessibility and appropriateness of services, prejudice and stereotyping, and powerlessness. Ideas for the next steps in Reconciliation were seen as the responsibility of the following groups: the government, non-Indigenous Australians, and Indigenous Australians. Even in a small sample of Indigenous Australians, a myriad of views on each theme was present, highlighting the importance to not view them as a homogenous group. In line with pre-apology research (Mellor, Bretherton & Firth, 2007) many agreed that the apology was an important symbolic step in Reconciliation, but it must be accompanied by practical undertakings. The daily experiences of Indigenous Australians were similar to those found in pre-apology research (Mellor, 2003) and the responsibility for pursuing Reconciliation was seen as multi-faceted, ranging from systemic changes by the government to interpersonal relations between Australia’s Indigenous and non-Indigenous people.

Keywords: Australian Aboriginal, Parliamentary apology, reconciliation, forgiveness, prejudice

Dispute resolution, restorative justice and cultural relevance

BISHOP, H. (Department of Justice)

The aim of the current study was to provide a space for Indigenous voices and examine the impact of policy on practice. This paper will discuss the work the author has been doing in a remote Aboriginal community in the Northern Territory as the Cross Cultural Mediator for the North Australian Aboriginal Justice Agency. The role of this position is to foster and broaden conflict resolution capacity without diminishing pre-existing conflict management strategies (that the practitioners themselves referred to as interventions) and respecting the cultural needs and priorities of the community. It was necessary for the author to learn first from the people themselves in order to know how to be able to start on their’s and subsequently her journey together. The work required attention to detail, that so that the important features and vital elements of culture were not missed. As the author comes from another Indigenous background she needed to learn patience so that she could build a firm appreciation of their cultural imperatives and thus appreciate more deeply their dispute resolution systems and polities. This way of working was difficult against the underlying backdrop of the Northern Territory Emergency Response Act 2007, (Government intervention) under which the Aboriginal people being worked with are controlled. The paper will explore the necessary elements, behaviours and communication necessary for mutual liberation while the NTER continued to undermine the work and oppress and control the people being worked with. While on the one hand government policy in Australia is to further reconciliation between Aboriginal and non Aboriginal people the policy of intervention in the Northern Territory undermines this goal.

Keywords: Aboriginal community, Australia, conflict management, cultural needs, reconciliation
Readiness for offender rehabilitation

Chair(s): DAY, A. (Deakin University)

Much of the future understanding about offender rehabilitation is likely to come from moving beyond recidivism outcome studies towards a better understanding of the processes by which offenders can be successfully rehabilitated. An understanding of treatment readiness can help to explain treatment success and failure. In this invited symposium we discuss how treatment readiness is likely to be an important determinant of programme engagement and completion, offer a framework from which to understand and assess readiness, and describe interventions that might be used to modify or address low levels of readiness at an individual and systemic level.

What is treatment readiness?

DAY, A. (Deakin University)

This paper introduces the construct of treatment readiness and how it might inform the development of offender rehabilitation programs. Psychological and environmental determinants of treatment readiness are discussed in relation to the need to match the needs of the individual with those of the context in which offender programs are offered.

Assessing treatment readiness: A case study

VESS, J. (Deakin University)

The purpose of this paper is to illustrate the concepts of treatment readiness using a detailed case description of a sex offender with limited success in previous treatment experiences. Various factors are considered that influence treatment readiness, both generally and specific to sex offenders, beginning with the assessment process and continuing through treatment planning, treatment delivery, and ongoing risk management. The sequence of the paper starts with a review of the case history, current criminal justice and clinical context, assessment findings, case formulation and treatment recommendations. This is followed by an assessment of treatment readiness in this case, resulting in an expanded case formulation and treatment recommendations, including recommendations for the facilitation of treatment readiness.

The psychometric assessment of treatment readiness

CASEY, S. (University of South Australia)

Despite first being articulated in an offender context more than a decade ago, there have been few attempts to clearly operationalise the readiness construct and develop appropriate measurement tools. A lack of clarity regarding definition and measurement poses a dilemma for practitioners. On the one hand, there is an expectation of evidence-based practice which necessitates a clear understanding of what works when, where, and for whom, while on the other, little is available in terms of psychometrically sound assessment tools to measure treatment readiness. This paper presents an overview of evidence-based assessment, with a particular focus on the assessment of readiness for both case conceptualisation and treatment planning, and treatment monitoring and evaluation.

Finding the “will and the way” in offender rehabilitation: Maintaining treatment readiness in a compulsory drug treatment prison

VESS, J. (Deakin University)

The purpose of this paper is to illustrate the concepts of treatment readiness using a detailed case description of a sex offender with limited success in previous treatment experiences. Various factors are considered that influence treatment readiness, both generally and specific to sex offenders, beginning with the assessment process and continuing through treatment planning, treatment delivery, and ongoing risk management. The sequence of the paper starts with a review of the case history, current criminal justice and clinical context, assessment findings, case formulation and treatment recommendations. This is followed by an assessment of treatment readiness in this case, resulting in an expanded case formulation and treatment recommendations, including recommendations for the facilitation of treatment readiness.
BIRGDEN, A. (Compulsory Drug Treatment Corrections Centre, Corrective Services NSW)

In August 2006 a drug treatment prison (the CDTCC) was established under the Compulsory Drug Treatment Correctional Centre Act 2004 in Sydney. This legislation is unique in Australia. A program of compulsory drug treatment and rehabilitation for repeat drug-related male offenders aims to: (1) provide ongoing judicial supervision from the NSW Drug Court, (2) treat drug dependence, (3) prevent and reduce re-offending and (4) promote community reintegration. The CDTCC service delivery model is theory based and provides a set of principles to ensure the humane and ethical assessment, treatment, and management of offenders. While the law is compulsory, the procedures and roles of staff within the Program have been established to develop a therapeutic alliance and engage offenders in change. Treatment readiness and maintenance is considered central to effective service delivery. Educational, psycho-educational and therapeutic programs are carefully sequenced. Case management strategies ensure natural justice processes, apply motivational interactions, deliver contingency contracting and support autonomous decision-making. Measures of treatment readiness are applied and re-applied at regular intervals. The outcomes of the assessments, and anecdotal information regarding offender perceptions of the program, will be presented. It will be argued that the active focus on participant motivation and capacity overcomes the compulsory nature of the program.

Keywords: drug treatment prison, compulsory drug treatment, offenders, treatment readiness, Case management

Recent Australian studies on perfectionism using the Frost et al. Multi-dimensional Perfectionism Scale

Chair(s): HICKS, R. (Bond University)
Discussant(s): HICKS, R. (Bond University)

These studies reflect papers chosen for presentation from a series of some fifteen student research projects completed since 2005 in an Australian private university, on the correlates of perfectionism as assessed using the Frost et al. Multidimensional Perfectionism Scale (MPS). There will be a brief overview presentation on the findings of the studies and five papers selected to represent specific emphases. One paper will examine the clinical applications of perfectionism in relation to brooding and reflective pondering; two will examine the use of the MPS in health and body-image studies involving the media; a fourth paper will examine stress among university students in relation to perfectionism, coping strategies and personal values; and the fifth paper will examine the psychometrics including confirmatory factor analyses of the MPS across the Australian studies. Time for questions is made available throughout, including open discussion in the brief final wrap-up session. The key learning objectives include: (1) to demonstrate that perfectionism continues to be an area of substantial interest in academia and in clinical and health psychology practice and that new research findings continue to inform researchers and professionals; (2) to show that perfectionism and depression are related (confirming known data), but that a specific component of rumination, reflective pondering, is responsible for mediating the relationship; (3) to highlight that media influences how we feel about our body shape, and that the influence is consistent with both cultivation (exposure) theory and objectification (self-internalisation) theory but also with one’s own perfectionist attitudes; (4) to demonstrate that the personality factors of perfectionism and
neuroticism in particular mediate the relationship between media influences and body dissatisfaction; and (5) to understand the similarities and differences in the US and Australian responses to the items and scales of the Frost et al. MPS, supporting its use; following internal consistency and confirmatory factor analyses of the Australian data.

Comparing brooding and reflective pondering as mediators between perfectionism and depression using the Frost MPS, the Lovibond DASS and the Hoeksema Response Style Questionnaire

MCHUGH, M. (Bond University)

Harris, Pepper, and Maack (2007) identified rumination as a mediator between maladaptive perfectionism and depression, but did not examine whether the two components of rumination, brooding and reflective pondering, acted similarly or that one was more prominent than the other. This project examined the proposition that brooding and reflective pondering contributed equally as mediators between maladaptive perfectionism and depression in a sample of 213 Australian University students. The 213 students completed self-reports for the Frost Multidimensional Perfectionism Scale (Frost et al., 1990) measuring (maladaptive) perfectionism, the Response Style Questionnaire (Nolen-Hoeksema & Morrow, 1991) measuring rumination and its subscales, and the DASS (Depression, Anxiety & Stress Scales, Lovibond & Lovibond, 1995). The current study found that rumination (combination of reflective pondering and brooding) mediated the relationship between perfectionism and depression; and that reflective pondering alone, but not brooding alone, mediated the relationship between perfectionism and depression. These results supported the Harris et al. paper but further suggested that reflective pondering is the main cognitive mechanism contributing to depression, especially among respondents scoring higher on the maladaptive perfectionism scales. Reflective pondering and the thought processes associated with maladaptive perfectionism (doubting of actions, concern over mistakes, recollections of parental criticism and expectations) are clearly associated and overlap significantly. In a clinical setting attention should be focused on the cognitive thought processes with steps to alleviate the problems associated with perfectionism and reflective pondering.

Keywords: depression, perfectionism, brooding, reflection, university students

Perfectionism and media as correlates of body image satisfaction. Do cultivation and self-objectification theories help explain body image satisfaction?

MURRAY, D. (Bond University)

Food purchasing habits, exercise regimes, and dietary actions often stem from dissatisfaction with one’s body image. But where does the dissatisfaction originate and what is the relation to perfectionism? The origins may be in media exposure and correlates may be perfectionist attitudes and peer/self pressures. It is argued by some that the greater the amount of television exposure the more likely the participants, especially female, are to see TV as ‘real life’ and to endorse and internalize the images portrayed. On the other hand it is argued by others that individuals (mostly females) internalize a third-party view (others’ views) of their body image (Objectification theory). This study examined the correlates of body image dissatisfaction and also whether the two theories were supported. Self-report questionnaires were completed by 265 Australian university students. To demonstrate the relationships with cultivation theory, this research included as variables amount of TV exposure and magazine reading to identify influences on body image. To demonstrate the links with objectification theory, the Sociocultural Attitudes Towards Appearance Questionnaire (SATAQ) was used to assess the degree of internalization of media messages. Other scales used included Body Image Satisfaction (Body Shape), and a demographics questionnaire containing items on age, gender, overall body satisfaction (item), and media influences (time spent reading or watching; and the specific content involved). Correlation findings showed that there were strong relationships between body image and perfectionism; between overall body
satisfaction and specific body image attitudes; and between body image and socio-cultural influences (especially peer pressures, information, and internalization). Regression analyses predicted body image from independent variables of perfectionism, TV exposure and socio-cultural influences. When the relationships were considered against cultivation and objectification theories, the evidence showed that both theories were supported: amount of exposure (cultivation) and degree of internalization (objectification) both contributed to body image. The results showed perfectionism was associated with body image dissatisfaction; and that perfectionism along with TV exposure and the socio-cultural variables (including internalization) both contributed to body image responses. Implications of the findings are discussed in relation to the two theories.

Keywords: perfectionism, body satisfaction, self-objectification theories, peer pressures, internalization

Maladaptive perfectionism and neuroticism as mediators between sociocultural influences and body image dissatisfaction.

PEDERSEN, L. (Bond University)

Recent figures from the Australian Bureau of Statistics show Australians are now on average among the fattest in the world. Yet emphases in the media highlight thinness as the ideal. As a result we have much effort spent by many to ‘meet the ideal’. Diets and exercise regimes abound in the aim to ‘lose weight’ and ‘look trim’. But we still do not understand what the correlates are of the body dissatisfaction that drives many. One question raised in our research asked whether certain personality traits such as perfectionism and neuroticism place some individuals at a higher risk for body image/ body shape dissatisfaction. This study examined the relationships among maladaptive perfectionism, neuroticism, sociocultural influences and body image dissatisfaction, using a non-clinical sample. Self-report measures were completed by 265 university students and community members aged 18-40 years. Instruments completed included the Frost et al. Multidimensional Perfectionism Scale (MPS); the IPIP scales assessing the Big Five personality factors; the Body Shape Questionnaire measuring body preoccupations and concerns characteristic of bulimia and anorexia, and the Sociocultural Attitudes Towards Appearance Questionaire-3 measuring three variables relating to sociocultural influences (thin ideal internalisation, pressures, and information).

The findings showed that maladaptive perfectionism and neuroticism (negative and faulty thinking) fully mediated the relationship between media as an information source regarding beauty/thinness and the resulting body image dissatisfaction. These personality attributes should be taken into account by counselors in clinical applications which need to address the thinking processes involved, to improve treatment outcomes, and by the media in relation to how messages are delivered and may be picked up by vulnerable individuals.

Keywords: perfectionism, neuroticism, sociocultural influences, body dissatisfaction, media

Perfectionism, coping strategies, values, and stress in a student population

CVET-CVETANOVIC, L. (Bond University)

Identifying predictors of stress in students’ lives is instrumental in assisting to alleviate their stress. The aim of this study was to examine the relationships between perfectionist tendencies, coping strategies, personal values and stress in a student population. The Frost Multidimensional Perfectionism Scale (FMPS), the Brief COPE, the Depression Anxiety and Stress Scale (DASS), and a Survey of Personal Values (including the values of achievement, goal-orientation, variety and decisiveness) were completed by 192 students, who were aged between 18 and 62 years (M= 25.5). Results revealed that highly maladaptive perfectionists experience more stress than do adaptive perfectionists, though both suffer from stress outcomes. Closer examination revealed that Negative coping strategies and both adaptive perfectionism and maladaptive perfectionism contributed to stress. While personal values did not correlate with stress, the valuing or
undervaluing of achievement was found to be correlated with perfectionist tendencies. An implication of these findings for counseling and remedial educational programs is that stressed students with maladaptive perfectionist tendencies in particular would be likely to benefit from learning more effective coping strategies—avoiding the use of negative coping strategies and learning ways to cope positively with stress. Programs could also consider the role values play for perfectionists and highlight how to develop and maintain personal values of achievement. This study has contributed to the perfectionism literature by demonstrating the links between perfectionism and negative coping strategies and between perfectionism and achievement as a personal value.

Keywords: stress, perfectionism, coping strategies, personal values, students

Inter-correlation and confirmatory factor analysis data on the Frost et al. Multidimensional Perfectionism Scale over more than 750 Australian respondents

HICKS, R. (Bond University)

The Frost et al. MPS has been used extensively in many different countries around the world including Australia, but internal psychometric and validation data on how the MPS operates within the Australian context is not readily available. This study aims to address this gap. As part of a series of studies several groups of participants comprising some 750 Australian university students, employees and the unemployed completed the Frost et al. MPS, along with a variety of other scales. The data on the MPS were extracted for purposes of this paper, and the scales inter-correlated (the six scales are: Concern over mistakes, doubting of actions, parental criticism, parental expectations, personal standards, and organization). These were compared with the data available in the Manual. In addition internal consistency analyses of the items and scales, and confirmatory factor analyses, were conducted to examine how well the MPS model was reflected in the Australian data. Current limited findings are generally supportive of the inter-correlation matrix, reflecting similarity of operation across cultures; in addition the item-scale homogeneity relationships are also supportive. The confirmatory factor analyses are to be completed and the results presented in due course. Given the importance of perfectionism in links with clinical and health areas, and in relation to socio-cultural influences (from media), specific data is needed on how well constructed psychometrically the MPS is, and how it operates in the Australian culture. This paper supplies some of this information, and indicates the confidence academics and practitioners can have in the questionnaire. Perfectionism continues to be a source of concern for many in their daily lives, and perfectionist attitudes are easily transferred to the next generation. It is hoped this data on the MPS provides further support in the battle to improve personal and family life-styles, through the supportive and cautionary evidence presented.

Recommendations to the U.S. National Biodefense Science Board for disaster mental health and psychological support

Chair(s): DODGEN, D. (Office of the Assistant Secretary of Health and Human Services for Preparedness and Response)

Discussant(s): REVEL, J. P. (International Committee of the Red Cross)

The Disaster Mental Health Subcommittee of the U.S. National Biodefense Science Board provided the foundation for the development of the Board’s report and recommendations regarding provision of psychological support in the aftermath of a disaster. The subcommittee consisted of 12 “invited experts” in disaster mental health and cabinet-level federal appointees to represent the perspective of various government entities. The subcommittee engaged in an intense process of examining the international literature and exploring strategies across five months. The final report is wide-ranging, and includes fairly dramatic recommended changes in the ways that psychological support is provided and includes strategies that could change the United States society’s perceptions and understandings of psychological support. These recommendations fall into four broad categories: Intervention and operational strategies, communications and messaging, education and training, and issues that cut across all three categories. These recommendations may prove useful for countries developing strategies for psychological support. The chair and each of the presenters were integrally involved in developing the recommendations on the topics they will describe. The discussant was integrally involved in developing international humanitarian psychological support for a major Non-Governmental Organization (NGO), and later was central to revising and improving the psychological program for another major NGO. For a quarter century he has been assisting developing and developed countries with health and psychological programs. The learning objectives of the symposium are to help participants to understand recommendations for: (1) integrating psychological support into the Concept of Operations for government and civilian response agencies, (2) ensuring there is an appropriate research agenda on psychological support in public health emergencies and disasters, (3) improved assessment of psychological needs in public health emergencies and disasters, (4) improving the training of professionals and the public in disaster mental health and psychological first aid (5) a strategy for effective disaster and mental behavioral health communications, (6) ensuring that the needs of at-risk and culturally diverse individuals are effectively served, and (7) the usefulness of these recommendations for developing and developed countries.

Integrating mental and behavioral health into all levels of disaster preparedness and response

REISSMAN, D. (National Institute of Occupational Safety and Health)

In the United States, there is a need for an overarching framework to coordinate response efforts aimed at the behavioral and mental health needs of disaster-affected populations. Such a framework must be able to address diverse and dynamic scenarios. The intervention recommendations in this report are designed to address a broad span of public health and social concerns, including coordination, service provision, and health surveillance. Reactions to public health directives are also important to assess, such as required vaccination, evacuation or sheltering in place, or hand-washing to avoid the spread of infection. A shared (common) operational picture informed by monitoring population health and the recovery environment can better target mutual aid, risk communication, and the distribution of limited resources. In addition, this should be integrated with screening and triage to ensure that specific needs are addressed in a timely and appropriate manner. Information required includes assessing current beliefs about intervention strategies, trusted information sources, unmet health and social service

Recommendations for education and training in disaster mental and behavioral health

JACOBS, G. (Disaster Mental Health Institute)

Recommendations regarding education and training focused on two areas: disaster mental health theory/practice, and community-based psychological first aid. Psychological first aid, as used by the committee, refers to psychological support that is both used to improve one’s own resilience and is provided by non-mental health professionals to family, friends, neighbors, co-workers, and students. It focuses on education regarding traumatic stress and on active listening. The term also incorporates more sophisticated psychological support given by primary care providers to their patients. Properly executed, psychological first aid is adapted to the needs of each group or community (i.e., group of people with shared interests) implementing it, ensuring that the psychological first aid that is introduced in the community does not conflict with the world view of the group. It also builds on the strengths of the community in which it is being implemented. The recommendations also focused on two groups, professionals and the general public. The mental health professions are encouraged to incorporate disaster mental health as an integral part of their curricula. In addition, health care professionals (e.g., medicine, pediatrics, nursing, and epidemiology), the full range of emergency responders (e.g., law enforcement, fire service, emergency medical responders), coroners and morgue staff, disaster relief personnel, faith-based professionals and leaders, disaster response leaders (e.g., incident commanders, emergency managers, and civil service and elected government leaders), and educators would be encouraged to train their professions both in disaster mental health theory, and in advanced forms of psychological first aid, customized for each profession. It was also recommended that the general public be trained in psychological first aid. The success of psychological first aid as a strategy depends on the penetration of the training in the affected population. If a significant portion of the population is trained in psychological first aid, then, in the event of a public health emergency or disaster, there will always be someone nearby to provide psychological support. A populace educated in psychological first aid will help ensure that the limited available time of disaster mental health professionals is reserved for those who are most in need.

Disaster mental and behavioral health recommendations for communications and messaging

BROWN, L. (Louis de la Parte Florida Mental Health Institute)

The aim of this presentation is to help participants understand that communication and messaging plays a central role in
influencing individual and collective behavior, feelings, and thoughts and is an essential mental and behavioral health intervention in disaster preparedness/response. During a disaster, accurate, timely, and credible information distributed through a variety of sources and media is a key determinant of human impact, operational effectiveness, and social and economic consequences. Information during a crisis can promote life-saving and altruistic behaviors and discourage actions that hinder an effective response. Disaster mental and behavioral health specialists with expertise in crisis and risk communication can maximize effectiveness in communicating with the public during and after crises. Explaining complex scientific concepts in plain language and graphics is difficult, and the opportunity for misunderstanding is high. In contrast to the risks posed by flood waters or falling debris, where there are familiar cues, communicating risks of invisible and novel agents such as radiation and bacteria is a far greater challenge. The preparation and testing of messages before an event can maximize the potential that instructions given during an event will be comprehended. Recognition of the need for cultural competence in dealing with groups that are different from one’s own is also critical. Communication and mental and behavioral health education, training, and intervention are linked and represent areas that can bolster community resilience. The communications recommendations highlight the ways in which disaster preparedness can be enhanced by the incorporation of mental and behavioral health principles into communication. A valuable disaster mental and behavioral health communication strategy includes: (1) Mass communication messages that deliver psychoeducation, information on sources of help, and other mental and behavioral health topics related to specific hazards/threats and disaster phases, (2) Education and training regarding the integration of mental and behavioral health/social science principles and emergency risk communication (3) A process to identify, educate, and train a cadre of mental and behavioral health experts to serve as consultants, interviewees for resources for the media, and (4) Establishes and enforces policy, with respect to disaster and emergency health issues.

Keywords: disaster preparedness, crisis, altruism, cultural competence, communication strategy

Disaster mental and behavioral health recommendations regarding vulnerable and at-risk populations

BOYD, E. (Disaster Mental Health Institute)

The Disaster Mental Health Subcommittee of the NBSB recommended that responsiveness to culture and diversity must be supported in principle and in practical fact in any disaster behavioral health plan. Issues of culture and diversity should be carefully vetted and implemented into all plans, programs, curricula, and efforts related to disaster preparedness, response, and behavioral health. Vulnerable, at risk populations should be addressed in all facets of disaster planning, preparedness, recovery, and research, including disaster mental and behavioral health efforts. Vulnerable populations are those who may require additional assistance before, during, or after an emergency. Functional areas include maintaining independence, communication, transportation, supervision and medical care. These populations may include children, older adults, people from diverse cultures and religions, individuals with limited language proficiency, individuals with disabilities, and those with limited ability to transport themselves to access services. This presentation will focus on issues that must be addressed in order to be truly culturally-responsive in the provision of psychological support to meet the needs of vulnerable and at-risk populations for communities which have experienced disaster.

Re-envisioning the clinical psychology curriculum in Australia

Chair(s): PACHANA, N. A. (University of Queensland)
Discussant(s): KNIGHT, B. (USC Davis School of Gerontology), MERRICK, P. (Massey University)

This symposium will focus on outcomes from a national Australian Learning and Teaching Council supported project examining empirically supported, internationally-benchmarked and public health and policy-responsive innovations to the existing postgraduate clinical psychology curriculum in Australia. The latest research in each of the areas of competency assessment, supervision strategies, regional and rural issues, training and service delivery models and fitness to practice policy strategies will be reviewed. A range of practical examples of teaching, supervision and practice strategies are presented. The key learning objectives are: (1) To outline the rationale behind, and strategies to implement, competency-based assessment within training programs (2) To present an overview of effective supervision strategies in clinical training and outline their effect on student and client outcomes (3) To outline the many issues facing regional universities concerning recruitment of students as well as placement and supervision issues, presenting data from a recent student survey on the issues (4) To outline the evidence for, and give working examples of, e-therapy strategies that are in use, offering suggestions as to their incorporation into a clinical training program (5) To outline the likely benefits and costs of a Problem Based Learning teaching model in clinical psychology training (6) To present the rationale for, obstacles to, and benefits which may flow from a Fitness to Practice policy embedded within clinical postgraduate training programs (7) International discussants place the above within an international context.

Competency-based assessment in clinical psychology: Rationale and strategies

PACHANA, N. A. (University of Queensland), SOFRONOFF, K. (The University of Queensland)

Internationally the standard of training in clinical psychology at the postgraduate level has moved from a model wherein hours of study equated skill, towards one in which competencies must be demonstrated via evidence at both the student as well as the program level. This shift in training emphasis is outlined and implications for the Australian postgraduate training environment are presented. Examples of practical means of benchmarking and assessing competencies in an international as well as Australian context are offered. Our review of the extant literature reveals a small but growing empirical as well as theoretical literature attempting to describe models and examples of competency-based models of clinical training (e.g. the cube model of core competencies of Rodolfa et al., 2005). Our review dovetails with results from a survey of first-year postgraduate clinical psychology students undertaken in Semester 2, 2009 nationwide. This data is presented alongside data from a long-standing and award-winning competency-based assessment strategy developed at the University of Queensland. Students overwhelmingly indicated that demonstrations of their developing clinical skills were most highly valued in their training; unfortunately such evaluations were utilized infrequently compared to traditional assessment techniques. Discussion of implementation of, as well as practical examples from the UQ competency-based assessment protocol, are offered. Clinical training programs in Australia are influenced by many drivers: Commonwealth policy, University and registration board regulations; student numbers and demands, and placement availability and access to supervisors. The demonstration of competence in provision of clinical services is poorly articulated and infrequently incorporated into clinical training programs in psychology at the postgraduate level. Existing models of competency benchmarks and toolkits are available (e.g. Kaslow et al., 2009) and deserve broader consideration within the Australian context.
Keywords: competency-based assessment, clinical psychology training

Toward effective supervision in clinical psychology training

O’DONOVAN, A. (Griffith University; The University of Queensland), HALFORD, K. (Griffith University; The University of Queensland)

There is a strong professional consensus that clinical supervision is a critical element of training in clinical psychology. However, there are significant limitations in the evidence of its effectiveness in promoting supervisee competence or positive client outcomes. This study reviews what aspects of clinical supervision influence supervisee and client outcomes, and assesses the extent to which such characteristics are represented in clinical psychology training in Australia. An extensive literature search identified 56 empirical papers on supervision, among which only 12 assessed whether clinical supervision was related to client outcomes from therapy. Postgraduate trainee experience of clinical supervision was assessed in a survey sent to all first year clinical psychology students enrolled in a clinical psychology program in Australia. One hundred and ninety students (approximately 55% return rate) returned the survey. The literature review suggested supervision has three main functions: formative (the development of supervisee skill and competency), normative (the maintenance of professional standards) and restorative (support, emotional processing and personal development). The empirical literature establishes that specific forms of clinical supervision do enhance supervisees’ clinical skill development, self-efficacy and professional resilience. The process and content of supervision predicts the client-therapist working alliance, client retention in therapy and possibly client outcomes. A substantial limitation of current methods of supervision is the reliance on unreliable sources of information, particularly the verbal reports of supervisees, to assess supervisees’ clinical competence and clinical outcomes for clients. The survey of current Australian clinical psychology students shows that students regard supervision as the most effective teaching method for learning clinical psychology. However, students’ self-report of therapy process is the most widely used method of monitoring the student’s therapeutic competence. In contrast direct observation of student therapy, participation in co-therapy and reviews of recording of therapy by supervisors is much less frequently used. The effectiveness of supervision within clinical psychology is likely to be enhanced by more frequent direct monitoring of supervisees’ competence, and attention to the contingencies on supervisors for providing the normative function of quality control over therapy delivery.

Keywords: supervision, clinical psychology training

Training in clinical psychology in regional Australia

HELMES, E. (James Cook University)

The Australian population is concentrated in capital cities, and clinical training programs at the large urban universities tend to be better resourced than those at smaller, regional universities. It is not known whether the quality of training differs between regional and urban universities and whether students differ in their experiences during clinical training. During semester 2, 2009, first-year postgraduate clinical psychology students were surveyed. Students from 20 of the 35 universities provided responses, with 29% of the 190 students being from regional universities. Survey questions covered ratings of the quality of training, teaching methods used, effectiveness of teaching methods, responsiveness to student needs, assessment methods used in the program and their effectiveness, monitoring of therapeutic work and therapy workloads, exposure to clinical research, clinical supervision, and overall workload and stress levels. Comparisons were made between urban and regional training programs on the 55 items that were surveyed. As an exploratory study, two-tailed tests with alpha = .05 were used. Five items showed differences between urban and regional training programs. Students rated the effectiveness of lecturers using their own clinical cases as higher among urban universities, and also the use of portfolios of client work as an assessment method. Students at urban universities were also monitored by video tape recordings more
frequently and exposed to clinical research of their teachers more frequently. Finally, students at urban universities were significantly less likely to consider a placement in a rural setting compared to those at regional universities. At best, students indicated a moderate interest in undertaking a placement in a rural setting. Overall, there were more similarities between urban and regional training programs than there were differences. Where there were differences, they tended to favor the urban universities in terms of training that was illuminated by both clinical work and clinical research of the teaching staff. Such differences are also associated with the other resources available in larger universities. Nonetheless, the lack of differences in perceived quality of training and the majority of other aspects suggest that training across Australian universities is largely comparable in both urban and regional environments.

**Online provision of psychological services by trainee clinical psychologists: A model, initial experiences and implications for defining competence in electronic service provision**

MURRAY, G. (Swinburne University), KYRIOS, M. (Swinburne University)

E-therapy is a federally-supported modality of psychological service provision, as exemplified by Anxiety Online (www.anxietyonline.org.au), based at Swinburne University of Technology and launched in November 2009. E-therapy raises many issues for the training of clinical psychologists, particularly in relation to defining competencies for electronic modalities of service delivery. In this context, the present paper aims to introduce and critically discuss Anxiety Online as a placement for clinical psychology trainees. Literature on the evidence base for e-therapies is reviewed, with a focus on data showing that therapist-assisted online CBT treatments may be superior to self-help versions. The Anxiety Online model will be introduced in detail, and the steps taken to roll out Anxiety Online through clinical psychology programs discussed. Data from the first 6 months of operation of the service will be presented. There is strong evidence for the efficacy of online CBT for anxiety and other emotional disorders, especially when the client/patient has access to an online therapist to assist their progress through treatment. Similarly, there are strong a priori grounds for arguing that a range of clinical competencies can be developed through trainees’ participation as therapists in such programs. The federal Department of Health and Ageing has recognized this service provision/training synergy in the large-scale funding of Anxiety Online. However, the relevant accrediting bodies (e.g. APAC, the APS College of Clinical Psychologists) do not have fully formed positions on electronic service provision. Clinical placements with Anxiety Online are currently recognized as client contact hours by the Counselling College, but as “other placement hours” by the Clinical College. Guidelines for describing competencies that are (and are not) developed by online therapy provision are urgently required. One challenge facing Clinical Psychology training in Australia over the next decade is to engage with the reality of online service provision. Fortunately, there is momentum around this issue nationally. The scrutiny of Anxiety Online from various perspectives (government, the profession, the university sector, and the public) provides a unique opportunity to open up and rapidly progress debate on the clinical psychology competencies that are demanded by, and trained through, online therapy.

**Can Problem Based Learning integrate the junkyard curriculum in clinical psychology?**

BAILLIE, A. (Macquarie University, University of New South Wales), PROUDFOOT, H. (Macquarie University, University of New South Wales)

Problem Based Learning (PBL) is a constructivist educational method that originated in the undergraduate medical program at McMaster University and has become popular in medical education. The key features of the method are that teaching takes place in small groups focused on realistic
clinical problems facilitated by a tutor whose role is to facilitate application of existing knowledge, to facilitate the identification of gaps in knowledge, and to facilitate learning goals. New information is typically found by learners outside the tutorial and reported back to the tutorial. The method is thought to establish lifelong learning and so may have appeal in clinical psychology training programs. What then would be the likely costs and benefits of changing to a PBL based clinical psychology training program? As part of this study a narrative literature review was conducted. Few papers reported on the use of PBL in clinical psychology and none reported empirical outcomes so we turned to literature on the effectiveness of PBL in postgraduate education in any health profession. There are few randomized trials. Learners prefer PBL based small group learning compared to large format didactic lecturers and believe they have better outcomes. However there are few differences in short and long term outcomes compared to traditional teaching methods. One review concluded that the costs of changing to PBL are considerable. PBL has not been specifically evaluated in clinical psychology but has shown few advantages over traditional teaching methods in the training of other health professionals. The cost of switching to a PBL model may be substantial. Existing clinical psychology programs may use a range of teaching methods in an uncoordinated and piecemeal fashion and so may benefit from a more coordinated and coherent match of teaching methods to the content or aims of training. Alternative teaching models are briefly discussed.

Keywords: problem-based-learning, clinical psychology

Fitness to Practice

SOFRONOFF, K. (The University of Queensland), HELMES, E. (James Cook University)

The past decade has seen a groundswell of policy related to the introduction of formal Fitness to Practice (FTP) assessment for students enrolled in tertiary programs that lead to professional qualifications. It is recognised in some quarters that such a policy is essential for programs with a clinical orientation whereby students gain a license to practice. There are, however, difficulties that arise in the measurement of the construct of ‘fitness’ and in the implementation of such policies with many believing that students should only be assessed on academic performance and that non-academic evaluation of suitability is contrary to the role of a university. The literature base for discussion of FTP comes most strongly from schools of medicine and from social work. There is relatively little discussion in the psychology literature about evaluation of FTP or suitability for the profession. We draw data, however, from a survey of Clinical Program Directors and from a clinical program that is currently using an FTP protocol. The paper will outline issues and concerns related to FTP, for example the need to balance the university’s duty of care to students, placement agencies and clients. There is a clearly identified need for students to be prepared “emotionally, behaviourally and ethically” for being on a placement and this is currently often not assessed in any formal manner. Some of the factors relevant to FTP include a student’s physical or mental health, interpersonal skills, violation of ethical codes, demonstrating a risk to others and being unable to undertake required placement or professional activities. The notion of a formal FTP policy is still controversial in many university settings with individual program directors facing difficulties in finding a way to exit a student who may be considered unfit for the profession on non-academic grounds.

Regulatory focus and decision making processes: Weighing risks and benefits

Chair(s): KOEHLER, T. (The University of Melbourne)
Discussant(s): ROE, R. (The University of Maastricht)

Regulatory Focus Theory (Higgins, 1997, 1998) proposes that two orthogonal self-regulatory processes underlie goal achievement: promotion and prevention focus. Each of these motivational foci differs in their influence on decision making and cognition (Higgins, 1997, 1998); while a promotion focus entails an attention to desires and positive outcomes, a prevention focus is based on attention to obligations, responsibilities, and negative outcomes. It is reasonable to assume that an individual’s predispositions (traits) towards preventing losses versus promoting gains will have a significant impact on decision making processes and the subsequent decisions which are made.

The aim of the current symposium is to look at the influence of these two trait-based regulatory foci on decision-making processes in five different decision-making contexts. Moreover, this symposium will explore how context specific cues trigger state promotion versus prevention orientations and how these orientations affect preferences regarding decision-making. Key learning objectives from this symposium include: 1) understanding how both trait and state promotion and prevention focus affect decision-making processes in different contexts, i.e., decision-making with regard to voting behavior, paying taxes, deceptive behavior, and job choices. 2) exploring the cognitive and affective dynamics underlying the relationship between regulatory foci and decision-making processes such as assessing the role that promotion and prevention focus play in the framing of information and the creation of preferences. The breadth of the outcome variables in the current symposium highlights the universal utility of the regulatory focus concept for explaining behaviors related to the decision-making process. Implications from this research will be applicable to many related concepts in Work and Organizational Psychology such as the influence of affectivity and Goal Orientation on important organizationally relevant variables. Furthermore, the variety of data collection and data analytic methods in combination with the diversity of nations and populations from which data were collected suggest that the findings presented in this symposium are highly reliable and generalizable. Implications from the research will be discussed by an eminent scholar in the field of motivation research and work psychology who will critique the papers and provide an outlook on opportunities for future research.

Regulatory focus and political decision making: When people favour reform over the status quo

BOLDERO, J. (University of Melbourne), HIGGINS, E. (Columbia)

The present two studies were designed to examine the impact of self-reported use of promotion- and prevention-focused strategies on “risky” or “conservative” decisions about economic reform when economic conditions are described as average. Study 1 examined the impact of individuals’ chronic regulatory focus on strategy use, whereas Study 2 examines the impact of manipulated regulatory focus. In Study 1, participants chronic regulatory focus was assessed using Higgins, Friedman, Harlow, Idson, Ayduk, and Taylor’s (2001) 11-item Regulatory Focus Questionnaire whereas is Study 2 regulatory focus was manipulated by asking participants to write about either their personal hopes and aspirations or their personal duties and obligations, thus experimentally inducing either a promotion or a prevention focus, respectively (e.g., Freitas, Liberman, & Higgins, 2002). They then read an economic report that was designed to portray Australian economic conditions as average in the preceding financial year and that expressed that the Australian Government had decided that Australia’s economic future could only be assured by sweeping economic reforms (i.e., those that were risky). Further, it was stated that the Government wished to introduce a range of economic reforms. Participants then indicated whether or not they supported the proposed
reforms. In both studies, consistent with Regulatory Focus Theory predictions (Higgins, 1997, 1998), prevention strategy use was associated with the conservative choice and promotion strategy use was associated with the risky choice. In Study 2, identical effects were found for manipulated regulatory focus. Furthermore, being prevention focused was associated with prevention strategy use. Being promotion focused was associated with promotion strategy use by those who reported that current economic conditions were relatively poor. These studies are the first to demonstrate that the self-reported use of promotion and prevention strategies are associated with “risky” or “conservative” decisions and that strategy use is associated with being promotion or prevention focused when conditions are described as average.

Keywords: promotion, prevention, risky decision-making, conservative decisions, reform

Unlocking decision risk – the impact of self-regulatory focus on risky decision making

THA THAN, P. (University of Melbourne), BARSKY, A. (University of Melbourne)

According to prospect theory, people’s attitudes toward risks concerning gains may be quite different from their attitudes toward risks concerning losses. Thus, the framing of the same problem can have significant impact on individuals’ risk preferences (Kuhberger, 1998). The questions, when and why a riskier alternative is preferred over a safer option, however, is still debated among scholars. The aim of this research paper is to shed more light and enhance our knowledge on decision risk by applying the motivational principle of self-regulatory focus, which is concerned with how people are motivated to experience pleasure and avoid pain in different ways. Following an extensive literature review, we developed a conceptual model of decision risk using regulatory dispositions (promotion and prevention foci) as the main predictors of risky choices, as individuals attempt to achieve gains (pleasure) and avoid losses (pain). This model takes into consideration important contextual factors such as one’s outcome history, which has been shown to have significant influence on people’s risky choices. Based on the strategic inclinations described by Higgins (1997) and the empirical findings that have been reported, the model suggests that individuals with a promotion focus will prefer riskier choices in search for gains, while individuals with a prevention focus will prefer less risky choices as a means to avoid losses. However, such predictions may alter when one’s outcome history is also factored into consideration. Consistent with traditional studies, this model will rely on individuals’ subjective value of gains and losses and perceived outcome uncertainty (the distortion of probabilities) to help predict and explain the findings. The suggested model highlights how the application of regulatory focus theory can help improve our understanding of the mechanisms that influence risky decision making by individuals. The theoretical proposition of promotion and prevention value functions (subjective values) and the variations in perception of probabilities delve deeper into the topic of risky choices, thus unifying our knowledge of decision risk. Most notably, we would have the means to predict when and why a risky alternative is preferred.

How to inform the public about the use of public finances? Framing information, regulatory fit of recipients and tax compliance

KIRCHER, E. (University of Vienna), HOELZL, E. (University of Vienna)

Information campaigns on taxes and spending policy of the government as well as the provision of public goods can improve both citizens’ understanding and acceptance of taxes and their compliance. Information campaigns can either focus on the advantages of taxes for the collective or on disadvantages in case of tax evasion. We argue that information campaigns are more effective if the messages correspond to recipients’ regulatory focus. A 3 x 2 between-subjects design with regulatory focus (promotion vs. indifferent vs. prevention) and goal-framing (positive vs. negative) as independent variables
was used to investigate effects on tax compliance as dependent variable. Regulatory focus of participants was assessed by a questionnaire which yielded data to split the sample into a group with predominant promotion focus and a group with predominant prevention focus. In the second study, a 2 x 2 between-subjects design with situational regulatory focus (promotion vs. prevention) and goal-framing (positive vs. negative) as independent variables and tax compliance as dependent variable was used. ANOVAs with goal-framing and dispositional regulatory focus in study 1 and goal framing and situational regulatory focus in study 2 as independent variables and tax compliance as dependent variable were performed. The interaction between regulatory focus and goal framing was in both studies significant. Consistent with the hypothesis, tax compliance was higher under conditions of regulatory fit. We argue that the effectiveness of positively and negatively framed information about the use of tax payments for public goods and the consequences of tax behaviour depend on recipients’ regulatory focus. Neither framing can be considered as generally more effective. In two studies, interaction effects between regulatory focus and goal framing on tax compliance were found. For recipients under promotion focus, information highlighting the potential gains increased tax compliance; for recipients under prevention focus, information highlighting the potential losses increased tax compliance. The effect of regulatory fit held for both dispositional and situational regulatory focus.

Keywords: public finances, framing information, regulatory fit, tax compliance, information campaigns

Regulatory focus and deceptive behavior: Avoiding blame versus over claiming credit

SANKEY, M. (University of Melbourne), BARSKY, A. (University of Melbourne)

The psychology of credit and blame assignments as well as organizational factors facilitating these behaviors have received considerable research attention. However, little is currently known about the types of people who are more prone to committing these deceptive acts. The current study suggests that regulatory focus theory will aid in predicting the deliberately unethical acts of taking credit and avoiding blame. Assignments of credit and/or blame are considered to be thought out, conscious acts that result from an individual’s calculated decision making process. In organizations, vital rewards (e.g., positive feedback, bonuses, respect) hinge on credit for perceived success. Conversely, punishments (e.g., negative feedback, pay cuts, derogation) hinge on blame for failure (Grant & Bateman, 1993; Jackall, 1983; Gibson, 2003). Given that promotion-focused individuals are more sensitive towards positive outcomes (i.e. gains and non-gains), it is hypothesized that they would be more inclined to commit the deceptive act of taking credit for others’ success in order to increase the likelihood of attaining a positive outcome (e.g. being promoted). In contrast, as prevention-focused individuals are more oriented towards negative outcomes (i.e. losses and non-losses); it is hypothesized that they would be more inclined to commit the deceptive act of avoiding blame for their own failure in order to increase the likelihood of avoiding a negative outcome (e.g. being fired). Moreover, it is predicted that such behaviours are more likely to occur when individuals pursue a goal in a manner that sustains their regulatory orientation. Data will be collected through an online quiz show using approximately 200 undergraduate students. Other measures will include surveys of trait regulatory focus, conscientiousness and demographic variables. Data will be analyzed using multiple regression. Data analysis is underway and results will be presented at the conference. Our paper makes three significant contributions to the literature. First, we introduce regulatory focus as a predictor of deceptive workplace behavior. Second, we examine the interplay between chronic and situational regulatory focus and deceptive workplace behavior. Finally, we address the dearth of literature comparing blame and credit patterns (see, e.g., Gibson, 2003; Grant & Bateman, 1993).

Keywords: regulatory focus, deceptive behavior, blame, credit, decision making
The role of regulatory focus in occupational decision making: An integration with personality and cultural values

KOELHLER, T. (University of Melbourne), KURTESSIS, J. (American Institutes for Research)

Though both personality and cultural values have been empirically linked to occupational interest and the career development process (Barrick, Mount, & Gupta, 2003; Hartung, Vandiver, Leong, Pope, Niles, & Farrow, 1998), Kluger’s (2004) suggestion that regulatory focus may be related to occupational interest remains unexamined. We hypothesize that promotion focused individuals strive for jobs that contain more novelty, non-routine tasks, risk, and opportunities for growth and innovation. Prevention focused individuals strive for jobs that are safe, contain more routine tasks and highlight compliance. The current study integrates previous research on regulatory focus, personality, and cultural values to examine their influence on occupational decision making. Data was collected through an online survey-based study of 521 undergraduate students, of which 187 students (36%) identified themselves as international students (i.e., born outside the US). Measures included surveys of trait regulatory focus, the Big Five personality characteristics, self-efficacy, locus of control, and preferences for job characteristics (outcome variable). The data was analyzed using multiple regression. Results show that personality factors predict regulatory focus. Some narrow bandwidth facets of personality and interactions between the personality factors contributed incremental variance beyond these broad personality factors. Results further suggest that the relationship between several personality facets and preferred job characteristics was mediated by regulatory focus. Lastly, we found a significant moderating effect of cultural values on the relationship between regulatory focus and preferred job characteristics. Our study is framed within well researched theories of job characteristics and motivation, and contributes to the current literature in several ways. First, we examined the unique predictive ability of narrow bandwidth facets of personality beyond that of broad bandwidth factors. Second, we have answered calls in the literature to integrate theories of personality and motivation when examining preferred job characteristics (e.g., Barrick et al., 2003), and lastly we extend the regulatory focus and personality literatures by incorporating the moderating role of cultural values. Future research has to extend the exploration of regulatory focus as a mediator and the role of cultural values as a moderator for the relationship between regulatory focus an job-related outcomes variables.

Keywords: regulatory focus, occupational decision making, personality, cultural values, big five model of personality
Research on the teaching and learning of Australian university psychology: Evidence-based innovations for improving student learning

Chair(s): REECE, J. (School of Health Sciences, RMIT University)

There is active, dynamic and influential research on the teaching and learning of university psychology being conducted in Australia, and this symposium will present the findings from four studies to illustrate the current state of the field. The four papers explore different aspects of the scholarship of teaching and learning, and use a variety of methods, but a common thread among these studies is a commitment to scientific rigour in the quest for evidence-based innovations for improving student learning. The four studies cover a diverse range of teaching and learning areas: postgraduate clinical training, peer review of university teachers, perspectives on feedback, and critical thinking in first-year students in the context of developing their appreciation of research methodology. Each of the studies is based on a sound theory of pedagogy, and both qualitative and quantitative data inform the outcomes. These studies are all eminently practical, and describe the evaluation of teaching innovations that can be easily incorporated into practice. The learning objective of this symposium is simple but powerful: to provide teachers of psychology with “food for thought” by presenting a range of evidence-based innovations for teaching and learning. In addition, it is hoped that involvement in the symposium will facilitate collaborations among the key players in the scholarship of teaching and learning of psychology in Australia—the Australian Psychology Educators’ Network (APEN) and the Teaching, Learning and Psychology Interest Group of the Australian Psychological Society (TLaPIG)—and their international counterparts.

Hard science and soft heads: Critical and creative thinking in the context of first-year group research projects

REECE, J. (School of Health Sciences, RMIT University), CRANNEY, J. (Department of Psychology, University of NSW)

One of the aims of a special course for first-year psychology majors is to introduce them to the psychological science (compared to ‘folk psychology’) way of thinking, by having them engage in a range of research-related activities. First, in this research, students are participants in an experimental study, which they then write up as a research report in scaffolded stages. In subsequent lecture and practical sessions, they undertake a number of exercises, including operationalising variables (e.g. ‘love’), designing hypothetical studies (thus discovering the advantages and disadvantages of quasi-experimental and experimental designs), and criticising mock research articles. Simultaneously, in small groups they are given a limited set of topics from which they develop research questions, leading to specific hypotheses, which they then test. This is their first experience in designing their own study to test a hypothesis, which includes operationalising variables, developing materials, and gathering and summarising data. The collaborative learning environment is essential at this transition stage, with the final step being the group oral presentation of their study. The results of this research showed that the ability to design a study improved from Weeks 1 to 11. Students rated in-class design exercises, and mock article critiques, as assisting development of this skill. Knowledge of cognitive fallacies and research methodology improved from Weeks 1 to 11. Students rated the in-class quizzes as contributing to this improvement. A distinction average mark was obtained on the capstone group research project; students indicated that they learnt more effective oral presentation skills and more about how to conduct research. In conclusion, both objective indicators as well as student evaluations suggest that this introduction to psychological science is an intense but rewarding experience. Overall, students are well on their way to becoming “psychologically literate citizens”.

Peer review of teaching: A five-stage model for building communities of reflective teaching practice

CHESTER, A. (School of Health Sciences, RMIT University), KIENHUIS, M. (School of Health Sciences, RMIT University)

This paper examines the development, implementation and evaluation of a peer review of teaching (PRoT) pilot amongst psychologists and other health science academics. The ten staff participating in the program (six males, four females) included relatively new and more experienced colleagues. A reference group developed a 5-stage cyclical model of PRoT in which participants were randomly allocated to cross-disciplinary pairs, attended training in PRoT and took turns to be both reviewer and reviewee. Review documents were collected and analysed and all participants interviewed about their experiences. Although the pilot was not restricted to face-to-face teaching, the majority of reviews focused on in-person classroom practice. At the completion of the pilot participants expressed their enthusiasm for PRoT, noting the value of the cross-disciplinary, reciprocal model. PRoT was perceived to be important in the development of a community of collegial, reflective practice. In this presentation participants in the pilot will describe their first-hand experiences. In addition, the effective characteristics of the program will be examined and potential limitations explored.

Comparing student and academic perspectives on feedback: Discrepancies, challenges and moving forward

ELGAR, K. (Discipline of Psychology, School of Health Sciences, RMIT University)

A common student perception of feedback in higher education is that it is often lacking in detail, usability, and timeliness; however, many staff members resent the lack of investment students place on engaging with, or even collecting, feedback on work. Despite increasing recognition of the role of feedback in student learning and course satisfaction, few studies have sought to contrast student and academic perspectives of feedback in a discipline to identify reasons for why this frustration occurs. This paper highlights the key similarities and differences in the conceptualization, use and preference for feedback observed between staff and students in the Discipline of Psychology at RMIT University, following a detailed survey of their feedback practices. Further to this, demographic, academic, and personality variables are explored to help explain what predicts feedback preferences and feedback satisfaction in both staff and students. Guidelines and good practice suggestions are provided to assist staff in overcoming the discrepancies between student and academic perspectives on feedback.

Keywords: higher education, work feedback preferences, course satisfaction, student learning, academic feedback

Objective structured clinical examinations in clinical psychology: A pilot study

YAP, K. (Discipline of Psychology, School of Health Sciences, RMIT University)

Although there is agreement among psychologists on the importance of core competencies in clinical practice, there is a lack of research and development into the assessment of these competencies. Supervisor ratings remain the main method of assessing clinical competence, even though they are highly subjective and unreliable. The aim of this study was to examine the use of an objective structured clinical examination (OSCE) for the assessment of clinical interviewing skills in a Clinical Psychology program. Used in most medical schools internationally, the OSCE requires students to undertake a series of stations which simulate clinical situations. In each station, students perform a structured clinical task with a standardised patient (a trained actor) while being observed by an examiner. The student’s
performance is rated using a standardised scoring sheet. Participants were first year Doctor of Psychology (DPsych) students at Monash University ($n = 9$). There were seven OSCE stations (five 16-minute and two 8-minute stations) with a wide range of psychological presentations. The Spielberger State-trait Anxiety Inventory was administered before and after participating in the OSCE. Participants also completed a post-OSCE 13-item survey. The results showed that participants experienced significantly higher levels of pre-OSCE state anxiety ($M = 51.8$, $SD = 14.9$), compared to post-OSCE state anxiety ($M = 40.2$, $SD = 9.1$), $t(8) = 3.339$, $p = 0.01$. In general, students agreed that the OSCE was a valid assessment of their clinical interviewing skills and noted that the stations were realistic and relevant to their course. Mean scores across all 12 stations indicated a pass standard performance by the majority of participants. Students noted in their post-OSCE survey that the assessment was a worthwhile exercise and supported its inclusion into the DPsych program. However, they were less certain about whether it provided a fair assessment and felt that performance was affected by anxiety. Several students suggested that the OSCE would be more effective as a formative rather than a summative assessment tool. In summary, this pilot study indicates that students were receptive to OSCEs, but may require more preparation for the examination process to reduce performance anxiety.

Keywords: objective structured clinical examination, clinical training, clinical interviewing skills, assessing clinical competencies, student assessment

**Restoration and restorative environments**

Chair(s): HARTIG, T. (Uppsala University)

Recent years have witnessed rapidly growing interest in the health resource values of natural environments. A core component of the work in the area concerns the processes that mediate between experiences in natural environments and outcomes relevant to health. To date, processes of stress reduction and attention restoration have received the most attention. In line with this emphasis, the present symposium brings together researchers who are working with a variety of practical issues that involve restoration and the restorative values of nature experiences. Their presentations will inform you about conditions from which people need restoration; some of the processes that fall under the restoration rubric; some of the ways in which socio-physical environments create a need for, work against, or promote restoration; and environmental design and management efforts and approaches to therapeutic intervention that can benefit from knowledge of the restorative values of natural settings. After this symposium, participants will be able to: (1) distinguish and describe basic types of psychological restoration addressed in research on nature as a restorative environment, (2) describe some of the ways that natural settings and elements of nature are or could be used in health care contexts, and (3) give examples of the use of psychological research on restorative environments in efforts to address environmental design and management problems and to enhance therapeutic interventions.

**Using agricultural land as restorative places in densely built environments? An experimental study**

MARTENS, D. (Swiss Federal Research Institute WSL)

Due to increasing residential density in many European cities, pressure on public natural
environments is growing; a shrinking area of natural environments is called on to serve more people seeking psychological restoration. Close-to-urban areas are often cultivated agriculturally and could serve restoration reasons. The growing interest in organic food leads to different agricultural management, which eventually has an effect on the aesthetic perceptions of users seeking restoration. We combine the field of restoration psychology with land use planning questions, aiming to positively influence people’s everyday restoration: what effect does the management strategy have on human restoration and well-being? An experimental design compares the effect of extensively versus intensively managed agricultural land. Video presentations of both conditions and a walk on a treadmill serve as the treatment. Participants, a representative sample of Zurich, Switzerland, are randomly assigned to either film, or to a control group, watching no film. All participants walk on a treadmill individually to exclude effects arising from physical activity or social interaction. The Perceived Restorativeness Scale assesses the perceived restorative quality of each treatment. Additionally, psychological well-being is measured by standardized scales before and after the treatment, and in a follow-up measure to analyze longitudinal effects. Group differences are analyzed by a between-subject covariance analysis. We expect differences between the effects of extensively versus intensively used agricultural land. The subscale scores of the Perceived Restorativeness Scale might explain these differences, mediating the effect of the environmental manipulation. The effect of physical activity can be excluded as an alternative explanation due to the control group, which was active though without perceiving an agricultural environment. The results contribute towards conceptualizing further research in the field of restoration psychology by distinguishing different natural conditions, measuring their specific perceived restorativeness. Aside from this, practical implications for environmental development can be drawn. Close-to-urban natural areas in particular could serve the need for restoration from everyday demands for urban visitors.

A multidisciplinary study on the relations between the ecological characteristics of urban green spaces and users’ perceived benefits and well-being

CARRUS, G. (University of Roma Tre)

Green areas in the urban environment represent an opportunity for promoting human health and well-being. From an applied viewpoint, it is important to gain a better understanding of the relationships between the physical characteristics of green spaces and the psychological processes leading to perceived psychological benefits and well-being, in order to develop more effective health promotion strategies. The study is part of a multi-disciplinary research program supported by the Italian Ministry of Scientific Research as a “Research Project of National Interest”. We aimed at investigating the relations between structural characteristics of urban green areas (e.g., amount and naturalness of greenery) and psychological outcomes (e.g., perceived benefits and well-being). A set of possible mediating factors was also considered, including cognitive (e.g., attitudes towards and perceived restorativeness of green areas), affective (emotional reactions) and behavioural responses (e.g., activities performed). The role of frequency and duration of visits was also explored. A comprehensive model analysing the mediation effect of psychological factors and experience modalities in the relationship between greenery and well-being was tested. Four Italian towns at different latitudes were selected for the study (Bari, Rome, Florence and Padua). We identified 5 sites in each town, characterised by different amounts of greenery and different degrees of naturalness, ranging from urban plazas, with few trees and shrubs, to large green areas, with little presence of man-made elements. Participants (N = 400) were contacted at the different sites, and asked to fill in a questionnaire about their experience and attitude toward green areas. Preliminary results outlined a complex picture of people-green areas relationship and its effects on well-being. Subjects reported
different physical and psychological benefits from visiting urban natural environments. Specific behaviours were found to be associated with cognitive and affective responses to the green areas, and to different beneficial outcomes. Further analyses are in progress, to test the overall model, including mediated relations. This study has yielded encouraging preliminary findings on the role of experiences in green areas in health promotion. Results will be discussed with reference to psychological models of human well-being, and health-oriented management of natural environments.

Keywords: urban environment, health promotion, urban green areas, natural environments, well-being

The role of attention restoration in stress-reducing effects of indoor plants in a hospital room

DIJKSTRA, K. (University of Twente)

Natural environments have shown to hold potential stress-reducing properties. Previous research has demonstrated that the stress-reducing effects of indoor plants in a hospital room can be explained by the mediating effect of the perceived attractiveness of the hospital room (Dijkstra, Pieterse & Pruyn, 2008). When investigating the restorative effects of nature, the focus is often either on stress reduction (Ulrich’s 1983 theory of psychophysiological stress-reduction) or on attention restoration (attention restoration theory, Kaplan & Kaplan, 1989). The specific relation between the two processes is hardly ever considered. The current study therefore included measures for both attention restoration and stress reduction. This study aimed to shed more light on the specific role that attention restoration plays in stress-reducing effects of indoor plants in the built healthcare environment. A single-factor between-subjects experimental design (nature: indoor plants vs. no plants) was used in which participants ($n = 87$) were presented with a scenario describing hospitalization with appendicitis. Subsequently, they were exposed to a photo of a hospital room. In this room were either indoor plants, or a control condition in which no indoor plants were present. Afterwards, perceived stress, perceived attention restoration, and perceived attractiveness of the hospital room were measured. Exposure to the hospital room with indoor plants evoked reports of lower perceived stress, greater perceived attention restoration, and a higher perceived attractiveness of the hospital room. Moreover, a series of mediation analyses demonstrated the specific relationship between those variables. The hospital room was perceived as being more attractive when indoor plants were present. This subsequently led to attention restoration, which in turn resulted in participants feeling less stress. The current study demonstrated that exposure to a hospital room with indoor plants leads to attention restoration and less stress. Moreover, our study demonstrates how the concepts of attention restoration and stress are related. Furthermore, this study provides insight into how the beneficial effects of indoor plants come about.

Keywords: natural environments, indoor plants, hospital, attention restoration, stress

Attentional effort and restoration in mindfulness meditation training

LYMEUS, F. (Uppsala University), HARTIG, T. (Uppsala University), LUNDGREN, T. (Uppsala University)

Mindfulness-based stress reduction (MBSR) programs may ultimately help people to better avoid stress as they manage the demands of everyday life. Such programs initially require effortful directed attention from their participants, so the benefits of mindfulness practice may not be realized during the initial training. The present study assessed the effects of mindfulness training on attentional capacity, both during practice sessions and over the longer term, as program participants acquired competence in mindfulness practice. Our examination of short-term effects considered the moderating role of an environmental enhancement; we compared change in attentional capacity during practice with and without nature imagery. University students ($N = 51$) were randomly assigned to either an 8-week MBSR program or a waiting list control group. Program participants were further randomly assigned to weekly training sessions...
with or without the projection of nature images during a practice period. Members of the control group attended weekly rest sessions with the same duration as the mindfulness practice sessions, but they only viewed the nature images. At an initial training session (T0) and at every other session thereafter (T1-4), the subjects completed the Necker Cube Pattern Control Test (NCPCT) and Letter–Digit Substitution Test (LDST) before and after the period (20-min) allocated for practice/rest; the measures at T0 are reference values. Control group members, who watched nature images during the rest session, improved in LDST performance on average, consistent with attention restoration. In contrast, mindfulness program participants showed pretest-posttest declines in performance; practice apparently required attentional effort. The decrement was only slightly smaller with the group that practiced with nature images. The program participants and control group members had a similar pattern of improvement in pretest attention scores from T0 to T4. Initial attention scores predicted frequency of practice and attendance at training sessions; those with less initial attentional capacity participated less. Attentional effort required by mindfulness training may hinder its adoption by those people who might benefit the most. For them, regular, brief periods spent in natural or other restorative environments may work as an alternative, alone or as preparation for mindfulness training.

Keywords: mindfulness training, stress reduction, restorative environments, nature imagery, attention restoration

Restorative environments: New researchers, new questions

Chair(s): Hartig, T. (Institute for Housing and Urban Research, Uppsala University)

As a complement to research on environmental stress, research on restorative environments has been drawing the attention of increasing numbers of researchers and practitioners in the environment-behavior-design field. This symposium brings together four new contributors to restorative environments research, all of whom are using psychological theory and methods to specify and address knowledge gaps. Their presentations will cover diverse aspects of restorative processes and the environmental characteristics that promote (versus merely permit) restoration.

Work and restoration in open-plan offices during different sound exposures

Jahncke, H. (Laboratory of Applied Psychology, Centre for Built Environment, University of Gävle)

Research on restorative environments has so far paid little attention to how environmental sounds might affect restorative processes. The aim of the present study was to investigate cognitive, emotional, and physiological effects of different office sound conditions during work and rest periods. Adults (N = 37) went through one practice session and two experimental sessions. In each experimental session they worked for two hours on attentionally demanding tasks, and then had a 14-min period for rest. Sound was manipulated in both the work and rest periods. Sound during the work periods varied across the experimental sessions in terms of sound level and amount of irrelevant speech (30 LAeq + little irrelevant speech versus 60 LAeq + much irrelevant speech). Sound during the rest periods varied across the two experimental sessions in terms of watching a nature film in silence versus listening to noise without a film. Subjects performed two cognitive tasks (SART and Arithmetic) and rated their tiredness and
motivation at arrival, after the two hours of work and after the rest period. They also gave saliva and urine samples at different time points during the session. Preliminary results indicate the predicted effects of the sound manipulations during the work and rest periods on performance and self-reports of fatigue. The presentation will include a more detailed account of analyses, including those with the physiological data. The present study helps address a gap in knowledge concerning the effects of the aural environment on the depletion and restoration of adaptive resources.

Keywords: restorative environments, restorative processes, environmental factors, work, rest periods

Health benefits from natural elements in hospitals

BRINGSLIMARK, T. (Norwegian University of Life Sciences)

The study that will be presented is part of a larger research project in Norway that aims to investigate possible health benefits from natural elements in hospitals. The natural elements include window views to nature, pictures of nature, and natural materials such as wood. Within evidence-based design the main issue has been to create built contexts for healing by focusing on elements in the environment that can enhance the healing process, such as elements of nature. As part of the larger study we have first conducted a study on preferences for different degrees of wood in patient rooms by using employees at a hospital as an expert group. Some preliminary results from the larger study which also includes window view to nature and the inclusion of pictures of nature in patient rooms will also be presented. We used data-manipulated pictures of a patient room with different degrees of wood on a continuum from no wood to all wood. The room with no wood represents a standard patient room. An anonymous e-mail questionnaire was sent out to employees at a Norwegian hospital. The e-mail questionnaire was adjusted so that all the pictures were shown in a random fashion. The participants were asked to rate the pictures on twelve adjectives describing the room. All the items in the questionnaire were taken from standardised measures related to preferences for both exterior and interior settings. The results indicated that it was the room with an intermediate level of wood that was the most preferred. This room was also rated as most Pleasant, Natural, Calming, and Secure, and as the least Boring room. The rooms on both end of the continuum were the least and second least preferred rooms. Hospital employees tend to prefer patient rooms with an intermediate level of wood. The results also indicated that standard patient rooms without wood were the second least preferred, whereas there are limitations to how much wood is preferred. Further research within this project will evaluate more directly the possible beneficial health effects of nature elements in hospitals.

Keywords: health benefits, hospital, natural elements, wood, healing

The contribution of small-scale patterns of natural scenes to restoration

JOYE, Y. (Philosophy Department, Centre of Logic and Analytic Philosophy, University of Leuven)

Up until now most experimental studies in restorative environments research have mainly investigated restorative responses toward natural versus urban environments/elements in their entirety. However, natural scenes are fractal, which means that – among others – visible structure and detail keep appearing as one progresses from the largest to the smallest scales of the scene. In contrast, most urban structures often lack (that degree of) visual detail on smaller scales. The main aims of the present study were (a) to investigate whether restorative qualities (e.g. “fascination”) are also associated with the smallest details of natural versus urban scenes and whether low-level structural features (i.e. complexity and coherence) contribute to this. 40 students participated in the experiment. The stimulus set consisted of sixty high-resolution photographs depicting both natural and urban content. The photos ranged, for example, from views of entire landscapes or streetscapes, to views of individual elements, such as individual trees or buildings. The images varied in coherence, complexity and distance from
which they were photographed. All photographs belonged to either of three categories: (a) they could either be images of the entire scene \((N=20)\), (b) a detail taken from that entire scene \((N=20)\), or (c) a further detail taken from this detail of the entire scene \((N=20)\). The zooming ratio between the three image categories was held constant and the details were always extracted from the center of the source image. Subjects had to perform two tasks in the experiment. First, on a computer screen they saw the complete stimulus set in a random order and they were instructed to look as long at all the individual pictures until they found them no longer interesting to look at. For all pictures, viewing time was recorded. After this, in the second task, the subjects watched the images again and had to rate on a scale from 1 to 7 the degree to which the scene was coherent, attractive, complex, fascinating and whether it conveyed a warm glow. Preliminary analyses indicate that, on average, subjects watched the “natural” photographs significantly longer than the urban scenes. Moreover, it seems that for the images of details of the natural scenes viewing time increases on zooming in, whereas viewing time for the urban images declines for the pictures of urban details. This study for the first time addresses the issue whether the smaller scales of natural versus urban scenes are also a source of fascination, and hence might also contribute to the restorative character of natural scenes.

**Keywords:** restorative environments, natural elements, urban environment, photographs

### Influence of human made objects on perceived restorative quality in natural environments: A virtual reality study

**PALS, R. (Faculty of Behavioral and Social Sciences, Department of Psychology, University of Groningen)**

Research has show that restorative characteristics commonly hold at a higher level in natural settings than in urban settings. Less is known about what and how specific features of the environment influence perceived restorative characteristics. In this study we looked at how the presence and design of human-made objects in a natural setting influenced perceived restorative characteristics, preference and experienced pleasure. Virtual environments (VE) were used to systematically vary specific environmental features (street furniture) while keeping all other factors constant. Ninety-nine participants were randomly assigned to three virtual environmental conditions in a between-subjects design: a natural setting with metal street furniture (modern, unnatural design), a natural setting with wooden furniture (natural, organic design), and a natural setting without furniture. The study took place in a virtual reality theatre. Participants were exposed to a 3D presentation of the VE on a half immersive screen. After a 12 minute tour in the VE, participants evaluated perceived restorative characteristics of the environment, preference for the environment, and experienced pleasure in the environment. Also, respondents explicitly evaluated how well the street furniture harmonized with the environment. Preliminary results showed that when participants were explicitly asked to evaluate how well the furniture harmonized with the environment, the wooden furniture scored significantly higher than the metal furniture. However, when participants evaluated the perceived coherence of the environments on a more global level, no differences were found between the three conditions. We are currently conducting more detailed analyses, among which we examine the possible moderating effects of familiarity and personal need for structure. Results of these analyses will be presented at the conference. Although participants stated that the wooden furniture harmonized better with the natural environment than the metal furniture, the presence and design of street furniture did not influence perceived restorative characteristics, preference and experienced pleasure in the natural setting.

**Keywords:** restorative characteristics, natural settings, urban settings, preference, pleasure
Retirement transition and adjustment: Time perspective and patterns of change

Chair(s): HESKETH, B. (University of Western Sydney)
Discussant(s): ROE, R. (University of Maastricht)

The papers presented in this symposium illustrate strong theoretical perspectives relevant to the process of profiling transitions from full time employment through bridge employment and other transition activities to retirement. Time is a strong theme in the symposium, including time perspective, longevity estimates, and a longitudinal focus. Key learning objectives include: Understanding the role of theory in guiding research and practice; placing a focus on time related constructs in psychology, a neglected area; highlighting the importance of multiple patterns to transition, rather than a normative approach; introduction to innovative methodologies that both address longitudinal data, and provide an approach for measuring self-estimated patterns. The first paper uses longitudinal data from the USA Health and Retirement Study to examine the predictors of longitudinal change patterns of retirees’ bridge employment status. The predictors included individual attributes (e.g., age, gender, years of education, self-report health, total wealth, and retirement income), preretirement job-related variables (e.g., work stress and job satisfaction), family-related variables (e.g., marital quality, marital status, and spouse working status), and retirement planning activities (e.g., psychological planning and financial planning). Using mixture latent Markov modeling, a subset of United States nationally representative longitudinal data (N = 2713) from the Health and Retirement Study that were collected in 1998, 2000, 2002, 2004, 2006 were analyzed. This subset of the data includes retirees who were not retired in 1998, but considered themselves to be retired in 2000. Retirees’ bridge employment statuses over time were derived from Data collection in 2000-2006. Most predictors were derived from the 1998 data collection, except for retirement income. Three retiree subpopulations were identified according to longitudinal change patterns of retirees’ post-retirement employment status: 43.1% of retirees in the sample were classified into the latent class for “stayers” who were never employed after their retirement; 14.8% of retirees were classified into the latent class for “stayers” who were always employed after their retirement; and 42.2% of retirees were classified into the latent class for “movers” who changed their previous employment status at some point during the span of the study. Results from mixture latent Markov modeling also showed that gender, Global Financial Crisis, so the results also illustrate the effect of context on retirement intentions. The final paper presents a theory of retirement transitioning and decision-making that integrates key themes in organizational psychology research, drawing on the findings of the first three papers of this symposium to demonstrate how theory can guide future research and practice.

Profiling retirees’ longitudinal change patterns of bridge employment

WANT, M. (Maryland University)

This study aims at examining the predictors of longitudinal change patterns of retirees’ bridge employment status. The predictors we examined here included individual attributes (e.g., age, gender, years of education, self-report health, total wealth, and retirement income), preretirement job-related variables (e.g., work stress and job satisfaction), family-related variables (e.g., marital quality, marital status, and spouse working status), and retirement planning activities (e.g., psychological planning and financial planning). Using mixture latent Markov modeling, a subset of United States nationally representative longitudinal data (N = 2713) from the Health and Retirement Study that were collected in 1998, 2000, 2002, 2004, 2006 were analyzed. This subset of the data includes retirees who were not retired in 1998, but considered themselves to be retired in 2000. Retirees’ bridge employment statuses over time were derived from Data collection in 2000-2006. Most predictors were derived from the 1998 data collection, except for retirement income. Three retiree subpopulations were identified according to longitudinal change patterns of retirees’ post-retirement employment status: 43.1% of retirees in the sample were classified into the latent class for “stayers” who were never employed after their retirement; 14.8% of retirees were classified into the latent class for “stayers” who were always employed after their retirement; and 42.2% of retirees were classified into the latent class for “movers” who changed their previous employment status at some point during the span of the study. Results from mixture latent Markov modeling also showed that gender,
years of education, marital status, spouse working status, and marital quality were all significant predictors of these longitudinal change patterns of bridge employment status. This study confirmed that multiple longitudinal change patterns of retirees’ bridge employment status do exist and they can be predicted by variables in different aspects of retirees’ life. The findings support the dynamic perspective which emphasizes bridge employment as a longitudinal workforce participation process between one’s retirement decision and entering full retirement.

### Exploring the influence of time perspective on retirement planning and adjustment

**EARL, J. (University of New South Wales)**

As the bulk of our international populations continue to age there are two important areas where psychology can contribute: promoting retirement planning and positive retirement adjustment. Time perspective (TP) may provide useful insights to the way that people view their past, present and future. This may influence the propensity to plan and cope with the future. This study explores the relationship between TP, retirement planning and retirement adjustment. In particular the paper reports on a study in which relationships between TP and retirement planning are replicated and new relationships between TP and retirement adjustment are explored. 570 retirees aged 45 years and older, recruited via the National Seniors Association, participated in the study. Participants were invited to complete an on-line survey that included demographic information (length of time retired, gender, age, education, household income), a shortened version of the Zimbardo Time Perspective Inventory (ZTPI), as well as pre and post retirement measures of Retirement Planning (RPQII). Hierarchical multiple regression analysis was used to compare the contribution of demographics and TP to pre and post retirement planning and to compare the relative contribution of demographics, TP and planning (pre and post) to variations in retirement adjustment. TP accounted for additional variance in pre and post retirement planning beyond that explained by demographics. Future and Past Negative TP both predicted pre-retirement planning. Present Fatalistic TP negatively predicted both pre and post retirement planning. Contrary to expectations, but consistent with earlier findings, Present Hedonistic TP predicted both pre and post retirement planning in a positive direction. TP accounted for additional variance in retirement adjustment beyond that explained by demographics and planning. Analysis of the regression coefficients revealed that Past Positive TP and Present Fatalistic TP were predictors of retirement adjustment. As retirement adjustment increases, past positive TP increases but present fatalistic TP decrease. Results from our studies suggest that TP may provide important and additional insight to the process of retirement planning and in facilitating retirement adjustment. The possibility of designing interventions that encourage a past positive TP and address present fatalistic attitudes to time perspective are explored.

### Predictors and anticipated outcomes of planned retirement transition patterns

**GRIFFIN, B. (Macquarie University)**

Using the Theory of Work Adjustment (TWA) and self rated life expectancy as a framework we aimed to: 1) test transition patterns and their relationship to satisfaction and performance; 2) further explore self assessed longevity as a predictor of retirement transition; 3) test TWA P-E fit as a predictor of anticipated retirement satisfaction; e) Examine the impact of the Global Financial Crisis (GFC). Method: In collaboration with the NSW Department of Premier and Cabinet, a web based survey was administered covering demographic information, planned patterns of retirement, work values, and current and anticipated job satisfaction, and well being, health and financial status. Questions also addressed intended activities during
retirement, extent of planning, and self rated competence in managing retirement. Data were available from 3157 respondents from six public service agencies, representing 12% of their workforce. The median age was 45-54, and just over half were female. Participants self nominated into one of three patterns of anticipated retirement transition: A) Fulltime or part-time/ casual work, followed by retirement with no work (32.6%); B) Fulltime or part-time/casual work, official retirement, then part-time paid work either related or unrelated to previous work, leading to no work (33.1%); and C) Fulltime or part-time/casual work, switch to part-time or reduced hours, followed by official retirement with no work (34.3%). Among other differences, those with lower income or less education chose A over B or C. Self assessed longevity affected anticipated retirement age. Planned patterns of activity and satisfaction in retirement mirrored current values, providing support for the PE Fit framework. The GFC affected 20% of the respondents, mainly those planning to retire in the next three years. The data provide additional support for earlier retirement research and highlighted the varied patterns of transition intentions of current late-career workers. Support was found for a P-E fit approach within a self-assessed longevity framework, but noting the impact of external factors such as the GFC and changing Government superannuation rules.

Keywords: planned retirement, transition patterns, satisfaction, performance, Global Financial Crisis

From theory to practice in retirement decision-making and transition planning

HESKETH, B. (University of Western Sydney)

This paper has theoretical and practical aims. Theoretically it aims to draw upon the three studies presented in the symposium and other retirement research to highlight the relevance of several key psychological perspectives on retirement planning, namely: 1) career paths and patterns – developmental career theories; 2) P-E fit and adjustment theories; 3) time related issues in decision-making including time discounting; 4) goal setting and project planning. Practically, the paper aims to put theory and data to practice by presenting a structure for retirement decision-making and transition planning. Data will be synthesized from the three presentations and a review of the literature to highlight the relevance of the frameworks. With lessons learned from research on errors in training, and the development of adaptive skills, these frameworks will be used to outline approaches and materials that can be developed in retirement planning packages to provide greater assistance to those planning retirement in the context of changing financial and governmental regulations. The result of this synthesis will be presented in the form of practical ideas and activities that can be adapted and used in future research on retirement planning, and provide a basis for applying the growing body of evidence relating to adaptive performance to adaptation to retirement. It is hoped that this paper will synthesize the research presented in the symposium, providing an opportunity for commentary by the discussant.

Self-related concepts in the understanding and treatment of psychopathology

Chair(s): MOULDING, R. (Swinburne University of Technology)
Discussant(s): KYRIOS, M. (Swinburne University of Technology)

The area of self perceptions and “the self” has seen wide expansion over the past few years, with increasing interest from clinicians and clinical researchers seeking to understand its role in the aetiology and treatment of psychopathology. More recently, there has been growing interest amongst researchers and clinicians from the cognitive-behavioural field who are interested in using self-related concepts in their understanding of psychopathology. This symposium aims to explore the importance of a range of self-construals in the aetiology and treatment of psychopathology within a cognitive-behavioural framework. We will start with a broad overview of self in psychopathology, where Dr Sunil Bhar will discuss various conceptualisations of the self and the available empirical evidence for their role in psychopathology. The role of specific self-concepts in improving our understanding and treatment of specific psychopathologies will be illustrated in the following three papers. The paper by Ahern and colleagues examines the relationship between intrusions with moral themes and specific self-perceptions (i.e., self-ambivalence and self-worth contingent on moral standards) and discusses the implications for the understanding and treatment of Obsessive-compulsive problems. Moulding and colleagues suggest that self-ambivalence, and control may partially relate to OCD through faulty reasoning processing and inferential confusion. The final paper by Dr Nelson and colleagues proposes that a disturbance in the basic sense of self may represent a marker of psychotic vulnerability.

Self and psychopathology: An introductory overview

BHAR, S. S. (Swinburne University of Technology), KYRIOS, M. (Swinburne University of Technology)

The relationship between the self-concept and vulnerability to anxiety, depression, and personality disorders has been the focus of much interest in psychological theories. At least two aspects of the self-concept have been nominated as pathogenic: The content of self-concepts (i.e., types of beliefs about the self, the positivity or negativity of these beliefs), and the structure of self-concept (i.e., the coherence of the self-concept, certainty of beliefs about the self, and self-complexity). From a cognitive perspective, critical beliefs about the self are forwarded as constituting pivotal vulnerability factors for depression. Similarly, central to the cognitive model of anxiety disorders is belief that the self is vulnerable. More recently, various beliefs about self have been differentially linked to various personality disorders. Structurally, discrepancies between perceptions of actual and desired self concept have been associated with depression and anxiety. Moreover, failures to integrate positive and negative beliefs about one’s self-concept, and achieve a stable view of self are purported to underlie borderline, obsessive-compulsive and narcissistic personality disorders. This paper reviews the empirical basis of these assertions, discusses the findings and limitations of such research and identifies questions that require further research.

Keywords: self-concept, anxiety, depression, personality disorders

The role of self-ambivalence and contingent self-worth in the experience of unwanted intrusive thoughts

AHERN, C. (Swinburne University of Technology), KYRIOS, M. (Swinburne University of Technology)

Using a cognitive framework, this study examined self-perceptions as a vulnerability to obsessive-compulsive disorder (OCD). Specifically, Guidano and Liotti’s (1983) model of self-ambivalence and the notion of self-worth contingent upon moral standards were
investigated as possible mechanisms to explain how individuals come to notice their unwanted intrusions. Additionally, this study specifically examined whether intrusions with moral themes related to self-perceptions. All analyses controlled for the influence of depression. The sample comprised 120 first year undergraduate psychology students who were administered a semi-structured interview and self-report questionnaires. Results indicated that ambivalence about meeting personal moral standards was a particular vulnerability to experiencing obsessive-compulsive (OC) phenomena. There was no support for a model of intrusions with moral themes being associated with self-perceptions independent of depression. The importance of depression was highlighted, directions for future research discussed and implications of the findings explored.

Keywords: obsessive-compulsive disorder, self-ambivalence, self-worth, self-perceptions, depression

Self-ambivalence, self-efficacy and inferential confusion, and their relationships with OCD symptoms

MOULDING, R. (Swinburne University of Technology), FORGIONE, K. (Swinburne University of Technology), NEDELJKOVIC, M. (Swinburne University of Technology), KYRIOS, M. (Swinburne University of Technology)

The inference based approach to obsessive compulsive disorder (OCD) proposes that in OCD the following sequence occurs. First, the individual perceives the world normally (e.g., “My hands are clean”), but they have a feeling of doubt that leads them to distrust their sense-information (“...but maybe...”). In response, the individual starts to question their sense information, constructing a fictitious story – or narrative – that things might be dangerous (e.g., “...and I know that germs are invisible, so my hands might be contaminated”). As a result of the story, the individual further doubts their initial sense information and acts as if their narrative were instead true (“Therefore, my hands are dirty, so I should wash.”) This faulty reasoning process is known as “inferential confusion”. The narratives the individual constructs in OCD are said to follow themes regarding the distrust of the self – that the self may be evil or incompetent (Aardema & O’Connor, 2007). Although inferential confusion has been found to be related to OCD, underlying self factors have not been explored. The present study explored whether self-related beliefs (i.e., the self as immoral, the self as incompetent) underlie inferential confusion in a nonclinical sample (112 participants; 91 females) who completed self report questionnaires. Inferential confusion, self ambivalence and anxiety control were significant predictors of obsessive compulsive symptoms, and inferential confusion partially mediated these relationships. These findings suggest that the relationships of self ambivalence and anxiety control operate partially through inferential confusion. It was concluded that inferential confusion in OCD may partly be driven by a feeling that the self is immoral (but could be moral) or that the self is incompetent (but could be competent).

Anomalous self-experience in the prodromal phase of schizophrenia and other psychotic disorders

NELSON, B. (ORYGEN Youth Health Research Centre), YUNG, A. R. (ORYGEN Youth Health Research Centre)

Over the last fifteen years, there has been increased interest in the early phase of schizophrenia and other psychotic disorders. The focus was initially on the first episode of psychosis but soon reached further back to the pre-onset or prodromal phase. Several strategies have been introduced to identify individuals in the putatively prodromal phase of psychotic disorder. The most widely used of these approaches is the “ultra-high risk” (UHR) approach, which combines known trait and state risk factors for psychotic disorder. Phenomenological research indicates that disturbance of the basic sense of self may be a core phenotypic marker of psychotic vulnerability, particularly of schizophrenia spectrum disorders. Disturbance of basic self-experience involves a disruption of the sense of agency and ownership of experience,
associated with a variety of dissociative symptoms and anomalous cognitive and bodily experiences. In this study, we investigated the presence of basic self-disturbance in a UHR group and whether it predicted onset of psychotic disorder. A total of 41 UHR subjects and 12 first episode psychosis subjects were recruited from Orygen Youth Health, Melbourne. Fifty-two non-clinical control subjects were recruited from the community. Subjects were assessed for basic self-disturbance using the EASE questionnaire. A range of other clinical variables were also measured. Subjects were assessed at baseline and at 12 months follow up. Preliminary data will be presented. Levels of self-disturbance were significantly higher in the UHR sample and the FEP sample compared to the non-clinical control group (p < .001). Further follow-up is required to assess the predictive utility of self-disturbance in the UHR sample. Identifying self-disturbance in the UHR population may provide a means of further “closing in” on individuals truly at high risk of psychotic disorder, particularly of schizophrenia spectrum disorders, thus supplementing the UHR identification approach. This would be of practical value by reducing inclusion of “false positive” cases in ultra-high risk samples, and of theoretical value by shedding light on core features of psychotic pathology.

Keywords: schizophrenia, psychosis, sense of self, self-disturbance

**Sexuality among older people**

Chair(s): MCCABE, M. (Deakin University)

This symposium examines factors related to sexual dysfunction (ED) among older men and women. Frequently older people’s physical and emotional needs are addressed, but their sexual needs are frequently ignored. Yet sexuality is important in peoples’ lives, whatever their age. The first paper in this symposium examines the factors related to sexual expression among older people. This information was used in a workshop context to change participants’ attitudes and behaviours when working with older people. The second paper considers the results of a series of studies that examined the relationship between sexual functioning and relationship satisfaction among older men and women. This paper is particularly relevant in informing our understanding of the place of sexual functioning within a broader context. These findings have implications for the treatment of sexual dysfunction using either medical, psychological or combination therapy approaches. The final paper takes this topic further by discussing the implications of the medication of sexual dysfunction, particularly in relation to erectile dysfunction. The role of social, psychological and emotional factors in the development and maintenance of ED are discussed.

**Mapping sexual expression and ageing**

BARRETT, C. (La Trobe University)

The aim of this study is to understand the context of sexual expression in people aged 65 years and older in order to develop effective responses. The study involved a meta analysis of information in the research evidence; government policies and literature related to sexual expression and ageing. The information was mapped and utilised to develop a storyboarding workshop for aged care service providers to enable them to develop effective responses to behaviour that is labelled as sexually inappropriate or changed sexual behaviour. Educational strategies were also developed to promote healthy sexual
expression. Workshops were piloted, evaluated and disseminated across aged care services in Victoria. The meta analysis revealed a number of factors influencing sexual expression including: societal views of older people; the values and beliefs of service providers and family members; cognitive changes in older people; the education provided to service providers and opportunities for appropriate expression provided to older people. The contextual factors arising from the analysis were mapped and an evidence base relating to each was included in a storyboarding workshop aimed at understanding sexual expression in context. In workshops, participants were invited to explore current stereotypes of older people and beauty and how these impacted on their values and beliefs about ageing and sexual expression. Next, workshop participants were provided with best practice information relating to the experience for older people, the effects of cognitive changes and the legislative requirements. The final component of the workshops involved participants applying this information to an existing situation in their workplace and identifying new management strategies. The process of mapping the context of sexual expression has enabled workshop participants to adopt person-centered responses to sexual expression. Participants report that the workshop provides them with: practical strategies they have not previously considered; permission to talk about sexual expression; and the opportunity to improve the health and wellbeing of older clients.

Sexual dysfunction in romantic relationships among older people

DEAKIN UNIVERSITY, McCabe (Deakin University)

This paper considers the factors related to sexual dysfunction among older women, men and couples. The interactive role of biological, psychological, interpersonal and cultural factors in shaping sexual functioning among older men and women are discussed. Two studies will be presented. The first examines aetiological factors related to sexual dysfunction in older women, and the second examines factors related to erectile dysfunction in older men. The overlap of the various types of sexual dysfunction in women, as well as data related to the causes of the overlap is also considered. Further data are presented on the different types of factors that impact on female sexual dysfunction. In particular, among women, we found a strong association between sexual dysfunction and relationship functioning. This association was not so strong for men. Sexual dysfunction had a negative impact on the interpersonal relationship among older men, as well as men’s self-esteem, masculinity and confidence. Male sexual dysfunction was found to impact on their partner’s sexual dysfunction and vice versa. The need to consider the relationship in the treatment of sexual dysfunction among older people is central to effective therapy.

Keywords: sexual dysfunction, older people, aetiological factors, erectile dysfunction, self-esteem

Viagra: the little blue pill with big repercussions

BARNETT, Z. (University of Queensland)

Erectile Dysfunction (ED) affects millions of men and their partners worldwide. Therefore, it is reasonable to conclude that the proliferation of research centred on Viagra [Sildenafil Citrate], might also look at the impact it has made on individual lives and on interpersonal relationships. The social and psychological aspects of treatment are clearly absent from the majority of research in this area. Indeed, the advent of Viagra has seen diminishing sexual capacities once linked with normal ageing, now pathologised as sexual dysfunction. This culture of medicalisation of sexual function tends to ignore possible alternative psychological factors that underpin, and co-occur with a problem such as ED. Unfortunately, there is a lack of discussion around expectations, conversations, consensual issues, and partner attitudes in the literature. This paper identifies a number of gaps in the extant literature including the social, psychological and emotional impact that Viagra has had on current sexual relationships and the experiences of older men and women.
Shared leadership, diversity climate and managing change at the workplace

Chair(s): HOCH, J. (Michigan State University), MICHEL, A. (University of Heidelberg)

Discussant(s): PEARCE, C. L. (Claremont Graduate University)

Change is a constant challenge faced by management. Change comes in the forms of organizing work by sharing leadership and coordinating teams, dealing with different forms of diversity and cultural background, and coping with employees’ efforts to resist change. This symposium presents empirical research that examines these important issues that affect change in organizations, and their relation to team performance. The five papers in this symposium report the results of field studies in organizational settings, with an overall N of over 10,000 participants. Implications from the studies presented are discussed with the purpose of helping management deal with these ubiquitous changes related challenges facing companies today. The first paper investigates the impact of diversity climate and non-racist behavior on team cohesion and team effectiveness in the military. In line with anti-discrimination laws the results emphasize that organizations should continue to take actions to minimize racist behaviors and create a climate for diversity. The second study investigates, through longitudinal analysis, how politics and organizational climate influence employees’ readiness and resistance to change. The authors find that a negative relationship between perceived politics and readiness for change is moderated by organizational climate. The author of the third paper investigates the impact of shared leadership, in addition to coordination and diversity on team performance, among consultant project teams in a longitudinal study. Results show that coordination and diversity, versus shared leadership (SL), are two different and separate processes yielding performance gains in work teams. The fourth paper examines the impact of global diversity settings and
culture-driven norms on coordination preferences and shared leadership; these include norms for the frequency and timing of communication, autonomy, conflict management. The authors find that teams are better that manage their differences with knowledge about the cultural background. The fifth presentation aims to broaden our understanding of successful implementation of organizational changes. The author shows, using a cross-cultural research design, that the fit between the way leaders and employees exchange relevant information has a positive impact on how change tactics are perceived and influence people’s commitment towards change.

**What makes a team effective? The importance of diversity climate, non-racist behaviors and team cohesion**

MICHEL, A. (University of Heidelberg)

Working in a modern world means successfully integrating employees with diverse demographic backgrounds and competencies in highly performing teams. There is increasing interest in politics, industry and science on employees’ perceptions of diversity climate and their impact on employees’ behaviors in organizational teams. Previous research on diversity climate has mostly focused on its antecedents (e.g. McKay & Avery, 2006; Mor Barak, Cherin, & Berkman, 1998). In this study we extend existing research by examining consequences of diversity climate for teams in organizations. More precisely, our aim was to investigate which role diversity climate plays with reference to team effectiveness. The following assumptions were tested. First, we assumed that diversity climate is positively related to team cohesion. Second, we postulated that team cohesion in turn correlates positively with team effectiveness. Third, we hypothesized that team cohesion mediates the positive relationship between diversity climate and team effectiveness. Finally, we assumed that the positive relation between diversity climate and team cohesion is pronounced, when racist behaviors within teams are low. Data were collected in 164 military units with a total of 8380 respondents. To test our hypotheses we followed the procedure developed by Preacher and Hayes (2004) and applied a bootstrapping approach. As assumed, we confirmed the positive relationships between diversity climate and team cohesion and between team cohesion and team effectiveness. Our results further indicate that team cohesion significantly mediates the positive relationship between diversity climate and team effectiveness. In addition, the positive effect of diversity climate on team cohesion is intensified, when racist behaviors in the units are low. Extending prior research our results pronounce the importance of diversity climate in organizations by showing its positive effects on team cohesion and team effectiveness. In addition, aligning with the anti-discrimination laws our results emphasize that organizations should continue to take actions to minimize racist behaviors. To conclude, managers should always bear in mind that high diversity climate and low racist behaviors seem to make a meaningful contribution to team effectiveness.

*Keywords: teams, diversity, climate, cohesion*

**Ready or not…? A multilevel study of organizational climate on change recipients’ readiness for change**

MATSYBORSKA, G. (University of Belgique)

Despite insights into the importance of process factors like change fairness, participatory management and leadership in explaining successful implementation of change projects, there is still some reasonable variance in people’s attitudes toward change that needs to be explained. In this inquiry it is advocated that one should also account for the context factors under which change emerges. We are interested in the role of two key work context factors: (1) organizational politics and (2) organizational climate in shaping people’s readiness towards change. With reference to work on situational trait relevance, organizational climate is assumed to be a contextual amplifier and/or contextual buffer for the negative effects of organizational politics onto readiness for change. When people perceive the organizational climate as psychologically safe (high on trust in top management, history of change and quality of change communication) they are more likely to engage themselves to support change and
maximize their return. However when faced with a work environment as psychological unsafe, an extra level of uncertainty is added to an already risky situation caused by the highly political environment. This thereby minimizes the likelihood of a suitable return on investment and therefore yields higher resistance toward change. Data were collected in Belgium from 2,543 employees of 84 companies representing a wide variety of industry sectors. In a first survey we collected work context data on politicking and organizational climate. Two weeks after measuring the context we acquired data into people’s readiness for change. Consonant with our hypothesis, the relationship between individual perceived politics within an organization and readiness for change in times of change is moderated by the organization’s climate. Applying the principles of situational trait relevance to the relationship between politicking and readiness for change suggests that politicking – readiness correlations are stronger in situations providing relevant cues for expressing political behavior. So the strength of the negative correlation between politicking and readiness for change is dependent on the specificity of the situation.

Keywords: organisational climate, change, readiness

Is the most effective team leadership shared? The impact of shared leadership, age diversity, and coordination on team performance

HOCH, J. (Michigan State University)

There is increasing research on shared leadership in teams. Shared leadership (SL) describes “a dynamic interactive influence process among individuals in groups for which the objective is to lead one another to the achievement of group or organizational goals or both” (Pearce & Conger, 2003; p. 1). There is evidence that SL enhances team performance (e.g., Ensley, Hmieleski, & Pearce, 2006; Pearce & Sims, 2002). However, there is not much known about how SL relates to, or is distinct from, other processes of motivation and performance gains in teams, such as (age) diversity or coordination of individual expertise. The aim of the present investigation therefore is to further relate literature on SL, diversity, and coordination, in order to find out and explore more about the successful processes of SL, or motivation and performance gains in teams. In the present paper we examine the impact of SL, moderated by age diversity and coordination, on team performance. Using a field sample of 26 organizational consultant project teams, followers assessed their team’s SL and coordination. Six weeks later, supervisors rated their teams’ performance. Results indicated that SL predicts team performance and both age diversity and coordination moderate the impact of SL on team performance. SL was positively related to team performance when age diversity and coordination were low, whereas age diversity and team coordination where more strongly related to team performance when SL was low. Particular strong effects of SL on team performance were evident when both age diversity and coordination were low, whereas SL was not related to team performance when both age diversity and coordination were high. We find that coordination and diversity, versus shared leadership (SL), are two different and separate processes yielding performance gains in work teams. Since they are different, they interact in predicting performance. Our research thus extends both the literature on SL as well as literature on diversity in teams. Summarizing, there are multiple ways towards performance gains in teams, and the present investigation further tracks two of them.

Keywords: shared leadership, diversity, team performance

Coordination and shared leadership in global teams

KOELR, T. (University of Melbourne, Australia)

Global teams (i.e., multicultural, distributed teams) have become increasing prevalent in organizations. These teams are often fully or partially self-led as direct supervision is rare in a distributed context. To be effective, team members in these teams need to find ways to coordinate their work successfully despite differences in their cultural preferences for teamwork and challenges due to the technology-mediated nature of their
communication. Only limited previous research has looked at cultural differences in coordination preferences and the ways in which team members in self-led global teams manage these differences. One important aspect of traditional self-led teams (i.e., collocated and culturally homogenous teams) are group norms as they provide structure and rules for appropriate behavior (e.g., Feldman, 1984; Ray & Bronstein, 1994). The current study examines how the creation of team norms for coordination can help global teams manage their cultural differences and function in a global distributed context. We gathered data from seven American/Finnish student teams and six American/German student teams during two international classroom collaborations. The current study utilized participant observation to assess cultural differences in coordination and leadership expectations, the development of team norms, and the ways in which the teams used these norms to coordinate and lead themselves. The available data was analyzed using a grounded theory approach. Findings show that culture-driven norms exist for coordination preferences, such as norms for the frequency and timing of communication, norms for autonomy, and norms for conflict management. These coordination norms strongly affected coordination and subsequently team functioning at the outset of the collaborations. Over time, though, the student teams gradually built team norms that allowed the teams to essentially manage themselves. At the end of the collaboration students largely negated the existence of leadership within their teams, describing their teams as leaderless, but guided by strong norms. As students learned about their own and the other team members’ cultures, members were able to better manage their differences and more likely to engage in coordination patterns adapted to each other’s cultural preferences. Team norms created structure that helped the teams to successfully lead themselves.

Keywords: coordination, shared leadership, teams

BOUCKENOOGHE, D. (University of Quebec, Canada)

This inquiry explores employees’ reactions toward planned change, and more specifically the role of different change tactics used by managers to create a buy-in into change. Although the literature is replete with studies that explored the effects of different change strategies onto attitude formation, research into this topic is inconclusive about how these tactics affect employees’ reactions toward change. In sum, the main purpose of this project is explaining these equivocal results by building further on extant leader-membership-exchange (LMX) research and social information processing theory. It is assumed that the reaction of change recipients is determined by the nature of their relationship with change agents. More specifically this study will focus on the alignment of cognitive styles between both parties. To put it differently, we assume that cognitive fit/misfit in the change agent – change recipient dyad moderates the relationship between the selected change implementation tactics and people’s responses toward change. A cross-cultural research design was used that included samples of supervisors and teams who were subject to a recent or ongoing organizational change process (Belgium and Canada). Two surveys were administered to two populations of respondents: (1) supervisors and (2) teams of employees. In an attempt to extend the scope of LMX theory – with its exclusive emphasis on the quality of the affective component in an LMX relationship – we believe the social information processing theory adds some relevant insights into the formation of attitudes toward change by highlighting not only the quality of the affective component in the supervisor – employee relationship, but also by stressing the homogeneity in information processing styles (i.e. cognitive component) between both parties. Basically, this study extends our knowledge into change recipients’ attitude formation by demonstrating that cognitive fit between supervisors and change recipients has a positive impact on how change tactics are perceived and influence people’s commitment towards change even when these tactics are sanction or legitimization-based.

Fit or not to fit? How cognitive matching between supervisors and change recipients moderates the change implementation – commitment to change relationship.
Should I stay or should I go:
What keeps employees in the workplace

Chair(s): PALERMO, J. (Deakin University)

A recent survey of 2000 managers by the Australian Institute of Management found that the majority of managers identified skills shortage as having a negative impact on profits, performance and staff morale. Identifying the factors that are most important in shaping employee attitudes toward remaining at an organisation is critical to allow for the design of target interventions which may potentially mitigate the reduction of employee turnover. This symposium aims to inform delegates about the most important predictors of intention to remain. It presents empirical studies that investigate the factors that impact on employees' intentions to remain in their organisational roles across the work life span.

The first study explores the experience of graduate nurses and investigates factors that predict their intention to remain in their new roles. The second study examines an IT population, an industry group notorious for high staff turnover. This study in particular focuses on the factors related to trust and perceived support that appear to significantly impact upon intention to remain. The third study investigates factors affecting allied health professionals intention to remain comparing regional versus metropolitan groups for potential differences. The last study in this symposium investigates issues of particular concern for an ageing population by examining the factors that predict workability, that is, one's subjective or objective assessment of ability to work into the future. The symposium will discuss the implications of these findings in the context of boosting the organisations ability to retain talent. Symposium participants will gain an increased understanding of the factors that affect intention to remain and their application in organisational settings, with particular implications for designing organisational development initiatives.
Factors influencing turnover for graduate nurses

WALKER, A. (Deakin University)

The transition from student to qualified nurse is widely recognized as one of the most stressful times during a nurse’s career. Previous research reveals absenteeism, intention to quit, and turnover are significant issues affecting the nursing profession in Australia. Turnover is particularly problematic amongst newly qualified nurses, although the reasons for this remain unclear. The present study adopted a social exchange perspective to explore the stressors experienced by graduate nurses (GNs) during their first year of clinical practice and the factors influencing turnover in this population. The study focused on the role of support in influencing important individual and organisational outcomes. Specifically the mediating role of organisational support in the relationship between psychological contract breach and intention to remain was explored. 79 graduate nurses (GNs) in their first year of clinical practice were asked to complete a survey at Time 1 (within 3 months of starting) and at Time 2 (from 9-12 months of starting). The results indicated that support has a positive impact on how GNs manage stress, and their intention to remain employed by the organisation. The findings confirmed the significance of employment relationships in retaining newly qualified nurses, and the importance of maintaining positive exchange relationships with GNs from an employer’s perspective. The findings of this study have important implications for the nursing profession and organisations employing newly qualified nurses.

Keywords: turnover, graduate, stress, absenteeism, intention to quit

Predicting intention to remain in the organisation: A social exchange perspective

WALKER, A. (Deakin University)

Research has highlighted that the types of relationships that form between employees and their employers can impact employee attitudes and behaviours. Identifying the factors that are most important in shaping employee attitudes toward remaining at an organisation is critical to allow for the design of target interventions which may potentially mitigate the reduction of employee turnover. The primary aim of this research was to investigate the impact of various social exchange constructs such as perceived support (organisational, supervisor, and co-worker) and psychological contract breach in predicting employee intention to remain with an organisation. A sample of 107 Information Technology employees participated in this study by completing an on-line questionnaire. Results indicated that employees who perceived high levels of organisational and supervisor support, were more likely to remain with the organisation. Alternatively, when employees perceived that the organisation had not fulfilled promised obligations, they were more likely to leave the organisation. It was also found that perceived organisational support fully mediated the relationship between perceived employer breach of obligations and intention to remain with the organisation while supervisor support partially mediated this relationship. The implications of this study suggest the need for more emphasis by employers on issues related to psychological breach and perceived organisational support to ameliorate the adverse affects of staff turnover particularly for workers in Information Technology

Keywords: employee attitudes, employee turnover, social exchange, supervisor support, information technology

Factors impacting upon allied health practitioner’s intention to leave their employment in metropolitan and regional Victoria.

VON TREUER, K. (Deakin University)

Staff retention is critical to the sustainable delivery of quality health services. Therefore, an understanding of the impact specific workplace factors have on an Allied Health practitioner’s (AHP) Intention to Leave (ITL), may greatly inform employee retention strategies. The aim of this study was to concurrently examine many factors that may lead to a person's decision to leave an
organisation. Two metropolitan and 13 regional agencies from Victoria participated in the study. Participants comprised of 202 AHPs representing 15 occupational groups. They were mostly female, worked full time and in acute health settings. Participants were asked to complete an online survey. The survey consisted of demographic questions, the Work Environment Scale (WES), the Psychological Contract Inventory (PCI), Organisational Commitment, Personal wellbeing index (PWI), job satisfaction and ITL. Qualitative data were also collected. The ITL for AHP was found to be 51.3% in smaller regional agencies, in a larger regional setting the ITL was at 19.7%, whereas the two metropolitan sites were 32% and 51.3%. Predictors of ITL were similar between both the regional and metropolitan groups. Job satisfaction contributed to 47.6% and 38.8% of variance in the regional and metropolitan groups respectively. Lack of Psychological Contract fulfillment contributed to 39.3% of variance in the regional group and 25% of variance in the metropolitan group. Organisational commitment (affective subscale) contributed to 22.9% of variance in the regional group and 13.5% of variance in the metropolitan group. Lack of Psychological contract fulfillment also contributed to low levels of job satisfaction. Qualitative data were analysed and were consistent with the inferential analyses, thereby further contributing to understanding these factors impact on ITL. This study found that low job satisfaction and lack of psychological contract fulfillment contributed to higher ITL in the Allied Health sample overall. Furthermore lack of psychological contract fulfillment was strongly associated with low job satisfaction. Qualitative data added some insights into the reasons why and when psychological contract was unfulfilled. These findings point to potential retention strategies.

Keywords: staff retention, health care services, organisational commitment, intention to leave, job satisfaction

Retiring later: Improving the workability of the ageing workforce

PALERMO, J. (Deakin University)

Australia has one of the world’s most rapidly ageing workforce populations. Early retirement stands to lose the Australian labour force over 1 million person years of potential working life. Recent government policy reforms have raised the aged-pension age, signaling the need to boost to the number of older workers in employment. Whilst the benefits of increasing the participation of older workers emphasise economic outcomes, the social and health implications of prolonging work life may be overlooked. Without the development of workplace policies and programs that support the wellbeing of older workers, prolonging work life may be achieved at the detriment of the health and wellbeing of employees. The health and social impacts of prolonging work life are yet to be tested. This study aimed to investigate the relationships between workability, intention to remain now and into the future, and psychosocial factors related to worker health and wellbeing. A workability measure (ability to capably fulfill work requirements) was used to predict length of working life. This measure was included in a test battery with other scales that measure occupational stress and related psychosocial and workplace factors. The cross-sectional study involved 305 participants from a general worker population. Surveys were distributed through participants’ organisations and completed online. Results showed, as predicted, that workability was a significant and positive predictor of intention to remain into the future, and was mediated by occupational stress. Ability to cope with stress, leadership culture, value congruence and low occupational stress were significant predictors of increased workability. Differences between workability and health were not found between older and younger workers. Studying factors that prolong employment may enable retirement to be delayed in a manner that is sensitive to the context of workers and their health needs. The results of this study suggest that many of the factors that predict workability and therefore intention to remain are in fact modifiable organisational factors. Implications for organisations are in developing strategies for promoting workability of workers across the lifespan, and not just older workers.

Symposia

Abstracts of the 27th International Congress of Applied Psychology

Showcasing new, novel and user friendly scales

Chair(s): KHAWAJA, N. (Queensland University of Technology), GOMEZ, I. (Queensland University of Technology), TURNER, G. (Queensland University of Technology)

Effective, valid and reliable scales are vital for psychological services and research. In spite of hundreds of existing scales, there are still areas that lack adequate and appropriate scales. The objective of the symposium is to showcase four newly developed scales. The scales address salient theoretical and practical gaps in the literature. They possess unique features and were developed using rigorous test development procedures. The first paper presents Multicultural Mental Health Awareness Scale (MMAS). It is the first scale that measures the cultural competency of the Australian mental health professionals. Keeping in view the diversity in the Australian society, the mental health professional requires multicultural counselling skills. The scale measures their multicultural knowledge and skills and self-awareness within the Australian context. The second paper presents a 2-way Social Support Scale. Social support is pivotal in the psychosocial well being of an individual. This is the first time a psychometrically sound scales captures the giving and receiving of the emotional and instrumental support. The third paper highlights the Cerebrovascular Attitudes and Beliefs Scale – Revised (CABS-R). The scale for the first time, measures stroke related health beliefs. Keeping in view the serious nature of the stroke, it is essential to explore a stroke survivor’s beliefs and attitudes so that an intervention is planned in an effective manner. Finally, the last paper presents the Disability Standards Questionnaire (DSQ) developed to assist the Endeavour foundation with the evaluation of their program. The scale was developed for the intellectually disabled respondents. It is always a challenge to communicate with the intellectually disabled due to their limited cognitive ability. Therefore, the scale uses a pictorial format to assist the intellectually disabled individuals in expressing their opinions and need effectively. This unique feature has not been used previously.

Development of a Multicultural Mental Health Awareness Scale

KHAWAJA, N. (Queensland University of Technology)

It is becoming increasingly important for a mental health professional to develop multicultural counselling competencies in order to address mental health issues presented by culturally and linguistically diverse (CALD) individuals in the Australian multicultural society. The present study describes the development of an instrument to assess the multicultural competencies of mental health professionals in Australia. The scale was developed to assess the effectiveness of a multicultural mental health training program. Mental health professionals from Queensland, Australia (N = 268) participated in the study by completing a questionnaire battery. Items on the new scale were generated to parallel the Queensland Transcultural Mental Health Centre (QTMHC) training program’s objectives. The results describe a 35-item Multicultural Mental Health Awareness Scale. Factor analysis of the scale revealed three factors of multicultural counselling competencies: Awareness, Knowledge, and Skills. These factors were in line with Sue et al.’s (1982) multicultural counselling competencies. The scale has satisfactory internal consistency, test-retest reliability, concurrent validity, and discriminant validity and can be used to evaluate the effectiveness of the multicultural competency training programs in mental health. Keeping in view the need to enhance the mental health professional cultural competency through education, training and practice, the scale is a very positive addition to the literature. It can be used in clinical and research settings to evaluate the professionals’ multicultural counselling skills.

The development and validation of the 2-way Social Support Scale (2-way SSS)

SHAKESPEARE-FINCH, J. (Queensland University of Technology), OBST, P. (Queensland University)

Social support is an integral variable in psychosocial well-being across a broad array of contexts. For example, giving social support has been found to predict of lower mortality rates whereas receiving emotional support has been related to feelings of self-worth and satisfaction within the work context. The construct is broad and multifaceted however, current instruments tend to focus on a single aspect of support such as the structural notion of source of support or a functional aspect such as emotional versus instrumental support. Most scales have been developed for use in a particular context and hence, results and methods are rarely replicated or are comparable. Currently, there is no psychometrically sound scale that captures the comprehensive shift of measuring giving and receiving emotional and instrumental support. The research draws on a series of studies executed in the development of the 2-way Social Support Scale (2-way SSS). Cross-sectional studies employing students, participants from different work places, and the broader community (N = 854) completed surveys that comprised a large item pool of social support questions. In the latter development stages constructs such as life satisfaction and depression were also included to assess predictive validity and the Berlin Social Support Scale (Schwarzer & Shulz, 2000) was included for convergent validity. Horns Parallel Analysis, which was engaged to determine the number of appropriate factors to extract from the Principal Components Analysis and revealed a stable four-factor structure comprising 20 items. Confirmatory analysis with a different sample established the reliability of this structure and regression analyses with varying groups provided further evidence of scale validity. The developed 2-way SSS provides an elegant four-factor measure of both receiving and giving emotional and instrumental support. The scale provides a solid instrument applicable to a variety of contexts that will permit replicability and comparability in future social support research.

Keywords: social support, psychosocial well-being, emotional support, instrumental support, 2-way Social Support Scale

A new tool for assessing attitudes and beliefs about exercise in stroke survivors

SULLIVAN, K. (Queensland University)

The aim of this study was to develop a theoretically grounded scale for assessing health beliefs in stroke survivors and assess its psychometric properties. This new scale, the Cerebrovascular Attitudes and Beliefs Scale – Revised (CABS-R) was developed from the Health Beliefs Model. The CABS-R has multiple subscales, each of which corresponds to a known modifiable risk factor, and is comprised of items designed assess beliefs about a range of stroke prevention behaviours. In this study data for two subscales, weight loss and exercise is presented. One hundred and twenty six Brisbane residents aged 50 years and older completed the CABS-R. One month later, 70 participants completed the CABS-R again. Internal consistency, test-retest, and exploratory factor analyses were performed on the exercise and weight loss subscales (minimum n = 60 participants). Analyses showed that these CABS-R subscales have moderate-to-good internal consistency and that scores are relatively stable over time. A four factor solution was identified, suggesting the CABS-R validly assesses beliefs about stroke susceptibility and seriousness, and the perceived benefits of, and barriers to, exercise and weight loss for stroke prevention. The CABS-R provides a psychometrically robust tool for researchers and clinicians to assess stroke related health beliefs. To address the significant psychological challenges that stroke survivors report post-event, such beliefs are now being included in novel stroke prevention programs aimed at increasing physical activity and reducing stroke risk.

Keywords: Health Belief Model, stroke, Cerebrovascular Attitudes and Beliefs Scale

The Disability Services Questionnaire (DSQ): A self-report questionnaire to measure standards of employment services for individuals with Intellectual Disability

Keywords: employment services, Intellectual Disability, self-report questionnaire

Abstracts of the 27th International Congress of Applied Psychology
ARMSTRONG, D. (Queensland University), ZIMMERMAN, J. (School of Psychology & Counselling, Queensland University of Technology), BIGGS, H. (Queensland University of Technology), KHAWAJA, N. (Queensland University of Technology)

The current climate of quality assurance dictates that, in order to receive funding and accreditation, organisations which provide supported employment opportunities for individuals with an intellectual disability must demonstrate their performance against the 12 disability services standards for employment services. Many of the assessment tools that are used with individuals who have an intellectual disability are either designed to be completed by a carer or proxy, or lack psychometric rigor. The aim of this research was to create a psychometrically sound and reliable means of eliciting the feedback of supported employees regarding the performance of their business service. A number of initial pilot phases were conducted to determine appropriate question and response formats, resulting in a pool of 86 simple statements and a pictorial graph response option being chosen. These items were used in a large pilot study in which 571 questionnaires were distributed to supported employees from Endeavour business services drawn from 10 locations across Queensland. Training and development officers assisted the supported employees in completing the questionnaire with the assistance of facilitator and supported employee instruction sheets.

Principal components analysis (PCA) was undertaken to determine the most parsimonious factor structure while pragmatic consideration was taken when choosing which items to remove to ensure that the underlying constructs of all 12 standards were measured. PCA with an oblimin rotation resulted in a 35 item questionnaire ($N = 286$). This revealed a four factors solution accounting for 46.02% of the variance. The factors identified were: work environment and conditions, respect and individual needs, knowledge of service processes, and participation. These factors display good internal consistency (Cronbach’s alpha range from .68 to .90) and content validity. The results of this research support the notion that it is possible to apply rigorous psychometric principles to test construction with difficult to assess populations.

Consultations with experts in the target population as well as imagination in the test construction arena are valuable tools in designing practical measures that are user friendly.

Abstracts of the 27th International Congress of Applied Psychology

Social and emotional concepts in education and learning

Chair(s): MACCANN, C. (University of Sydney)
Discussant(s): ROBERTS, R. (Educational Testing Service)

Educational success can reasonably be considered a globally important goal for most students and most countries. On average, OECD countries spend over 6% of their GDP on education (OECD, 2007), showing the importance that developed countries ascribe to education. Cognitive abilities explain about 25% of the variation in students’ grades. However, social and emotional variables can add substantially to this prediction, accounting for aspects of academic performance related to maintaining positive relationships with teachers and peers, the motivation to study, or resilience to the frustration of academic failure or setbacks. This symposium comprises a range of such social and emotional constructs. Each paper describes different scenarios by which socio-emotional constructs might feed into the process academic success. These scenarios include: (a) the role that constructs such as emotional intelligence play in the process of learning cognitive tasks, (b) the translation of personal resources into coping behaviors and adjustment to university, (c) the way that personality may lead to use of problem-focused or avoidant coping that then impacts on students’ grades at high school and college, (d) the various influences that positive psychology constructs such as optimism and hope may hold on achievement in high school, and (e) the need to select medical students on the basis of their interpersonal skills as well as cognitive or academic performance. Studies deal with both high school and university populations, highlighting the ways that social and emotional constructs are useful at different educational stages. Key learning objectives of the symposium include: (1) developing an increased awareness of the variety of socio-emotional and noncognitive constructs that may be relevant for academic achievement. These include self-efficacy, coping styles, interpersonal understanding, emotional intelligence, optimism, and broad models of personality; (2) understanding the processes by which these soft skills and tendencies affect learning and achievement, including the interaction among these socio-emotional tendencies and the limitations of such skills in predicting academic achievement; and (3) developing an awareness of the applications of social and emotional concepts can in educational settings, including selection, development, curriculum design, and policy.

Trait emotional intelligence, subjective state and learning using emotional cues

MATTHEWS, G. (University of Cincinnati), FELLNER, A. (University of Cincinnati)

It is claimed that emotional intelligence (EI) can be measured as a personality trait using questionnaires. However, little research has validated such ‘trait EI’ measures against objective behavioral data. Another limitation of existing studies is their predominant focus on perception of emotion, neglecting other aspects of emotion processing. This presentation summarizes two recent studies that attempted to link trait EI to discrimination learning, using facial emotions as cues. The first study compared emotive and neutral features as cues. The second study investigated the role of EI in two-person team performance; EI might especially facilitate team learning. In Study 1, 180 participants were required to categorize animated characters as terrorists or non-terrorists, using a cue that might be either positive or negative emotional expression, or a neutral cue (hat size). In Study 2, 311 participants performed either solo or as part of a two-person team, either in collaboration or competition. In both studies, there were 100 trials; feedback was provided following choice to allow learning. Standard measures of personality, ability and emotional state were obtained. Study 2 also used a situational judgment test (SJT) for EI, and a subjective teamwork scale. Study 1 showed that facial emotion is a more effective cue for learning than the psychophysically matched neutral cue. Study 2 showed that performance was better in the teamwork conditions, relative to solo performance. In both studies, standard
psychometric measures were generally ineffective in predicting performance, as was trait EI. However, the subjective state of task engagement (energy, motivation, and concentration) related to faster learning in both studies. Trait EI showed some capacity to predict subjective state and perceptions of teamwork, even with other personality factors controlled. The findings add to existing results showing that trait EI is at best a weak predictor of performance on tasks requiring processing of emotional information. However, trait EI may relate to subjective experience of performance tasks. The studies also suggest that variation in states is more directly related to emotional processing than are dispositional measures of personality and ability.

Keywords: emotional intelligence, personality traits, emotional processing, subjective states, emotional cues

The relationships between personal resources, proactive coping, personal outcomes and academic success in first year students

BURTON, L. (University of Southern Queensland), NELSON, L. (University of Southern Queensland)

This research was designed to enhance our understanding of social and emotional variables that influence well-being and success at university. The research was undertaken in two stages. Study 1 examined the relationships between general self-efficacy, proactive attitude, proactive coping, academic achievement and self-reported adjustment. Personal outcomes were operationalised as academic success (e.g., grade point average, GPA) and a self-reported measure of adjustment to university. Study 2 added measures for optimism, instrumental and emotional support seeking, global well-being, affect, and general psychological distress. Specially, the research examined whether proactive coping mediated the relationships between personal resources and outcomes. Participants were convenience samples of students enrolled in first year psychology courses at USQ. Study 1 participants (N = 188) were recruited during Semester 2, 2008; Study 2 participants were recruited during Semester 2, 2009 (in progress). In both studies, participants completed an online survey via the Psychology Department’s secure (password protected) website. Study 1 results showed that adjustment was significantly correlated with GPA, general self-efficacy, proactive attitude, and proactive coping, respectively. GPA was significantly correlated with both proactive attitude and self-reported adjustment. Multiple regression analyses showed that adjustment is predicted by proactive attitude, general self-efficacy, and proactive coping. Both general self-efficacy and proactive coping were significant predictors of GPA. Results indicated that proactive coping partially mediated the relationship between internal resources (proactive attitude and general self-efficacy) and self-reported adjustment. Study 2 data is currently under analysis and key findings will be reported at the symposium. Study 1 demonstrated a positive relationship between adjustment, proactive attitude, general self-efficacy, and proactive coping strategies. Additionally, as expected, self-reported adjustment was related to academic success. These findings provide implications for curriculum design and delivery and for transition programs for first-year students. Study 2 findings will provide further insight into the relationships between personal resources, proactive coping, and personal outcomes in commencing university students.

Keywords: social factors, emotional factors, well-being, academic performance, self-efficacy

Students’ approaches to coping with stress can impact their academic achievement

Coping styles often delineated into: (a) problem-focused coping (PFC), aimed at taking action to change or ameliorate the stressor; (b) emotion-focused coping (EFC), aimed at modifying the negative emotions generated by the stressor; and (c) avoidant coping (AC), aimed at avoiding the stressor altogether. This research addresses whether students’ tendency to use these coping strategies relates to their school achievement, and whether such relationships are mediated by personality and
cognitive ability. Over three studies, U.S. students completed self-paced proctored computerised test batteries. Study 1 participants were 375 eighth-graders, study 2 participants were 301 ninth- and tenth-graders and study 3 participants were 1063 university students. Students completed age-appropriate measures of coping tendencies under different frames of reference (e.g., coping with exams, coping with assignments), as well as big five personality, cognitive ability, and life satisfaction measures. Students’ also self-reported their grades from the previous semester (parent-reported grades were also obtained in studies 1 and 2). In study 1, PFC correlated positively with grades (.31 to .38) whereas both EFC and AC showed small but consistently negative correlations with grades (-.01 to -.16). Coping explained 6 to 10% of the variation in grades beyond Conscientiousness and ability. In study 2, PFC correlated positively with school grades (.28 to .31), AC negatively (-.19 to -.28), and EFC negatively but trivially (-.09 to -.12). Coping explained 3 to 4% of variation in grades above big five personality and ability. In study 3, AC showed the strongest correlation with grades (-.22 to -.27), though PFC, and EFC also correlated with grades (.13 to .22 for PFC, -.14 to -.16 for EFC). Coping explained 3% of variation in grades above big five personality and ability. Students’ approaches to coping with stress impact on their academic achievement, although the effects are partially mediated by personality. Such results suggest that the mechanism by which Conscientiousness and Neuroticism affect school performance is through choice of coping strategies. School-based interventions on dealing with stress might best address problem-focused coping strategies at the secondary level, but avoidant coping strategies at the tertiary level.

Keywords: coping styles, problem-focused coping, emotion-focused coping, avoidant coping, cognitive ability

The role of some strategic noncognitive factors in adolescent academic achievement

NIXON, J. (Australian Council for Educational Research)
The inclusion of measures of interpersonal understanding in undergraduate medical admissions tests

Currently students wishing to gain admission to medical courses have to sit a multiple-choice selection test, the Undergraduate Medicine and Health Sciences Admission Test (UMAT). This test has three sections, one of which is called ‘Understanding People’. The aim of the current research is to investigate the construct validity of this section of the test: whether it is the case that candidates who obtain high scores on the ‘Understanding People’ section actually have higher levels of interpersonal aptitude than those who obtain low scores on this section. Studies have found that individuals skilled at understanding emotions have a rich ‘feelings’ vocabulary and also that reading literature teaches individuals to have imaginative insight into the minds of others (Charon, 2000; Ortony, Clore & Collins, 1988). This investigation will therefore also examine the relationship between a test of verbal reasoning and the UMAT ‘Understanding people’ construct. The participants for this study will be 400 Year 11 students who will be taking UMAT in Year 12. The students will be from diverse schools, which include a range of socio-economic groups and rural/urban areas in Victoria. Interpersonal aptitude of participants will be measured using the following: Mayer, Salovey, Caruso Emotional Intelligence Test (MSCEIT, 2002), the Emotional Intelligence Questionnaire (EIQ, 1999). Verbal reasoning of participants will be measured using verbal reasoning items from the General Achievement Test (GAT, VCAA 2009). Correlational analyses will be used to investigate the relationships between candidate performance on these measures. At the time of the symposium, interim results will be available as data collection will take place during semester 1, 2010.
Social axioms: Investigating the role of belief systems in social, cultural and clinical psychology

Chair(s): LAM, B. C. P. (Hong Kong Polytechnic University), XIAOHUA CHEN, S. (Hong Kong Polytechnic University)
Discussant(s): LEUNG, K. (Hong Kong Polytechnic University)

Leung and Bond originally proposed the construct of social axioms, i.e., generalized beliefs about how the world functions, to account for cross-cultural variations. Since then, research around the globe has proven that belief systems are also important for understanding a wide range of social behaviors and psychological issues in various domains of psychology, e.g., social, cultural and clinical psychology. In this symposium, we will present our work on the current progress and application of social axioms in psychology research. First, Presenter 1 will examine gender differences in beliefs using cultural-level data. Second, Presenter 2 will construct a model connecting social axioms, personality factors and Hierarchic Self-Interest (HSI), a second order value construct, among international students in Germany. Third, Presenter 3 will disentangle the components of the religiosity factor of social axioms by linking it with other spiritual measures as well as locus of control. Fourth, Presenter 4 will explore the relationships between social axioms, coping styles and moral development dimensions in Italian culture, and suggest emic interpretations of her findings. Fifth, Presenter 5 will present her study examining age differences in social axioms, self-esteem, and life satisfaction among children, adolescents, and young adults, testing a mediation model across these three age groups in Hong Kong. Sixth, Presenter 6 will present a cross-cultural study in Australia and Hong Kong, testing the linkages between social cynicism, body image and self-esteem, which will suggest the usefulness of social axioms in future body image research. Lastly, our Discussant will discuss the presented papers and suggest some future directions for this line of research.

Men are more cynical than women around the world, but male dominance can elevate women's social cynicism

LEUNG, K. (City University of Hong Kong)

Because of pan-cultural male dominance, women should show more cynicism than men in diverse cultural contexts. This conjecture was evaluated in a global study of social axioms, or general beliefs about the world. Results showed that men were generally more cynical than women. Men's higher concern for competition is likely responsible for their higher cynicism, because compared to women, men generally showed higher reward for application, i.e., the belief in the usefulness of effort and application. The effect of male dominance on women's social cynicism is likely masked by men's competitiveness, because compared to men, women generally showed higher fate control, the general belief that events are generally pre-ordained but alterable. Consistent with the argument that male dominance elevates women's social cynicism, sex differences in social cynicism were smaller in societies where women had lower status.

Keywords: male dominance, cynicism, competition, social axioms

Sojourner students: Their personalities, values, and images of the human being in a global perspective

BOEHNKE, K. (Jacobs University)

Most pronouncedly after the fall of the Iron Curtain, one of the marker events of the social change often labeled globalization was that many youngsters from formerly communist countries, but essentially from almost all regions of the globe, have sought tertiary education at universities in Western Europe and North America. At the private Jacobs University Bremen, Bulgarians are the largest non-German group in a student body encompassing individuals from almost 100 nations. The study reported here some 220 students of that university who come from
over 40 different countries. Data on the Big Five (Costa & McCrae), Social Axioms (Leung & Bond), and Hierarchic Self-Interest (HSI; Hagan et al.) were obtained. Analyses of variance were performed after grouping respondents into eight cultural regions in accordance with Inglehart’s classification. In a second analytic step a prediction model of HSI (a second-order construct comprising of first-order indicators of individualism, materialism, social comparison orientation, Machiavellism, and acceptance of social inequality, thereby being a measure par excellence of an internalization of capitalist values) is presented. The model explores the role of personality and social axioms as predictors of HSI and focuses on differences between South-East Europeans and students from other parts of the world, utilizing Schwartz’s culture-level value measures as a means to decompose culture’s impact on individual-level HSI.

Facets of religiosity and control in the social axioms scale

SAFDAR, S. (University of Guelph)

Two types of religiosity can be distinguished (Seidlitz, et al., 2002), God-based and spirituality-based. The Spiritual Transcendence Index (STI; Seidlitz et al., 2002), for example, includes Belief in God and Spirituality sub-scales. As the names suggest, these measure a measure of belief in God and a non-theistic spirituality, as well as giving an overall Religiosity score. This distinction is not made specifically in the Social Axioms Scale (SAS; e.g. Leung et al., 2002), a measure of socially endorsed beliefs about how the world, in particular the social world, works, although considerable effort has been expended on validating the SAS cross-culturally. Only one of the SAS items refers specifically to a supreme being, so the question arises as to the type of religiosity assessed in the SAS. Another gloss on religiosity is to see it in terms of powerful external forces. The Locus of Control (LOC) construct has enduring popularity with researchers, in particular Rotter’s (1966) original bi-polar (internal vs. external) model. However, Smith, Trompenaars and Dugan (1995) have argued that Levenson’s (1981) tri-partite model has greater cross-cultural validity. In Levenson’s model, as well as an internal orientation, external determinants are divided into powerful others and luck/fate. An internal orientation is often regarded as the most rational one and powerful others may be divine, so there appears, here, to be an echo of the old anthropological division (Tambiah, 1990) of epistemologies into rationality/science (internal control), magic (luck/fate) and religion (powerful others). A similar division is also apparent in three of the five sub-scales of the Social Axioms Scale: reward for application, fate control, and religiosity. In the present study then, the SAS is examined with the STI and Levenson’s LOC scale to consider (1) whether the spirituality dimension of the SAS relates more strongly to the ‘God’ or the ‘spirituality’ sub-scale of the STI, and (2) the overlap (if any) between the SAS and LOC.

Social axioms in Italian context

COMUNIAN, A. L. (University of Padua)

The aim of this presentation is to examine a) the dimensionality of social axioms in Italian culture, in particular as an emic exemplar of social axioms and b) the relationships between social axioms and coping style and moral development dimensions in Italian culture. The hypotheses suggest that one may raise the question whether the five dimensions representing social axioms are comprehensive. In particular, in Italian culture the Religiosity dimension is influenced by complex emic meanings that we propose to study in this research. We would expect that they should relate to a variety of personal and social behaviours reflecting the Italian cultural and historical legacy in a distinctive way. This research also examines how in the Italian context these axioms may help explain personal and social behavior alone or in conjunction with other psychological constructs. On the whole, it can be concluded that social beliefs seem to offer a valuable new way for researchers to
The role of social beliefs in body image research: A cross-cultural examination

LAM, B. C. P. (Hong Kong Polytechnic University)

Personal control beliefs have been extensively studied in body image research, but research on social beliefs is scarce in the literature. In the current study, we examined how individuals' cynical beliefs about the social world, i.e., social cynicism, predict body esteem and moderate the linkage between body esteem and self-esteem. Two-hundred and five female college students were recruited from Australia and Hong Kong. Our results showed that social cynicism was negatively associated with appearance esteem and weight esteem. On the other hand, social cynicism weakened the impact of weight esteem on self-esteem. In other words, among socially cynical women, weight dissatisfaction does not influence their general self-evaluation due to their skeptical attitudes toward social norms and expectations attached to thinness. Clinical applications of the present findings and future research directions are suggested and discussed.

Keywords: social beliefs, cynical beliefs, body esteem, social cynicism, body image
Social norm influence and field experiments

Chair(s): KEIZER, K. (University of Groningen)

In this symposium a number of studies will be presented that all were conducted in a field setting and give insight in workings and possible application of social norm influence. A social norm is the behavior commonly (dis)approved (i.e. injunctive norm) or the behavior common (i.e. the descriptive norm) in a setting. We present research that gives more insight in the processes through which perceived norms influence behavior and the factors that moderate this influence. In this symposium we show how social norm influence on the one hand exacerbates societal problems, and how on the other hand social norm influence can be used as a very effective tool to combat the very same problems. The different studies not only provide insight in the workings of social norm influence, but they also serve as handles for designing effective and powerful interventions. The practical relevance of the presented research and its conclusions is strengthened by the fact that all studies used field experiments to test the different hypothesis. The field experiments showed clear effects of norms on real-life problems in real-life settings.

The cross-norm inhibition effect: How observing litter can lead to stealing

KEIZER, K. (University of Groningen), LINDENBERG, S. (University of Groningen), STEG, L. (University of Groningen)

Prior research has shown that people are more likely to litter in pre-littered settings than in clean settings. We think that this is not only due to people copying the norm violating behavior of other people (in this case littering), but that goal-framing mechanisms are at work as well. Observing that others did not conform to a certain norm weakens people’s goal to act appropriately. This process would also inhibit the influence of other norms on behavior in that setting (i.e. a cross-norm inhibition effect).

Based on this assumption, we hypothesise that people who observe that others violated a certain norm in a specific setting are more likely to violate other norms in that setting. We conducted a series of (between subject) field experiments to test our hypothesis. Subjects in the experimental conditions were confronted with a setting that showed that others had violated a certain norm (our context norm, e.g., setting sprayed with graffiti), whereas the subjects in the control condition were confronted with the same setting without these signs of norm violating behavior by others (e.g., setting free of graffiti). In all the experiments, we observed whether or not subjects violated another norm (our target norm) in that setting. For example whether or not they would litter a flyer they had received, or help someone by posting a letter this person lost. In all experiments, we compared the percentage of people violating the target norm between the control and experimental condition. In all the experiments, a (significantly) higher percentage of people violated the target norm (like “do not litter” or “help others”) when they observed others had violated the context norm. For example 69% of the people littered a flyer they received in a setting with graffiti compared to 33% when the graffiti was absent. The research reveals that observing that other people violated a certain norm will result in a cross-norm inhibition effect which makes it more likely that people will violate other norms. The cross-norm inhibition effect seems to inhibit all kinds of norms including rules and pro-social norms like helping others.

Using peer influence to promote environmental conservation

GOLDSTEIN, N. (UCLA)

The purpose of these experiments was to demonstrate that peer influence could be used to promote environmental conservation in hotels. Many travelers are asked via signs to reuse their towels at hotels to help save the environment. However, despite the fact that the majority of hotel guests do participate in such programs some time during their stay, we...
have never observed a single hotel actually communicate this normative information. We conducted two experiments examining whether conveying this normative information to guests would produce greater towel reuse than messages traditionally used by the hotel industry, which simply focus on the benefits to the environment. Whereas the first study investigates the effects of communicating norms of fellow hotel guests, the second study examines whether informing guests the norms of the previous occupants of their particular room (which we refer to generally as the provincial norm) can make the effect of norms on behaviors even stronger. We created a number of signs urging guests to reuse their towels and randomly assigned them to rooms in a hotel. In Study 1, we compared the effectiveness of a sign conveying that the majority of other hotel guests had participated in the conservation program against the standard environmental appeal used by most hotels. In Study 2, we added a third sign that conveyed that the majority of guests in that particular room participated in the program. Consistent with predictions, in Study 1, we found that communicating the social norm elicited greater towel reuse than simply communicating the benefits of the program to the environment (i.e. the industry standard appeal). In Study 2, we replicated this effect and also found that the sign communicating the norm of the particular room yielded the highest participation rate. The findings of these studies demonstrate the importance of peer influence in promoting environmental conservation. The results of Study 2 in particular suggest when attempting to influence others via peer influence, it is important to ensure that the norms of the reference group are as situationally similar to the intended audience’s circumstances or environment as possible.

Aligning normative messages to promote water conservation

SCHULTZ, P. W. (California State University), DICIANNI, W. (California State University), ESTRADA-HOLLENBECK, M. (California State University)

Prior studies have shown that feedback can be an effective tool in motivating conservation behavior. Our previous research has focused on normative feedback, whereby individuals receive group-level feedback about the behavior of similar others (descriptive norms). While our previous studies have shown that descriptive normative feedback can be an effective tool at promoting conservation behavior, such messages have also been shown to produce boomerang effects. That is, for individuals who consume at a rate that is less than the norm, receiving normative information can produce an increase in consumption. In this talk, we sketch a broad theoretical model describing the psychological processes associated with behavioral feedback. New data is then presented from a field experiment designed to reduce residential water consumption. Participants in the pilot study were 126 households from a southern California coastal community. Of these households, 25 participated in a pilot feedback experiment. These 25 households received real-time feedback about their household-level water consumption, combined with a normative message about the consumption of the other 24 households participating in the study. Feedback was provided continuously for one month. One member from each household also completed a questionnaire measuring self-reported behaviors, attitudes, motivation, and beliefs about water conservation. Statistical analyses showed a 14.4% reduction in water consumption among the 25 treatment households. In addition, results showed a moderation effect, whereby households who were motivated to conserve water prior to the treatment showed a larger effect, compared to households that were less motivated. The talk concludes with a discussion of the implications of these results for large-scale applications, and the importance of developing solid theoretical models that can be used to inform conservation programs and messaging.

Mediated influences of perceived norms on cooperation in real-life social dilemmas

THØGERSEN, J. (Aarhus University)
It is now broadly accepted that a too narrow conceptualization of perceived norms has led to its importance often being underestimated. However, an additional source or underestimating the impact of norms has received much less attention: a too narrow conception of the processes through which perceived norms influence decision-making (i.e. intention formation) and behavior. This paper reviews theory and research suggesting a number of usually overlooked paths between perceived norms and behavior, which expand the total effects attributable to perceived norms. Based on this evidence, I propose that perceived norms affect behavioral intentions not only directly, but also indirectly, injunctive norms through personal norms and descriptive norms through self-efficacy. In addition, I propose that descriptive norms, at least with regard to cooperating in a social dilemma, influence behavior through the perceived efficacy of cooperation. Reanalysis of meta-analysis data based on field studies, primarily regarding large-scale social dilemmas (pro-environmental behavior) and mediation analysis of survey data. It was found that: a) Injunctive and descriptive norms are positively correlated. Since both can be inferred from the other, this is a two-way influence. Hence, the influence of each of these norm constructs is partly mediated through the other. b) The influence of injunctive norm on BI is partly mediated through personal norms. c) The influence of descriptive norms on BI is partly mediated through perceived efficacy. d) After controlling for BI, descriptive norms have an influence on behavior, which is partly mediated through perceived efficacy. e) Just like perceived efficacy moderate the relationship between BI and B, so do descriptive norms. f) These mediated influences mean that the total effects of perceived norms on BI and B are considerably larger than the direct effects. A too narrow conception of the processes through which perceived norms influence decision-making (i.e., intention formation) and behavior leads to underestimating the importance of perceived norms. This is especially true when the focus is on cooperation in social dilemmas, including pro-environmental behavior. Research in this and other areas has suggested a number of additional paths between perceived norms and behavior, which expand the total effects of norms.

Abstracts of the 27th International Congress of Applied Psychology

Social, cognitive and legal psychological perspectives on counter-terrorism: Innovations in theory and research

Chair(s): GOODMAN-DELAHUNTY, J. (Charles Sturt University)
Discussant(s): GOODMAN-DELAHUNTY, J. (Charles Sturt University)

A multidisciplinary multinational panel demonstrates how findings from social, cognitive and legal psychology are advancing theory and research in defining terrorist acts, assessing causes of terrorism, investigating and preventing terrorism. The symposium presents cutting-edge research on the role of group processes, social identity theory, collective political action, situational crime prevention, non-intrusive inquisitorial interviews and risk assessments used in counter-terrorism. These researchers draw on interviews with terrorists, feedback from CT interviewers, measures of psychological commitment to social groups, social identity analysis, and inter-group conflict. Their research indicates why psychological approaches that focus on individual personality types and psychopathy have limited utility in risk assessment and prevention of terrorism. They illustrate why approaches to counter-terrorism that incorporate accusatorial and coercive interrogative methods increase the likelihood of false confessions or false information about risk of hostility, and how a new proposed Australian definition of terrorism entails problematic concepts of psychological harm and mental illness, and unrealistic expectations of expert assessments of mental states. Together, these innovative approaches to counter-terrorism highlight evidence-based advances at the interface between psychology and the law. These unique contributions of psychology to this emerging forensic field will interest practitioners, researchers and legal policy-makers.

Empirical evidence that support for political violence is associated with the perceived failure of democratic alternative tactics

LOUIS, W. (University of Queensland)

It is often argued that political violence and terrorism arise when democratic, non-violent tactics are perceived as ineffective. Interviews of captured terrorists and the autobiographies of violent leaders support the argument of strategic considerations, and highlight the failure of democratic alternatives as a key stimulus to political violence. However, it is possible that within particular political contexts, both violent and non-violent actors perceive that democratic alternative tactics would fail, in which case strategic beliefs must be seen as rationalizations of violent choices rather than predictors. Until the present research, there has been a gap in the literature, with no empirical data testing the hypothesis that beliefs about the utility of alternative democratic tactics differentiate between activists who support political violence more or less strongly.

Neither mad, bad nor sad: The role of social identity in understanding commitment to terrorist groups

THOMAS, E. F. (Murdoch University)

It is widely accepted amongst scholars of terrorism that terrorists rarely, if ever, exhibit the sorts of psychological abnormalities commonly observed amongst members of other illicit groups (e.g. criminals). Indeed, decades of research has been unable to systematically identify any one clinical feature (mad, bad or sad) that explain the behaviour of people that commit such acts of hostility. In this paper I will put forward a perspective on terrorism as extreme psychological commitment to a social group. Further, I will discuss the ways that terrorism can be understood as a form of collective action, where participants mobilise as a group to try and alter the circumstances of a broader social
group. Putting these two propositions together, I will argue that the social identity approach to collective action has much to bring to an analysis of the radicalisation process. Utilising available interview and scholarly sources, informal qualitative analyses will illustrate the core point that that commitment to terrorist social groups can be understood through the lens of social identity. Understanding the ways that social groups become important, relevant and meaningful to people is arguably at the core of understanding terrorism. The social identity analysis provides one such account and terrorism scholarship can benefit from this large literature in better understanding questions of group processes, leadership, legitimacy and inter-group conflict in the terrorism context.

Balancing terrorist motivation and capacity in determining and preventing terrorist attacks

MORGAN, F. (Crime Research Centre, University of Western Australia), CLARE, J. (Crime Research Centre, University of Western Australia)

The theory of situational prevention has recently been applied by Clarke and Newman (2006) to the prevention of terrorist attacks. Situational crime prevention has been applied successfully in many contexts and it combines the more fundamental approaches of rational choice and routine activities theory. For example, whatever motivations that terrorists may have, they require the means to overcome physical, practical and geographic barriers to achieving what they want, or equivalently the 'rational' motivational aspects of terrorism are bounded by various practical opportunities that can potentially be altered. In two recent book chapters the presenters re-examined this application of the situational approach and found that it significantly extended the theory as originally applied to crime. This presentation will examine key papers applying situational prevention to terrorism and crime. The presentation will (1) demonstrate the areas in which theory is extended when applied specifically to terrorism rather than broadly to crime; (2) examine evidence for and against this approach to terrorism, and (3) contrast the theory with other approaches to terrorism by experts in the fields of psychology, political science or law enforcement. The implications of the situational approach for terrorism prevention policy are examined and the balance of strategies that may be best applied are reviewed.

Improving the diagnostic value of interrogations for intelligence purposes: A positive, scientific approach

MEISSNER, C. A. (University of Texas at El Paso), EVANS, J. E. (University of Texas at El Paso)

Much is known about the problems of coercive interrogative methods and the likelihood of eliciting false confessions or false interrogative information. The current paper describes a positive psychological approach in which we seek to better understand factors that improve the diagnostic value of interrogative information applicable to counter-terrorism. These include non-intrusive ways to determine the intent of interviewees, real-time detection of deception and hostile intent. We discuss a series of studies involving both well-controlled laboratory methods and field assessments of real interrogations that focus on the collection of human intelligence from alleged terrorists. In this context we contrast the use of accusatorial vs. inquisitorial approaches to interrogation and note their implications both for the elicitation of information and assessments of credibility. We describe our attempts to develop other "tools" that might facilitate both training and practice in the interrogation room, including the use of virtual human tutoring systems and a credibility assessment instrument intended to facilitate analysts' evaluations of interrogative information.

Keywords: false confessions, coercive interrogative methods, counter-terrorism, credibility, terrorism

Psychological harm and criminal liability: From assault to terrorism offences
To present a legal psychological review and theoretical analysis considering the merits of the 2009 proposal by the Australian Federal Government to amend the definition of terrorist act. The proposed reform would return to the controversial 2002 position where pure psychological harm, rather than only actual or threatened physical harm, is part of the definition of terrorist act within the Criminal Code Act 1995 (Cth). However, assessing possible rather than actual psychological harm, would also be one route to creating criminal liability under the proposed reforms. This paper tracks the legal psychological possibility of gathering and using evidence of actual psychological injury in Anglo-Australian criminal law which allows prosecution of aggravated assaults in the absence of physical injury. The assault law example is then compared to the challenges for the psychological expert, judicial officer or jury under the proposed reforms to the Australian terrorist act definition whereby an assessment could be required of whether the alleged terrorist action causes, or is likely to cause, serious harm including psychological harm. The use of expert psychological testimony to establish that the defendant caused purely psychological harm to a complainant has led to successful prosecution for assault in England. However, the way in which psychological harm has been described by some courts remains problematic. At times, discussion of psychological harm by the courts reflects impoverished understandings of mental illness and of the nature of the expert’s possible assessment of the complainant’s mental state. The proposed amendment to the Australian terrorist act requires assessment of likely future harm to an unspecified victim, rather than actual harm already suffered by an identifiable victim, and this adds new challenges and controversy in using psychological harm as one way to determine criminal liability. The proposed amendment to the Australian terrorist act definition is of dubious utility and poses many challenges for anyone asked to do the required risk assessment.
Subjective diversity perceptions: The "real" diversity?

Chair(s): ICAPMODE, Meyer (University of Zurich), SHEMLA, M. (Dresden University of Technology)

Discussant(s): ROßNAGEL, C. (Jacobs University Bremen)

Diversity has been defined as "differences between individuals on any attribute that may lead to the perception that another person is different from self" (van Knippenberg et al., 2004). Given that, and considering that some studies show that perceived differences mediate the relationship between actual differences and team outcomes (Harrison, 2002), one would expect that studies in this field investigate when individuals perceive differences, how these perceptions are shaped, and what consequences they have on the team. However, most research in this field continues to conceptualize and operationalize diversity in terms of the objective differences between individuals in teams (e.g., tenure, age, values). Therefore, we see great need in advancing research that examines subjective perceived diversity. In this symposium we present new theoretical and empirical insights into what diversity perceptions consist of, how they relate to and interact with objective team diversity, and what influences they have on team processes. In the first contribution, empirical findings reveal that negative effects of objective age diversity on team effectiveness are mediated through subjective age diversity, thus emphasizing the centrality of salience and perception in the diversity phenomenon. The second contribution investigates the sources of subjective diversity perception. It concludes that the interplay between individuals’ perception of diversity – which has little connection to actual demographic diversity - is important for performance. Similarly, in the third contribution the authors suggest that actual diversity faultlines are not necessarily noticed by group members and must be perceived in order to have an effect on group processes and outcomes. The authors found that perceived faultlines had an influence on coalition formation, intensity of conflict, and level of performance. In the last paper, the authors report that an important consequence of perceived diversity in teams is the extent to which team members’ affects are likely to be shared. Together, these contributions point to the idea that subjective diversity is a useful and necessary aspect to be considered. The four contributions pose a challenge to the prevalent conceptualization and measurement of team diversity and highlight new approaches for helping diverse teams to reach their full potential.

Age-diversity salience and conflicts in teams as mediators of the impact of objective age diversity on team effectiveness

WEGGE, J. (Dresden University of Technology)

Over the past decade demographic trends have focused increasing organizational attention on issues related to the successful management of an ageing workforce. One aspect that has received rather scant attention in this analysis is the increase in age diversity within work groups. As employees work into late midlife, not only the number of older employees but also age diversity in organizations has increased. Moreover, prior research on group composition indicates that age diversity in teams is not unproblematic (e.g., Joshi & Roh, 2009). The mechanisms underlying potential disadvantages of age diversity in teams such as increased conflict and turnover, however, are not well understood. Therefore, we investigated how negative effects of objective age diversity might develop by examining two potential mediating variables: subjective age-diversity salience in combination with conflicts in teams. In particular subjective age-diversity could explain how negative effects of objective age diversity on team effectiveness (e.g., job satisfaction, team identification, innovation) are elicited. Based on social identity theory, we constructed a new measure of age-diversity salience in teams (that proved to be reliable with an alpha of .82) and tested the mediating role of these subjective diversity perceptions and traditional conflict scales by applying structural equation models to data acquired in a field study with 157 natural work groups of a
major county administration (N = 722). The results of our study support the assumption that actual age-diversity in teams yields subjective perceptions of age-diversity that, in turn, lead to emotional and task conflicts. Moreover, both types of conflicts resulted in low team effectiveness in our study. A complete mediation model including these paths showed the best (and very satisfactory) model fit. Thus, objective age differences in groups can be expected to be more salient, triggering emotional and cognitive conflicts, which in turn impair group efficiency. The present studies support the importance of subjective perceptions of age-diversity in teams and encourage interventions seeking to improve successful conflict management in teams.

Keywords: age-diversity salience, conflict, team effectiveness, job satisfaction, innovation

Social category salience moderates the effect of diversity faultlines on information elaboration

MEYER, B. (University of Zurich)

Previous research showed that perceived diversity can mediate the effects of actual diversity on group processes and group performance. However, previous measures of perceived diversity can be criticized for surveying the construct with a limited number of attributes that were selected by the researchers. We argue that such a selection can be arbitrary and that a measure of perceived diversity must take any important salient diversity attributes – also referred to as social categories – into account. We develop such a measure by qualitatively inquiring about salient social categories. The strength of their salience is subsequently rated by the participants. The categorization-elaboration model (CEM) proposes that social categorizations moderate the relationship between group diversity and information elaboration, which is seen as a key determinant of group performance. Therefore, we test whether our measure of category salience moderates the connection between actual group diversity and the elaboration of task-relevant information. 172 participants were assigned to 43 groups of four. Participant gender, bogus personality feedback, seating position, and colored cards were employed to create two diversity faultline conditions. In the strong faultline condition, groups were split into two homogeneous subgroups with high inter-subgroup dissimilarity on these attributes. In the weak faultline condition, no such split existed. Faultline strength was used as a measure of actual diversity. Groups worked on the Survive In The Desert task. Their interactions were coded with the Discussion Coding System (DCS). Participants stated a myriad of social categories for their salience judgment. These were greatly unrelated to surface-level characteristics frequently employed in diversity research, such as age and gender. Apart from actual age diversity, social category salience was unrelated to measures of actual diversity including personality, motivation, and faultline strength. Social category salience moderated the effect of faultline strength on elaboration: Individuals in strong faultline groups with low levels of category salience elaborated most. Elaboration was positively related to task performance. Individuals report diversity perceptions on categories that are usually not elicited in diversity research. Groups with high levels of actual diversity and low levels of social category salience can benefit from their diversity.

Perceived demographic faultlines in groups and the effects on conflict, coalition formation and group outcomes

JEHN, K. (Melbourne Business School)

This research examines the effects of group faultline activation on coalition formation, conflict, and group outcomes. We distinguish between dormant faultlines (potential faultlines based on demographic characteristics) and active faultlines (members actually perceive subgroups based on the demographic characteristics) and hypothesize that while dormant faultlines do not automatically turn into active group divisions, a group’s entitlement configuration can activate...
divisions among group members. We examine the relationship between activated faultlines and conflict, coalition, and group performance. Study 1 was a construct validity study to verify the psychometric properties of the active group faultline measure. The second study provides the cross-validation of our constructs and an empirical test of our theoretical model using 40 student workteams with dormant faultlines based on one demographic characteristic, race. The third study with 32 workteams also tests the hypotheses with dormant faultlines based on two demographic characteristics (race and gender). In our research, we relied on a multi-method approach: pre- and post-experimental questionnaires, contextual ratings by independent raters, content-analyzed audiotapes, observational reports with behavioral indicators, and objective measures of group performance. The groups in all three studies worked on a sequentially interdependent production task. A 2 (dormant vs. no dormant faultline) x 2 (2 entitled configuration vs. no entitled) ANOVA factorial design showed that groups with dormant faultlines and a group personality configuration with two entitled had more active faultlines than without such members. We also found that groups with active faultlines were more likely to form coalitions, have high levels of group conflict, and lower levels of performance. Team identification moderated the effects of activated faultlines on group processes such that a strong workgroup identity decreased the likelihood that activated faultlines led to coalition formation and conflict. This research suggests that objective demographic characteristics that members may align on are not automatically noticed by group members and must be activated to have an effect on group processes and performance.

Keywords: group faultline activation, coalition formation, conflict, group performance, personality

Explaining affective linkages in teams: A multilevel examination of the role of subjective team diversity

To expand on the understanding of how affective states are linked within teams, this study examines the role of team diversity in the process of emotional contagion. Emotional contagion is a phenomenon in which an emotion of one person spreads to others. Previous studies, conducted mainly in the lab, have focused on individual tendencies that influence the intensity of this phenomenon, such as susceptibility to emotional contagion and individualistic and collectivistic dispositions. This study is the first to examine the role of the team in the process of emotional contagion and to do so in the context of natural work teams. Particularly, I propose that affective states linkages in teams are affected by the extent to which the team is diverse, such that affective linkages between team and member is higher in teams with high diversity compared with teams with low diversity. The sample consisted of 341 individuals in 61 natural teams from four different German organizations. Data was collected from two sources and at two points in time, 2 weeks apart from each other. Importantly, team diversity was conceptualized as team members’ subjective perceptions of team diversity. Such a conceptualization follows definitions of diversity that emphasize the subjective aspect of the phenomenon, and is in line with the finding that the effects of actual diversity are mediated through perceived diversity. Hierarchical linear modeling revealed that the affective state of the other team members was related to an individual team member’s affect. These affective linkages were moderated by subjective team diversity such that the strength of the linkage was stronger for members in teams with high diversity. This research suggests that affective linkages between team members are influenced not only by individual dispositions but also by team characteristics. Particularly, the findings shed light on the active role that subjective team diversity has in shaping team processes.

SHEMLA, M. (Dresden University of Technology)
Sustainable transportation

Chair(s): STEG, L. (University of Groningen), NORDLUND, A. (Umeå University)

Car use causes various environmental problems, such as air pollution, excessive use of nonrenewable resources, congestion, and extensive land use. “Business-as-usual” will not lead to sustainable transportation. Promoting environmentally sustainable transportation is therefore important – policy-makers have to work with different instruments, technological experts need to produce eco-innovations within the transport sector, and individual travelers need to reduce private car use and/or switch to more pro-environmental travel modes. Behavior that relates to transportation is, however, complex, both in its variety and in the factors that influence these behaviors, pointing towards the importance of research on sustainable transportation. In this symposium researchers in environmental psychology and traffic and transport psychology will present research addressing a number of urgent questions: How well can private car use be predicted with determinants such attitudinal factors, personal capabilities, and contextual factors? How well do soft policy measures, targeting reduced private car use, work? And, Are there behaviorally-related problems with introducing new technology within transportation?

When the train comes to town: Important factors in switching from car to train

NORDLUND, A. (Umeå University), WESTIN, K. (Umeå University), OSTMAN, V. (Örnsköldsviks Municipality)

Personal transportation in the future should be constructed in such a way that necessary environmental considerations are taken into account, while the opportunity for mobility and availability for services is held stable or increased. In today’s society the majority of person journeys are made by car, a travel mode known for its negative environmental impact but with an excellent record of getting you where you need to be in your everyday life. If personal transportation in the future is to be sustainable we need alternatives to the car that are perceived to be attractive to the public. When working towards a sustainable transportation infrastructure as well as sustainable personal and professional traveling behaviors, it is important to understand the different factors influencing individual behavior. The current study presents preliminary questionnaire data from an ongoing research project. The project studies factors such as individual values, attitudes, and norms, the social and physical context that individuals inhabit, individuals’ personal capabilities, and transportation routines that individual have developed, before and after the opening of a new 190-kilometer railroad on the coast line in the northern part of Sweden, where no railroad had previously existed. The focus will be on how values, beliefs, and norms (VBN Theory, Stern 2000) will predict individuals’ intentions or willingness to switch from travelling by car to train once the rail traffic starts. This relationship will be further analyzed within the relevant demographical and geographical context.

Keywords: transport, sustainability, environmental factors

The influence of knowledge and values on energy efficient driving

STEG, L. (University of Groningen), GORSIRA, M. (University of Groningen), BOLDERDIJK, J. W. (University of Groningen), KEIZER, K. (University of Groningen)

We studied the extent to which the norm activation model can predict energy efficient driving. We also examined the extent to which values, as well as three types of knowledge (knowledge about (1) the causes and (2) the consequences of global warming, and (3) knowledge about how to drive energy efficiently) predicted the Norm Activation Model (NAM) variables and energy efficient driving. We hypothesised that knowledge and values influence people’s awareness of problems resulting from car use, which results in higher outcome efficacy, personal norms, stronger intention to drive energy efficiently, and more energy-efficient driving. We conducted a questionnaire study among 83
inhabitants of the city of Groningen, The Netherlands. As hypothesised, people were more likely to drive in an energy efficient way when they felt a moral obligation to do so. Feelings of moral obligation were stronger when people were aware of the negative (environmental) consequences of car use (awareness of consequences) and when they felt they could help to reduce these problems by driving more energy efficiently (high outcome efficacy). Values explained 35% of the variance in problem awareness. Knowledge about the consequences of global warming explained only 5% of the variance in problem awareness, while the two other types of knowledge were not significantly related to problem awareness. Moreover, we found that knowledge was not significantly related to any of the other NAM variables and energy efficient driving, while values were predictive of personal norms and intentions to drive energy efficiently.

Quality of life and social normative information: A study of sustainable transportation behaviour

KORMOS, C. (University of Victoria), GIFFORD, R. (University of Victoria)

This study evaluated the impact of descriptive social normative messages and anticipated changes to quality of life (QoL) on individuals’ willingness to reduce their private vehicle use. Previous research has demonstrated the utility of social-norm marketing campaigns for eliciting behaviour change in other domains, but their effectiveness for promoting change to transportation choices remains relatively understudied. An experimental, field-intervention design was employed in which faculty, staff, and students (N = 81) at the University of Victoria were asked to attempt to reduce their private vehicle use by 25% for a month. Participants assigned to low or high social norm conditions received messages that either few or many campus commuters had switched to sustainable commuting, whereas those in the control condition did not receive such information. The participants completed daily transport journals. Consistent with previous studies in other behavioural domains, normative message content caused a short-term change to behaviour: high social norm information increased sustainable transportation behaviour. However, message content did not predict long-term behaviour change; participants in both high and low normative message conditions exhibited a greater decrease in private vehicle use than did those in the control condition. These results also demonstrate that social norm messages are more influential on commuting behaviour than on other types of transportation behaviour. In addition, in line with the existing literature, participants anticipated an overall neutral change to QoL under the hypothetical 25% reduction in private vehicle use: they anticipated decreases to some individually-relevant QoL items but improvements to some collectively-relevant QoL items. Unlike in previous studies, however, the participants also expected improvements to health and money, two individually-relevant qualities. The findings suggest that dissemination of information about positive trends in others’ commuting-related transportation decisions may serve to highlight cooperation and thus be useful to promote pro-environmental behavioural change, even when current adoption rates are low. QoL-related findings support the use of a compensatory decision-making model, which has previously been suggested to underlie QoL evaluations (e.g., De Groot & Steg, 2006). Information about specific anticipated QoL impacts may be used by policy-makers to increase acceptance of sustainable transportation measures.

Does purchasing an “eco-car” increase the vehicle distance travelled?

FUJII, S. (Kyoto University)

For a sustainable transportation system, zero-/low-emission vehicles (i.e., eco-car) such as an electric or hybrid vehicles would play an important role because of their lesser impact on the environment. However, technology improvement, which contributes to fuel efficiency through reduced energy costs, leads to a reduction in the price for energy services.
Therefore, one might drive much more. For this reason, part of the energy conservation due to technology vanishes. It is plausible to hypothesize that the shift from ordinal gasoline vehicles to eco-cars results in increases in distance driven. This research tested this hypothesis. In this study cars powered by 1.5 litre engines, which currently lead eco-car sales (Prius is the most prevalent in this category of eco-cars) were targeted. Fifty-four respondents who purchased this category of car within 6 months in Japan were obtained using internet survey monitoring data. We conducted two waves of internet surveys to investigate driving distance; wave2 was conducted about 8 months after wave1. Driving distance, as measured by odometer readings, revealed that the driving distance for those who perceived their car to be an eco-car was 1.64 times higher than for those who did not perceive their car as an eco-car about 1 year after purchase. The increase in driving use was particularly prominent for those who presumed that eco-car use could solve environmental problems. The amount that their driving use increased was 104%. These results supported our hypothesis and imply that introducing new technology alone cannot solve environmental problems. Soft transport policy measures are thus designed to motivate users of private cars to voluntarily change their car use by switching to more sustainable travel modes. A screening process identified 50 projects implemented in Sweden. Eighteen projects were left out due to insufficient documentation. A total of 32 projects were included and analyzed with regard to types of measures used, type of implementation strategies and noted effects on changed travel behavior. The results showed that a weak design is often employed in soft policy projects. A common technique was to give incentives (e.g., free travel pass) to participants. Another technique was information provision. Feedback on travel behavior was documented in three projects. However, several different techniques were often used in the same project. Effect measures after the project ended were scarcely used. Documented effects were an increase in frequency of public transport use (+36.11%) and biking (+43%) and a decrease (-21.57%) in frequency of private car use. Other effects analyzed were change in travel per week and change in travel per kilometre.

Keywords: soft transport policy measures, sustainable travel, public transport, transport, Sweden

FRIMAN, M. (Karlstad University), GÄRLING, T. (Karlstad University)

The aim of this study is to review implementations of soft policy measures. A consistent definition of such policy measures has not yet been developed, a typical feature is, however, that they influence individual choice by means of information and persuasion. Frequently implemented examples of soft transport policy measures to reduce private car use include workplace travel plans, personalised travel planning, public transport marketing, and travel awareness campaigns. Soft transport policy measures are thus designed to motivate users of private cars to voluntarily change their car use by switching to more sustainable travel modes. A screening process identified 50 projects implemented in Sweden. Eighteen projects were left out due to insufficient documentation. A total of 32 projects were included and analyzed with regard to types of measures used, type of implementation strategies and noted effects on changed travel behavior. The results showed that a weak design is often employed in soft policy projects. A common technique was to give incentives (e.g., free travel pass) to participants. Another technique was information provision. Feedback on travel behavior was documented in three projects. However, several different techniques were often used in the same project. Effect measures after the project ended were scarcely used. Documented effects were an increase in frequency of public transport use (+36.11%) and biking (+43%) and a decrease (-21.57%) in frequency of private car use. Other effects analyzed were change in travel per week and change in travel per kilometre.

Review of soft policy measures for changed travel behavior in Sweden

FRIMAN, M. (Karlstad University), GÄRLING, T. (Karlstad University)

The aim of this study is to review implementations of soft policy measures. A consistent definition of such policy measures has not yet been developed, a typical feature is, however, that they influence individual choice by means of information and persuasion. Frequently implemented examples
Teacher development in an era of accountability

Chair(s): RILEY, P. (Monash University), HALFORD, W. (University of Queensland)

Discussant(s): BUTLER, R. (Hebrew University of Jerusalem)

Increasing accountability in the education arena of schools should directly impact teachers’ motivations and behaviours, yet this has not yet been directly studied in detail. Our topical and timely objectives are to examine implications for teachers’ sense of responsibility (paper 1), ethical communication behavior (paper 2), professional development (paper 3), and motivational approach for teaching (paper 4). Individual paper presentations vary along additional key salient dimensions to these four dimensions of teacher development on which the symposium is focused. Cultural settings studied include the U.S., U.K., Germany, Israel, and Australia. Developmental stages span from teacher education students through to experienced teachers. Theoretical perspectives draw from both motivation theories and sociocultural perspectives. Data sources are from surveys, mixed-methods, and longitudinal designs. Collective contributions across the set of papers show that pressure to ensure high student performance can undermine rather than support both teacher professional development, and the quality of teachers’ support for student learning; that accountability and reward systems which are discrepant with teachers’ own sense of professional responsibility are unlikely to engender benefits; and, that recent changes in the communication landscape raise issues of “professional cyber-safety” which pose risks to the fitness to practice of teachers who undertake emotional work involving high levels of interpersonal contact with youth. In view of the findings, implications are offered with regard to how accountability systems could better be improved. Following individual paper presentations, and audience questions specific to each paper, our Discussant will make her presentation and invite audience rejoinders. Our Discussant is a distinguished research professor in the field of motivation, who has made seminal contributions in the areas of both student and teacher motivation, and whose present ongoing program of research concerning the relevance of teachers’ motivations to their own behaviours and students’ outcomes, is highly germane to the symposium proposal. She will make individual comment and critique on each presentation, before integrating across overarching themes and deriving main implications and fruitful directions for future research endeavours in this area. The session will end with audience questions and discussion around the issues raised.

Teacher responsibility in an era of accountability

KARABENICK, S. (University of Michigan), LAUERMANN, F. (University of Michigan)

There has rarely been a greater focus in the U.S. on the accountability of teachers for student achievement. Although accountability takes center stage, it is closely aligned and often used interchangeably with responsibility. They are not synonymous, however; teachers may feel responsible for some aspects of student learning even if not accountable, and while accountability systems require monitoring and control for compliance, the actions of those who feel responsible may be self-determined rather than extrinsically motivated by the consequences imposed by those systems. Our presentation will: (a) unpack the concept of teacher responsibility into its multiple components, (b) report the results of empirical studies of teachers’ beliefs about responsibility, and (c) discuss implications for accountability systems. A qualitative study was conducted with teachers (n = 25) in the U.S. and two quantitative studies using a newly-developed responsibility scale with teachers in Germany (n = 200), and Israel (n = 250). We will present results of empirical studies that support a six-component model according to which teachers’ responsibility beliefs can be categorized, as well as linkages between responsibility and related constructs. The presentation will emphasize the inherent complexity of teacher responsibility as an overarching concept that incorporates aspects of intrinsic motivation,
locus of control, organizational citizenship, and collective responsibility – constructs that are powerful predictors of student academic success. The results indicate that teacher responsibility includes not only formal duties but also organizational citizenship (e.g., that a responsible teacher “comes early, stays late and is never totally done with work”). Moreover, some teachers extended their responsibilities well beyond the context of school to such roles as feeding students and finding them homes. The results suggest that the implementation of accountability systems in combination with reward systems interact with teachers’ personal sense of responsibility on multiple levels. If the criteria that determine teachers’ sense of professional responsibility are not consistent with the criteria according to which they are judged accountable, an environment of accountability is unlikely to nurture responsibility. A deeper understanding of the criteria and determinants of teacher responsibility, therefore, has important implications for teacher motivation.

Usage of social networking sites among prospective teachers – ethical implications for “fitness to practice”

MORRIS, Z. J. (Monash University)

The concept of “cyber-safety” in relation to children and adolescents and bullying behaviours has been well publicised, but to date, too little attention has been given to “professional cyber-safety”. Teachers who utilise Social Networking Sites such as Facebook and MySpace place their personal identity in the same digital environment as their students, and this may potentially pose a threat to their professionalism, by eroding personal and professional boundaries. Due to the rapid expansion of technology, clear legal and ethical guidelines are not yet defined, opening up the possibility for developing professionals, who have been immersed in such technology for many of their formative years, to find themselves exposed to charges that they are not “fit to practice”. Teacher education students \( N = 150 \) enrolled in their final years of secondary teacher education degrees completed a survey detailing their current and prospective use of Social Networking Sites. 89% of participants actively used Social Networking Sites; only 9% indicated that they would definitely delete this profile when they began teaching, and less than half (47%) indicated that they would change their privacy settings when they began teaching. 3% of participants indicated that they would accept a “friend request” from a current student, a further 12% indicated that they might accept such a request. Further, 33% of participants indicated that they would accept a “friend request” from previous students who had finished Year 12. Possible underlying motivations for Social Networking Behaviour are discussed in relation to established extant theories of personality and adult attachment. The results suggest that pre-service teachers generally intend to continue to present their personal identity through Social Networking Sites once they assume the role of a teacher. Failing to alter privacy settings to limit public access to their profiles, or adding students as “friends”, may expose early career professionals to new ethical issues involving “dual relationships” and possible blurring of boundaries between their clients and themselves as professionals; calling into question their fitness to practice. The personal information disclosed through Social Networking Sites may influence the appraisal of whether or not the individual demonstrates fitness to practice, or is found to be unfit as a result of prior behaviour made accessible through Social Networking Sites, that is unbecoming to the profession.

Keywords: professional cyber-safety, teachers, social networking sites, fit to practice, professional boundaries

Teachers’ professional development under reform pressure

OPFER, D. (Cambridge University)

Teacher professional development (PD) has become a major focus of school accountability initiatives because of the belief that the success of the efforts hinge, in large part, on the effectiveness of teachers. Recent research provides some preliminary guidance about the characteristics of ‘effective professional
development’: that it is ongoing, collaborative, practice-based, and uses active learning pedagogy. This evidence suggests that professional development experiences that share all or most of the characteristics can have a positive influence on teachers’ classroom practices and student achievement. This paper explores both teacher and school level conditions that make ‘effective professional development’ more or less likely to occur. It pays particular attention to those schools at the bottom of league tables and under the most pressure to improve. A national, random sample of teachers in primary and secondary schools in England was surveyed about their professional development practices and the conditions which influenced their professional development and teaching practice. Teacher surveys were received from 329 primary schools - a response rate of 36%, and 59 secondary schools - a response rate of 56% of the schools selected for participation. SEM was used to identify individual and school conditions associated with ‘effective PD’. Teachers in schools at the bottom of league tables are the least likely of responding teachers to participate in ‘effective professional development’. Three factors are associated with a lack of effective PD for these teachers: 1) an individual belief in teaching practice and teaching success as static; 2) the lack of a collective learning orientation in the school; and, 3) PD participation that is determined and required as a function of performance management. Accountability pressure is not resulting in more effective professional development. The evidence from this study in England indicates that accountability pressure creates an external locus of control for teacher learning. If teacher professional development is to achieve its promise for improving teacher practice, ‘required’ PD should be limited and more attention paid to changing individual and collective beliefs about professional development, which play a significant role in determining the types of learning in which teachers participate.

Performance pressure: Implications for teachers’ motivational approach for teaching

SHIBAZ, L. (Hebrew University of Jerusalem)

Recent reforms emphasize student performance, assessed typically using standardized tests, to measure teacher and school accountability. Although intended to improve educational outcomes, largely through increasing teacher motivation, these reforms have been criticized for potentially negative implications for the quality of teaching, learning, teacher-student relationships, and school and teacher commitment to struggling students (see Hursh, 2005; Ryan & Brown, 2005 for reviews). Extrapolating from our recent achievement goal approach to teacher motivation (e.g. Butler & Shibaz, 2008), our main objective was to examine the proposal that pressure to ensure high student performance influences the quality of teaching, specifically teacher support for student learning, at least partly by influencing the quality of teachers’ motivation. Moreover, existing inventories have not conceptualized PP as a distinct school climate dimension. 300 elementary school teachers in Israel completed measures of goal orientations for teaching and school climate; the latter including four new items to assess PP. Six months later, teachers completed a measure of their support for student questioning and help-seeking. Results confirmed responses to PP items loaded on a separate factor, distinct from school climate dimensions of perceived principal support and excessive work demands. Scale reliability was acceptable. As hypothesized, PP emerged as the strongest organizational climate predictor of teachers’ performance goals for teaching; associated with both strivings to demonstrate higher ability than other teachers (performance-approach) and to avoid the demonstration of inferior teaching ability (performance-avoidance). Perhaps most important, performance approach orientation for teaching mediated the negative consequences of performance pressure on teachers’ support for student questioning and help seeking in
classroom. These results are important. On the one hand, they confirmed conceptualization of PP as a dimension of school climate and showed that PP does enhance concerns to prove high teaching ability, as advocates of accountability assume. On the other hand, performance goals have been shown to be negatively associated with teacher wellbeing. Our results demonstrate further how increasing motivation of this kind undermines, rather than supports, the quality of teachers’ support for students and learning.

Teacher identity development

Chair(s): RICHARDSON, P. (Monash University)

Discussant(s): HORENCZYK, G. (Hebrew University of Jerusalem)

A large and burgeoning body of research is focused on teachers’ general career motivations. Our symposium takes a step further to consider larger aspects of teacher identity and their relationship to teacher development in specific domains. The perspectives included are those of personality theory (paper 1), subject-specific teaching motivations (paper 2), teaching motivations in relation to attitudes toward student diversity (paper 3), and in relation to burnout and career plans (paper 4). Theoretical perspectives include personality, goal, and expectancy-value theories; methodologies encompass intensive and open-ended data collection, through to large-scale and longitudinal studies; the developmental spectrum spans teacher education students through to experienced teachers; and contexts examined include the United States, Australia and Turkey. Collectively, these papers provide multiple perspectives on teacher identity and development, demonstrating the relevance of personality dimensions to teachers’ career choice, planned effort and commitment (paper 1); the relevance of teaching career motivations identified in developed countries to commencing biology teachers in Turkey (paper 2); the impact of teaching goals on attitudes and practices towards minority and poor students (paper 3); and the relative contributions of selected personal and environmental variables to teacher burnout symptoms and planned persistence in the profession (paper 4). The Symposium is timely in the current climate of teacher shortage, and makes a useful contribution in developing theoretically grounded approaches. Following a brief introduction by the Symposium Chair, each presenter will summarise the objectives, methods, data sources and conclusions from her/his research, allowing for brief question and comment time at the conclusion of each presentation. The Discussant is a well-known researcher whose work is in the
direct areas of the research presentations of this proposal, who will draw together and highlight key findings, themes, and productive future research directions.

**Teachers: from factors to facets**

QUIN, K. (Monash University)

Researchers investigating elements of personality influencing career choice have used the Five-Factor theory of personality with limited success, perhaps from reliance on its broad factors rather than on specific facets within those factors. It has been suggested (Hurtz & Donovan, 2000) that more specific facets might yield stronger results. The first aim of this study was to identify whether specific facets of personality measures might reveal more information about personality traits of beginning teachers. A longitudinal study of the teaching commitment of beginning teachers (Watt & Richardson, 2007) found that individuals high on intrinsic and altruistic motivations for initially choosing teaching were also those who planned to persist longest. A second aim of this study was to see if there was a relationship between personality facets and teaching commitment factors. Practising teachers with up to three years’ experience were interviewed to identify personality traits they thought important for teachers. Responses were compared to the Adjective Check List Correlates of the NEO PI-R Facet Scales (Costa & McCrae, 1992). A cohort of 74 volunteer trainee secondary teachers in their third year of a four-year course completed new personality questionnaires designed to identify influential personality facets. Correlations between personality facets and teaching commitment factors were examined. Specific facets rather than broad personality factors were more successful in identifying personality traits possessed by trainee teachers. Prospective teachers scored high on: competence, dutifulness, achievement-striving, self-discipline (facets of the Conscientiousness factor); warmth, gregariousness, positive emotions (facets of the Extraversion factor); straightforwardness, altruism, compliance, tender-mindedness (facets of the Agreeableness factor). Scores were low on: modesty (facet of the Agreeableness factor); anxiety, angry hostility, and depression (facets of the Neuroticism factor). High scoring facets also correlated with teaching commitment factors of planned effort and planned persistence. Higher Deliberation and lower Impulsiveness facets also correlated with planned effort; and facets of Feelings and Trust correlated with planned persistence. Measures of personality facets could be useful in providing guidance to prospective teachers and employers. Reasons for the greater apparent sensitivity of personality facet measures over factor measures are discussed. Results also suggest a link between motivation and personality theories.

**Why do Turkish students choose teaching biology as a career? A perspective from a developing country**

KILINC, A. (Ahi Evran University)

The shortage of teachers, career changers, the ageing teacher force and problems in attracting well-qualified people to teaching are the main current challenges to the teaching career. As a consequence, policymakers and teacher recruiters around the world strive to understand how to attract individuals to this profession. However, research regarding the attractors into teaching has been conducted almost entirely in developed countries and has not focused on particular subject areas to be taught. In addition, only limited lists of attractors have been used. Accordingly, the main purpose of this presentation is to examine what attractors influence people who choose teaching biology as a career, and what aspects of Turkish culture lead people to make this career choice. The questionnaire used in this study included open-ended questions about the backgrounds of the participants, and attractors were used to determine the student teachers’ ideas about their career decisions. The sample consisted of 37 freshman biology student teachers (31 female, 6 male). The results showed that the enjoyment of working with young people, enjoyment of biology, and perceived light workload were attractors that were most commonly reported by student
biology teachers. Even though student teachers in the present study were aware that they had little chance of recruitment to teaching positions due to the competitive job market in Turkey, they listed these as top reasons, making them strong attractors. On the other hand, the Turkish sociocultural structure also affected student teachers in different ways. For example, relative to their counterparts in Western countries, participants mostly expressed that they behaved according to their parents’ directions while making a career decision. This situation may stem from the fact that Turkish people are more externally controlled, perhaps because of an underlying cultural characteristic such as collectivism. Consequently, recruitment units around the world should take into account not only the attractors related to the subject area to be taught, but also the sociocultural characteristics within which teachers are situated.

**Keywords:** attractors, biology teaching, Turkish culture, career choice, cultural characteristics

A longitudinal study of pre-service teachers’ attitudes toward diversity, their motivational beliefs, and proposed instructional practices

KUMAR, R. (University of Toledo)

This four-year, eight-wave sequential design study draws on achievement goal theory and multicultural education to examine the relationship between change in pre-service teachers’ endorsement of mastery-focused and performance-focused instructional strategies (MF-IS & PF-IS) and three time-varying covariates: pre-service teachers’ personal achievement goals, beliefs regarding minority and poor students, and comfort with student diversity. Research emerging from a goal theory perspective strongly supports the beneficial influence of MF-IS on positive academic and psychological outcomes for students, as opposed to the detrimental effects of PF-IS. To date, there is no research from this theoretical perspective that has examined whether teachers’ attitudes toward student diversity relate to the kind of instructional strategies they are likely to adopt. This paper seeks to address this issue. The sample included students in the first-year Orientation seminar, the Principles of Democratic Education course halfway through the program, and final-year student-teaching seminar. Hierarchical Linear Growth Curve Modeling will be conducted for the final paper. Results presented here are based on stepwise regression analysis with the first 4 waves of data (NMF= 243, NPDE= 525, NSTS= 380). Holding mastery-approach goals was significantly predictive of endorsing MF-IS (β=.31). Pre-service teachers who were less mastery-approach focused (β=.10) and more performance-approach focused (β=.07) were significantly more likely to endorse PF-IS. Personal performance-avoid goals were negatively associated (β=-.07) and mastery-avoid goals were positively associated (β=.09) with PF-IS. Pre-service teachers who held stereotypic beliefs about minority students and were uncomfortable with diversity were significantly less likely to endorse MF-IS (βstereotypic beliefs, MF-IS= -.13; βdiscomfort with diversity, MF-IS= -.12) and more likely to endorse PF-IS (βstereotypic beliefs, PF-IS= -.14; βdiscomfort with diversity, PF-IS= -.21). Controlling for pre-service teachers’ demographic background and years in college, the predictors explained 25.6% and 25.4% of variance in MF-IS and PF-IS, respectively. The study provides empirical evidence, based on insights offered by achievement goal theory, for the relation between pre-service teachers’ personal goals and instructional strategies they endorse. Pre-service teachers who are encapsulated in their stereotypic beliefs, and experience difficulty interacting with students they perceive as different from them, cannot serve their students well.

**Keywords:** achievement goal theory, multicultural education, mastery-focused instructional strategies, performance-focused instructional strategies, attitudes

Personal and environmental variables that predict burnout and persistence among early career teachers

DE ALWIS, N. (Monash University), WATT, H. (Monash University), RICHARDSON, P. (Monash University)

Since the start of this decade a shortage of suitably qualified teachers has existed in
Australia and elsewhere. With an ageing teacher workforce nearing retirement, the lack of teachers in the profession is expected to increase. Worsening the shortage, many early career teachers exit the workforce within three to five years of entry. As a result, there is a need to identify factors that affect early career teacher attrition, in order to better support and sustain them in the profession. The concept of burnout, which is a state of physical and emotional weakening brought on by the conditions in the workplace, has been linked to premature attrition of teachers (Freudenberger, 1974). Since it has been argued that when studying the concept of burnout both personal and environmental factors needs to be taken into consideration, this study attempts to identify such factors that affect burnout as well as planned persistence. Data were collected as a part of a longitudinal project looking at attitudes and motivations of teachers. The Factors Influencing Teaching Choice (FIT-Choice; Richardson & Watt, 2006) project collected data from participants initially enrolled in secondary, primary/elementary, and early childhood teacher education in 2002/3 at three Australian universities (N=291), at each of three timepoints: beginning of teacher education (P1), end of teacher education (P2), and 1-5 years following professional entry (P3). For this study selected data from P2 and P3 were included. Path analyses showed declining self-efficacy, low school resources, high work demand, and stress all predicted teacher burnout and planned persistence. Burnout dimensions and planned persistence were also interrelated. By investigating which personal and environmental variables predispose teachers to burnout and attrition, administrators and schools can identify teachers most at risk, and act to support them. Environmental stressors can be modified (e.g. more resources and less demand) in order to prevent burnout and aid teachers to continue in the profession. Personal resources will also need to be bolstered through assisting teachers’ coping and affirming their skills to foster self-efficacy. Such actions should not only benefit teachers but also flow onto their students.

Keywords: planned persistence, teacher attrition, burnout, personal factors, environmental factors

Teacher motivations: Extending the big theories

Chair(s): KILINC, A. (Ahi Evran University)

Discussant(s): ECCLES, J. (University of Michigan)

We present new empirical research on teaching motivations from diverse motivational perspectives. Collectively, we draw on expectancy-value, adult attachment, possible selves and goal theories; to illuminate career choice among teachers, ideal and feared teacher selves, and achievement goals in teaching. Studies vary in developmental stage (pre-service vs. practicing teachers); cultural setting (Australia, US, Norway, Germany, Israel); research methods (quantitative and qualitative) and theoretical perspectives. We contend motivational theories have insufficiently informed research regarding teaching motivations. We extrapolate from well-established motivation theories to ask, what kinds of values and expectancies, possible selves and goals are relevant for teachers; whether and how we can measure them; whether and how they matter, for teachers, students, and schools. Transposing theoretical concepts required the development of theories which were originally developed to apply to students, not to teachers. A range of sophisticated methodological approaches examine robust empirical data from different cultural settings. Collectively, the four studies offer three powerful theoretical contributions. First, we show how established motivational theories can be fruitfully applied to exploring how individuals approach the complexities of teaching. Second, whether teacher motivations matter both for their own plans, wellbeing, and behaviours, and for the quality of their instruction and students’ engagement in learning. Third, teacher motivations are influential from the outset of their entry to teacher education and continue to play out across their teaching careers. The Symposium is timely and makes a useful contribution in developing theoretically grounded and psychometrically strong approaches to examining teaching motivations.
Following a brief introduction by the Symposium Chair, each presenter will summarise the objectives, methods, data sources and conclusions from her/his research, allowing for brief question and comment time after each. This will leave approximately 20 minutes for the distinguished Symposium Discussant to make specific comment on each paper, draw contributions of individual papers together, elucidate and critically comment on common themes, and invite audience rejoinders. Her own research expertise and perspectives regarding motivations, and self and identity processes will bring an especially valuable dimension to this discussion.

An expectancy-value approach to the study of teacher motivations

WATT, H. (Monash University)

The Eccles et al. Expectancy-Value (EV) model (1983) conceptualises classes of motives, which I apply to the question – what motivates people to choose teaching? Within EV, expectancies and task values are major influences on choices. Developed to explain gendered high-school mathematics enrolments, it has since been applied to other domains, including mathematics-related career choices. Research concerning teachers has not typically drawn upon the extant motivation literature, tending to examine variously operationalised motives, not integrated within a solid theoretical framework. A comprehensive review highlighted intrinsic, extrinsic and altruistic motivations as most important (Brookhart & Freeman 1991). However, definitional imprecision and overlapping categorisations are evident from one study to another; e.g., desire to work with children as sometimes intrinsic vs. altruistic. EV provides a comprehensive framework into which previously identified motives can be incorporated; it also suggests additional motivations including expectancies. Previously identified motives fit under EV values, further divided into intrinsic, utility, attainment, and cost values. Robust measures were developed and the resultant scale psychometrically validated across two cohorts of Australian preservice teachers (Ns=488,652; Watt & Richardson, 2007). The FIT-Choice scale has subsequently been used in other cultural settings, including the US (N=511), Germany (N=210), and Norway (N=131). It is not obvious what kinds of expectancies and values we should expect to be most salient, whether results would reflect or challenge prevailing stereotypes, and by extension the kind of people who become teachers. Current stereotypes include the choice of teaching as a family-flexible career, high altruistic motivations and teaching as a “fallback” career. Consistent with EV, expectancies and values were highly rated across settings. Among the values subclasses, altruistic and intrinsic were rated high, and extrinsic (e.g., teaching providing time for family) only moderately. Fallback career was rated low. Teaching motivations further predicted professional engagement dimensions. Intrinsic and altruistic motivations showed positive correlations, while extrinsic-type motivations showed negative correlations. For cost, perceiving teaching as highly expert positively predicted engagement; suggesting people are attracted to teaching as cognitively stimulating (Richardson & Watt, 2006). In conclusion, EV provides a comprehensive theoretical framework within which teacher motivations can be soundly measured.

Keywords: expectancy value theory, motivations, altruism, culture, teaching

Adult attachment theory: classroom relationships as corrective emotional experiences – an unconscious motivator to teach?

RILEY, P. (Monash University)

Studies in conscious, and therefore articulated, motivation to teach have gained considerable attraction, while unconscious motivation has been largely overlooked or ignored. While there are obvious methodological difficulties associated with unconscious motivation, the lack of research in the area is surprising for two reasons. The first is that interest in the area began in the late 1950s with some promising studies and theoretical work (see for example, Stern, Masling, Denton, Henderson, & Levin, 1960; Stern & Masling, 1958; Wright & Sherman, 1963). The second, and perhaps more important, reason is that significant
numbers of early career exits suggest that some key developmental issues facing new teachers are probably not being adequately identified and addressed with current research protocols. Adult attachment theory, which extended the use and development of attachment theory, has been proposed as a useful paradigm through which to examine teachers’ unconscious motivation (Riley, 2009). The theory predicts that that an individual’s relational history contributes unconscious motivation to join the profession, along with resilience factors and vulnerabilities, potentially leading to either positive classroom experiences or early exits. To examine this proposition data were collected from pre-service and experienced teachers in two mixed-method studies. The first (N=308) employed the Experience in Close Relationships Questionnaire (ECR) and the second (N=73) a revised form (ECR -R). Both studies collected demographic and open-ended data on attractors to teaching. Analysis of the questionnaires revealed high incidence of insecure attachment, suggesting many teachers may enter the profession unconsciously seeking corrective emotional experiences through student interactions. Qualitative analysis revealed that 46.2% of respondents based judgments of personal success or failure as teachers on whether they make a difference in students’ lives. Further, the desire to make a difference was undefined in all cases, but correlated with feelings of anger toward students who “did not [or would not] play by the [teacher’s] rules”. These results are open to multiple interpretations, but appear to support the hypotheses, suggesting that the importance of unconscious motivation is at least as powerful a predictor of teacher success as conscious motivation, which challenges current teacher education and support practices.

Keywords: adult attachment theory, conscious motivations, unconscious motivation, resilience, vulnerabilities

What does possible selves theory have to offer the study of teacher motivations?

RICHARDSON, P. (Monash University)
possible selves operate independently, and, as a joint system. Possible selves theory provides a new perspective on motivations which impact beginning teachers’ perceived goal achievement, perceived demand and stressfulness, satisfaction and liking, planned effort and persistence.

Keywords: possible selves theory, teacher motivation, ideal selves, feared selves, actual perceived selves

What do teachers want to achieve and does it matter? An achievement goal approach to teacher motivation

BUTLER, R. (Hebrew University of Jerusalem)

I shall present results from an ongoing research program which extrapolated from goal theory to examine the proposal that schools are an achievement arena also for teachers. As expected, responses of teachers in Israel (Butler, 2007) and Germany (Retelsdorf, et al, in press) to a new measure of Goal Orientations (GOs) for teaching loaded on four factors reflecting mastery, ability-approach, ability-avoidance, and work-avoidance goals for teaching. More important, results from studies using diverse methodologies (cross-sectional and longitudinal), informants (overall, some 600 teachers and 1200 of their students) and data-analytic strategies (hierarchical regression, SEM, multilevel modelling) confirmed that teachers’ GOs were coherently and differentially associated with teacher wellbeing (Retelsdorf, et al, in press) and adaptive versus avoidant help seeking (Butler, 2007). They also predicted not only teacher endorsement of mastery versus performance-orienting instructional practices, but also student reports of teacher encouragement of student question-asking (Butler & Shibaz, 2008). Overall, mastery GO emerged as very adaptive; ability- and work avoidance GOs were both maladaptive, in rather different ways. These results make a significant contribution to extending and validating an approach to teacher motivation that offers a new perspective for understanding and studying teachers, teaching, and teacher influences on students. This framework can be faulted, however, for failing to consider ways in which motives for teaching and learning differ. I shall also present new data from studies that examine whether strivings to achieve close and caring relationships with students constitute a distinct class of relational goals for teaching. Responses of 120 trainee and 290 practicing teachers in Israel who completed an expanded version of the Goal Orientations for Teaching measure confirmed that five new relational goal items loaded on a fifth factor, distinct from the other four kinds of achievement goals. Several months later, students in the classes of 50 randomly selected teachers reported on their teachers’ instructional practices. Data analyses currently underway will examine the novel prediction that teachers’ relational GO for teaching will emerge as the strongest predictor of teachers’ socioemotional support as reported by their students several months later.

Keywords: goal theory, achievement, goal orientation, teacher wellbeing, help-seeking
The contribution of biological and environmental factors in health related behaviours: The role of cognition and psychological change

Chair(s): STREET, S. (School of Psychology and Counselling and Institute of Health and Biomedical Innovation QUT)

A central theme of modern psychological theory and practice is the notion that cognitive function across the lifespan is a result of the reciprocal influence of both biology and the environment. Disruptions to cognition can occur as a result of a multitude of factors encompassing any combination of biological or environmental precursors and can drastically alter a person’s life trajectory. Furthermore, cognitive impairment and dysfunction are rapidly becoming an overwhelming health care burden worldwide as industrial and developing nations struggle to cope with the incipient increase in neurological and cognitive pathologies such as dementia and stroke. A better understanding of how biology and the environment operate individually and interactively to create the conditions in which cognitive dysfunction might emerge is critical for better management of this growing social and public health issue. Moreover, an understanding of this interaction will provide valuable information on which to base interventions to either prolong cognitive function into old age or manage environmental conditions to reduce the impact of cognitive dysfunction in at risk or already affected groups. This symposium will provide a snapshot of research including observational studies investigating factors that might contribute to reductions in the risk of cognitive decline in old age and interventions to increase compliance or psychological readiness to engage in positive health related behaviours. The first study presents data examining the interactive effect of omega-3 polyunsaturated fatty acids and physical activity as factors predicting mild cognitive impairment in older adults. The second study provides the results from a brief motivational interviewing intervention with obstructive sleep apnoea patients to increase compliance in the use of CPAP therapy. The third study reports on the results of an investigation into the effects of complex mental or physical activity on cognitive function in a sample of older women. The final study will examine behaviour change in relation to physical activity in a group of stroke victims. This symposium brings together several lines of research that will be informative for psychologists with an interest in cognition and health behaviour.

Interaction of n-3 polyunsaturated fatty acids and physical activity predict reduced risk of mild cognitive impairment: preliminary results.

STREET, S. (School of Psychology and Counselling and Institute of Health and Biomedical Innovation QUT), SINN, N. (Sansom Institute for Health Research University of South Australia), MILTE, C. (Sansom Institute for Health Research University of South Australia), HOWE, P. (Sansom Institute for Health Research University of South Australia)

The aim of the current study was to examine the interactive effect of omega-3 polyunsaturated fatty acids (n-3 PUFA) and physical activity in the expression of mild cognitive impairment in older adults. Male ($n=50$) and female ($n=33$) adults $>65$ years satisfied the selection criteria and agreed to participate. MCI was identified using the following criteria: A Standardised Mini-Mental State Exam (SMMSE) score of greater than 24; and a score on the Verbal Paired Associates 1 (VPA1) from the Wechsler Memory Test 1.5 SD below the mean; or a DemTect score of between 9 and 12. The MCI ($n=53$) and non-MCI ($n=29$) classification was dichotomised for use as an outcome variable in subsequent logistic regression analyses. Physical activity was assessed with the LASA Physical Activity Questionnaire (LAPAQ). Participants also provided a pre-prandial blood sample from which erythrocyte levels of the n-3 PUFAs docosahexaenoic (DHA) and eicosapentaenoic (EPA) acid were analysed. Binary logistic regression was conducted using MCI/non-MCI as the outcome and three predictor variables:
n-3 PUFAs; total time engaged in physical activity (TPA); and an interaction between n-3 PUFA and TPA. n-3 PUFA was significantly associated with a reduced risk of MCI (OR 2.124 [CI 1.094 - 4.127]). The interaction between n-3 PUFA and TPA was also significantly associated with a reduced risk of MCI (OR 1.0065 [CI 1.000 – 1.012]). An increased erythrocyte concentration of the n-3 PUFAs EPA and DHA was associated with increased odds of a non-MCI classification. The combined effects of physical activity and n-3 PUFAs EPA and DHA may provide additional protective benefits against the development of MCI in adults over the age of 65 years.

**Keywords:** omega-3 polyunsaturated fatty acids, physical activity, cognitive impairment, older people, risk

### Improving adherence to continuous positive airway pressure therapy with motivational interview

SMITH, S. (Centre for Accident Research and Road Safety QUT)

Obstructive Sleep Apnoea (OSA) is a common and serious sleep disorder with high associated health costs. Continuous Positive Airway Pressure Therapy (CPAP) is the standard treatment for moderate –severe OSA. Despite the effectiveness of this treatment, adherence is generally poor. Psychological factors are the major predictors of adherence. A Motivational Interviewing (MI) intervention was designed to target and improve specific beliefs associated with poor adherence. This randomized control trial assessed the benefit of adding a brief MI to treatment as usual for OSA (TAU). 101 consecutive patients (68% male) who were newly diagnosed with OSA and naive to CPAP, were randomly assigned to nurse-led MI + TAU (50 participants) or to TAU only (51 participants). MI patients received 2 x 30-45 minute sessions of MI before starting CPAP, and one 20-30 minute booster session 1 month after CPAP prescription. The intervention was standardized through training and a treatment manual. Objective CPAP adherence (hours of machine use per night) was assessed at 1, 2 and 3 months. Intent-to-treat analyses demonstrated that by 3 months, patients who received MI+TAU used CPAP 50% more of the time than those who received TAU alone (4.61 vs. 3.08 hours per night, p=.05, “effect size” d=.58). MI+TAU patients accepted CPAP more readily (4% vs. 25% rejection rate, p<.01) and started treated much earlier after receiving the prescription (9 days vs. 34 days to fill CPAP script, p<.01). Of patients who received MI+TAU, 61% adhered to CPAP >4 hrs per night versus 37% who adhered >4hrs in TAU only (p=.02). Motivational Interviewing is a brief and effective intervention which improves CPAP acceptance and adherence rates when compared to standard care alone. Change mechanisms appear to be better self-efficacy (confidence) in being able to use the treatment, and lower perception of the impact of potential Barriers to CPAP use. The intervention was well accepted by the patients.

**Keywords:** continuous positive airway pressure therapy, motivational interviewing, obstructive sleep apnoea, treatment, self-efficacy

### Episodic memory benefits in older women by means of cognitive and physical activity interventions

KLUSMANN, V. (Charite Universitatsmedizin, Benjamin Franklin campus, Berlin, Department of Psychiatry)

A decline in episodic memory is part of the cognitive aging process. Cognitive trainings have proven to be effective in improving specific cognitive skills but mainly lack in transfer effects and thus everyday relevance. A broader approach should be more advantageous. In addition, preclinical and clinical studies suggest that physical activity might also contribute to cognitive fitness. Results from the basic neurosciences suggest that environmental enrichment is crucial in generating these cognitive benefits. This study was designed to directly compare in elderly humans the effects of a broad, rather unspecific cognitive activity with a physical one. This randomized controlled trial evaluates a cognitive and a physical standardized 6-month intervention in 230 healthy women aged 70 to 93 years. The women participated in either a computer course (n=81) or an exercise course (n=80) or in the control group (n=69). Interventions consisted of 90-minute sessions thrice per week. Cognitive pre-post-
assessments included two different episodic memory tasks, a classical word list recall and newspaper story recall. Group differences (intention-to-treat) in change of cognitive performance were evaluated by analyses of covariance adjusting for corresponding baseline measure, intelligence, and years of education. Both the cognitive and the physical intervention groups showed significantly better episodic memory than the control group. In story recall, \(F(2,224)=4.44, p=.01\), the gain of the intervention groups was due to a significant increase in performance, whereas in word recall, \(F(2,224)=4.14, p=.02\), the advantage resulted from maintained performance levels in contrast to a significantly decreased performance in the control group. Physical exercise and broad mental activity are both means to enhance cognitive performance in older women. Performing a new stimulating activity in old age helps to delay age-related decline in those cognitive domains where pronounced losses otherwise occur. The enrichment characteristics of both activity types can explain the comparable effects. Novelty and challenge are assumed to be of particular importance.

Keywords: episodic memory, cognitive aging, cognitive ability, cognitive fitness, performance

**Stay Active Stop Stroke (SASS/SASS-E) program trial: A pilot test of an intervention to enhance physical activity and psychological factors in people post stroke.**

SULLIVAN, K. (School of Psychology and Counselling and Institute of Health and Biomedical Innovation QUT)

The aim of the current study was to extend an existing physical activity intervention for people with stroke from one that manipulates psychological variables only to one incorporating combined resistance and aerobic training exercise. This project extends an intervention called Stay Active Stop Stroke (SASS), a psychological intervention based on an expanded version of the Health Belief Model (HBM) to include an exercise component. Five post-stroke participants (male = 1) engaged in the SASS program, which included a formal education component highlighting the modifiability of stroke risk through exercise. Group activities designed to enhance key psychological variables (e.g. self-efficacy, perceived benefits of exercise) were also conducted. Participants also completed one hour of combined resistance and aerobic exercise once per week for eight weeks. Pre and post intervention tests were administered to measure health beliefs, knowledge and psychological factors including exercise self-efficacy. Participants were also tested on physical variables including anthropometric measures, strength tests and functional fitness. Participants will be followed up at 3 and 6 months for further psychological tests. Trends in the data showed increases between pre and post intervention scores on stroke knowledge (9.6 to 10.2), readiness to exercise increased from 3.6 (between preparation and action) to 4.6 (between action and maintenance). This result is likely to be due to the small sample size. Nonetheless, there were increases between pre and post intervention scores on stroke knowledge (9.6 to 10.2), readiness to exercise increased from 3.6 (between preparation and action) to 4.6 (between action and maintenance). There was also an increase in self-efficacy from 59.25 (SD=23.28) to 70 (SD=26.52). Although none of the outcome measures reached significance, there were increases in some key variables including self-efficacy and readiness to exercise. These improvements suggest the lack of significance could be due to several factors including the low sample size obtained, the method of SASS delivery or the length of the intervention. Follow up data is to be obtained over the next 6 months to ascertain the robustness of any positive changes with respect to engaging in exercise in this group.

The development and management of cross-cultural competence within military contexts

Chair(s): MCDONALD, D. (Defense Equal Opportunity Management Institute)

Today’s militaries must be ready for a diverse range of missions focused on humanitarian, security, stabilization, and intelligence operations. To accomplish these missions, foreign language, regional, and cultural capabilities have become increasingly important. Consequently, the United States has placed considerable emphasis on developing and maintaining this expertise. Due to the unpredictability of future needs, adaptability in these capabilities is of pre-eminent concern. The development of cross-cultural competence (3C) offers the means by which this adaptability can be achieved. Simply stated, 3C for individuals refers to the knowledge, skills, abilities, and attitudes (motivations) which may enable individuals to interact with, or adjust to an array of cultures other than their own, even without prior exposure to those cultures. This differs from the notion of possessing expertise of a particular culture or region. By definition, however, 3C should foster development of regional or cultural expertise. 3C also not only refers to adapting to international cultures, but also to the cultures within one’s own borders and institutions. Therefore, 3C also has relevance to intra-organizational teamwork, leadership, group-problem solving, and communications, particularly in culturally diverse organizations. To institutionalize 3C, substantial organizational cultural change is required, particularly as the military still relies on traditions that stress uniformity and homogeneity rather than strength through differences. Such a cultural change requires a multi-faceted approach through functions such as recruiting, selection, promotions, systems development, research, training, education, mission operations for success, and the priority given to 3C in strategic plans, policy, doctrine and the budgets which drive them. Successful institutionalization also requires a valid measurement strategy not only at the individual level, but also at the organizational level as a demand signal sent back from operations to the aforementioned functions. A comprehensive measurement strategy will allow system adjustment and thus “institutional adaptability” to changing cultural needs or landscapes (i.e., organizational 3C). This symposium explores how military organizations view implementation of 3C within their own institutions; discusses how measures, metrics are applied, and challenges to effective measurement. Lastly, this symposium also highlights the concept of 3C related adaptation, both at the individual and organizational level.

Institutionalizing cross-cultural competence (3C) in the US Department of Defense

GREENE, A. (Office of the Under Secretary of Defense for Personnel and Readiness, Defense Language Office)

Cross-cultural competence (3C) – defined by the US Department of Defense as “the ability to quickly and accurately comprehend, then appropriately and effectively act, to achieve the desired effect in any culturally complex environment” - has been established as a critical enabler for mission success for the Total Force (DOD civilian and military personnel - active and reserve, officer and enlisted). 3C enhances the ability of units and individuals to perform successfully within the full spectrum of operations to include joint operations in a variety of cultural landscapes. The 3C concept has yet to be institutionalized in DOD doctrine and policy, thus reinforcing DOD’s need to provide comprehensive and overarching guidance to manage the development, measurement and sustainment of 3C for the Total Force. To address this gap, the Office of the Under Secretary of Defense for Personnel and Readiness (OUSD P&R) is developing a “3C Roadmap” that will: (1) establish a common approach to defining and developing 3C; (2) define and prioritize DOD’s Requirements for 3C; and (3) build and sustain a 3C-capable Total Force. This Roadmap is a direct result of the 2009 symposium, co-sponsored by OUSD P&R.
Developing a strategic cross-cultural competence (3C) learning continuum: The lifelong battle rhythm of 3C

SANDS, R. (Air Force Culture and Language Center)

Developing cross-cultural competence in a military organization is dependent on the learning and experiential interventions that are orchestrated over a lifetime of a Soldier, Airman, Sailor, etc. These “interventions” although composed of different content and delivery platforms are similarly aligned to 3 general learning (competence) objectives, cognitive knowledge, procedural skills, such as cross-cultural and intercultural communication and participant/observation and the development of “behavioral” skills, such as cultural relativism. This presentation will suggest a “battle rhythm” of necessary interventions that need to be sequenced appropriately that take advantage of existing institutional learning and training applications as well as applied “experiential” situations in the military for the development of cross-cultural competence (3C). These interventions take the form of 1) curricular education – both in professional military education (PME) and continuing professional education (CPE), 2) curricular training – both in predeployment and existing training programs, and 3) experiential in the deployment of individuals to theater environments where 3C is critical in mission success. The individual interventions become “stages” of competence development and may focus on one or all three of the competence objectives, dependent on variables such as length of intervention, the facilitated nature of intervention - instructor-led or paced, individually-paced, or self-reflected, the platform of delivery - either residential or distance-learning and the components of curriculum, based on learning style and platform - simulations, direct knowledge transfer, interactive student discussions, and self-reflection, to name a few. This battle rhythm can also play an active role in developing 3C proficiency guidelines where the number and type of intervention an individual completes can provide a framework for how proficiency is expressed and measured. This presentation will highlight the learning interventions, methodologies and content utilized to drive learning and insight within the individual, specifically types of existing educational interventions in use or being developed by the United States Air Force and then explore the fit of these interventions into the Air Force 3C Battle Rhythm of 3C learning.

The importance of intercultural competencies in dealing with diversity at work

VAN DER ZEE, K. (Institute for Integration and Social Efficacy, University of Groningen, The)

Previous work on the role of intercultural competencies at work has pointed at the relevance of five traits to success in a culturally diverse work context: cultural empathy, open-mindedness, social initiative, emotional stability and flexibility (van der Zee, Atsma, & Brodbeck, 2004; van der Zee & van...
Abstracts of the 27th International Congress of Applied Psychology

Oudenhoven, 2000, 2001). From a theoretical point of view, these traits can be divided in traits that function as a buffer against threat (e.g., emotional stability) and social traits (e.g., social initiative) that make individuals feel attracted to the challenging aspects of diversity (van der Zee, van Oudenhoven & de Grijjs, 2004; van der Zee & van der Gang, 2007). As a result, these two kinds of traits will be related to different appraisals of and different responses to characteristics of diverse work settings. In this presentation we will present data from samples of business students and employees on the predictive value of the five traits against different work outcomes. The five traits are measured with the Multicultural Personality Questionnaire (van der Zee & van Oudenhoven, 2000, 2001). Consistent with our theoretical perspective, data from a large employee sample suggest that individuals high on social traits particularly appraise opportunities associated with cultural diversity in their company, whereas stress-related traits primarily function as a buffer against perceived threats associated with increasing diversity. In line with this finding, a laboratory study revealed that stress-related traits may protect individuals from negative responses to diversity under threatening circumstances. By contrast, social traits did not provide protection against the influence of threat on openness to diversity. Interestingly, an additional dataset shows that individuals in work contexts with high emphasis on security and rules, such as the military and the police, tend to score higher on such stress-related traits compared to professions with less emphasis on control, but on the other hand obtain lower scores on open-mindedness. The implications of these findings for employee selection and training are discussed.

Keywords: cultural empathy, openmindedness, social initiative, emotional stability, flexibility

Assessing cross-cultural competence as an organizational construct in the military

VAN DRIEL, M. (Defense Equal Opportunity Management Institute)

The measurement of cross-cultural competence is becoming increasingly important within the military context. Much is known about the measurement of individuals’ cross-cultural competence; however, comparatively less is known about the measurement of organizations’ cross-cultural competence. This is surprising as cross-cultural competence has been observed to have clear implications for organizational functioning and outcomes, especially in military missions involving the promotion of peace, stability, and security (Elron, Halevy, Ben-Ari, & Shamir, 2003; Fitz-Gerald, 2003, Soeters & Moelker, 2003). Due to the limited knowledge available regarding cross-cultural competence at the organizational level, a variety of research efforts on the development of measures that will enable the assessment of cross-cultural competence as an organizational construct within the United States military. A general overview of these research efforts will provide insights into the utility of assessing the cross-cultural competence of military organizations as well as highlight relevant organizational and psychometric theory. This overview will allow an in-depth discussion of the development of a measure of military organizations’ cross-cultural competence. The development of this measure involved an initial study that provided evidence for determining whether attributes of military organizations contribute to their cross-cultural competence, and whether organizational actions and initiatives are reflective of cross-cultural competence. Data from this study revealed the criticality of a variety of military organizations’ cross-culturally related preparation and resources. Furthermore, the data also allowed identifying a number of organizational actions and initiatives as critical components of organizations’ cross-cultural competence. These results indicated that there is a distinction between attributes of organizations that contribute to their cross-cultural competence, and organizations’ cross-culturally competent performance. Using these data, a measure was constructed and deployed to military service members (N=3366) representing over 50 military organizations. The data from this second study provided evidence for the construction of a psychometric measure of organizations’ cross-cultural competence. This measure was found to effectively capture differences in cross-culturally related preparation, resources and
cross-cultural performance between organizations included in the dataset. The implications of using this measure to provide guidance for the development of cross-cultural competence at the organizational level will be discussed in greater detail.

Keywords: cross-cultural competence, military, organisation, stability, performance

The strategic assessment of cross-cultural competence: Measuring the lifelong battle Rhythm of 3C

BRITTAIIN, M. (Air Force Culture and Language Center)

Building cross-cultural competence (3C) within an entire branch of the military requires a strategic and holistic perspective to not only development of that skill, but also to measuring and assessing the effectiveness of intervention efforts. Previous attempts at developing 3C in military settings have often focused on ad hoc and disparate interventions that do not fully account for the multitude of factors that influence an individual’s development of the new skills, which could range from their pre-dispositional characteristics, the effectiveness of the specific intervention, or even the predominant culture of the organization. Specifically military organizations should approach 3C development holistically, actively integrating and coordinating the respective learning interventions and factoring them into a rhythm that supports and builds on the competence objectives offered through each intervention as well throughout the entire development cycle. This presentation will focus on the efforts of a branch of the US military to build cross cultural competence within the total population of the service branch and across the full spectrum of learning and experience. It will discuss the components of their integrated, multi-level strategic assessment plan designed to measure the development of 3C across the span of Airmen’s career of education, training, and deployment experiences. More specifically, the paper will discuss the assessment measures designed to capture changes in individual ability (e.g. both downrange in the theater as well as in the classroom), the effectiveness of curricular and training effectiveness, and even changes within the organizational climate for skill transfer. It will leverage results and lessons learned from past iterations of interventions to present the key learnings and experiences at various levels of the continuum that facilitate insight and expedite transition from one stage to the next. Moreover, the paper will also address the selection implications of their development continuum, exploring the critical biographical, personality, and affective characteristics that may potential predispose individuals to more easily acquire and develop cross-cultural competence.

The development, maintenance and treatment of body image concerns

Chair(s): RICCIARDELLI, L. (Deakin University)
Discussant(s): RICCIARDELLI, L. (Deakin University)

Body image has been recognised as a central component of the individual’s self-concept for decades, and body image concerns have become pervasive across different age and cultural groups, and among both men and women. Body image is one of the first aspects of children’s self-concepts to develop, and given that physical attributes are both visible and easily accessible it is not surprising that children as young as six years of age already demonstrate body image concerns. The first paper in the symposium provides a comprehensive assessment of the body image concerns among both preadolescent girls and boys. These include body shape dissatisfaction, attitudes and feelings about body and appearance, the desire of being more muscular, height satisfaction, and social physique anxiety. Body image concerns increase in frequency and severity during the adolescent years, as this is a time of substantive social, physical and cognitive change. Studies are also showing that body dissatisfaction and related behaviours are increasing in developing non-Western countries, and that one of the main factors contributing to these problems are sociocultural pressures to attain an ideal body shape. The second paper examines the perceived pressure from the media, family and peers regarding the body image ideal on the body dissatisfaction and body change behaviours among Chinese adolescent girls and boys living in China. While body image problems develop during childhood and adolescence, these continue to be maintained during adulthood. Therefore, it is important that more research examines the risk factors and evaluates treatment programs for both adult women and men. The third paper examines the relationship between body image and self-esteem across age and gender in adults aged between 20 and 86 years, whiles the fourth paper examines the evaluation of a group based cognitive behavioural therapy program for treating body image concerns among adult women and men. Finally, the discussant will address directions for future research and the implications of the findings for improving the health and well-being of each of the different age and cultural groups.

Body image in children aged 8-12 years and its relationship with participation in sports

NAVA, F. (La Trobe Univeristy), XU, X. (Sichuan Normal University), PIERSON, J. (La Trobe Univeristy)

Body image disturbances are becoming increasingly common amongst younger people. Indeed it is not uncommon for females and males in early adolescence to be dissatisfied with their body shape. This is of particular concern given the relationship between body image dissatisfaction and disordered eating. Further, recent evidence is emerging which suggests that preadolescent children may also experience body image concerns. There is also some recent evidence that which suggests that body image can influence a child’s willingness to participate in certain sports and physical activities. The purpose of the present study was to examine body image and its relationship with participation in organized sports among pre-adolescents in a survey design. 300 from grades 3 to 6 (8-12 years old) from a representative sample of 13 Catholic elementary schools in the Northern region of Melbourne, Victoria participated in the study. Demographic information was obtained regarding age, gender, and ethnicity. Information about body image shape satisfaction, attitudes and feelings about body and appearance, desire of being more muscular, height satisfaction, social physique anxiety, and participation in sports was also obtained. It was found that children as young as eight showed signs of body dissatisfaction and body image influenced their participation in aesthetic sports. Results, which have implications for child and adolescent health care professionals, will be discussed particularly in relation to the relationship between body image and participation in sport.
Sociocultural influences and body dissatisfaction among Chinese adolescents

XU, S. (Sichuan Normal University), MELLOR, D. (Deakin University)

There is evidence that rates of body dissatisfaction and disordered eating are increasing in developing non-Western countries. However, research into the factors that contribute to the body image perceptions and behaviors of non-Western populations is limited. Studies conducted with Western samples demonstrate that sociocultural factors play an important role. Perceived pressure from the media, family and peers regarding body image ideals have been shown to contribute to body dissatisfaction and the use of body change strategies. The findings are discussed in relation to previous research in both Western and non-Western contexts. The current study explored how these sources of sociocultural influence relate to body dissatisfaction and body change behaviors in 517 Chinese adolescents: 219 adolescent boys and 298 girls living in Chengdu in China. Chinese girls reported greater dissatisfaction and were influenced by sociocultural pressures to a greater extent than Chinese boys. Studies are now required to explore the nature of these influences and to further understand observed sex differences in the relationship between perceived sociocultural pressure and body perceptions and behaviors.

Keywords: body dissatisfaction, disordered eating, body image, body change strategies, China

The relationship between body image and self-esteem across age and gender: A longitudinal study

FULLER-TYSZKIEWICZ, M. (University of Canberra)

Despite research findings indicating that body satisfaction and self-esteem are related in adolescence and early adulthood, extant literature is less conclusive about the stability of this relationship in middle age and beyond. Moreover, the majority of previous studies have failed to consider the relevance of body satisfaction within the context of other domains of satisfaction that may have greater influence on self-esteem in mid- to later life, such as satisfaction with life achievements, relationships, community engagement and accumulation of material possessions. The purpose of the present study was two-fold; first, to re-evaluate the importance of body satisfaction for self-esteem changes across the lifespan and, second, to examine whether initial levels of body satisfaction were predictive of changes in self-esteem over a two-year interval. Participants were 150 men and 239 women aged between 20 and 86 years ($M = 59.73$) who responded to a questionnaire assessing self-esteem, body satisfaction and other key domains of satisfaction (e.g., satisfaction with health, relationships and community engagement) at baseline and two years later. Although the bivariate relationship between self-esteem and body satisfaction was stable across age and gender, the relative importance of body satisfaction for self-esteem changed over the lifespan for both genders. Furthermore, the longitudinal analyses revealed that T1 body satisfaction levels in female participants predicted T2 self-esteem, particularly for younger participants. Satisfaction with life achievements at T1 was also predictive of T2 self-esteem. None of the domains of satisfaction (including body satisfaction) were unique predictors of T2 self-esteem in male participants, even when potential age effects were controlled for. Present findings support the link between body satisfaction and self-esteem, but also highlight the importance of considering age- and gender-related differences in the magnitude of this relationship. Directions for future research to more fully assess the factors that may be moderating the relationship between self-esteem and body image in different age groups are discussed.

Group intervention for body image concerns in men and women

LEWIS, V. (Deakin University)

It is well researched that cognitive behavioural therapy on an individual level is effective in
treat ing body image concerns. However, little is known of the effects of group based treatment programs for women, least of all men. This paper discusses the outcome of several six week intervention programs run over the last three years to assist adults with body image concerns and eating disorders. Separate programs were run for men \( (N=15) \) and women \( (N=35) \). The programs were run by intern psychologists under the training and supervision of a psychologist specialising in body image and eating concerns. Male interns ran the men's group and women ran the women's group. The program followed a cognitive behavioural treatment approach partly including education about body image beliefs, challenging beliefs about the body and behavioural challenges were set as homework. Pre and post intervention questionnaires were administered to group members as well as a control group. The program showed improvements in body image perceptions to become more positive, higher satisfaction with the self and life in general. Participants reported the cognitive components to be the most effective and membership of a group as motivating them towards a positive body image. Results highlighted the need for societal change in terms of the way the body is evaluated as well as the specific components important for change to occur in an individual in terms of their body image and well being.

**The impact of ageing on capacity for and decisions about driving**

Chair(s): MACHIN, T. (University of Southern Queensland)

Discussant(s): DORN, L. (Cranfield University)

This symposium will focus on developing a better understanding of the impact of ageing on drivers' ability to detect and respond to hazards and obstacles. While these abilities are important in decisions about whether to continue driving, a range of other factors will also impinge on these decisions. The key learning outcomes are: 1. to increase the awareness of researchers of the critical abilities that influence drivers' ability to detect and respond to hazards; 2. to encourage health practitioners to reflect on the range of factors that influence decisions about whether to continue driving; 3. to assist drivers to better understand the impact of ageing on their abilities; 4. to encourage designers and engineers to develop technologies that counter the negative effects of ageing; and 5. to provide road safety policy makers with a better scientific base with which to consider new legislation.

**Hazard perception and cognitive ageing in older drivers**

HORSWILL, M. (University of Queensland)

One driving-related skill that has been found to relate to crash risk is hazard perception, which has been defined as the ability to anticipate potentially dangerous situations on the road ahead. There has been relatively little research in exploring this phenomenon amongst older drivers. What research there is suggests that hazard perception appears to slow after age 55 though this finding is based on a sample in which age was contaminated by pathology and participants were not matched across age groups. Our aim was to determine how hazard perception declined in a sample of healthy drivers who were matched across age and to investigate what cognitive, visual, or motor
Factors might underlie this decline. We compared response latencies using a validated video-based hazard perception test across three groups: 22 mid-aged (35-55 years), 34 young-old (65-74 years), and 23 old-old (75-84 years) drivers. The groups were matched for factors unlikely to change with age: gender, education level, and vocabulary. Participants also completed a battery of cognitive, vision, and motor tests. We found that the old-old group were significantly slower at responding to hazard than the young-old group and the mid-age group who did not differ from one another. This age difference was found to be mediated by individual differences in useful field of view (UFOV), contrast sensitivity, and simple reaction time. Hazard perception response latency, a measure that correlates with crash risk, does not appear to decline until age 75 in healthy adults, suggesting that signs of deterioration after age 55 found in a previous study could either be a result of pathology or of failure to match participants across age groups. This decline can be accounted for measures including UFOV and contrast sensitivity, both of which have also been found to correlate with crash risk in previous studies involving older adults.

*Keywords: hazard perception, age, reaction time, crash risk, driving*

**Evaluation of a group intervention to promote older people's adjustment to driving cessation**

PACHANA, N. (University of Queensland)

Many people voluntarily or involuntarily give up driving in later life because age-related changes, chronic medical conditions, the side-effects of medication or a combination of these factors affect their competence and confidence on the road. Driving cessation has been recognised as having substantial negative impact on the health and wellbeing of older people. However, rehabilitation efforts can assist older adults to maintain functional and activity levels even in the face of having surrendered their license. The University of Queensland Driver Retirement Initiative (UQDRIVE) program was developed to improve lifestyle and quality of life of older people facing driving cessation. Based on interviews with over 250 older drivers, retired drivers, family members and health professionals, it includes a number of community based group interventions to improve mobility and maintain social interaction. A randomised controlled trial of UQDRIVE is underway in Australia, with community-dwelling adults aged 60+ who had permanently ceased driving or were planning to do. Participants were randomised to either the UQDRIVE intervention or current practice (no intervention). Measures of wellbeing and lifestyle outcomes were undertaken prior to the intervention, immediately post-intervention and at three months post-intervention. For intervention participants, individual transport and lifestyle goal setting and evaluation using the Canadian Occupational Performance Measure (COPM©) were undertaken pre and post the intervention. Goals set by group participants included adjustment to driving cessation, driving safety, and role participation. Peer leaders are utilized in the delivery of the program content, which includes sessions on local transport options and pedestrian safety issues, (incorporating group outings and a safety audit of local area); coping strategies, grief, and depression; and setting individual transport and lifestyle goals. Preliminary analyses of COPM scores indicate significant differences pre and post in perceived performance (mean difference = 3.22 points; \( t = 7.11; df = 19; p < 0.0001 \)) and satisfaction with performance (mean difference = 3.53 points; \( t = 6.52; df = 19; p < 0.0001 \)) scales. It appears this intervention enhances coping of older adults with the often daunting prospect of ceasing to drive. Participants are able to express their sense of loss in a safe and supportive environment. The peer leader instills confidence in their ability to try alternative transport solutions. Implications for clinical practice are provided.

*Keywords: driving, age, driving cessation, transport, pedestrian safety*

**Obstacle avoidance and steering behaviour in younger and older drivers in changing light levels**

HINE, T. (Griffith University)
To investigate if a decline in motion sensitivity in older age carries over to performance in a simple steering task in a driving simulator where moving obstacles are to be avoided. Younger and older groups’ performance was compared at two light levels. There were 18 females and 14 males in the older group (aged 65 to 75 years old), and 17 females and 13 males in the younger group (18 to 22 years), each with a current license and without any reported vision problems. The steering task involved avoiding six cars randomly moving one at a time across the road from either left or right. Speed was moderated by the simulation program to control for speed-accuracy trade-offs. There were six trials at each of two ambient light levels: low (11.8 – 7.2 cdm-2) and mesopic (0.96 – 0.61 cdm-2) at low contrasts (0.22) and each trial involved avoiding six cars using a Momo force-feedback steering wheel to ‘steer’ virtual car down the road. There was more motion sensitivity amongst the older group than the younger while in the simulator, even though the younger group reported more general susceptibility to motion sickness. The older group reacted with steering wheel movement as fast as the young group, but became slower in the mesopic conditions. Responses were faster for obstacles coming from the left as opposed to the right. The younger group took wider berths around the obstacles than the older drivers, older females being worst of all. In general, older drivers did not swerve as much as the younger drivers. Differences in steering behaviour between the young and old group is not a simple matter of slower response times. Rather, the older group do not make a sufficiently wide berth around the obstacles compared to the younger group. This is also true of females vs males, and especially true in older females. It is suggested that older drivers do not have a good sense of the spatial extent of the vehicle compared to young drivers.

**Keywords:** age, motion sensitivity, driving, performance, moving obstacles

The effect of stimulus salience on attention to motion in older drivers

CONLON, L. (Griffith University)

We investigated how motion sensitivity and accuracy detecting abrupt change in a complex visual environment could be varied when the salience (contrast) of the target stimuli was manipulated. Reduced accuracy and poorer sensitivity to motion was expected in an older when compared to younger group. We also expected consistent with Lu and Dosher’s (1998) perceptual template model of attention that the addition of an attention cue would increase sensitivity and accuracy of the older relative to the younger group when the targets were of low but not high salience. Healthy older (over 60 years) and younger (20-40 years) drivers participated. The Useful Field of View (UFOV) and a measure of global motion sensitivity were used. Accuracy on the UFOV was assessed when the peripheral targets were of higher or lower salience than the central target. In the global motion task, signal elements were presented that were either of higher or lower salience than the concurrently presented noise elements. In a second manipulation an attention cue was presented prior to presentation of the high or low salience elements in the global motion task. Presentation of the higher salience target increased sensitivity to global motion and accuracy on the UFOV task when compared to presentation of the target of lower salience for older and younger groups. Although overall the older group had reduced sensitivity and accuracy, presentation of low salience targets produced greatest difficulties for the older group. Introduction of the attention cue which triggered top-down attention further increased sensitivity to motion and accuracy on the UFOV task for the older group only. Older individuals have greater difficulties than younger groups when extracting low salience target signals from higher salience noise in dynamic visual environments. Difficulties for the older when compared to the younger group were greater when the stimulus was of low salience, with older drivers being easily distracted by irrelevant salient stimuli. Adding an attention cue when the target stimulus was of low salience, increased the sensitivity of the older, but not the younger group. The implications of these findings for driving are discussed.

**Keywords:** motion sensitivity, age differences, global motion task, driving
**Abstract**

**Investigation of elderly drivers’ hazard perception and driving performance**

RENGE, K. (Tezukayama University)

The present study focused on the relationship between elderly drivers’ skill for perceiving traffic hazards and driving performance. The investigation was conducted in three driving schools in Japan. Participants totaled 95 drivers (mean of the age 71.7, 68 male and 27 female) who were divided into younger-elderly (from 65 to 70 years old), middle-elderly (from 70 to 75 years old), and senior-elderly (over 75 years old) groups. A hazard perception test was administered to them, after which they drove on a driving course. The frequencies of drivers’ head movements were counted as a measure of drivers’ searching behaviour. The fifteen traffic scenes and one scene for training videotaped by a high-vision camera (Victor JY-HD10) were presented to the participants. After looking at each scene, the participants answered on the sheets in the way of checking possible hazards. The hazards were classified into three types such as “obvious hazards (OH)”, “potential hazards (PH)”, and “hazards relating to prediction of other road users’ behavior (BH)” A total of 57 hazards were included in all of the scenes, 12 of which were OH, 28 were PH, and 17 were BH. Differences in the total scores for hazard perception demonstrated a significant effect of age group ($p < .05$). The senior-elderly group had lower scores than other two age groups. The main effect was especially shown for potential hazards ($p < .01$). The significant relationships were found between frequencies of head movements and the total scores of hazard perception ($r = .425$, $p < .01$), and the scores of PH ($r = .455$, $p < .01$). Senior-elderly drivers could have a weakness for perceiving potential hazards such as crossing cars, bicyclists and pedestrians from dead zones of roads. The participants with lower scores of hazard perception had lower driving performance (searching head movements), which indicates that the participants who don’t understand potential hazards show less searching behaviour at intersections.

**The International Classification of Functioning, Disability and Health Model: Implications for the use of tests and other measures**

Chair(s): OAKLAND, T. (University of Florida), MPOFU, E. (University of Sydney)

Discussant(s): THERON, L. (Northwest University), DAVIDSON, G. (University of Sunshine Coast)

The purpose of this symposium is to synthesize findings from a recent scholarship that discusses the status of test development and use in rehabilitation science and practice in light of the World Health Organization’s International Classification of Functioning, Disability and Health (ICF). This state-of-the-art literature is found in two recent (2010) books edited by Elias & Oakland: *Assessment in Rehabilitation and Health as well as Rehabilitation and Health Assessment: Applying ICF Guidelines* and with contributions from more than 100 world-renowned experts. The specific objectives of the symposium are to: (1) provide a brief overview of the ICF, with implications for assessment, (2) review prominent themes in reference to ICF-related measures of adaptation, adjustment, and participation, (3) map ICF domains that are over-represented and under-represented in current rehabilitation and health assessments, (4) explore the relevance of the ICF to interprofessional education, (5) identify needed advancements and trends in the use of the ICF in the context of assessment, and (6) showcase rehabilitation and health assessment procedures from under-represented ICF domains.

**Mapping rehabilitation and health assessments to the International Classification of Functioning, Disability and Health**

OAKLAND, T. (University of Florida)
The rapid proliferation of rehabilitation and health assessment tools historically has evolved in disciplinary silos thus hindering efforts to communicate effectively among members of multidisciplinary treatment teams. The WHO International Classification of Functioning, Disability, and Health (ICF) offers promise or aligning measures of health outcomes for multidisciplinary health care providers. The ICF proposes a finite number of structures and domains within which assessments could be understood as well as how the results of assessments can be interpreted to address functioning, broadly construed. Assessments designed to assess functioning in the biophysical domains aligned with the medical interventions have more use and research than those for personal and environmental factors that influence functioning. The symposium presents the outcomes of a comprehensive project to document and map measures used to assess functioning in both the biophysical and personal-environmental domains. Approximately 100 international leaders in rehabilitation and health assessments discussed state-of-the-art assessments that support important rehabilitation and health practices. Topics include real and virtual tools to measure functioning, the physical environment, and econometric features of one’s health status. Specific measures were mapped to the ICF. Their quality and evidentiary basis also were discussed. More than 60 major forms of assessments and more than 1,000 specific procedures and instruments were identified. Almost no measures (<.01%) were considered by these experts to need to be mapped to ICF domain. All ICF domains can be assessed using existing measures of functioning. Efforts to document the evidence base for the specific instruments are likely to continue in the foreseeable future. Measures that provide a parsimonious assessment of ICF domains are needed to ensure their cost-effectiveness and reduce the burden of care.

An International Classification of Functioning, Disability, and Health based model for assessing environmental barriers and facilitators to activity and participation

SANFORD, J. (Georgia Institute of Technology)

The aim of this study is to present an International Classification of Functioning, Disability, and Health (ICF) based model of environmental assessment that incorporates the interactive effects of person (i.e., body function and structure) and press (i.e., environmental barriers and facilitators) on performance (i.e. activity and participation). Many methods may be used to assess environmental contributions to performance. However, few adequately address the key person, press, and performance factors—qualities essential to developing effective environmental interventions. Further, assessment methods vary significantly in their comprehensiveness of information and how that information is used in determining environmental intervention. This presentation will propose a comprehensive model that builds and expands on relationship capacity and contextual factors as they define barriers and facilitators and impact activity and participation. This model draws on the ICF, current literature on environmental assessment, and ecological models of person-environment interaction. Specifically, the paper will review the differences in understanding of the interactions among key constructs, leading to the development of a model that incorporates and accounts for the interrelationships among these key factors. Analysis of existing models suggest the degree to which the environment acts as a facilitator or barrier to activity and participation can be assessed only in relation to an individual’s capacity and his/her performance outcomes. This finding resulted in the development of an assessment model that accounts for the interactive effects of body function/structure and strength of environmental demands (i.e., press) on activity and participation. Press includes individual factors (e.g. preferences and values); environmental factors include physical factors (e.g., attributes of space and products); social factors (e.g., values); and organizational factors (e.g., policies); external factors (e.g., legal restrictions, availability of interventions) outside the control of the
individual; and task factors (e.g., requirements of the activity, including lifting, pulling, and bending). The proposed model provides a framework for gathering information that is valid, reliable, and comprehensive. Such information is essential to the elimination of environmental barriers and promotion of environmental facilitators that provide an effective rehabilitation strategy.

Measures of physical and functional performance, including occupational functioning

HILLMAN, A. (University of Sydney), INNES, E. (Southern Cross University)

As assessment of physical aspects of functional performance typically first considers specific deficits in body structure and function and then may move on to an assessment of their possible impact upon activities and participation. Alternatively, an assessment process that first considers participation and the context for it facilitates a quick and accurate identification of each individual’s therapeutic needs. This process will be illustrated through the use of a work-related assessment continuum. A process that helps describe a person-environment-activity interface is discussed, including assessment methods that help address relevant International Classification of Functioning, Disability, and Health (ICF) components. This process is grounded in clinical experience and scholarship. An integrated suite of assessments has been developed that fit well with the ICF model. The order in which these assessments occur is crucial. A ‘top-down’ approach is described, one that starts with occupational role assessment, leading to the identification of routines and tasks associated with valued roles (e.g. work). A work-related assessment continuum illustrates this approach. This ‘top-down’ approach to assessment of physical performance is consistent with principles of the ICF model and provides a focus leading to deeper understanding, accuracy, and economy in both assessment and subsequent therapeutic interactions within a range of areas, including home and works settings.

Health utilities in cost-effectiveness analyses: Whose preferences count, and how?

CONNELLY, L. (University of Queensland)

To provide an overview of conceptual issues that are associated with utility weight measurement for cost-effectiveness analyses, including the use of pre-scored utility measures and so-called “direct” elicitation methods. The empirical consequences of eliciting weights from individuals who have experienced the conditions of interest, from expert medical panels and the general public will be discussed. Literature on utility weight elicitation will be discussed based on a conceptual framework in which various types of measurement error are characterized. Empirical evidence from the literature and from a recent survey of people with hearing loss will be discussed and the empirical consequences of asking different groups to characterize health-related quality of life (HRQoL) will be presented. HRQoL data from individuals who have actually experienced a particular condition of interest (e.g., hearing loss) and its attendant effects (e.g., difficulties with verbal communication) frequently are higher than similar data which are derived from the general population. Perhaps ironically, this suggests the use utility weight from samples of the former population tends to decrease the apparent cost-effectiveness of interventions that reduce the impact of health conditions on functioning. Answers to the question of whose preferences matter when eliciting utility weights, as indicators of HRQoL, have both philosophical and empirical dimensions. In a practical sense, the apparent cost-effectiveness of interventions designed to improve the HRQoL of individuals with an illness or a disability may be directly affected by the choice that is taken. The empirical consequences of such choices are of practical relevance, because many health sector funding bodies now require the
cost-effectiveness of interventions that are designed to improve HRQoL be reported.

More than just test scores: Holistic neuropsychological assessment utilizing the International Classification of Functioning, Disability, and Health (ICF) framework

LEBLANC, J. (Victoria British Columbia)

The aim of this study was to review the strengths and weaknesses of quantitative versus qualitative neuropsychological assessment approaches and the meaning of neuropsychological assessment in the context of the International Classification of Functioning, Disability, and Health (ICF). Literature regarding meaningfulness of neuropsychological assessment for individuals in a health-care setting will be reviewed in the context of the ICF framework. The presentation will emphasize neuropsychological assessment’s effectiveness for measuring an individual’s abilities related to body structures, body functions, identification of limitations and abilities in activities and participation, and the individual’s ability to perform in major life areas such as work and education. The merits and limitations of utilizing qualitative and quantitative methods of neuropsychological evaluation are reviewed in light of prevailing literature and from the author’s experience in working with hundreds of individuals in rehabilitation setting. A representation of assessment methods for providing both qualitative and quantitative information for all major aspects of cognition will be presented. Their ecological validity in respect to predicting functional skills will be emphasized. The functional implications of considering assessment from a holistic perspective, including an individual’s culture or other factors that may impact test performance, also will be discussed. The role of the rehabilitation neuropsychologist in the context of the treatment team is outlined together with the methods for increasing the effectiveness of the team as a whole. Neuropsychological assessment in the rehabilitation and other health-related settings provides information for various needs, including diagnosis, treatment planning and intervention, and establishment of competencies. Many aspects of ICF classification are pertinent for neuropsychological assessment, as obtained data are meaningful only in the context of a person’s holistic environment.

The International Council of Psychologists International Relations and Human Rights
World Summit: Part 1 of 2

Chair(s): NEIL, S. E. S. (The International Council of Psychologists), EL-ZAHHAR, N. (The International Council of Psychologists), SILVERBERG, R.L.N. (The International Council of Psychologists)

Discussant(s): SILVERBERG, R. L. N. (The International Council of Psychologists)

The aim of the symposium is to: 1. Present human rights issues including women’s, men’s and children’s rights; family rights, eradication of poverty, abuse, and violence; 2. Present international and cross-cultural issues; 3. Develop suggestion for action which are culturally relevant, and universal; and 4. Explore differences and similarities in human values.

Conflicts, violence, and peace: Models for establishing human rights and democracy within the frame of peace education

EL-ZAHHAR, N. (The International Council of Psychologists)

The purpose of this presentation is to illustrate the levels of conflicts and discusses the concept of peace. Also, it illustrates the preparation of individual and nations to establish human rights and democracy, and accept the process of peace and world mindedness through the Peace Education Model (El-Zahhar, 1995). On the other hand, it illustrates the strategic plan for Peace Education at formal, informal, and non-formal education. In addition, it illustrates a theoretical model to establish positive peace.

Keywords: conflicts, peace, human rights, democracy, Peace Education Model

Psychological values: Peace and well-being

O’ROARK, A. M. (The International Council of Psychologists)

The ICP conference theme for this year is Psychological Values Around the World. Group and individual values vary between and within cultural espoused values. Can psychological values transcend the global divides to provide a common ground for forging peace and well being for all? Ayn Rand’s hypothesis is that realizing full value requires thinking logically [based on facts], having and striving for goals, and being satisfied that who and what you are makes a positive contribution wherever you are. These conditions require well-being, good health and good functioning of body and mind; using conflicting perceptions and interests to create solutions to problems, while maintaining respect for the rights of self, others, and the environment. Shared values are the foundation of trust. Trust is the condition for cooperative human relations. Scientific psychology insists on collection of evidence to support choice of actions that lead to well-being. Well-being is a psychological goal and a psychological means toward peaceful interpersonal relations. Promoting psychological values around the world offers a pathway toward world peace.

Keywords: psychological values, peace, well-being, trust, interpersonal relationships

Implacable hostility leading to parental alienation

LOWENSTEIN, L. F. (The International Council of Psychologists)

One of the most insidious problems of the past half a century or so, and perhaps even longer, is the implacable hostility which results when a relationship ends between two partners. The children are caught in the middle and are manipulated normally by the custodial parent be it male of female who has custody in order to turn the children against and to totally reject that other party no longer as part of the family. The paper describes 28 ways of assessing the fact that this has occurred and also provides some remedies once it has occurred. Remedies are difficult due to the judicial system who may not always comply with the psychological implications of children who are alienated from
one of their parents. Hence the biggest hurdle is psychologists working with the judiciary.

**Cross-cultural comparisons of citizen’s attitudes toward war, invasion and torture and the implications for policy and action to protect human rights**

**MCCARTHY, S. (The International Council of Psychologists)**

The Personal and Institutional Rights to Aggression and Peace Survey (PAIRTAPS) was developed by the Group on International Perspectives of Governmental Aggression and Peace (GIPGAP) at Boston University. The survey includes several Likert-Scale items such as: World Peace is Possible and Governments Have the Right to Invade another Country which respondents rate on a 1 (strongly disagree) to 7 (strongly agree) scale. Respondents are also asked to provide definitions of Peace, War and Terrorism. Over the past years, the survey has been distributed in over 40 countries. Preliminary results were published in a 4 Vol. set by Praeger International released in 2009. Additional comparative data will appear in a 4-volume set by Springer to be released next year. This presentation will compare the divergent responses of citizens from several countries in Asia, Europe, South America and Australia, as well as the U.S. and discuss how these attitudes, in turn, influence national and international policy toward human rights issues, specifically torture, invasion and acts of war, and peace-building. Most agree that peace is a basic human right and that it is achievable, but definitions differ. For example, the Russian sample was more likely to define peace as an absence of violence and destruction, the Malaysian sample was more likely to define peace as related to a stable and economically profitable society and the Brazilians were more likely to define peace as the presence of positive qualities such as harmony, co-operation and safety. Differences in responses related to torture, invasion and war based on social and political history and current social factors will be explored, with a focus on uncovering the types of experiences,

The aim of the symposium is to present human rights issues including women’s, men’s and children’s rights; family rights, eradication of poverty, abuse, and violence; to present international and cross-cultural issues; and to develop suggestions for action which are culturally relevant, and universal and explore differences and similarities in human values.

The continuum of violence: From the girl-child to the woman to the older woman

DENMARK, E. F. (The International Council of Psychologists)

Violence committed against the girl-child has effects throughout the lifespan. When the girl-child grows up, she may see herself as a victim, which results in her being a target of violence that can continue into adulthood and old age. In some instances, when violence is experienced by the young girl, she may in turn as an adult commit violence against her children and parents. This cycle of violence is important for all psychologists in terms of intervention and treatment.

Keywords: violence, children, lifespan, victim, cycle

Parental acceptance-rejection theory studies

COMUNIAN, A. L. (The International Council of Psychologists)

Parental Acceptance Rejection Theory (PAR Theory) is a theory of socialization that focuses primarily on an aspect of parent-child interaction which has been labeled as the warmth dimension. Parental acceptance is theorized as a bipolar dimension that has acceptance on one end and rejection on the other end. The warmth dimension is the component of the parent child relationships that regards love, or the lack of thereof. Every individual can be placed on this continuum because everyone receives more or less warmth (or love) from his parents. Rohner (1975) sees parental acceptance rejection as a dimension of parenting, a continuum having to do with the warmth, affection, support, and caring, or simply love that children everywhere experience from their parents at one pole. At the other pole lies rejection or absence or withdrawal of acceptance and warmth. Exploratory factor analysis (EFA) studies have shown that the Parent Acceptance Rejection Questionnaire (PARQ; Rohner, 2005), which provides retrospective ratings of the relationships with mother and father during childhood, has four primary factors in more than 50 countries around the world. The factors are warmth/affection, hostility/aggression, indifferent/neglect and undifferentiated rejection. Using the same item clusters used in previous EFA studies, the current study examined the factorial validity of the 4-factor structure of the PARQ using confirmatory factor analysis (CFA). To achieve this aim, PARQ ratings were obtained from adults in the United States (N = 492) and Italy (N = 296). Results for both groups for ratings of both mothers and fathers showed good fit. Additional analyses at the item level also showed good fit for ratings of both mothers and fathers. Taken together, these findings indicated very good support for the theorized 4-factor model of the PARQ and for cross cultural application. Implications for further studies about environmental and situational influences of parental acceptance studies are discussed.

Keywords: parental acceptance rejection theory, socialisation, parent-child interaction, warmth, Parent Acceptance Rejection Questionnaire
Fathers and families: Responsibilities and challenges - Fathering: A life work for men and in some measure, women

NEIL, S. E. S. (The International Council of Psychologists)

Dr Neil will discuss Fathering from the perspective of the Satir Model from a practicing Family Psychologist’s viewpoint. She works in a multicultural setting in Melbourne, Australia. Dr Virginia Satir maintained in her Humanistic Growth Model that “the form of a family does not determine its functioning.” The integrity of fathering lies along the continuum of presence to absence, and involves physical and emotional inclusion or exclusion in families. Four levels of functioning must be honoured in family life: firstly, the Biological Father; secondly, the Real Father (involving many Fathering images in the child); thirdly, the Imaginative Father (portrayed from the mother to the children in the fathers’ absence); and fourthly, the Cultural Father. The Satir Model promotes the Eye of Compassion instead of the Psychology of the Enemy. Fathering is a multifaceted job for both men and, in some measure, women. Future family policies must lead to more fully integrated fathering in the lives of modern families. Clinical cases from “The Multicultural Family Chessboard” and “The Psyche and Soma” therapy techniques will be briefly discussed.

Keywords: fathers, humanistic growth model, family policies, presence

The International Handbook of Cross-Cultural Counseling: An illustration of activist scholarship

Chair(s): HEPPNER, P. (University of Missouri)
Discussant(s): BLUSTEIN, D. (Boston College)

Counseling psychology in the United States has maintained a strong voice for social justice, and in so doing, has “uniquely positioned itself as a major resource for meeting the many pressing challenges of our global era” (Marsella, p. ix, 2009). Nonetheless, U.S. based models of counseling and psychology in general have both positively and negatively the science and practice of mental health professional worldwide. The International Handbook of Cross-Cultural Counseling (2009) is the first book to broadly illustrate the scope of counseling within different cultural contexts across 26 countries around the globe. Moreover, the book provides an in depth discussion about the status and current developments of the counseling profession in numerous countries around the globe. Most importantly the book explicitly ties cultural assumptions to counseling activities across the world. “In my opinion, the ...International handbook provides a substantive foundation for resisting the pressures of hegemonic globalization to impose a uniform and homogenized Western-based culture across the globe.” (Marsella, p. ix, 2009). In essence, the Handbook is an act in context that promotes social justice through activist scholarship. Key objectives of this symposium are to: (a) depict activist scholarship by discussing the process of developing and producing the handbook based on guiding principles of diversity and social justice, (b) illustrate the synthesis of indigenous and international perspectives, (c) promote a local and international professional identity in the counseling profession, (d) depict the role of cross-cultural collaboration as an act of social justice not only between two individuals, but institutions, and counties as well around the

Swimming against the stream: The Handbook as activist scholarship

NORSWORTHY, K. L. (Rollins College)

Western psychology, particularly U.S. psychology, has had a profound impact globally. Unfortunately, it is often uncritically transported to and applied in other parts of the world without regard for local context, worldviews, indigenous wisdom and “ways.” Our colleagues from outside the west often experience many barriers to having their scholarship published in western mainstream journals; thus we are deprived of important psychological knowledge that is needed to truly understand and address the lived experiences and suffering of human beings across cultures and contexts. Psychologists and academics who successfully publish in dominant professional journals and publishing houses can use our privilege and access to resources to work in solidarity and as allies with our colleagues from various parts of the world to change this situation. We, the coeditors of the International Handbook of Cross Cultural Counseling, view this book as a form of activist scholarship whereby we made critical decisions about book content, contributors, and even language and APA style usage in an effort to privilege voices and ideas that often are not included in dominant psychological narratives and venues. Rich discussions emerged among ourselves as coeditors and also with our contributors about how best to “decolonize” this volume and support a different kind of book that drew out what has been known all along but often not expressed in public professional venues – how to reinvent psychology as a profession in a global context. The presenter, one of the book coeditors, will discuss our process of developing and producing the handbook based on guiding principles of diversity and social justice. She will describe how these principles influenced our choice of content (for example, an emphasis on indigenous wisdom and practices that are at the heart of healing and helping in various cultures) and how we collaborated with various chapter contributors given their specific contexts (inconsistent access to internet, etc.), translation challenges (since the book is in English), and socio-cultural values and worldviews. The presentation will conclude with a discussion of several conundrums we faced in producing the book and what we learned through the completion of this very exciting project.

Keywords: culture, indigenous wisdom, professional journals, International Handbook of Cross Cultural Counseling, psychological narratives

Connecting the counseling communities: The handbook as international and indigenous scholarship

LEUNG, S. M. A. (The Chinese University of Hong Kong)

In a special issue of Applied Psychology: An International Review on “internationalization of counseling psychology”, Savickas (2007) identified four objectives or strategic goals important to the counseling profession worldwide, which were: (a) to define counseling psychology (or the counseling profession) from an international perspective, (b) to crystallize a cross-national professional identity, (c) to encourage construction of indigenous models, methods, and materials, and (d) to promote international collaboration. In many ways, the Handbook aimed to play a role in moving the international counseling profession along the strategic objectives proposed by Savickas (2007). The editors of the Handbook are convinced that cross-cultural and international perspectives are instrumental to addressing the Western cultural biases that have permeated counseling theory and practice. A good proportion of the Handbook chapters were authored or co-authored by scholars from countries around the world, offering their voices on the development of the counseling profession in their regions, presenting indigenous concepts and practices, and articulating on the needs and future directions of counseling professionals. We hope that the aggregation of these “voices” would enrich the cultural diversity of the literature, and bring forth perspectives and insights that are vital to solving human problems and concerns globally and locally. The editors of the Handbook also
view the involvement and contributions of international authors as practices and illustration of collaboration in equal partnerships. Whereas authors were given guidelines and informed of the objectives of the country chapters, they were given much freedom to present to readers themes and issues that the important to their countries. The editors have not met many of the authors in the country chapters yet the collaborations could still be facilitated and efficiently maintained through e-mails and other forms of communication. The Handbook was a complex project yet the editors and authors showed their commitment and resilience, and it was a good lesson on international collaboration for all those involved. In the presentation, examples and voices from the Handbook will be used to illustrate the synthesis of indigenous and international perspectives, the satisfaction gained through international collaborations, and the advancement in local and international professional identities.

**Keywords:** counselling psychology, professional identity, international collaboration

### Promoting social justice through cross-cultural collaboration around the globe

**HEPPNER, P. (University of Missouri)**

This presentation will provide observations and conclusions about the important role of cross-cultural collaboration in promoting social justice, and the essential interface with cross-cultural competence. The Handbook illustrates the promotion of social justice through culturally sensitive cross-cultural collaboration. Cross-cultural collaboration can be most rewarding, but also most frustrating. The outcomes can not only result in completion of important projects such as the Handbook, but perhaps even more importantly, in promoting social justice from the individual level to the macro level. The presentation will focus on ten conclusions about important ingredients or skills associated with successful cross-cultural collaboration: (a) positive initial contacts, (b) building a trusting, mutually beneficial, and appreciative relationship, (c) increasing levels of cross-cultural competencies, (d) learning by experiencing, (e) positive problem solving attitudes and approaches, (f) multiple benefits in preparing the next generation, (g) serving in a bridging role as a change agent, (h) institutional support, (h) an essential interface with cross-cultural competencies, and (i) good yuan-fen. The presentation will conclude that although cross-cultural relationships vary greatly across individuals, cross-cultural competencies are necessary but sometimes insufficient. Good yuan-fen, or the good luck by which people with the right chemistry are brought together for some reason, and find something meaningful in learning about our cross-cultural journey and collaboration. Moreover, it will be maintained that cross-cultural collaboration can be a powerful mechanism to promote social justice not only between two individuals, but institutions, and professions as well around the globe.

**Keywords:** cross-cultural collaboration, social justice, cross-cultural competence, problem-solving
The introduction of cyber technology in health management

Chair(s): STOKES, D. (Australian Psychological Society)

“e-health” encompasses the application of electronic technology to support the provision of health services and does this in a multitude of ways. This is becoming a more urgent and vital issue in both health policy and community importance with current attempts to implement the electronic health record. The papers in this symposium outline the various components of both the record itself, the associated initiatives to support it as well as the social and ethical implications. The application of such technology to individual therapy is discussed.

The development of e-health in Australia

STOKES, D. (Australian Psychological Society)

There are major initiatives and developments emerging in Australia in the area of e-health. Currently, the most important developments are moves towards an electronic health record (ehr) for every consumer in Australia, a unique identifying number for every citizen of Australia and every health provider (individual health identifier -- ihi), software that can guarantee secure messaging and communication between providers, and ultimately computer software and hardware that will enable a web-based national network to effect communication across health providers in Australia. The Australian Government has been talking about an electronic health record since the early 90s. Subsequently (early 2000) State governments and the Australian Government funded a body called NEHTA (National E-Health Transition Authority) to set data and hardware standards, create or adopt data elements and develop unique individual health identifiers for patients/clients, providers and provider organisations. This paper outlines some of those developments in more detail and identifies the major obstacles and issues that such an initiative faces.

Keywords: e-health, electronic health record, health care providers, Australia

Building blocks for electronic health records

LI, B. (Australian Psychological Society)

Like most other workplaces computers are taking over the administration of health care. In addition to practice administration, communication and financial transactions, software programs are being developed and refined to handle patient data, clinical interventions and coordination of patient care. Associated with these rapid developments in e-health is the issue of compatibility between various software programs. This not only reduces their intended functions, it ultimately poses risks from a patient safety and quality of care perspective – the key beneficiaries for e-health systems. The Australian Government, through the National E-Health Transition Authority (NEHTA) began a number of initiatives in an effort to overcome this. Two of the most significant initiatives to date are the proposal for a unique identifier for consumers and providers, and the agreement of a uniform set of standards for medical software. These developments will provide a solid foundation for existing and future developments in e-health. In addition, they will enhance Australia’s contribution to the development of e-health globally. The presentation will examine how the ehr will be constructed and applied and how it is anticipated that the individual health identifier will function in practice.

Keywords: computers, health care, practice administration, patient data, e-health

Who will have access to my e-health record?

LI, B. (Australian Psychological Society)

The benefits of electronic health records are well recognised. They allow for timely access, reduce errors in reporting and are portable and
therefore accessible. However, there are also a number of potential pitfalls: unfetted access by others, the handling of private and sensitive information and the use of personal health data for research and other purposes. In recognition of these issues, the Australian Government proposed that electronic health records will be “patient controlled” with various categories of authorised access. This presentation will briefly outline the development of privacy and confidentiality considerations for the electronic health record in Australia. It will also highlight some key features available to practitioners in practice management software designed to protect sensitive patient information.

**Keywords:** electronic health record, personal health data, Australian Government, practice management software

The digital clinic – opportunities and responsibilities

**FULLER, T. (Australian Psychological Society)**

Convenience, efficient, “user-friendly”, cost effective – these are all terms used to highlight the benefits and promise of the technological advancements in web-based communication, service provision (e.g. e-therapy) and software packages. Psychologists and allied health service providers, especially those in private practice, appear to be missing out on the benefits and opportunities that exist and neglecting responsibilities to consumers. For example, a recent Australian Psychological Society survey of psychologists in private practice revealed that only a third of respondents used some form of practice management software to support their practice. Alarmingly, only a small fraction of these used some form of secure/encrypted messaging to protect confidential information. If this result reflects the practices of other allied health professionals, and without government incentives to do more, it would be reasonable to assume it does, it appears that many practitioners have much to gain and more to learn. This presentation aims to inform and alert health professionals to some of the key issues when harnessing the potential of a digital clinic with a particular focus on e-therapy and the standards needed to be instituted.

**Keywords:** web-based communication, e-therapy, practice management software, confidentiality
The lives of Australian Aboriginal and Torres Strait Islander women

Chair(s): GRIDELY, H. (The Australian Psychological Society)

This symposium will discuss the role of Indigenous Australian women. These presentations are developed in sequence so that an historical overview discusses the ways in which colonisation has impacted on the lives of Aboriginal women, their health and wellbeing and the diverse ways in which they are and have been positioned and recognised in Australian society. A brief discussion about traditional and contemporary roles within the family and community and dynamics of family relationships and extended family life, particularly as grandmothers, mothers and daughters will be undertaken. Discussions about the social determinants, the strengths and stressors that affect the lives of Aboriginal women and their families will be presented. Indigenous experts will present specific papers into key issues such as domestic violence. Promising initiatives and discussion around developing genuine and long-term solutions from those working in field will be presented. Throughout, the role of Indigenous Australian women themselves in leadership and community empowerment is a major theme.

‘Mothers of Sin’: Australian Aboriginal and Torres Strait Islander women’s perceptions of their identity and gender

DUDGEON, P. (The School of Indigenous Studies, University of Western Australia)

This presentation sets the context for the symposium, briefly presenting a historical overview of Indigenous Australia and the current demographic situation of Indigenous Australian peoples today. Aboriginal women were described in various derogatory terms in historical accounts. ‘Mothers of sin of the north’ was used to describe this presenter’s foremothers. To understand and describe how the processes of colonisation have shaped perceptions of gender and cultural identity the presenter engaged with her lived experiences as an Aboriginal woman, woven with interviews from other Aboriginal women from the Kimberley region of north west of Western Australia. In this address, the presenter discusses the story of her grandmother’s life during a period of state surveillance that was concerned with controlling Aboriginal people, particularly, women. The oppressions that have and continue to confront Aboriginal women are unique to their group. Aboriginal women have suffered racism unlike white women; they have suffered sexism unlike Aboriginal men, and perceptions of their traditional roles have been distorted so that there is a belief that their roles as women were better under the structures of western colonization rather than being the slaves and chattels of Aboriginal men. As the frontier expanded, they were used for sexual services by white settlers, and yet Conversely viewed with contempt in terms of their gender by their oppressors and by white society. Despite these historical oppressions, many Aboriginal women have maintained a strong sense of themselves and their identity. An important project in the struggle for Indigenous self-determination will be for Indigenous women to challenge sexist and racist perceptions about themselves and to talk up, reclaim women’s power and status in both the dominant society and in Indigenous society.

Keywords: Australian Aboriginal, women, identity, gender, colonisation

The social and emotional well being of Australian Aboriginal and Torres Strait Islander women

JONES, T. (Private Consultant)

This presentation examines the social emotional well being of Aboriginal people, with particular emphasis on women. The literature shows that Aboriginal women continue to occupy an unequal place in contemporary society on every measure. Specifically, in Western Australia Aboriginal women had higher unemployment rates and lower average
weekly income compared to other women; some 62 per cent of Aboriginal women were dependant on government pensions and allowances as their main source of income, and were likely to be under financial stress. Aboriginal women made up approximately 48 per cent of women prisoners in the justice system in 2004. These statistics are similar across Australia. Overall the patterns of personal stressors experienced by Aboriginal women were higher in all areas and some were unique to them unlike those experienced by other women. The negative impacts of these social determinants upon Aboriginal health and wellbeing are well documented. The net effects of these social determinants upon Aboriginal women are reflected in the various government reports which shows that infant mortality rates were two to three times higher; hospital admission rates for children were twice that of others; the rate of child protection notifications have increased. Indigenous Australian women were three times more likely to report being a victim of physical or threatened violence than non Aboriginal women. In New South Wales, Aboriginal women reported domestic violence related assault at six times the State average, were four times more likely to be a murder victim and seven times more likely to be a victim of grievous bodily harm than other women. Indigenous Australians, both men and women, were over four times more likely to be hospitalised for alcohol related mental and behavioural disorders than other Australians. Alongside the effects of these social determinants, persistent oppression and transgenerational loss and trauma have had a negative impact on Aboriginal women’s health. Many positive achievements have been made by Australian Indigenous Women in a range of different levels and settings. These will be profiled to demonstrate how Australian Indigenous women are working towards empowerment and self-determination.

Keywords: emotional well-being, Australian Aboriginal, society, women, unemployment

Lessons from the field: Working in empowering ways with Australian Aboriginal and Torres Strait Islander women

WALKER, R. (Telethon Institute for Child Health Research)

Aboriginal women’s health status in general is besieged by issues of access to services, lack of cultural responsiveness and cultural safety, inappropriate health promotion, limited screening, high level risk factors, and early onset of chronic diseases. For example, Aboriginal and Torres Strait women have higher levels of diabetes and heart disease, and have poorer perinatal outcomes than non-Aboriginal women nationally. This is an area of grave concern given that there is sound evidence to show that providing targeted and
responsive antenatal care and screening of and treatment for specific conditions improves perinatal outcomes for Indigenous Australian women. This presentation overviewed examples of working towards addressing health and mental health issues in culturally competent ways. It is evident that a range of health strategies are needed to address the complex array of social and environmental determinants that contribute to the disparities in health status, level of care, and outcomes of Aboriginal and Torres Strait Islander peoples. There is growing evidence that establishing and implementing culturally appropriate programs targeting specific diseases also results in effective improvements to Indigenous Australian peoples’ health and lowers risks in a relatively short time. Despite the many successful programs being led by Aboriginal women and their allies a recent audit of antenatal service delivery in Western Australia reveals a significant gap in the knowledge and culturally responsive practice of many services signalling the need for greater cultural competence at all levels (system, organisational, professional, and individual) across the health sector. The rationale for developing a cultural competence assessment process for health services is documented in a raft of existing policy guidelines and frameworks (both State and Federal) that aim to address the health inequities experienced by Aboriginal people. These are based on recognition that existing services and approaches to improving the health and wellbeing of Aboriginal Australians have not been successful. There is increasing recognition of the need for health practitioners and those responsible for the delivery of health services to develop strategies and structures that take account of the historical, cultural and environmental experiences and contemporary circumstances of Aboriginal people.

Keywords: Australian Aboriginal, women, chronic disease, screening, cultural safety

The process of knowing and learning in organizational research: How to shape and create practice knowledge?

Some lessons learnt from researches in Health Organizations/Health Settings

Chair(s): SCARATTI, G. (Universita’Cattolica Del Sacro Cuore)
Discussant(s): BOSIO, A. C. (Universita’Cattolica Del Sacro Cuore), KANELIN, C. (Universita’Cattolica Del Sacro Cuore)

The symposium will propose ideas and papers that contribute to the development of the field of knowing and learning in organizations and social contexts. The specific focus will be on innovative ways of studying and sustaining knowledge management and knowledge sharing, intended as ways through which a social system can reflect, improve, and change. The assumption at the basis of the call-for-proposal is that organizational knowledge provides better outcomes and advantages when it is close to the real contexts, when it is meaningful for people who create it, and when it is congruent with the ethical conditions that are used to sustain the research and its impacts. Key learning objectives include: to show findings on how people, networks, and communities of practice can create and exchange knowledge, improving individual and organizational learning and performance; to consider new methodologies for gathering tacit and situated knowledge in social and organizational contexts; to present case studies and examples that push forward the research and the intervention around knowing in complex social contexts; and to reflect on context dimensions and the impact of studying on knowledge management and knowledge sharing. The symposium aims to be interdisciplinary, including different approaches and methodologies from a broad range of fields.
that are keen to develop qualitative and combined analysis to improve their “lens” and to share their cultural perspectives in doing research (professionally and academically): psychology, sociology, human ecology, health science, anthropology, community-based research. The symposium is intended to provide considerable scope for discussion with and contributions from participants.

Working together in the space between expertise and ignorance

NICOLINI, D. (IKON, Warwick Business School, University of Warwick), MENGIS, J. (IKON, Warwick Business School, University of Warwick)

This paper critically appraises the widespread idea that working together in interdisciplinary conditions requires the integration of knowledge, which, on its part, requires some form of ‘sharing’ or ‘shared knowledge’ and the integration of different knowledges. We build on the theoretical concepts of common ground/grounding and interactional/contributory expertise in two cases of product development projects to analyze the processes through which common ground evolves in practice. The data were collected through multiple methods. We combined participant observation, ethnographic interviews, semi structured interviews (N=47), and the analysis of project documents and scientific papers produced during the initiative. We find that what is usually glossed as “sharing” or “integrating knowledge” is better understood as a processual effort to build common ground. This consists in a continuous process of both developing common knowledge and dissecting differences (dependencies), and also of confirming and questioning the legitimacy of experts. We depict these processes as relational and dialectic - positioning one’s own expertise at the same time as admitting ignorance relative to others’ expertise. Our analysis and discussion allows us to revisit the relationship between personal and communal common ground and refine theory on interdisciplinary collaboration by delineating grounding activities as specific to tasks characterizations. The article argues that the ideas of sharing and integrating knowledges are problematic and that the development of common ground in interdisciplinary projects does not resemble the consensual collaborative activity through which shared understandings are (perhaps) developed in other settings. Instead, ongoing grounding activity is characterized, to some extent, by delimitating learning across professional boundaries, by establishing interactive expertise and by understanding differences and dependencies that legitimize ignorance and expertise.

Keywords: integration of knowledge, shared knowledge, product development projects, common knowledge, expertise

Knowing and learning in clinical contexts

GORLI, M. (Universita’Cattolica Del Sacro Cuore)

The paper discusses a specific methodology to detect and to analyze professional practices as a way to sustain organizational reflection and change. Based on an intervention conducted in a health district in Northern Italy, the work shows the use of a projective interview technique, the “interview to the double”, for the search of meaning around the practices in place and the possibility to rethink them. Opportunities and critical aspects of this tool in articulating and representing practice are presented, together with its potential in developing hypothesis for organizational change, and the process that, stemming from it, was developed in the specific context. The action-research intervention described is based on a psycho-sociological approach where narrative and ethnographic tools sustain the joint-work of researchers and organizational actors. Other than the “interview to the double”, the project utilized a group of core-tools like mapping exercises, ethnographic and narrative forms, group action plans and evaluative methodologies. The study is based on a qualitative analysis, with the assumption that a specific context can only be studied by going in depth into it and by getting close to how people know, practice and learn in it. The paper shows the use of the “interview to the double” as a way for situated learning and as a possibility for involving people in inquiry processes around their daily sequences of activities. The tool provides the organizational
actors with the possibility to share languages, evaluative criteria and meanings that are often implicit or taken-for-granted. This methodology also gives the opportunity to undertake transformative actions, and through which it is possible to refine professional identities and practices. The approach and the tools utilized show the richness of the tacit and situated knowledge detected and its potentiality when used for reflexivity and transformational actions in organization. The article argues that the ideas of shaping and sharing knowledge are strong and useful when accompanied by an approach close to people that allow them to reflect on the meaning of that knowledge and on the possibility to challenge it.

Keywords: professional practice, projective interview technique, organisational change, learning, transformational actions

Organizational learning in Alzheimer services: an action-research.

GOZZOLI, C. (Universita’Cattolica Del Sacro Cuore)

The paper illustrates an action-research experience carried out in an Italian Foundation with a great tradition in dealing with Alzheimer patients. The experience has involved three services (Alzheimer Diagnostic Unit; Alzheimer Unit; Alzheimer Integrated Daily Centre), different professionals (doctors, nurses and paramedics), and patient’s relatives (informal caregivers). The aim was directed to improve the quality of the services, with particular attention to the quality of relation between professionals and caregivers. The device used will be analyzed, as well as some crucial points which have characterized the process, and the effects on organizational learning. Data comes from different methods proposed with professionals and caregivers: semi structured interviews; clinical-social elaboration groups; DSVO (symbolic drawing of organizational life-space); CBI (caregiver burden inventory). Verbal data has been analyzed by content analysis with the support of the software Atlas-t, a symbolic – interpretative analysis on drawings and a statistical analysis on CBI. The most relevant consequences on organizational learning are illustrated: - the chance to individuate the fragmentations of services; - a deeper knowledge of different type of relations between professionals and caregivers characterized by important collusive processes that have strong consequences on organizational practices. Moreover, are taken into account the device and tools, in a critical re-view. The prospective and the device used in the experience, shows that organizational learning can be reached through a creative and participative process with opens new working and practices perspectives, in individual, in groups and in organizations. Hence the Alzheimer patients sharing care has improved.

Keywords: Alzheimer’s disease, Alzheimer services, organisational learning, care

Knowledge translation in the context of organizational change

ALUWIHAR, D. (University of Alberta), OLSON, K. (University of Alberta)

In this paper we use a case drawn from a healthcare setting to discuss the influence of organizational change on knowledge translation. The case under consideration is the implementation of an outpatient fatigue clinic in a large cancer centre in Western Canada, where a large-scale organizational change is currently underway. Many authors report that fatigue is the most distressing symptom experienced by cancer patients. Using principles drawn from knowledge translation, including application of evidence, broad consultation and collaboration, the authors recently developed a comprehensive multidisciplinary fatigue clinic to address this concern. The clinic is considered priority by senior administration, as it aligns with a core value of timely symptom management. However, implementation of the fatigue clinic has been delayed as it must now share the corporate agenda with organizational change. This paper draws its arguments from literature on organizational change, power, decision-making, adaptability, and knowledge translation. We use principles from the literature above to provide recommendations about how to move knowledge translation activities such as our fatigue clinic forward, despite the additional considerations required to effectively implement major organizational
change. The positive patient outcomes associated with working together to translate knowledge generated through research into changes in clinical practice are well established in the health care literature. Organizational change introduces some additional factors for consideration in this process but need not be viewed as an obstacle to knowledge translation.

Keywords: healthcare, organisational change, knowledge translation, fatigue, decision making

“From health knowledge into safe practices”: the role of patients’ and caregivers’ online communities

GRAFFIGNA, G. (Universita’Cattolica Del Sacro Cuore)

Medicine is both a science and a therapeutic practice. The (diffused) idea that a therapeutic practice could only be driven by formal science achievements and that scientific knowledge can be directly transmitted from healthcare professionals to patients is disconfirmed by several evidences. Knowledge about health and prevention require important processes of sharing and co-construction among healthcare professionals and patients. In this regard, online patient communities seem to be a privileged observatory to study knowledge co-construction processes that take place between patients and caregivers in regard to the management of health and illness. Furthermore Internet is becoming a more and more promising medium for research and interventions in the healthcare setting. The paper discusses the results of a qualitative study articulated in two phases and based on online communities with cancer patients and their caregivers, constructed ad hoc for the research purposes. The online communities run for more than a month and were aimed at exploring how patients and caregivers spontaneously negotiate and construct their preferences when deciding treatment and palliative settings. In particular the research explored how participants experience their “time with cancer” and attribute value to chemotherapy that is aimed at expanding life expectations but with the “cost” of really important side effects. “Time” is a crucial organizer of the illness experience and it assumes a new dimension and value after the diagnosis of cancer. Furthermore patients and caregivers attribute different meanings to time after the cancer diagnosis and show a different approach to the management of daily life with the disease. This implies the construction of very peculiar criteria in deciding about treatments and palliative settings. These findings may orient therapeutic interventions more attuned to patients’ and caregivers’ needs. Furthermore, online communities are very useful tool to allow participants to disclose experiences, reciprocally express emotive support, share knowledge and co-construct “good practices” related to health and illness daily management.

Keywords: therapeutic practice, scientific knowledge, healthcare, knowledge construction, cancer
Abstracts of the 27th International Congress of Applied Psychology

The psychology of Asian terrorism

Chair(s): SARWONO, S. (Persada Indonesia University)
Discussant(s): KNOWLES, M. (Monash University)

Terrorism has been one of the most challenging threats the world is facing and would be faced in the unforeseeable future. Obviously, terrorism continues to pose serious threat to the international security and peace as well as economic prosperity and social development. Despite the fact that many terrorists suspects/perpetrators have been killed and apprehended and prosecuted, a number of terrorists figures which are now in the penitentiary and detention centres remain at large and are still potentially capable of influencing others with terrorism ideology that would lead to massive terrorist acts or attacks. The possibility is greater because radical movements, organizations and paramilitaries still exist in many countries like the Middle East, South and Southeast Asian, and some western countries. International organizations and governments have taken some measures to counteract terrorism, some with success and some others with less success. It is obvious that one cannot fight terrorism using military or police force only. Even when combined with economic, social or political approaches, they are still not very efficient. The Indonesian and Singaporean experience reveals that only when the police adopt psychology in their techniques and tactics, the counterterrorism act can be brought to its maximum results. However, after exchange of experience between the Indonesian and Singaporean police psychology services (February 2009, in Jakarta), it is evident that although there are many similarities, what has been done in Indonesia, cannot be automatically applied in Singapore and vice-versa. Therefore it is needed now to develop a common understanding of the psychology of terrorism and how to counteract it in some countries, and look for general principles. In this symposium, research results (academics) as well as experiences (practice) of some countries will be shared and discussed.

Radicalization by internet

KHADER, A. (Behavioural Sciences Unit, Home Team Academy), TAN, E. (Behavioural Sciences Unit, Home Team Academy)

Can one be radicalised by the Internet? With the arrests of several individuals globally in recent years who had plans to pursue “violent jihad” after being attracted to terrorist and radical ideas through the mass media, the threat of online radicalisation is real and burgeoning. Given the limited available research on this phenomenon, there is a pressing need to study online radicalisation, how it takes place and therefore to counter and mitigate it. This presentation draws on the psychology of the internet, internet radicalisation and discusses an analysis of radical websites. It suggests implications for multi-tier prevention and interventions.

Keywords: radicalised, Internet, terrorism, radical ideas, mass media

Psychology of terrorists: 4 types

HAMDEN, R. (Human Relations Institute)

psychology as frameworks for analyzing terrorism and terrorists; to explore the psychological processes that creates a terrorist; and the development of unbiased and analytical thinking capabilities of terrorist’s psychology. This program in Terrorist Psychology uses a clinical, psychoanalytical, and social psychology framework for studying terrorist groups and individuals, terrorist origins, goals, dynamics, ideologies, counterterrorism, and homeland security. Work in this course involves examination of the structure and dynamics of terrorists in North America, South America, Europe, the Middle East, Africa, Asia, and Australia. Terrorist strategies and tactics, the hot spots from which they evolve, the ways they operate, the use of the media, and theories of counterterrorism or negotiations are all covered. The history, present, and future of terrorism are indicated. Participants will
review definitions and typologies of terrorism, analyze specific concepts in context, discuss thoughts about terrorism. Differing types to identify and negotiation styles with each study of terrorist personalities and terrorist groups, including types, tactics, and trends on a worldwide scale as well as domestically on issues of prevention and Global Building. The aim is to increase awareness of cultural and multi-cultural issues through study of how social problems and social movements are related to, and affect, minority groups; to prepare for more advanced study in criminal justice/homeland security; and to learn the four types of terrorists: definition, assessment, categorizing, and counter-action.

Keywords: terrorism, counter-terrorism, psychological processes, homeland security, personality

The approach to re-educate terrorist convicts

DAHLAN, W. (University of Indonesia)

The aim of the current study was to examine the approach to re-educate terrorist convicts. Qualitative approach with focused-group discussions (weekly for 3 months) and face to face semi-structured interviews with 44 terrorist convicts in Jakarta in 2 prisons and outside prison (for ex-convicts). The participants were willing to discuss about their ideology with the facilitators even though they were hesitated at the beginning. The participants had very strong ideology and refused other ideologies and perspectives. The seniors had an important role in maintaining the ideology of the others. There is a strong phenomenon of group think. In one to one interviews, their opinions could be different. They seemed to have cognitive dissonance, so there was a possibility to change their attitude. However, the changes would happen at individual level and non ideological (strategic/tactical) issues only. The key word is critical thinking. Critical thinking makes it possible to argue against or for particular issue, regardless the person behind the issue. Critical thinking should and could be trained through systematic and structured dialogue.

Keywords: terrorism, critical thinking, cognitive dissonance, ideology, group think

Terrorism catastrophizing, perceived stress and death anxiety among university students of Pakistan

KAMAL, A. (National Institute of Psychology, Quaid-i-Azam University, Islamabad.), NAYAB, R. (National Institute of Psychology, Quaid-i-Azam University, Islamabad)

The purpose of the current study is to find the impact of terrorism among university students in terms of terrorism catastrophizing (TC), perceived stress (PS), and death anxiety (DA). The study, based on cross-sectional research design, consisted of 430 university students (male N=183, female N=247) from eight universities of Pakistan from Peshawar, Islamabad, Rawalpindi, Multan and Bahawalpur through purposive sampling technique. Terrorism Catastrophizing (TC) Scale (Sinclair & Alice, 2007), Perceived Stress (PS) Scale (Cohen et al., 2001) and Death Anxiety (DA) Scale (Goreja & Pervez, 2000) were used. Comparison was made among students regarding their gender, status of living, seen/affected by terrorist activity, religious inclination, and avoidance of crowded places, public transport & travel out of station due to terrorism. Pearson correlation showed a highly significant positive correlation between TC, PS & DA. Statistical analysis regarding gender has shown that both male and female students have higher level of TC & PS while females have more anxiety of death then males, whereas both hostel ides and day scholars have higher level of TC, PS & DA. Students who have seen or affected by terrorism, found to be more inclined towards religion, perceive high stress, more avoidant to visit crowded places and hesitant to travel out of station then students who have not seen or not affected by terrorist activity. Students who perceive high stress and death anxiety found to be avoidant of crowded places, public transport and travel out of station.

Keywords: terrorism, perceived stress, death anxiety, hostel ides, religion
The South African Personality Inventory

Chair(s): VAN DE VIJVER, Fons (Tilburg University)

The present study focuses on the development of a new personality inventory for South Africa (South African Personality Inventory, SAPI), locally derived from indigenous conceptions of personality in all 11 language groups. This project spans two stages: qualitative exploration and test development. In the first stage, data were collected by means of interviews in stratified samples from the 11 groups. The data were content-analyzed to derive the main personality dimensions as encoded in lay people’s perceptions. In the second stage, scales tapping these dimensions will be developed from the output of the first stage and psychometrically tested, again per language group. Importantly, both stages employ the native languages: the interviews were conducted in each group’s own language, and the final inventory will in each of the 11 language versions. This provides a valuable chance for emic expression and assessment of personality constructs. There are no a priori expectations whether culturally specific constructs would emerge or not; cultural differences either among the South African cultural groups or between them and Western groups are not hypothesized. Rather, the first stage of the project aims to explore indigenous perceptions of personality as comprehensively as possible. The final inventory might have a core common structure and specific constructs per group, or even have different structures in the different groups. The symposium has two parts. This first part describes the general background, item analysis procedure and two examples of studies of specific clusters.

The South African Personality Inventory: How far have we proceeded?

DE BRUIN, G. (University of Johannesburg)

The present study focuses on the development of a new personality inventory for South Africa (South African Personality Inventory, SAPI), locally derived from indigenous conceptions of personality in all 11 language groups. This project spans two stages: qualitative exploration and test development. In the first stage, data were collected by means of interviews in stratified samples from the 11 groups. The data were content-analyzed to derive the main personality dimensions as encoded in lay people’s perceptions. In the second stage, scales tapping these dimensions will be developed from the output of the first stage and psychometrically tested, again per language group. Importantly, both stages employ the native languages: the interviews were conducted in each group’s own language, and the final inventory will in each of the 11 language versions. In addition, this paper describes the analytic procedures used to evaluate and select items for inclusion in the SAPI. Qualitative analysis of the SAPI data revealed nine broad clusters of personality attributes. Each cluster corresponds with a higher order trait and is represented by several correlated first order factors, which in turn, is represented by correlated items. Analysis is aimed at developing homogenous personality scales and subscales that function equivalently across different language groups. In step 1 items that correlate poorly with its designated higher order trait score are eliminated. In step 2 items are subjected to common factor analysis with oblique rotation. In step 3 the correlations between the factors are subjected to a higher order factor analysis. The higher-order structure is then transformed to an orthogonal hierarchical solution with the Schmid-Leiman procedure, which shows the relations of the items with the higher order factors and the first order factors. This transformation allows for the evaluation of items with respect to the entire hierarchical organization of the trait domain. Separate analyses are obtained for English and indigenous African language groups. Higher order and first order factors are compared across language groups by means of coefficients of congruence to evaluate construct equivalence across groups. A combination of qualitative and quantitative approaches has been adopted. The qualitative studies are briefly described. The analytic procedure of the quantitative stage is
demonstrated with empirical data. The current state of this multi-year project is described.

South African personality inventory: openness, facilitating, relationship harmony, soft heartedness

DE BRUIN, K. (University of Johannesburg), MARAIS, C. (University of Johannesburg), NEL, A. (North-West University (Potchefstroom))

The objective of this part of the project is to use obtained data from the South African Personality Inventory (SAPI) research project to generate and test valid and reliable items for Openness, Facilitating, Relationship Harmony, and Soft Heartedness. The four separate studies employ a common methodology that is outlined. Results of each cluster are presented. In each analysis the same procedure is followed. Principal component analysis will be conducted to determine whether all the items derived from the qualitative study have a loading of at least 0.20 on the first unrotated component. The analysis is repeated for each sub-cluster and identified items that failed to have a loading of at least 0.30. Items that fail both criteria (i.e. relating to the overall construct and relating to the sub-cluster) are not included in further analyses. Principal axis factor analysis is conducted on the remaining items to determine the amount of factors. The solution will then be rotated according to the Direct Oblimin criterion. Correlations between the factors are subjected to a higher order analysis, requesting only one factor. The higher order solution is transformed to a Schmid-Leiman hierarchical solution. The output of the study will be a questionnaire to measure intellect in a culture-informed manner across many ethnic groups in South Africa.

Development of a first draft experimental South African Personality Inventory

MEIRING, (South African Police Services)

The paper report on the developed of a first draft experimental South African Personality Inventory (SAPI). The experimental inventory was conceptualized on the theoretical assumptions of a 9 cluster structure. A further aim of the paper was to explore and examine the underlying dimensionality of the structure by administering the inventory to a multicultural group. The qualitative phase of the SAPI project yielded a nine cluster structure (e.g., Extraversion, Soft-heartedness, Conscientiousness, Emotional Stability, Intellect, Openness, Integrity, Relationship harmony and Facilitating) and consisted of 37 sub clusters and 191 facets. The original 52,000 utterances formed the basis of developing an experimental item pool. Dimensionality will be tested by making use of first order hierarchical factor analysis. A second-order factor analysis will be performed on the correlations of the first-order factors, after which a Schmid-Leiman transformation will be applied to obtain a hierarchical orthogonal solution. The original 52,000 utterances of the qualitative phase were transformed into 2194 content-representative items. 4 Anchor items representing each of the 191 facets content domains the clearest were selected as a first step in the inventory design. In a second step the items were further split into two experimental inventories of 180 and 182 items each. The two experimental inventories will be administered to a sample group of police recruits (N = 1500) at the South African Police Force. The results of the dimensionality will show the relations of the items with the higher order factors and the first order factors, which allow for the evaluation of items with respect to the entire hierarchical organization of the SAPI 9 clusters structure. Factors results will be compared across groups by means of a coefficient of congruence (Tucker’s phi coefficient). Values > 0.95 will be taken to indicate factor equivalence, whereas values < 0.90 will indicate that the factors are sufficiently different to warrant close inspection of the differences. A comparison will also be made between the results of the two inventories. This paper will be the first study to report and to test the dimensionality of the 9 cluster structure as conceptualized in the first phase of the SAPI Project by means of a first draft experimental inventory.
The tactile consumer

Chair(s): JANSSON-BOYD, C. (Anglia Ruskin University)

It has been recognized that touch can make an important contribution to the way in which consumer stimuli are handled and perceived (e.g. Ernst & Banks, 2002; Jansson-Boyd & Marlow, 2007; Peck & Childers, 2003). Over the last decade we have learned quite a few things about the role that touch can play in consumer experiences. However, there are still many unanswered questions in regards to the importance of touch in consumer settings. We still do not have answers to questions such as: Does tactile interaction affect the evaluation of all types of consumer stimuli? What happens when people have no previous experience of the tactile input (as the case may be when new products are launched)? Are people with extensive product knowledge more likely to want to engage in tactile interaction? This symposium will focus upon the ‘role of touch’ in consumption and seek to address some previously unanswered questions about touch. It will bring together researchers in the field to discuss how touch plays an important part in consumer behaviors. The presenters will cover a multifaceted perspective of touch and consumption, meaning that attendees will get an overall rounded view of up to date research within the area. Specifically the audience will learn more about: (1) Whether consumers make use of tactile inputs in their evaluations of products that normally generate little tactile interaction; (2) If subjective and objective knowledge effect the motivation to touch a product prior to purchase; (3) How a ‘novel’ class of c-fibre peripheral nerve afferents exist in human hairy skin, whose discharge properties correlate with subjective ratings of a tactile stimulus. (4) Whether or not 3D virtual touch impact on consumer behavior in interactive marketing. This research symposium is particularly aimed at researchers with an interest in consumer psychological aspects. However, it should also be of interest to researchers that focuses on haptics in general.
Making touch count: When do consumers evaluate tactile product features

JANSSON-BOYD, C. (Anglia Ruskin University)

This research explores whether or not tactile evaluation takes place for stimuli that normally generate ‘limited’ tactile interaction. It has previously been suggested that consumers’ product evaluations are positively affected by tactile interaction. However, it is not known if it is applicable to products that people generally touch for brief periods of time, such as fast moving consumer goods. Tactile sensing and visual appreciation were compared with combined visual and tactile sensing of surface textures for two types of products (soap and biscuits). Three types of textures on the outside of either a soap or biscuit box and three sample swatches of the textures attached to the boxes were used in the study. Three soap or biscuit boxes were visually evaluated by the participants. This was followed by a blind haptic evaluation (meaning that participants could only feel but not see the stimuli) of the three textures, and then by a combined visual and tactile evaluation of the three differently textured boxes (either soap or biscuit boxes). The results show that people draw upon the tactile input when they evaluate products that normally generate ‘limited’ tactile interaction. Additionally, the results also demonstrate that the use of different types of surface textures have the capacity to change the way in which fast moving consumer products are perceived. This research furthers the understanding of how consumers use touch to determine overall likeability of products. The findings are of specific use for marketers and designers alike. From a marketing point-of-view it is important to consider when tactile interaction should be encouraged (depending on whether or not it is certain that the texture will be evaluated positively). Whilst designers should ensure that they are utilizing materials that are more likely to generate a favorable product perception.

Touch and prior knowledge: The more you know, the more you need to touch… Maybe

PECK, J. (University of Wisconsin-Madison)

This research examines consumer subjective and objective knowledge and its effect on the motivation to touch a product prior to purchase. Prior research has shown that product categories vary in whether they motivate a person to touch. Specifically if a product category varies in a diagnostic manner in weight, texture, softness or temperature, then motivation to touch the product will be high. We extend this and find that consumers with more objective knowledge about a product category are more motivated to touch, regardless of the category. However, greater subjective product category knowledge does not necessarily result in a greater motivation to touch. Two studies are discussed. The first is a laboratory experiment using undergraduate students. Both objective and subjective knowledge of a product category are measured, as well as the motivation to touch a product. Two product categories are used, one in which the motivation to touch is greater, and the other in which the salience of touch is less. To demonstrate external validity, the second study is a field study with participants being deer and turkey hunters in the state of Wisconsin. We measure objective and subjective knowledge as well as motivation to touch hunting related products (guns and bows) prior to purchase. The results show that greater knowledge of a product category does not necessarily increase an individual’s motivation to touch. More subjective product knowledge does not increase motivation to touch. However, greater objective knowledge does increase the motivation to touch. Great objective product knowledge results in individuals being aware that differences in touch attributes do exist within a category. This research expands our understanding of the sense of touch by investigating prior knowledge and its relationship to touch. This research has implications for the type of media selected by manufacturers and highlights the importance of retail and trade shows as compared to non-touch media, especially for individuals with greater objective product knowledge.

Coding of pleasant touch by unmyelinated afferents in humans

MCGLONE, F. (University of Liverpool)

The aim of this study is to characterize the functional properties of a class of unmyelinated peripheral nerve afferents (C-tactile) found in human ‘hairy’ skin, which are hypothesized to provide the neural substrate for coding the affective and affiliative (pleasant) aspects of touch. Using the single nerve fibre electrophysiological recording technique of microneurography, a population of c-fiber afferents have been identified whose preferred stimulus is a low velocity stroking movement across a recorded unit’s receptive field. A purpose built rotary tactile stimulator (RTS) was developed to deliver controlled moving tactile stimuli across a unit’s receptive field, during microneurography recordings. The spike discharges of both myelinated and unmyelinated unit’s were subsequently correlated with the mechanical stimulus properties of the stimulus. Psychophysical ratings of a participant’s response to the affective qualities of the stimulus were also recorded, using a visual analogue scale (VAS). Neuroimaging (fMRI) studies provided evidence for the central representation of affective touch. Electrophysiological, psychophysical and neuroimaging data combine to demonstrate that a ‘novel’ class of c-fibre peripheral nerve afferents exist in human hairy skin, whose discharge properties correlate with subjective ratings of the pleasantness of a tactile stimulus. Soft brush stroking on hairy skin was perceived as most pleasant when it was delivered at velocities that were most effective at activating C-tactile afferents (1 - 10 cm s⁻¹), with a linear correlation between C-tactile impulse frequency and subjective pleasantness ratings. In contrast, the response of myelinated afferents increased with faster velocities (30 cm s⁻¹), and showed no relationship with pleasantness ratings. fMRI data, recorded during stroking the arm with a soft brush, showed activation in the posterior insular and orbitofrontal cortices. C-tactile processing is tuned to slow, gentle tactile stimulation of hairy skin, of a type that occurs during close affiliative interactions with conspecifics such as the nurturing behaviours carried out between mothers and infants. Such tactile interaction may be distinct from sexual function as C-tactile receptors have not been found in genitalia. A system of C-tactile afferents, projecting to insular and orbitofrontal cortex, may thus constitute a privileged peripheral pathway for gentle, pleasant tactile stimulation of a social and affiliative nature.

The impact of 3D virtual touch in consumer psychology

JIN, S. A. (Boston College)

Tactile input plays a key role in consumers’ evaluation of products’ substance properties. This study investigated 3D virtual touch created by Novint Falcon haptics interfaces and its impacts on consumer behavior in the interactive marketing of automobiles. It was hypothesized that consumers’ instrumental Need for Touch (NFT) plays a significant moderating role in haptics interfaces. Novint Falcon is a haptic technology that interfaces with consumers through the sense of touch. It gives consumers a sense of touch with computer-generated environments, so that when virtual objects are touched through the haptics interface they seem real and tangible. The experiment employed a 2 (the nature of tactile stimuli: force feedback vs. no force feedback) X 2 (haptic orientation: high NFT vs. low NFT) full factorial between-subjects design. The results of the two-way ANOVA indicated a significant interaction effect between force feedback haptics stimuli and instrumental NFT on product evaluation (H1), $F(1, 229) = 4.60, p < .05, \eta^2 = .02$. The same pattern was found for enjoyment (H2), $F(1, 229) = 4.58, p < .05, \eta^2 = .02$. As hypothesized, consumers with high instrumental NFT experience a more positive product evaluation (H1) and enjoy the test-driving experience more (H2) when there are force feedback haptics stimuli and instrumental NFT on product evaluation. In contrast, consumers low in instrumental NFT experience a more positive product evaluation and higher enjoyment of test-driving when they are exposed to haptics stimuli without force feedback. The present study empirically reveals
that haptic stimuli with force feedback versus those without force feedback have different effects on consumers who differ in their instrumental NFT. The results are consistent with the theory that consumers high in NFT are more significantly influenced by a marketing message that incorporates stronger haptic stimuli (presence of force feedback in the current experiment) than weaker haptic stimuli (absence of force feedback), whereas consumers low in NFT are less affected by haptic stimuli. This individual difference factor in haptic information processing has theoretical significance as well as practical implications for marketing strategies.

The Tuning in to Kids parenting program: Outcomes with preschool, primary-school and pre-adolescent children

Chair(s): HAVIGHURST, S. (Mindful: Centre for Training and Research in Developmental Health, University of Melbourne)

This symposium will provide an overview of the Tuning in to Kids program and outcomes from three randomized controlled trials of the program. Tuning in to Kids teaches parents skills in responding to children’s emotions in ways that have been found to contribute to children’s emotional, social, and behavioural competence. Program content includes strategies to assist parents in regulating their own emotions as well as how to respond supportively to children in a way that promotes the development of emotional competence and reduces behaviour problems. We will present findings from three studies of the program: (1) an effectiveness trial with parents of preschool children; (2) an effectiveness trial with parents of primary school aged children with behaviour problems; and (3) an efficacy trial with parents of Grade six children. Learning objectives of this symposium include: understanding the contribution of parenting to children’s emotional development; understanding the theoretical underpinning of the Tuning in to Kids program; awareness of the Tuning in to Kids program content, including emotion coaching and emotion regulation strategies for parents and children; knowing how the program may be adapted for children of different ages/developmental stages; awareness of some of the practical issues encountered when delivering the program in different settings.

Tuning in to kids: Theory and program overview

HAVIGHURST, S. (Mindful: Centre for Training and Research in Developmental Health, University of Melbourne)
Emotional competence, or emotional intelligence, as it is commonly known, is central to healthy child development and is significantly affected by the role that parents and carers play in helping children to understand, regulate, and appropriately express emotions. Parental emotion coaching (i.e., supportive responses, verbally labelling emotions, using empathy, and teaching children to understand and regulate their emotions), has been found to be central to the development of children’s emotional competence. Parenting interventions have only recently started to address these causal links. The Tuning in to Kids program (Havighurst and Harley, 2007) aimed to target these emotion-focused aspects of parenting to improve emotional and behavioural outcomes for children. The mode of change involves parents attending to low/moderate intensity negative emotions and supporting, soothing, and helping the child to regulate the emotion so that when the emotional intensity lessens, the child can problem solve with support from the parent. Parents are also taught skills in becoming aware of and able to regulation their own emotions because parents’ emotional functioning affects the emotion climate of the home as well as offering pivotal models for children about how to express and manage emotions. This first presentation will explain the theoretical model behind the Tuning in to Kids program and give an overview of the program content.

Tuning in to Kids - A community effectiveness trial with a sample of preschool children and their parents

WILSON, K. (Mindful: Centre for Training and Research in Developmental Health, University of Melbourne)

The study aim was to evaluate the effectiveness of the Tuning in to Kids program (TIK) in a real-world setting, i.e. when delivered by staff from community agencies. We addressed two questions: (1) can real-world practitioners be successfully trained to deliver TIK with high fidelity (content and process)? And (2) Are there significant improvements in parenting and child outcomes for TIK program participants? Preschools in the City of Knox were randomised into intervention and waitlist conditions, plus four practice preschools. Parents of children in 4-year old programs in 2009 were invited to participate in a TIK program. Practice preschools offered the program in term 1 (4 groups, 37 parents), intervention preschools in terms 2 or 3 (5 groups, 62 parents) and waitlist preschools in term 4 (7 groups, 68 parents). Parents completed Time 1 questionnaire booklets in February/March for waitlist and pre-program for intervention. Preschool teachers completed questionnaires for 124 children. Time 2 data was collected seven months later. Parent questionnaire booklets included psychometrically validated measures of child behavioural and emotional functioning, parenting and parent wellbeing. Teachers completed the Social Competence and Behavior Evaluation in Children (SCBE-30). Post-program qualitative data was collected from intervention parents and practitioners. Forty professionals from the City of Knox and local agencies attended one of two 2-day TIK facilitator training workshops. Training focused on theoretical principles underlying TIK and practising emotion coaching skills. Practitioners demonstrating an acceptable understanding of theory, emotion coaching and group process skills willing to make the required commitment to study protocol were selected for the trial; 26 practitioners co-facilitated at least one TIK group. Practitioner reflection, self-report measures and checklists were used to assess content and process fidelity. Content fidelity was high and process fidelity generally satisfactory. Post-program qualitative data was positive. Preliminary findings will be presented. Positive program evaluation by participants indicates that the TIK program can have successful outcomes in “the real world”.

The effectiveness of Tuning in to Kids with primary school children with behaviour problems
HAVIGHURST, S. (Mindful: Centre for Training and Research in Developmental Health, University of Melbourne)

Tuning in to Kids is currently being evaluated in an effectiveness trial with primary school aged children with behaviour problems. The program is delivered by clinicians trained in the program as part of an early intervention service offered by the Child and Adolescent Mental Health Services (CAMHS) in partnership with Department of Education and Early Childhood Development and the Catholic Education Office schools. The CAMHS and Schools Early Action (CASEA) programs based at Austin and Bendigo Hospitals partnered with Mindful: Centre for Training and Research in Developmental Health at The University of Melbourne, to conduct this research trial. Schools in two locations, one a metro and one a regional/rural area, were randomly assigned into intervention or 12 month wait-list control conditions. All children in Prep to Grade 3 classes at the identified schools were screened for behaviour problems using a 7-item parent and teacher questionnaire. Those children scoring the highest 10-15% for behaviour problems were invited to participate in the early intervention program. The sample consisted of 93 intervention and 54 control children, their parents and teachers. The intervention included an eight week program for the child targeting social-emotional skills and an eight week Tuning in to Kids program for one of their parents. Teachers were also given assistance in how to manage children’s challenging behaviours. Assessment was conducted at pre, post, 6 and 12 months follow up for the intervention group, and twice, twelve months apart for the control group. Preliminary results will be presented examining differences between the intervention and control participants on parent reports of parenting and child emotional and behavioural functioning. Participant evaluations suggest parents find the program useful in helping their child to understand and manage their emotions, and that it offers an important complement to changes made by the child. Additional conclusions will be drawn about the program’s effectiveness in schools with children with behaviour problems.

KEHOE, C. (Mindful: Centre for Training and Research in Developmental Health, University of Melbourne)

Tuning in to Teens: Preliminary findings from a community efficacy trial with a sample of pre-adolescent children and their parents

Puberty has been associated with increases in mood variability, experience of negative emotionality and an increase in the intensity of negative emotions. The ability to recognize and effectively manage emotions during this time may be central for providing the protection and strengths to navigate the challenges of this period of development and protect adolescents from developing behavioural and emotional problems. Parents continue to be central in teaching young people these skills. Recent studies have found that emotion-focused aspects of parenting appear to be protective for adolescents during this period of development and may assist the young person to regulate and understand their emotions. This study investigated parent-child outcomes of a six-week group parenting program focused on promoting emotional competence in both parents and children. 110 schools from lower socioeconomic areas of the northern, western and eastern suburbs of Melbourne were randomised into either intervention (Tuning in to Teens Parenting Program), or control conditions (High School Transitions Questionnaire Study). 227 grade six students (aged 11-13 years; 126 intervention) and one of their parents/primary carers took part in the study. Of these, 126 intervention parents completed questionnaires at 3 time points, before and after the intervention and when their child was in Term 2 in their first year of secondary school. Control dyads completed the same questionnaire at the first and third time point. Preliminary results for pre-teen behavioural and emotional outcomes, parent emotion socialisation of their children, parent emotional wellbeing, and family functioning will be presented. Qualitative feedback from intervention parents showed parents found the program helped them improve emotional
communication in the family. Tuning in to Teens parenting program may offer an emotion-focused approach to strengthening parent-child connection and preventing behavioural and emotional difficulties during adolescence.

Therapist-assisted e-Interventions

Participants' involvement and personal gains in online support groups

BARAK, A. (University of Haifa, Israeli)

Much evidence exists to support the success of online support groups (OSG) in reaching their goals. These findings, however, show that many online support groups' participants go through change processes but quite a few of them do not. Moreover, some studies and research reviews showed the lack of impact of OSGs in causing significant change in participants. These inconsistencies raise a question on the actual effectiveness of OSGs in providing mental help to their participants. The current presentation argues that there are possible moderators that interact with participation in OSGs which contribute to the inconsistent findings. Specifically, it is argued that participants' level of involvement is a key moderator in causing personal change. In order to test this hypothesis four studies were conducted. In the first study, 20 participants in an OSG for adolescents in severe emotional distress were followed up through their forum postings. Positive correlations were found between number of messages posted by participants and their emotional relief and suicidal thoughts. In the second study, positive correlations were found between number of messages posted and number of responses received and ratings of relationships with parents by 41 adolescents who participated in an OSG for adolescents experiencing problematic relationships with their parents. In the third study, positive correlations were found between number of messages posted and number of responses received and ratings of interpersonal relationships in 44 adolescents who participated in an OSG for adolescents experiencing social isolation. In the fourth study, level of involvement was compared among a helped, an un-helped, and a neutral group of participants (n = 20 in each) who took part in various OSGs. It was found that the
helped group posted more main and response messages, wrote longer, and used more emoticons than the two other groups. It was thus concluded that participants who are more active, involved, and engaged in OSGs are those who gain more from participation.

**How frequency and form of therapist support impacts on the effectiveness, user experience and accessibility of online mental health interventions**

AUSTIN, D. (Swinburne University)

The aim of this study was to discuss findings from multiple randomised controlled trials and an open trial conducted by our research team on therapist-supported online interventions for panic disorder and post-traumatic stress disorder (PTSD). The results and conclusions from multiple trials have provided substantial evidence about the role of the therapist in improving the effectiveness, user experience and accessibility of online interventions. In our trials of therapist-supported online programs for panic disorder and PTSD, participants have reported a strong therapeutic alliance and a high level of satisfaction with the programs. A RCT found that an online intervention for panic disorder was just as effective in reducing panic severity and related psychological symptoms when participants received frequent emails (3 per week) as when they received infrequent emails (1 per week). Furthermore, the frequency of therapist contact made no difference to participants’ perception of treatment credibility, satisfaction and their alliance with their therapist. Another RCT found that online intervention for panic disorder supported by psychologist-delivered emails was just as effective in reducing panic severity and related symptoms as the same online intervention supported by General Practitioners seeing users for face-to-face therapy. We have also found CBT for panic disorder delivered online to produce comparable outcomes to face-to-face CBT delivered by clinical psychologists. In an RCT, participants receiving online CBT had equivalent reductions in panic severity and related symptoms as face-to-face CBT, and both types of delivery were rated equally credible and satisfying. Online interventions can be just as effectively accompanied by email-support from a psychologist as face-to-face support from a GP or psychologist. Further, online interventions can be successfully delivered with only 1 email contact per week from a therapist. Online-delivered CBT also compares favourably to face-to-face delivered CBT. Hence, online programs are a time and cost-efficient way to deliver best-practice mental health interventions and enable greater access to treatment than traditional delivery models.

**Keywords:** online interventions, panic disorder, post-traumatic stress disorder, cognitive behavioural therapy

**Do we need a therapist: Evidence from recent RCTs of Internet-based treatment of depression and anxiety disorders from the VirtualClinic**

TITOV, N. (University of New South Wales)

Depression and anxiety are common and disabling, yet only a minority of people with these conditions receive evidence based treatment. The emerging literature on Internet-based cognitive behavioural therapy (ICBT) programs indicate they can reduce barriers to accessing treatment, are associated with excellent and reliable clinical outcomes, and are acceptable to consumers. Dissemination of ICBT programs will be facilitated if their administration was less reliant on clinicians. Review of recent randomized controlled trials exploring the relative benefits of therapist vs. non-therapist ICBT for people with depression, generalized anxiety disorder, or social phobia, conducted at the VirtualClinic (www.virtualclinic.org.au). Participants who received non-therapist administered ICBT demonstrated adherence rates, obtained similar clinical outcomes, and reported the same levels of satisfaction as participants who received therapist-administered ICBT. The magnitude of clinical benefits is comparable to that obtained from good face to face treatment. Sophisticated ICBT programs can be successfully administered by non-therapists, under supervision by mental health professionals.
ICBT has the potential to increase the capacity of existing mental health services.

Keywords: depression, anxiety, Internet-based intervention

**Time perspective: Explorations across cultures, ages and health related behaviours**

Chair(s): MILFONT, T. (Victoria University of Wellington), FIEULAINÉ, N. (University of Lyon)

Discussant(s): VAN DE VIJVER, F. (Tilburg University)

Interaction with time is a fundamental characteristic of human experience, both objectively (defined by the clock) and subjectively (personal constructs of time). The relevance of the time perspective studies derives partly from the modern contradictory situation that has developed in many societies. From the global perspective, with the recent financial crisis in mind, we are witnessing drastic changes in the usual way of living and the collapse of modern economic relations that lead to changes in the relationship with time. Growing mobility of society as a whole also entails the possibility of change in temporal perspectives of the individual, as a result of changes in dynamics or by emergence of transitions from one pattern to another. Participants of the symposium are members of the International Research Network on Time Perspective and use a common tool in their research: the Zimbardo Time Perspective Inventory (ZTPI). Although several scales have been developed to measure time perspective, ZTPI seems to overcome most of the limitations of other measures by utilizing multi-item scales and by taking a multidimensional approach to time perspective (measuring five time frames: Past-Negative, Past-Positive, Present-Fatalistic, Present-Hedonistic, and Future). The aim of this symposium is to present new findings from research using the ZTPI across different cultural contexts and several research aims. The first presentation by Sircova A. will introduce a collaborative cross-cultural research project investigating the structural equivalence of the Zimbardo Time Perspective Inventory across 22 countries. Presentation two, by Fieulaine N. and Martinez F., will demonstrate the role of TP and desire of control in adolescents’ substance use in France. The third presentation by Chistopolskaya K. will address the important issue of suicidal
behavior and its prevention in Russia. The fourth presentation by Earl J. will discuss developmental dynamics of TP in the Australian context. In the last presentation, Leite U. and colleagues will report findings from research linking time perspective with paranormal beliefs and irrational thinking. These presentations capture the variety and innovative nature of current research using the ZTPI, they address issues of measurement equivalence and also a variety of contexts the construct of time perspective is applicable.

**ZTPI: Establishing equivalence across cultures**

SIRCOVA, A. (Umea University)

The aims of this research project are twofold: 1) to explore the intercultural variations in person’s time perspective and to ensure the comparability of research between countries; and 2) to establish equivalence of the available translations of the Zimbardo Time Perspective Inventory (ZTPI) and examine the specifics of an individual’s time perspective in different cultural settings. The research questions are addressed through the collection of data obtained in each country that has conducted a language and culture adaptation of the ZTPI. Participants of the existing international network were invited to submit their ZTPI data for a comparative study. This resulted in data from 22 countries (Europe and worldwide), with an overall sample of 10,975 participants. To compare the factor structures of all versions of the ZTPI, exploratory factor analysis with subsequent Procrustes (Targeted) rotation was performed. Exploratory factor analysis was performed upon the aggregated weighted correlation matrix. The original five-factor structure of the ZTPI was supported. Both identity and proportionality coefficients were above .95 for the majority of the countries, suggesting that the factor composition was similar, and with the differences in factor structures resulting from different inter-factor correlations. The obtained results support the hypothesis that the temporal orientations viewed as personality traits are common among studied cultural groups. The implications of these cross-cultural findings for promoting a more valid and reliable assessment of time perspective dimensions, as assessed by ZTPI, are discussed.

**Keywords:** intercultural variations, time perspective, Zimbardo Time Perspective Inventory, cultural settings, personality traits

**Time perspective and substance use in adolescents: The buffering effect of desire for control**

FIEULAINE, N. (University of Lyon)

While the predictive role of time perspective (TP) in substance use is well established, it remains to be seen how and when (or for whom) it occurs. In line with the framework of self-regulation theory, we examined how individual differences in desire for control moderated the relationship between TP and cannabis use. This study thus investigated the role of desire for control (DC) as a buffering factor in the impact of TP on cannabis use and evaluated the role played by this moderating effect in the predictive utility of the theory of planned behavior (TPB) as applied to cannabis use. Study was prospective in design, with DC, TP and TPB variables assessed at Time 1 and behavior measures taken 1 week later (Time 2). 690 high school students from an urban area in center France participated during normal class hours. DC was measured using Burger’s Desire of Control Scale, TP was measured using a short version of the Zimbardo’s Time Perspective Inventory (ZTPI) and cannabis use was self-reported using a multi-items measure. As expected, significant relations were found between TP and cannabis use. DC appeared to be only partially related to substance use. Interaction effects between TP and DC dimensions were predictive of cannabis use. Relation between TP and cannabis use appeared as buffered by DC in several ways. In relation with socioeconomic status (SES) indicators, results suggested how DC and TP interactions lead to vulnerability profiles, which can in turn act as pathways through which SES is related to substance use. Although this study confirms the utility of TP in predicting substance use, this relation appeared as conditioned by individual differences in DC. This last construct thus appears as worthy of interest in the analysis of substance use, and might help deepen
comprehension of the influence of TP over health behaviors. Moreover, results can be of use in improving health-promoting and risk-reducing interventions, and can be helpful in avoiding certain counterproductive effects linked to time-focused intervention. Implications for TP research and interventions designs will be discussed.

Keywords: time perspective, substance use, adolescents, desire for control, theory of planned behavior

Time perspective and attitudes to life and death of young people after recent suicidal attempt

CHISTOPOLSKAYA, K. (Moscow Research Institute of Psychiatry)

Different time perspectives correspond to different worldviews; some of them have been shown to be more strongly linked to well-being, and some – less. In this study we aimed to find out how these time perspectives are connected with attitudes toward life and death in young people after recent suicidal attempt. 32 people (age 18-25, 13 men, 19 women) after recent suicidal attempt (self-poisoning, 2-14 days) were asked to fill in the questionnaires: Zimbardo Time Perspective Inventory (ZTPI), Hardiness survey (Maddy), Death Attitude Profile-Revised (DAP-R; Wong, Reker, Gesser), Fear of Personal Death Scale (FPDS; Florian, Kravetz) and Depression Scale (Beck). Past Negative time perspective occurred to be positively correlated with attitude toward death characterized by Escape Acceptance (death as a relief from sufferings of life; DAP-R) and Depression, negatively correlated with fear of transcendental consequences of death (death as unknown; FPDS) and all dimensions of Hardiness Survey (Commitment, Control, Challenge, and Hardiness). Present Fatalistic time perspective was positively correlated with Approach Acceptance of death (belief in a happy afterlife), Escape Acceptance (DAP-R scales) and fear of forgetting (loss of social identity; FPDS), and negatively correlated with all dimensions of Hardiness Survey. Future time perspective was positively correlated with fears of consequences to personality (loss of abilities to think, feel, of wholeness of self) to aspirations (self-fulfillment), to body (body decomposition) and transcendental consequences of death (FPDS); there was some positive link to Control scale from Hardiness Survey as well. Past Positive time perspective has shown moderate positive correlations with Fear scale (DAP-R), as well as fear of transcendental consequences of death (FPDS) and all dimensions of hardiness, and negatively correlated with Neutral Acceptance of death (as a natural phenomenon; DAP-R). Present Hedonistic time perspective occurred to be irrelevant to these variables in this sample. Past Negative and Present Fatalistic time perspectives play major role in attitudes toward life and death in acute postsuicide, while Past Positive and Future time perspectives may be viewed as defensive factors. Further research is needed to specify these findings.

Keywords: suicidal attempt, time perspective, attitudes, depression, personality

Exploring changes in time perspective across age and time

EARL, J. (University of New South Wales)

Zimbardo and Boyd (1999) promote the existence of five different time perspectives (TP): Future, Present-Fatalistic, Present-Hedonistic, Past-Negative and Past-Positive. The five factor structure proposed has been confirmed across multiple studies in more than 20 countries. It is not entirely clear how time perspective varies across age or across time. For example, while the test re-test validity reported by Zimbardo and Boyd (1999) were significant (0.70 – 0.80) these were reviewed after only over a four-week period. Research examining developmental changes in TP has been largely limited to Future TP. It has been proposed that people project further into the future as they move from childhood to adulthood. Understanding these age differences across all TPs, not only Future TP, is important if we are to assume that TP is relatively stable within individuals and across time. This study reports the results of a shortened version of the ZTPI (a) across two cohorts: university students (N=347; Mean age =20.14, SD =4.72) and retirees (N=570; Mean age =64.91, SD =5.93) (b) across time (6
months) within the younger cohort (N=73). From the first study we concluded that the student and retiree cohorts exhibited the largest differences on Past Negative and Future Time Perspective scores, whereby the younger cohort reported significantly higher Past Negative and lower Future TP compared to the retirees. In addition, the younger cohort reported a higher Present Hedonistic TP compared to the retirees. In the second study exploring differences within the younger cohort over a 6 month period, we found significant differences on Past Negative, and Present Hedonistic scores such that Past Negative scores decreased over time while Present Hedonistic scores increased. No other differences were found on other TP scores across the 6 month period, suggesting that these remained relatively stable. Findings suggest that Past Negative and Present Hedonistic scores may be subject to greater variations across time than the remaining three time perspectives.

Keywords: time perspective, age differences, five factor structure, validity, childhood

Belief in the paranormal, irrational thinking and its association with time perspective

LEITE, U. (Rio Verde University)

Time perspective has an overwhelming influence on people’s lives and is an important psychological construct associated with various human aspects. On the other hand, paranormal beliefs and irrational thinking are held by the general population across different situations, and may lead to the development of maladaptive behaviors. Given the importance of time perspective, paranormal beliefs and irrational thinking, this study tries to understand their links. A total of 459 Brazilian participants took part in this study, with ages raging from 13 to 84 years (M = 20.57, SD = 14.93), and the majority being female (63.6%) and Catholic (65.8%). Participants completed the following measures: Belief in the Paranormal Questionnaire (Vasconcelos & Tróccoli, 2004), Irrational Beliefs Questionnaire (Yoshida & Colugnati, 2006) and a Brazilian-Portuguese validated version of the ZTPI (Leite & Pasquali, 2008; Milfont et al., 2008). Regarding the time perspective factors, the highest score was observed for Past-Positive (M=3.47, SD=0.55), followed by Future (M=3.37, SD=0.44), Past-Negative (M=3.27, SD=0.57), Present-Fatalistic (M=3.18, SD=0.59), and the lowest, Present-Hedonistic (M=3.17, SD=0.55). Three paranormal belief factors (paranormal beliefs, common superstitions and spiritual protection) were positively and significantly correlated to all five ZTPI factors, except for Future which was only significantly and negatively correlated to common superstitions. The forth paranormal belief factor (evil vs. good) had no significant correlations with time perspective. Irrational beliefs was positively correlated with all five ZTPI factors (but Past-Negative), and also to three paranormal belief factors (common superstitions, spiritual protection, and evil vs. good). Statistically significant gender differences were also observed, with women scoring higher than man on Past-Negative, Past-Positive, Present-Fatalistic, and common superstition. The results confirm the prediction that the constructs are correlated, such that superstitious individuals also tend to hold irrational beliefs. And, more importantly, beliefs in the paranormal and irrational thinking were associated with more negative aspects of time perspective: fatalistic and hedonistic-present and past negative.

Keywords: time perspective, paranormal beliefs, irrational thinking, maladaptive behaviors, gender differences
Treating behavioural sleep disorders in children. A psychological perspective

Chair(s): BLUNDEN, S. (University of South Australia)
Discussant(s): LUSHINGTON, K. (University of South Australia)

This seminar will provide a basis for understanding the common sleep problems in normal children and families and how to recognize them and management strategies. This is aimed at practicing psychologists who work with children and adolescents. This symposium will: (1) Briefly describe normal and abnormal sleep in children; (2) Describe assessment and treatment of behavioural sleep disorders in children; (3) Describe the neuropsychological effects of behavioural sleep disorders in a group of 30 South Australian children; (4) Present data on pre, primary and high school samples of children with sleep disorders; (5) Present evidence of behavioural sleep treatments in children for nighttime waking; (6) Psychological treatments for sleep disorders in children with special needs. The key learning objectives are to understand: (1) The effects of normal and abnormal sleep patterns in children sleep patterns in children; (2) Assessment and diagnosis of behavioural sleep disorders in children; (3) Psychological techniques utilized in the treatment of behavioural sleep disorders in infants, school ages children and adolescents and in children with special needs. Psychologists are often seeing children in whom sleep is a major component of presentation and in many circumstances a clear management strategy will make significant impacts on child and parent functioning.

The neuropsychological and psychosocial effects of behavioural sleep problems in school ages children

BLUNDEN, S. (University of South Australia)

It is clear that the 2-15% of children with sleep disordered breathing (Snorers) show significant daytime deficits in memory, attention, cognitive function and behaviour. We aimed to evaluate whether the 30-40% of children with behavioural sleep problems (BSP) which are amenable to psychological treatments, also show these deficits. Families awaiting consultation for “sick” visits in five general practice clinics completed the Sleep Disturbance Scale for Children. A subset of children were categorized into groups: Snorers \((n = 11)\), BSP \((n = 13)\), Snorers + BSP \((n = 9)\), and controls \((n = 31)\). Children underwent psychological (Wechsler Abbreviated Scale of Intelligence, Children’s Memory Scale; Test of Everyday Attention and Auditory Continuous Performance Test) and psychosocial assessment (Child Behavior Checklist). With analysis of variance, it was revealed that, compared with children in the BSP and control groups, those in the Snorers + BSP and Snorers groups showed reduced intelligence and attention scores. By contrast, compared with children in the Snorers and control groups, children in the Snorers + BSP and BSP groups reported reduced social competency, increased problematic behavior, and reduced memory scores. Children in the combination of Snorers + BSP group showed more deficits than children in all other groups. In children, snoring and BSP, separately and together, are associated with impaired neuropsychological and psychosocial functioning. Furthermore, each sleep disorder is related to performance in disparate ways. Snoring was associated with intelligence and attention deficits, whereas BSP was associated with memory and behavioral deficits. Psychologists should be aware that 30-40 % of children present with BSP, which is amenable to treatment using psychological techniques and behavior modification techniques that may reduce the impact on their daytime function.

The frequency of sleep problems in Australian adolescents and the impact on academic and daytime functioning

LUSHINGTON, K. (University of South Australia)
Notably, the senior school years are characterized by high levels of parental expectation, demanding study regimens, and desire for success, all of which may mitigate against good sleep habits. Given the extensive literature demonstrating that sleep is important for learning, mood regulation, and effective social interaction in adolescents, the temptation to trade sleep for study may be counterproductive. However, our knowledge about sleep, study and well-being in Australian students is limited. The aim of the present symposium is to describe sleep, mood and stress in Australian adolescents and, in addition, to discuss the assessment and treatment of common adolescent sleep problems including: Delayed sleep phase syndrome, Sleep onset anxiety, and Study stress and sleep. Participating schools were recruited through the South Australian Science Teacher Annual Meeting. To date we have enrolled 353 Year 11 and 12 students aged 16-22 years ($M = 269$ and $F = 84$) from six South Australian high schools. Students completed an omnibus questionnaire examining sleep behavior, sleep problems, mood, stress, coping, parental and child academic expectation, health, diet and activity. The results showed that only 25% of teenagers reported sufficient sleep on school nights [never 12.4/13.2 (male/female); rarely 32.2/30.0; sometimes 27.3/32.6; usually 22.3/22.0; and always 5.0/2.2%]. A relatively high number of teenagers also reported daytime sleepiness: with 3.2% falling asleep in conversation, 25% on a bus/train, 7% at the movies, 27% watching TV, 18% studying, 3% doing a test, 20% in class, 6% working on the computer, 5% playing video games and 20% reading a book. A relatively high percentage 16% went to sleep after 2am on school nights and 24% on weekend nights indicating delayed sleep patterns in a sizeable portion of children. This was significantly but modestly related to worse mood and increased stress (all $p < .05$).

It was concluded that there exists a sizeable number of adolescent who have less than optimal sleep with consequent effects on their daytime functioning. Greater attention to sleep hygiene and managing sleep and study would be of benefit to students, families and schools. The treatment options for managing adolescent sleep problems need to be made more widely disseminated and made accessible.

Keywords: sleep habits, adolescents, sleep problems, sleep hygiene, sleep onset anxiety

**Behavioural sleep problems in special populations of children**

HEUSSLER, H. (Mater Children's Hospital)

The aim of this study was to describe the psychological and family centered approach to a number of sleep problems in special populations of children including: ADHD, Autistic Disorders, Smith Magenis syndrome & other Developmental syndromes, and Cerebral Palsy. Pathophysiology and when to consider medical implications will be discussed. A description of typical problems found in each population will be presented from published literature and case reports. Current state of understanding will be presented. An approach to the child with developmental difficulty experiencing sleep difficulty will be explored. The rate of sleep disorders in these populations is between 30% and 85%. It is reported to contribute to added stress to families dealing with developmental and behavioural issues in these children. Each case report will present a particular issue and understanding of various special groups will be discussed (e.g. Smith Magenis syndrome and the relationships to complex clock mechanisms that impact on psychological and psychosocial functioning). Cases where early management needs additional medical orientation will be discussed. Complicated relationships often exist between medical frameworks and psychological implications. Early identification and management of sleep problems in these high risk populations can result in significant improvements in functioning in both child and family. A number of strategies have implications for specific disorders. A review of strategies for a number of special populations will be discussed.

Keywords: sleep problems, children, attention deficit hyperactivity disorder, autism spectrum disorder, sleep problems

**The Sleepy Preschooler – Impacts on sociability, empathy and behaviour**
MICHELL, B. (University of South Australia)

There is a large body of research that illustrates the impact of sleep on cognitive and affective functioning and negative behaviours including conduct disorder, aggressive behaviour and ADHD-like symptoms. Studies suggest that if sleep problems are addressed in this age cohort, negative behavioural outcomes problems improve. The trait of empathy, which utilises both affective and cognitive functions, has been linked to negative behaviours such as conduct disorder and aggressivity. This relationship may be mediated by sleep. This study therefore aims to investigate the link between sleep and the affective and cognitive components associated with empathy and sociability in preschool Australian children. Children, their parents, and their teachers from Child-Care Centres across Adelaide took part in this study (Children; n = 37). There were two phases of data collection. In Phase One, parents/caregivers and teachers completed questionnaires relating to the children and their behaviour and psycho-social functioning within their home and child-care environment respectively. Scales used included the Conner’s Rating Scale, the Emotionality, Activity, and Sociability Temperament Survey for Children – Teacher and Parent Rating (EAS—T/P), Bryant’s Index of Empathy for Children, Perspective-taking Subscale of the Interpersonal Reactivity Index (IRI), items from the Child Behaviour Checklist (CBCL), the Children’s Sleep Habits Questionnaire (CSHQ), the Sleep Related Breathing Disordered Scale – Paediatric Sleep Questionnaire, and the Young Children’s Empathy Measure. Phase Two involved actigraphy, wherein the children wore actigraphy watches to bed for 3-4 nights (n = 24). At the time of submission, analysis had not been concluded. However, the data will be considered using correlational methods initially to explore the relationship between sleep, behaviour, sociability and empathy. In addition sleep will be considered in terms of the validity of sleep diaries versus actigraphy. Between group analyses will be conducted to analyse the different effects variable lengths of sleep time have on empathy, behaviour and sociability. There are a range of psychosocial factors that influence child development and behaviour in preschoolers. Research is continuing to highlight the important role of sleep in ensuring optimal development. Given that this preschool age cohort considered in this study is on the trajectory to begin school very soon, the importance of adequate sleep cannot be underestimated in terms of ensuring a smooth transition to school, and enhanced developmental opportunities. The findings from this study will be able to provide insight into typical sleeping patterns in preschoolers, the impact of napping vs. not-napping, differences in age, sex and sleep, and the other variables including empathy and sociability.

Keywords: sleep problems, conduct disorder, empathy, sociability, preschool
Treating insomnia in adults – what do psychologists need to know?

Chair(s): RAJARATNAM, S. (Monash University)
Presenter(s): ARMSTRONG, S. (Epworth Sleep Centre)

Psychologists have a great deal to offer the community in terms of treating sleep disorders such as insomnia. It is well recognized that non-pharmacological techniques such as CBT are safe and effective yet they are under-utilised. This symposium will provide a basis for understanding the evidence-based approaches to treating sleep problems non-pharmacologically. It will also incorporate the perspective of a psychiatrist who specializes in sleeping disorders. This symposium is aimed at practising psychologists who work with adults presenting with dysfunctional sleeping patterns such as insomnia. This symposium will: (1) Give an overview of common sleep disorders and the psychological components of these disorders; (2) Describe the ways in which the psychologist can assess and treat sleep disorders in adults; (3) Outline the common co-morbidities in insomnia; (4) Present data on the efficacy of CBT for insomnia; (5) Describe how behavioural factors including conditioning can maintain insomnia; (6) Describe how cognitive processes can maintain insomnia; (7) Present data on the efficacy of cognitive therapy for insomnia; (8) Discuss the limitations of medication in treating sleep disturbance; (9) Discuss the important role awaiting psychologists in the multidisciplinary treatment of sleep disorders.

Sleep Disorders in Australia: a wake-up call for psychologists

ARMSTRONG, S. (Epworth Sleep Centre)

The aim of this study was to establish conclusively that sleep disorders are an important public-health problem in Australia as in other western countries and argue that psychologists should be taking a leading therapeutic role in their management. Instead, in Australia there is a dearth of interest and participation from psychologists. This speaker will give: (1) a brief classification of sleep disorders, then focus primarily on the insomnias; (2) an overview of prevalence, incidence, aetiology and risk factors; (3) an outline of the consequences, morbidities and co-morbidities associated with insomnia; (4) estimates of the public health burden; (5) evidence that the behavioural management of sleep disorders, particularly CBT have established efficacy. It will be highlighted that much more research is needed to standardize criteria for, and apply rigor to, such variables as diagnosis, severity, duration, effects and outcome measures. In Australia there is a need for a higher exposure to sleep and sleep disorders at all levels of tertiary training as well as in professional training for psychologists already in the workforce. To further this cause, the Australasian Sleep Association (ASA) in collaboration with the APS is preparing seminars and workshops for psychologists.

Keywords: sleep disorders, Insomnia, cognitive behavioural therapy, Australasian Sleep Association, health

CBT for insomnia and bright light therapy in a clinical population

LACK, L. (Flinders University)

In clinical research trials, cognitive/behavioural therapy has been shown to be effective for the treatment of chronic insomnia. We evaluated whether the effectiveness of these non-drug therapies could be translated from research to a typical clinical population of chronic insomnia sufferers. Over 300 consecutive referrals from GPs to the Insomnia Treatment Program administered by registered psychologists at the Adelaide Institute of Sleep Health were...
evaluated. Co-morbidities of moderate psychiatric symptoms, other sleep disorders, and present pharmacotherapy were not excluded. The Program involved a home sleep recording, sleep education group session, and a series of five individual sessions including follow-ups at five weeks and three months after initiation of therapy. Components of therapy included well-established behavioural therapies (stimulus control and bedtime restriction), cognitive therapy (inappropriate beliefs about sleep and sleep/wake perceptual misjudgments), and bright light therapy when the insomnia was caused by circadian rhythm mis-timing. The different components received different emphases depending on the type of insomnia and estimated strengths of contributing causes in each particular client. Outcome measures included estimates of time taken to fall asleep, time awake overnight, total sleep time derived from sleep diaries, and various subjective measures of daytime functioning and feeling. There were very significant improvements from pre-treatment to both five-week and three-month follow-up in all sleep and daytime functioning measures with moderate to large effect sizes. The presence of other co-morbid sleep disorders (e.g., Obstructive sleep apnoea) or elevated depression seemed not to impair the effectiveness of the treatment program for the sleep measures and, in the case of depression, showed reduced depressive symptoms. Chronic insomnia can be effectively treated in the typical clinical population by trained psychologists using a range of various non-drug therapies selected for their relevance in individual cases.

Keywords: sleep disorders, insomnia, cognitive behavioural therapy, comorbidity, sleep education

A description of a new Cognitive Therapy (CT) approach to understanding and treating chronic insomnia

REE, M. (Marian Centre)

There is no doubt that Cognitive Behaviour Therapy (CBT) for chronic insomnia is an effective treatment (Morin et al., 2006). There is, however, room for enhancement with the average overall improvement of 50–60% suggesting that only half of patients treated with CBT become good sleepers (Morin, Culbert, & Schwartz, 1994). The aim of this paper is to describe the development and initial evaluation of a new treatment approach that was derived from a cognitive model of insomnia (Harvey, 2002). The model suggests that chronic insomnia is maintained by five cognitive processes operating both at night and during the day: (1) worry and rumination, (2) monitoring for sleep-related threat, (3) unhelpful beliefs about sleep, (4) misperception of sleep and daytime deficits and (5) the use of safety behaviours that maintain unhelpful beliefs. The aim of cognitive therapy (CT) for insomnia is to reverse all five maintaining processes during both the night and the day. In an open trial 19 patients meeting diagnostic criteria for primary insomnia were treated with cognitive therapy for insomnia. Assessments were completed pre-treatment, post-treatment and at three-, six- and 12-month follow-up. All patients were in the normal or mild range on the key outcome measure at post-treatment, with the pre to post treatment effect size being 5.17. No patient met diagnostic criteria for insomnia at post treatment. The significant improvement in both night-time and daytime impairment evident at the post-treatment assessment was retained up to the 12 month follow-up. The results suggest that cognitive therapy for insomnia is acceptable to patients, improves sleep, and improves daytime functioning. Overall, the results were strongest on measures of daytime functioning and moderate for measures derived from the sleep diary. The change in process measures across treatment suggest that the processes that cognitive therapy for insomnia set out to reverse do indeed appear to have reversed. In summary, preliminary results are encouraging, however, cognitive therapy for insomnia awaits evaluation in a controlled trial.

Keywords: cognitive behavioural therapy, insomnia, sleep, sleep diary, cognitive therapy

The role of medication in treating insomnia and the importance of collaborative relationships between psychologists and other health professionals

REE, M. (Marian Centre)

There is no doubt that Cognitive Behaviour Therapy (CBT) for chronic insomnia is an effective treatment (Morin et al., 2006). There is, however, room for enhancement with the average overall improvement of 50–60% suggesting that only half of patients treated with CBT become good sleepers (Morin, Culbert, & Schwartz, 1994). The aim of this paper is to describe the development and initial evaluation of a new treatment approach that was derived from a cognitive model of insomnia (Harvey, 2002). The model suggests that chronic insomnia is maintained by five cognitive processes operating both at night and during the day: (1) worry and rumination, (2) monitoring for sleep-related threat, (3) unhelpful beliefs about sleep, (4) misperception of sleep and daytime deficits and (5) the use of safety behaviours that maintain unhelpful beliefs. The aim of cognitive therapy (CT) for insomnia is to reverse all five maintaining processes during both the night and the day. In an open trial 19 patients meeting diagnostic criteria for primary insomnia were treated with cognitive therapy for insomnia. Assessments were completed pre-treatment, post-treatment and at three-, six- and 12-month follow-up. All patients were in the normal or mild range on the key outcome measure at post-treatment, with the pre to post treatment effect size being 5.17. No patient met diagnostic criteria for insomnia at post treatment. The significant improvement in both night-time and daytime impairment evident at the post-treatment assessment was retained up to the 12 month follow-up. The results suggest that cognitive therapy for insomnia is acceptable to patients, improves sleep, and improves daytime functioning. Overall, the results were strongest on measures of daytime functioning and moderate for measures derived from the sleep diary. The change in process measures across treatment suggest that the processes that cognitive therapy for insomnia set out to reverse do indeed appear to have reversed. In summary, preliminary results are encouraging, however, cognitive therapy for insomnia awaits evaluation in a controlled trial.

The role of medication in treating insomnia and the importance of collaborative relationships between psychologists and other health professionals
GRAY, C. (Psychiatrist, Brisbane)

The aim of this presentation is twofold: (1) educate the audience about the indications, contraindications, efficacy, and risks of hypnotic use in managing insomnia; (2) inform the audience about the potential role of psychiatry in the assessment and management of insomnia presentations in clinical practice. Results and findings from the available literature, such as meta-analyses, will be presented, and the speaker will highlight points of difference between the role of psychology and psychiatry in insomnia management. Reference will be made to the significance of the 4th National Mental Health Plan and the regulatory environment for health professionals. In general terms it is recognized that hypnotic medication is effective for short-term use in insomnia but that risks associated with hypnotic use may outweigh the benefits. Psychiatry has a definite role in the assessment and management of insomnia, along with psychology and primary care. The speaker will refer to case studies to highlight pharmacological and non-pharmacological pros and cons. Whilst hypnotics are effective for insomnia their utility is not universal and they carry risks, thus most treatment guidelines recommend CBT as the first-line of treatment. Psychiatrists and psychologists should strive to work together in managing insomnia disorders, whilst at the same time including GP’s.

**Trends in test development and use in countries with emerging test practices**

Chair(s): ILIESCU, D. (SNSPA University Bucharest)

Discussant(s): OAKLAND, T. (College of Education, University of Florida)

Testing is possibly the most prominent contribution psychology has brought to the methodology of science. Tests are so severely packed into the methodological apparatus of psychologists that most psychological practice is inconceivable without tests. Still, tests are not evenly represented throughout the world and psychologists sometimes have to make do without tests, or without tests which would live up to professional and ethical standards. Testing, as represented in the scientific and professional community at this point of time, is a result of development efforts which are localized to a few developed countries. Most of the time, tests are then exported through a mere translation or through a more complex process of adaptation to other countries, populations and languages. Translations and adaptations are needed, as well as Indigenous development of measures. Different countries which registered a gap from this point of view have taken different approaches to test adaptation and indigenous test construction. The intention for the symposium is to bring together discussants who would share their insights and experiences about the status of psychological testing in countries which struggle with developing their practices and portfolio. Key learning objectives include the following: (1) To better understand the infrastructure that supports a coherent national approach to test adaptation and construction; (2) To better understand the cultural and professional situations where adaptation and indigenous construction would function differently; (3) To understand the impact of emerging technologies in testing upon different areas of the globe.
Test development and use in South-Eastern Europe

ILIESCU, D. (SNSPA University Bucharest)

Most countries in South-Eastern Europe have had a sad history of psychology during the communist regimes governing these countries from the 1940s to the 1990s; in some countries psychology was dismantled as an academic discipline. Major differences exist between this part of Europe and the Western part; these differences are not only quantitative (a smaller number of available measures) but also qualitative (testing practices, ethics etc.). Still, psychological testing advances in these countries are due to efforts from academic areas and from local test publishers. The study aims to evaluate the current status of testing and research on psychological assessment in countries from South-Eastern Europe. Countries involved in the study are Romania, Bulgaria, Ukraine, Hungary, Serbia, Croatia, and Slovenia. Semi-structured interviews were conducted with test publishers (n = ~10), academics (n = 15) and test users (n = 30) in these countries. A structured questionnaire was deployed online for data collection in the participating countries. A total of 400 respondents commented upon the development of test practices in their respective country. The data was integrated with the results of the Research run in the whole of Europe by the EFPA Standing Committee on Tests and Testing. The results of the study show the driving forces behind test development in the area of South-Eastern Europe, while also delineating possible threats. An interesting pattern of similarity between the participating countries has emerged, showing a preference for test adaptation and not for the development of indigenous measures, while the lack of professionalized users is one of the major threats to the further development of tests and testing in the respective societies.

Keywords: psychological assessment, South-Eastern Europe, test development, test adaptation

Developing an Indigenous personality test in the Rainbow Nation of South Africa

MEIRING, D. (University of Stellenbosch)

Most of the personality inventories employed in South Africa are imported from Western countries and usually administered in English. These measures show important limitations. The use of English-language instruments is problematic for participants with an insufficient mastery of English, especially for black groups. This study describes an approach to the development of culture-informed, psychometrically sound inventory. The study aims at the development of a new personality inventory for South Africa (South African Personality Inventory, SAPI), locally derived from Indigenous conceptions of personality in all 11 language groups. This project spans two stages: qualitative exploration and test development stage. Semi-structured interviews were conducted with 1,320 participants, equally distributed across the eleven language groups. A total of 52,000 person descriptive-terms were derived, which were prepared for analysis, categorized, and clustered towards 191 facets. In the second stage, a pool of scales tapping items, using a five-point Likert-type format was developed from the output of the first stage. Content analysis as method was used in evaluating the data of the first stage. The 191 total facets were clustered under 37 sub-clusters and nine overall clusters. These nine clusters were Extraversion, Soft-heartedness, Conscientiousness, Emotional stability, Intellect, Openness, Integrity, Relationship harmony, and Facilitating. Both a combination of classical test theory and item response theory were utilized in the test development stage of the SAPI project. There are no a priori expectations whether culturally specific facets would emerge or not; cultural differences either among the South African cultural groups or between them and Western groups are not hypothesized. Rather, the first stage of the project aims to explore Indigenous perceptions of personality as comprehensively as possible. The final inventory might have a core common structure and specific facets per group, or even have different structures in the different groups.

Keywords: Personality inventory, Indigenous, Test development, South African Personality Inventory, South Africa
The state of affairs of psychological testing in Japan  

DE CARVALHO FILHO, M. K. (Kyoto University)  

The aims of this talk are to critically evaluate the current status of Japanese testing and research on psychological assessment, to discuss some of the barriers to the dissemination of those tests inside the country and abroad, and to discuss what is being done in order to change the current state of affairs. Japan has a long history of Western-style assessment and has been among the first Asian societies to develop and test instruments using current psychological principles and analytic strategies. In the last few decades, Japanese psychological studies and psychological testing have evolved considerably and have developed features that are not present in those of Western countries. However, reality is that the great majority of the psychological tests used in the country is still imported and translated from the West, despite the efforts of many Japanese researches in developing original instruments in all different areas of psychology. Despite the great reliance on foreign instruments for testing, the growth of Psychology in Japan has witnessed not only an increase in the production of original tests for research purposes but also an increase in the research on the use of psychological assessment. Regardless of all the achievements and the improvement observed in Japanese psychological testing, very little of it seems to be acknowledged abroad. One of the barriers to the dissemination of these tests abroad is the language. The great majority of work done in Japan on psychological testing is written in the Japanese language. In order to incentive dissemination of Japanese psychological research and testing abroad, several measures are being implemented. For example, lately, public universities are giving special incentives for researchers and professors to engage in international collaboration and to disseminate their results in English rather than in the Japanese language. The development of psychological testing in Japan has enabled important questions to be asked about the validity of Western measures to assess the uniqueness of personality and psychological attributes of Japanese individuals. This talk also intends to discuss some of these questions.

Development of psychological tests in Nigeria  

MIVANYI, Y. (University of Lagos)  

Testing, in psychology, like any other subject areas in Nigeria, is heavily foreign based. Most tests used by psychologists are adapted and are not necessarily used for their originally specified purposes. A few universities have test centers. Motivational level scales (MISS), socio-economic test batteries, embedded figures tests and psycho-educational research production are limited to school environment, less for industrial staff competence. The research in question surveys all the federal, state and private universities to establish categorical stock or psychological tests in diverse use in Nigeria, if any. This study fits well in time with the re-orientation in Nigerian education roadmap which unifies tertiary education entrance tests, including polytechnics (technology) college of education, being primarily teacher-training based. Follow-ups would include zonal and instructional seminars for enlightenment.  

Keywords: testing, motivational level scales, socio-economic test batteries, psychological testing, Nigeria
Trust in organizations: A multi-level perspective

Chair(s): GILLESPIE, N. (University of Queensland)
Discussant(s): TAN, H. H. (Singapore Management University)

Trust is recognized as fundamental for effective leadership and organizational success. Research shows trust enhances creativity, communication and problem solving, fosters commitment and organizational citizenship behavior, and facilitates team and organizational performance (Dirks, 1999; Dirks and Ferrin, 2002; Mayer & Davis, 1999). Trust is understood to be a “meso” concept that integrates micro-level psychological processes and group dynamics with macro-level organizational and institutional forms (Rousseau, Sitkin, Burt & Camerer, 1998). Recent work identifies fundamental differences in trust processes at the organizational and interpersonal levels (Gillespie & Dietz, 2009). Yet little attention has been paid to the multi-level nature of trust. The aim of this symposium is to showcase emerging trust research at multiple organizational levels, to provide a forum to develop deep and rich insight into the nature and antecedents of trust across levels. Collectively, the papers examine trust in supervisor-subordinate dyads, newly-formed temporary teams, ongoing teams, and the organization. They employ a diversity of methods (e.g. quantitative and qualitative surveys, interviews, case analysis, conceptual work), and samples (e.g. US, Australia, Portugal, UK and 20 European countries), to examine a range of antecedents and moderators at the individual (e.g. propensity to trust, values, risk aversion, gender), dyadic (e.g. supervisor support), group (e.g. conflict, collective values, task interdependence, task complexity), and organizational levels (e.g. control systems, HR processes, senior management actions, training programs). The primary focus is on trust from the employee’s perspective. By drawing together researchers working at different levels of analysis, the symposium will address the following learning goals: (1) Develop a holistic understanding of the multi-level nature of organizational trust; (2) Debate and critically reflect on the antecedents of employees’ trust in their supervisors, teams and organization, and how these may differ across levels and referents; (3) Identify practical insights into the role employees, team leaders, management and HR professionals play in building and repairing trust. The Discussant, an eminent researcher who has published on trust at various levels, will draw out insights and implications of the papers in relation to the learning objectives, and identify future research to advance an integrated understanding of organizational trust.

Trust between supervisors and subordinates: Antecedents and interaction effects on performance

GONZALEZ-MORALES, G. G. (University of Delaware)

Although there is an extensive literature on the benefits of developing trust-based relationships between managers and subordinates for both organizational and individual outcomes, very few studies actually looked at the viewpoint of both parties simultaneously. Due to their position in the organization, supervisors affect not only how employees interpret the organization’s actions, but also their decision to reciprocate. Recently Brower, Lester, Korsgaard & Dineen (2009) found that trust in manager only presented a significant relationship on individual-directed organizational citizenship behaviors (OCBs) when manager’s trust in subordinate was high. However, they did not find such interaction effects for organization-directed OCBs, in-role performance and intentions to quit. The present study aims to bring further evidence on the factors promoting trust in supervisor and the impact of mutual trust for organizational outcomes by: a) examining the interaction effect of trust in supervisor and trust in subordinate on subordinates’ in-role and extra-role performance; and b) examining the interaction effect of organizational cynicism and perceived supervisor support (PSS) on trust in supervisor. We collected data from 346 employees and their supervisors, from a variety of organizational settings. Job types included clerical, customer service, education, among others. Organizational size
Abstracts of the 27th International Congress of Applied Psychology

671

Symposia included micro, small and medium enterprises (SMEs) and large organizations. All scales presented good reliabilities. Our results suggest that trust in supervisor has a positive relationship with both in-role and extra-role performance when trust in subordinate is high and a negative relationship when trust in subordinate is low. Additionally, we found that organizational cynicism presents a negative relationship with trust in supervisor when PSS is low, but not when PSS is high, suggesting that PSS buffers the negative relationship between organizational cynicism and trust in supervisor. These findings highlight the role played by supervisors for the employee-supervisor relationship: on the one hand, PSS buffers the negative relationship between organizational cynicism and trust in supervisor; on the other hand, supervisors' trust in subordinate influences the strength and direction of the relationship between trust in supervisor and performance. Implications for researchers and practitioners will be discussed.

Keywords: trust, support, subordinates, supervisors, organizational citizenship behaviors

Trust in temporary work groups

KOEHLER, T. (University of Melbourne)

Members of Temporary Work Groups (TWGs) work together for a restricted amount of time to perform a complex common task (Sundstrom, De Meuse, & Futrell, 1990). Team members often have not worked together before and might not work together again for a while after task completion. Although trust is likely to be just as important for climate and performance in such groups (Meyerson, Weick, & Kramer, 1996; Zaccaro, Ardison, & Orvis, 2004), the traditional experiential determinants of trust are unlikely to be present. Trust must instead develop swiftly and from alternative sources (Meyerson et al., 1996). Though “swift trust” can be strong, it is likely to be more brittle than trust that is allowed to develop more slowly based on many displays of trustworthy behavior. The purpose of the current paper is twofold: 1) To establish the determinants of trust in TWGs and 2) to examine the factors that allow the initial trust in TWGs to develop into a less fickle form of trust should the group remain together for a more extended period of time. Based on an extensive literature review and on interviews with leaders of TWGs in the United States Army, we developed a conceptual model of trust in TWGs identifying proximal and distal determinants, genesis over time, consequences, and situational and personal moderators. We considered whether trust in TWGs is qualitatively or quantitatively different from trust in more traditional groups. Dispositional variables of the trustor (e.g., propensity to trust or risk aversion), perceived trustee ability and benevolence, situational necessity for trust, task interdependence and task complexity/difficulty, role clarity, and mutual fate control were some of the proximal determinants of trust identified in the model. Distal determinants included information about previous training or employment, rank, and membership in professional organizations. Situational and personal moderators included previous experience with similar working conditions or the influence of early failures on trust building. Implications for team building, maintenance, and leadership for organizations from the suggested model include, but are not limited to, providing proxies for trust and installing systems of accountability. Further implications will be discussed at the conference.

Keywords: trust, temporary work groups, determinants of trust, teams, performance

The nexus between values, conflict and trust in teams

AYOKO, O. (University of Queensland)

Scholars acknowledge the importance of examining the link between conflict and trust (Ronson & Peterson, 2008). Yet, empirical evidence testing this link is understudied (Ayoko & Pekerti, 2008; Rispens, Greer & Jehn, 2007) while available studies are largely quantitative. In this paper, we build on the above research by qualitatively: 1) exploring values and conflict as antecedents of trust and, 2) investigating the role of team members’ demography on the relationship between conflict and trust. We conducted 45 semi-structured interviews with team leaders and members in eight teams across two
organizations in Australia. Organization A is a small company involved in software development while Organization B is a large company involved in customer services, sales marketing and technical support. Interviews were audio-recorded and transcribed. Data were analyzed using NVivo software. Our qualitative data revealed some interesting results. First, participants indicated that individuals’ personal values shape team values supporting the notion that values held at various levels of the organization are vertically linked (Roe & Ester, 1999). Secondly, our results showed that the effect of conflict on trust depends on the type of conflict, the team environment, the way the conflict is managed and the extent of congruity in employees’ values. Specifically, respondents were of the view that cognitive rather than affective conflict has a positive impact on trust, while a climate of openness and transparency facilitates effective conflict management, which in turn, increases trust. Likewise, team members with similar values were more likely to trust each other. Finally and in terms of the role of employees’ demography on the interplay between conflict and trust, our data showed that males (more than females) viewed conflict as beneficial to trust because conflict provides an opportunity to express views and clarify issues. Overall, our results suggest that individual values impact team values while team environment, conflict management, value congruity and gender moderate the connection between conflict and trust.

Control as a driver of trust in the organization

DEN HARTOG, D. (University of Amsterdam)

During the last decade, a range of events have eroded both internal and external stakeholders’ trust in companies. The current financial industry crisis and a number of scandals in firms have led to a call for an increase in regulations, and internal control systems from the government and the public. However, we know little about how these control systems affect employees’ trust in the company. Do such systems enhance employees’ trust in the company or do such control systems erode trust? In the well developed literature on interpersonal trust that addresses trust between specific individuals, control is often proposed to have a negative relationship with trust, as controlling and monitoring behaviour signals distrust and enhances social distance (e.g. Lewicki, Mcallister, & Bies, 1998; Sitkin & Roth, 1993). However, the role of control systems for trust in firms and other institutions is likely to differ from interpersonal trust because of the different types of power dynamics and vulnerabilities involved. We propose that control systems enhance trust at the organizational level as controls shift the power dynamics and vulnerability in favor of the employee. We applied a mixed-methods design. The relationship of control and trust was analyzed based on survey data of 787 employees of European firms. In parallel, we conducted a qualitative study of 62 additional employees to further analyze and understand the relationship between control systems and employee’s trust in their company. Our quantitative analysis shows that output control, procedure control and sanctions are positively related to perceptions of organizational trustworthiness. The qualitative analysis demonstrates firstly that control is mentioned spontaneously and positively in regard to trust in the company. Secondly respondents relate control to trust in the company in two ways: a) the absence of control is seen negatively to promote a system of double standards and particularism; and b) the presence of control is seen as a signal of an organizations’ benevolence and integrity. Overall, our results suggest that at the organizational level, control contributes positively to perceptions of trustworthiness. The implications for theory and practice are discussed.

Keywords: trust, financial industry crisis, employees, interpersonal trust, control systems

Repairing Trust in Organizations: A case study of the BBC

DIETZ, G. (Durham University)
Recent organizational failures have shaken stakeholders’ trust of societal institutions (Edelman Trust Barometer, 2009). When an organization fails, the collapse in employees’ trust can damage its capacity to function. Organizations need to work swiftly to repair trust. Yet the emerging literature on trust repair has focused almost exclusively at the dyadic level, and it is difficult to translate the prescriptions to the organizational level. Gillespie and Dietz (2009) recently proposed a systemic, multi-level framework for restoring organizational trust. This paper uses their four stage model and repair principles to analyse a recent case study of successful trust repair at the British Broadcasting Corporation (BBC). The BBC's integrity and commitment to excellent broadcasting is fundamental to its culture and brand. Yet, in July 2007, senior managers learned of a series of incidents during live phone-in competitions involving deliberate lying to the audience. The affected programs included children’s programs and charity telethons. The ensuing public outcry led to huge fines and sanctions, and a massive internal trust repair effort. Using a retrospective case study method, we corroborate across primary and secondary data sources (e.g. all-staff internal emails, press releases, media interviews with key executives, internal investigation reports, and external news articles) to present a narrative of the failure, before analyzing the sequence and type of trust repair interventions, and their impact on BBC employees’ perceptions of the organization’s trustworthiness. Analysis revealed an extensive set of repair strategies including public acknowledgements of the failure, apologies by senior BBC representatives; internal and external diagnostic reviews (including investigation of millions of hours of broadcast); a mandatory training program on "Safeguarding Trust" for all staff, and new editorial guidelines. The reformative actions encompassed both ‘distrust regulation’ and ‘trustworthiness demonstration’ interventions, and the congruence principle. The BBC’s trust repair efforts closely matched the Gillespie and Dietz (2009) framework, directly supporting several of the propositions. However, in seeking to restore the confidence of external stakeholders, the BBC introduced restrictive editorial guidelines, antagonizing employees and potentially inhibiting their ability to perform their roles well. The implications for theory, applied psychological and management practice are discussed.

Understanding and buffering the consequences of social inequality: Asian and pacific perspectives

Chair(s): BERNARDO, A. (De La Salle University)
Discussant(s): YAMAGUCHI, S. (University of Tokyo)

Various indexes of social development refer to the development and wellbeing of individual members of society and to just and secure relationships among the diverse groups within society. In many Asian Pacific societies, there are social inequalities that impact on the attainment of these social development goals. The four papers in the symposium describe attempts to understand how social inequalities relate to developmental and social psychological processes in different ways. Ismail et al’s paper focuses on an important social development goal in Malaysia – the cognitive development of children – and explores how poverty or economic strain may indirectly impede child cognitive development through its impact on maternal stress among three ethnic groups in Malaysia. Bernardo’s study show how preference for conflict resolution procedures is influenced by social position within the hierarchical relationships between rich and poor in the Philippines; the rich more strongly prefer procedures that would allow them to exert their social dominance, whereas the poor more strongly prefer impartial procedures that would minimize the impact of social dominance. Hur’s paper describes how the effects of educational development programs aimed to help the poor on South Korean students’ emotion and learning vary depending on parenting styles. The paper focuses on a indigenous emotional concept (Han) to raises issues on related to the efficacy of educational programs directed towards assisting the poor. Kashima and Meegan’s paper assumes the negative effects of discrimination on well-being and examines how perceive group vitality enhances group self-esteem in the context of discrimination in Australia, thus indicating a way by which the negative effects of inequality may be buffered by discriminated groups. The four studies that use various theoretical lenses and methodological approaches used in psychology all underscore how social inequalities within the societies in focus complicate societal development processes by showing its influence on social and developmental psychological processes. The final paper points to possible psychological qualities that may attenuate the negative effects of social inequality.

The relationship between poverty and maternal stress on child cognitive development

ISMAIL, R. (University of Malaysia Sabah), KHALID, N. M. (University of Malaysia Sabah), BAHARI, F. (University of Malaysia Sabah)

To determine the relationship between poverty and maternal stress on child cognitive development in a Malaysian sample. Participants were 212 mothers from low income families. The mothers come from three different ethnic groups: Bajau, Malay-Brunei, and Kadazan. All mothers had at least one child younger than 36 months who was free from any chronic disease. The mothers were surveyed using the three instruments (a) Bayley Scales of Infant Development II (BSID-II), (b) Economic Strain Questionnaire (ESQ), and (c) Parenting Stress Index (PSI). Significant relationships were found between economic strain, maternal stress and child cognitive development. Mother’s personal characteristics, such as level of education and monthly income of the family, were also significantly related with economic strain and maternal stress. Significant differences were also found in economic strain and maternal stress among the ethnic groups. There were also gender differences in aspect of mental development of the children by gender, and ethnic group differences on the aspect of behaviour development. The results indicate the impact of poverty or economic strain on maternal stress and child cognitive development, and how social factors like mother’s education, gender, and ethnicity relates is related to these variables. Some implications for planning social development programs are discussed.
Conflict resolution amidst social inequality: Socioeconomic differences in preferred resolution procedures in the Philippines

BERNARDO, A. B. I. (De La Salle University)

A significant amount of research has demonstrated how societies have a tendency to form and maintain group-based hierarchies partly because of psychological tendencies for group prejudice, discriminatory behaviors, social roles and other social cognitive processes combine to maintain the inequalities and hierarchies between the groups. This tendency was studied among high- and low-socioeconomic status (SES) persons in the Philippines in relation to their preferences regarding conflict resolution procedures. It was hypothesized that compared to low SES persons, high SES persons would have a stronger preference for procedures that would allow them to exert their social dominance (bargaining & mediation) and weaker preference for impartial procedures that might attenuate their dominance (adjudication). 114 low-SES and 80 high-SES participants were presented hypothetical traffic-altercation scenarios where the SES of the driver and the pedestrian victim was manipulated in a 2 x 2 design. Participants were told to imagine they were the driver in the scenario and to rate and choose among four conflict resolution procedures: bargaining, mediation, inquisitorial or adversarial adjudication. They were also asked to explain their choices. As hypothesized high-SES participants preferred bargaining more strongly, and preferred the two forms of adjudication much less compared to low-SES participants. There were no group differences in preference for mediation; however, a significant interaction effect showed that high-SES participants rated mediation more favorably when the contending parties were of unequal SES, whereas the low-SES participants rated mediation more favorable when the parties were of equal SES. The results are discussed in terms of how various socially sanctioned forms of conflict resolution may be perceived by and opted for differently by Filipinos based on their status in relations the dominant SES group in Philippine society.

Is a high desire for education always beneficial? Bad education decisions of low social class parents

HUR, T. (Korea University), ZHANG, W. (Korea University), CHOI, S. (Korea University)

Education has been known to be one of the most effective and desirable ways to move from lower to higher social class in developing and even developed countries. So, in many countries including Korea, the governments and societies have tried to provide better and more opportunities for education to lower social classes. At the same time, almost all parents give priorities to their children’s education over every other important aspects of their life. Even though with the good nature of high motivation for education, the motivation can and is also causing many negative phenomena, such as excessive expenditure for education at both social and individual levels, loss of diversity in career, etc. The psychological explanations of the negative outcome of the good motivation until now, however, remain rather speculative. The present study examined the various qualitatively various roots of high motivation for education and their impacts on parents’ educational decision and behaviors. A survey with elementary, middle, and high school students and their parents has investigated the parents’ own psychological experience of ‘Han’, regret, and learning effect in their own education and the impacts on their parenting styles. People reported to experience ‘Han’, a Korean indigenous emotion, when people had deprivation of education-opportunities, regret when they were given but did not utilize education-opportunities, and leaning effect when they experienced directly or indirectly successful utilization of education-opportunities. The results revealed that parents’ negative emotions such as Han and regret were related with negative parenting styles, but the learning effects were related with positive parenting styles. Specifically, people who had experienced Han and regret...
highly in their own education chose inefficient decisions for their children, and consequently their children reported more sufferings. Such results suggest that the extraordinary education motivation could be either beneficial or dysfunctional depending on its origins. The findings were discussed in terms of implications for how educational efforts for disadvantaged social classes could be truly beneficial.

### The narrative of group vitality and its well-being benefits in the context of group-based discrimination

KASHIMA, E. (La Trobe University), MEEGAN, C. (La Trobe University)

Accumulated evidence suggests that being a target of discrimination imperils the individual’s physical and psychological well-being. Recent social psychological research has highlighted the importance of group identification in coping with discrimination. For instance, according to the rejection-identification model, perceiving that discrimination against in-group is pervasive enhances group identification which in turn provides ingroup members with well-being benefits. Support for this model has been mixed, however, which may be due partly to the narrow conceptualization of group identification as self-group association. We propose a new concept of perceived group vitality, a narrative dimension of group identity conveying a set of associated beliefs that “despite our current low status and discrimination against our group, we as a group are making progresses and there will be no discrimination against our group in the future”. We tested the well-being benefits of perceived group vitality and self-group association. In three studies, members of groups who are associated with discrimination in some contexts, namely lesbian women, women generally, and international students, were primed with a notion that discrimination against their group was either infrequent or pervasive. Perceived group vitality was measured by a questionnaire or manipulated with a written passage. Group identification was measured. Three well-being measures, depressed affect, personal and collective self-esteem, were also measured. We found preliminary evidence to suggest that perceived group vitality not only correlates negatively with depressed affect and positively with collective self-esteem, but it also moderates the negative impact of perceived discrimination. Furthermore, the buffering effects of perceived group vitality were independent from effects of group identification and were more consistent. The well-being benefits of perceived group vitality supports the contention that the meanings people attach to the continuing experience of their ingroup can shape their psychological well-being at the face of adversity.

**Keywords:** discrimination, well-being, group identification, coping, rejection-identification model
Understanding the influence of contextual factors on pro-environmental behaviour and resident well-being

Chair(s): GIFFORD, R. (University of Victoria)
Discussant(s): RAYMOND, C. (University of South Australia)

Recent studies suggest that a shift in basic human values and environmental concerns has been occurring across Western society, which may play a role in increasing support for environmental policies and programs. Whilst significant research attention has been paid to the basic structure and content of human values and environmental concerns, new theories and measurement techniques are needed to better understand the range of contextual factors which influence pro-environmental behaviour and well-being at the place-specific and neighborhood scales. The key objective of this symposium is to examine new constructs and measurement techniques for understanding how context/setting influences pro-environmental behaviour and residential well-being. The symposium is guided by the question: What contextual factors should be considered in environmental policy and decision-making and how should they be measured? Presentations will be delivered around the concepts of place attachment, neighborhood condition and quality of life. Place attachment refers to the positive cognitive and affective bonds which develop between an individual and a place, neighborhood condition refers to the different parts of the local environment which affect human health, and quality of life refers to individual satisfaction with the residential environment (e.g., freedom, privacy). The symposium will then consider how the concept of ‘regulatory fit’ influences environmental protection. After the four presentations, we will discuss future directions for these areas of research, and how each area may influence support for environmental policies and programs in Western society. Additionally, we will identify how these areas of research could inform the Millennium Assessment of Human Behaviour, as proposed by Paul Ehrlich.

The influence of human values and place attachment on the conservation of native vegetation

RAYMOND, C. (University of South Australia)

Australia has one of the highest extinction rates of native animal species in the world, which can partly be attributed to the extensive clearing of native vegetation on agricultural land. Little research or policy attention has been devoted to the contextual drivers of native vegetation conservation behaviour. In response, the aim of this study is to examine the relationships among human values, place attachment and native vegetation conservation behaviour in rural South Australia. It is hypothesized that those landholders who hold biospheric value orientations are more attached to place and are more likely to conserve native vegetation on private land. A postal survey was designed to measure human values, place attachments, environmental concerns, behavioural intentions and enduring native vegetation conservation behaviour. The survey was administered to 1,500 landholders in both the Eyre Peninsula and South Australian Murray-Darling Basin regions of South Australia using a modified Total Design Method. Rural landholders were firstly segmented into biospheric, altruistic or egoistic value orientations. Multiple regression analyses and structural equation modelling were then performed to test the relationships among value orientations, place attachments and vegetation conservation behaviour. Preliminary results indicate significant positive relationships among landholder value orientations, place attachments and enduring native vegetation conservation behaviour on private land. The role of place attachment in the design and delivery of policy instruments for the protection and restoration of native vegetation will be outlined. The implications of the results for the value-belief-norm theory will also be discussed.

Keywords: native vegetation, conservation behaviour, attachment, agricultural, values
Urban environmental stress: What do neighbourhood conditions do to residents and what do residents do to neighbourhood conditions?

HONOLD, J. (Humboldt Universitaet zu Berlin, Institute of Psychology - Cognitive Psychology)

Empirical evidence shows that urban environmental conditions such as air pollution, noise, population density or climatic factors may have impacts on the physical and psychological health of city dwellers. Among the few published studies addressing such effects on mental well-being, most have only investigated exposure to a single stressor. However, as suggested by literature on environmental stress, it is hypothesized that the accumulation of multiple ambient stressors is a key aspect of mental health consequences on a neighbourhood level. A geographical information system provided by an urban ecology research programme in Berlin was used to select socially and structurally comparable study sites with varying levels of critical environmental conditions (low vs. high). These environmental factors (traffic noise, air pollution, bioclimatic conditions and availability of public green space) had been determined by an online survey completed by 780 Berlin residents. A household questionnaire survey \((n = 420)\) was conducted among residents of these sites and combined with more objective stress measures and qualitative interviews from a sub-sample. It is hypothesized that residents from neighbourhoods with a high level of critical conditions differ from residents living in low-level areas with respect to their mental well-being, their housing and life satisfaction. It is also investigated if perceived stressor and annoyance levels, individual coping styles and situational factors mediated, respectively moderated this relationship. In addition, psycho-physiological stress indicators are contrasted with self-rated well-being. Interview data provide information about action tendencies such as pro-environmental behaviour and neighbourhood participation. Health risks will be estimated from the main results. By linking quantitative outcome measures with qualitative interview data, possible feedback loops on objective environmental conditions will be investigated. Interventions for education and sustainable city planning and development will be proposed.

Keywords: urban environments, environmental stress, pro-environmental behaviour, sustainable city planning, mental well-being

Quality of life in residential environments

PERLAVICIUTE, G. (University of Groningen)

A Quality of life (QoL) measure will be tested as an alternative instrument for assessing residential well-being. The applicability of the QoL measure will be tested with two questionnaire studies. In the first study, combined measures of importance and satisfaction allow distinguishing QoL aspects vital for satisfaction with residential environment (e.g. freedom, privacy), and identifying ‘hot’ residential issues in the neighborhoods of Groningen (The Netherlands) – namely important, but poorly satisfied QoL aspects (e.g. environmental quality, nature/biodiversity). In the second study, the effects of participation in residential decision making and surrounding nature on residential well-being are studied. Applicability of a multi-dimensional QoL measure to analyse residential well-being is tested. Importance and satisfaction scores for each QoL aspect are combined to discover the most important predictors of residential well-being and to identify the directions for urgent housing interventions in Groningen. It is analyzed in depth how participation in residential decision making is related with the well-being of residents. With regard to surrounding nature, people’s preferences for anthropocentric versus ecocentric greenery are studied. Advantages of applying a multi-faceted QoL measure in future environmental research are outlined. Implications and recommendations for policy-makers, builders, housing associations and developers are discussed to promote QoL of residents.

Keywords: quality of life, residential well-being, residential environment, decision making, environmental research
A tale of tailoring: Does regulatory fit increase messages persuasiveness?

LUCAS, S. (University of Groningen)

Marketing literature suggests that information is more persuasive when tailored to an individual’s motivational orientation. For example, positively framed messages are more persuasive for promotion-focused people, while prevention-focused people are particularly persuaded by negatively framed messages; this principle is called regulatory fit. In our study, we examined whether regulatory fit enhances the effects of environmental messages. We argue that curtailment behaviour (e.g. reducing showering time) is conceptually linked to prevention goals, and thus should fit the motivational orientation of prevention-focused people, while efficiency behaviour (e.g. purchase of energy-efficient equipment) is linked to promotion goals, and thus should fit the motivational orientation of promotion-focused people. Thus, we hypothesized that regulatory fit between message content (efficiency vs. curtailment behaviour) and motivational orientation (promotion vs. prevention, respectively) increases persuasion. Additionally, we expected that regulatory fit results in more positive attitudes and behaviour in line with the message. We assessed the motivational orientation (prevention vs. promotion) of 203 first year students of the University of Victoria. Next, participants read a message on the preferred strategy (curtailment vs. efficiency) to combat climate change of a local, on-campus, ‘green’ organization. We measured the persuasiveness of the organization’s message, attitudes towards the organization, and willingness to help the organization. An ANOVA showed that regulatory fit increased message persuasiveness; participants rated the message as more persuasive when the organization’s preferred strategy (efficiency or curtailment) fit participants’ motivational orientation (promotion or prevention, respectively). The effects on attitudes were marginally significant, while no significant effects on willingness to help the organization were found.
Unpacking relationships: Contexts, processes and outcomes

Chair(s): KARANTZAS, G. (Deakin University)
Discussant(s): WILKINSON, R. (CSIRO ICT Centre)

In this symposium we bring together four diverse papers that examine relationships from the perspectives of children, young and middle-aged adults, and present data using both the individual and dyad as the unit of analysis. The first paper by McGregor and Zimmer-Gembeck investigates how divorce, children’s perceptions of parental conflict and the parent-child relationship predict children’s optimistic and pessimistic relationship expectations. In the second paper, Webster and Fitness draw on an Emotion Focused Therapy approach in developing a measure of emotional signatures that can assist therapists in helping trauma survivors deal with relationship issues. In the third paper, Karantzas et al. propose and test a model of relationship functioning that includes key distal and proximal relationship factors known to influence relationship satisfaction. In the final paper, Cole and Karantzas, demonstrate how attachment style is linked to arthritis sufferers’ coping tendencies and psychological adjustment. Three of the papers place varying degrees of emphasis on attachment style, highlighting the powerful insights that can be gained into relationships from an attachment theory perspective. While all the papers highlight the inherent complexity of relationships, they also illustrate how life events and relationship histories influence the development of the individual and shape relationship outcomes.

Divorce and family relationships as correlates of children’s optimism and pessimism about their relationships

MCGREGOR, L. (Griffith University), ZIMMER-GEMBECK, M. (Griffith University)

Few studies have investigated whether children’s familial relationship experiences and perceptions influence the degree to which they hold optimistic and pessimistic expectations about familial and non-familial relationships. Therefore, the aim of this study was to investigate whether divorce, children’s perceptions of parental conflict and children’s perceptions regarding the parent-child relationship were associated with optimistic and pessimistic relationship expectations. A total of 837 children (9 to 13 years) from four Australian schools completed child-specific measures of familial and non-familial relationship expectations, perceptions regarding parenting practices and parental conflict. Information regarding family structure (i.e., divorced or intact) was provided by the parents of the participating children. A series of regression models revealed that the parenting dimensions of maternal warmth and paternal autonomy support were significant predictors of optimistic non-familial relationship expectations, while maternal rejection was the only parenting dimension that predicted pessimistic non-familial relationship expectations. The parenting dimensions of maternal warmth, structure, autonomy support, and paternal rejection and coercion were all significant predictors of familial relationship expectations. Furthermore, children from divorced families had less optimistic family expectations than children from intact families. In closing, while family structure, and maternal and paternal parenting contributed to children’s relationship expectations, children’s perceptions of maternal warmth was the most robust predictor of optimistic familial and non-familial relationship expectations. Consequently, it is particularly important that mothers foster warm and loving relationship with their children to ensure that children maintain positive expectations regarding their relationships. Furthermore, the findings highlight that fathers who provide sensitive and responsive support to their children that fosters autonomy, also bolsters children’s optimistic relationship expectations. These findings are important in understanding how children view relationships and can guide the development of programs aimed at enhancing positive parenting practices and cultivating
healthy relationship attitudes and beliefs in children.

Keywords: optimism, pessimistic expectations, relationships, parental conflict, parent-child relationship

Abandonment, annihilation, and attachment: The development of a psychological scale for identifying clients’ emotional signatures.

WEBSTER, M. (Macquarie University), FITNESS, J. (Macquarie University)

It has been widely reported that individuals who experience either childhood and/or adult trauma display dysfunctional behaviours in relationships. In particular, the way individuals behave in response to their emotions, and their ways of relating to others, derive in part, from the kinds of traumas they have suffered. These clusters of behaviours are referred to as emotional signatures. However, to date, there exists no measure of emotional signatures which can be used by therapists in deciding on how best to assist trauma sufferers in dealing with relationship issues. Therefore, using an Emotion Focused Therapy (EFT) approach, the aim of the study was to develop a self-report measure of emotional signatures. Prior to the development of the self-report measure or emotional signatures, a large set of items pertaining to the two primary dimensions of trauma (abandonment and annihilation) were reviewed by senior trainers in EFT to identify the items that best captured the two trauma dimensions. This review process resulted in the development of the Emotional Signatures Scale (ESS), a 70-item self-report measure comprising the trauma domains of abandonment and annihilation. The ESS along with a childhood trauma questionnaire and a relationship attachment questionnaire were then administered to 62 participants (M = 48 years) comprising of students and therapists. Factor analysis of the ESS revealed two, highly reliable factors totaling 50 items. The first factor comprised 24 items describing thoughts, feelings and behaviours associated with abandonment, while the second factor comprised 26 items describing thoughts, feelings and behaviours associated with annihilation. Both factors were positively associated with items from the Childhood Trauma Questionnaire. Furthermore, both ESS dimensions were significantly negatively associated with secure attachment and significantly positively associated with anxious attachment. The results of regression analyses, however, showed that although anxious attachment was a strong predictor of abandonment, annihilation was more strongly predicted by experiences of childhood abuse. Overall the results suggest that abandoned/neglected clients demonstrate relationship attitudes and behaviours characteristic of attachment anxiety, but that annihilated clients do not demonstrate any characteristic associated with attachment insecurity. Recommendations for further research on the ESS are discussed.

Keywords: trauma, dysfunctional behaviours, relationships, emotional signatures, Emotion focused therapy

The development of an integrative model of relationship functioning

KARANTZAS, G. (Deakin University), FEENEY, J. (University of Queensland), MCCABE, M. (Deakin University), GONCALVES, C. (Deakin University)

Industrialized western nations are currently experiencing high rates of relationship breakdown and divorce (Australian Bureau of Statistics, 2007; Bramlett & Mosher, 2002). Given the negative outcomes that accompany the dissolution of couple relationships, it is important to develop models that articulate the processes involved in maintaining healthy relationships, a call recently endorsed by Perlman and Duck (2006). Nevertheless, while research into expert and lay theories of relationships consistently demonstrate relationship functioning is multi-faceted in nature, few studies have attempted to develop integrative models to explain how relationship factors (i.e., attachment style, trust, intimacy, communication, partner support and relationship satisfaction) are associated and result in relationship outcomes. Therefore, the aim of this study was to develop an integrative model of relationship functioning. Data were collected from 75 cohabiting and married couples (M = 39.30 years) with a mean relationship duration of 15.04 years. All
participants completed questionnaire booklets that included self-report measures of attachment style, provisions of partner support, trust, intimacy, destructive conflict-centered communication and relationship satisfaction. The questionnaire took approximately 40 minutes to complete. A multi-group Actor Partner Interdependence Model revealed that the hypothesised model of relationship functioning was supported. Specifically, attachment style was associated with partner support and trust, while trust and the provision of partner support were associated with intimacy and destructive conflict-centred communication. In turn, intimacy was associated with relationship satisfaction. No gender differences were found across actor paths. However, analysis of partner effects revealed that men’s provision of partner support influenced women’s use of destructive conflict-centred communication. Furthermore, men’s use of destructive conflict-centred communication was negatively associated with women’s relationship satisfaction. In contrast, women’s attachment insecurity was negatively associated with men’s trust and provision of partner support. The integrative model of relationship functioning captures some of the most important relationship dynamics inherent in couple functioning. While no gender differences were found across actor paths, the partner effects highlight differences in relationship processes for men and women. Therefore, this model can inform relationship practitioners on how to best assist couples maintain fulfilling and satisfying relationships.

Keywords: relationship breakdown, divorce, relationship functioning, communication, relationship satisfaction

Coping and chronic illness: An attachment theory perspective

COLE, S. (Deakin University)

The relationship between coping strategies and the mental health outcomes of chronic illness sufferers is regarded as complex with studies reporting inconsistent findings. For instance, while some studies report that emotion-focused coping strategies lead to maladjustment and problem-focused coping strategies buffer against maladjustment, other studies report the opposite trends. Furthermore, health professionals seem unclear as to the intra-individual factors that influence chronic illness sufferers coping tendencies. More recently, researchers have argued that that these inconsistencies may be explained by attachment theory a theory of human bonding and, affect and distress regulation. Therefore, this research aimed to examine the differences in coping strategies employed by adults with a chronic illness from an attachment theory perspective. A total of 109 adults (19 males, 90 females) aged 18 to 55 years ($M = 32.2$ years, $SD = 10.7$ years) with a diagnosis of arthritis or arthritic-related illness participated in an online questionnaire which included measures of arthritis severity, attachment style, coping style and psychological adjustment. Using path analysis, arthritis severity was found to be positively associated with attachment, emotion-focused strategies associated with heightening distress (termed hyperactivating strategies), emotion-focused strategies associated with suppressing distress (termed deactivating strategies) and psychological adjustment. Furthermore, attachment was found to be significantly associated with coping and psychological adjustment. Specifically, attachment anxiety was associated with hyperactivating coping strategies and psychological adjustment, while attachment avoidance was associated with deactivating coping strategies. Finally, hyperactivating and deactivating coping strategies were associated with psychological adjustment. In contrast, constructive coping strategies (the use of problem-focused coping and support seeking) were not associated with psychological adjustment. The findings indicate that psychological adjustment to arthritis is associated with arthritis severity and the use of hyperactivation and deactivation emotion-focused coping strategies. Furthermore, the use of these coping strategies is associated with attachment insecurity and arthritis severity. The findings highlight the importance for therapists to consider an individual’s attachment style alongside their coping strategies in assisting a person to deal with a chronic illness such as arthritis.
Upholding a clean and green image: Environmental psychology in Aotearoa/New Zealand

Chair(s): MILFONT, T. (Victoria University of Wellington)

Clean and green, and 100% pure. This is the way New Zealand markets itself to the international community, and the country is famous worldwide for this image. Indeed, the clean and green image is ingrained in people’s views about the country. Research from the Ministry for the Environment has shown, for example, that consumers from three key export sectors (dairy products, tourism, and organic foods) from six different countries (Australia, Japan, Korea, Malaysia, the UK and US) would purchase substantially less if the environment of New Zealand was perceived as being degraded. Upholding a clean and green image thus has economic, social and environmental implications for the country. On the other hand, commentators and researchers have argued that this clean and green image does not correspond to the reality. In 2003 the ecological footprint for New Zealand was the sixth largest per capita among the OECD country members, and the per capita ecological footprint was also the sixth largest in 2005 for all nations with a population greater than 1 million. This symposium presents psychological research addressing environmental issues in New Zealand. A small (but growing) number of researchers are working in the environmental psychology field in the country. Showcasing environmental psychology research conducted in New Zealand to an international audience is the secondary objective of the symposium. Three papers will focus on specific environmental issues, including the role of emotion on transport mode, the role of identity on sustainable food consumption, and climate change beliefs. Two methodological papers will present the use of single-case research designs and action research for interventions designed to alter environmentally important behaviours. Despite the diverse...
approaches and areas of emphasis, the presentations are inter-linked by a common goal to use psychological research to address environmental issues. All presentations are from a single country, but researchers come from four different institutions within New Zealand and three of the presenters are originally from other countries (Brazil, New Zealand, and The Netherlands). Attendees will have the opportunity to learn about both environmental psychology research conducted in New Zealand, and the use of psychological research to tackle environmental issues.

The role emotion plays in the choice of commuting by bike

WOO, T. (University of Canterbury), HELTON, W. (University of Canterbury), RUSSELL, P. (University of Canterbury)

We investigated the relationships between affect regarding cycling, the actual choice of commuting by bicycle, and support for pro-cycling policies. The present study was part of a larger ongoing study at the University of Canterbury in Christchurch New Zealand to determine the role of affect and attitudinal beliefs for personal transport choice. In the present study, 35 women and 18 men were asked to complete a questionnaire. This questionnaire consisted of a measure of bicycle affect, an attitudinal survey of the social, environment, and personal harm caused by automobile usage, a set of items assessing the extent of support for pro-cycling governmental policy, a set of items assessing cycle use, and some demographic items. Measured affect regarding cycling did not significantly correlate with support for pro-cycling policies; attitudinal beliefs about the personal and social harms of automobile use did correlate with support for pro-cycling policies. Attitude and affect did not appear to interact in regard to policy support. There was, however, a significant interaction between affect regarding cycling and participant gender when predicting actual amount of time spent using a bicycle. Positive affect towards cycling significantly related to riding time for men, $r = .56$, but not women, $r = .03$. This presents an intriguing result as women expressed greater support for pro-cycling policies and rated higher on the harm due to automobiles questionnaire, whereas, men actually spent more time commuting by bicycle. While this is only a preliminary investigation in a larger ongoing project, the present findings indicate that the relationship between affect, attitude, and bicycle commuting is complicated by gender differences. As in previous studies, the men in our study generally expressed less pro-environmental beliefs and policy support than the women. However, those men with positive affective feeling towards biking did report riding more frequently than men without positive feelings. This was not the case with women. Marketing bike commuting may need to be considered in light of gender differences. For some users, a lofty pro-environmental message may not be as critical as expressing the directly experienced thrills associated with the activity.

Keywords: emotions, cycling, transport, attitudes, gender differences

Single-case research designs: Tools for 21stC environmental psychology

BLAMPIED, N. (University of Canterbury)

To illustrate from past and current research in environmental psychology the utility of a range of single-case research designs for evaluating interventions designed to alter environmentally consequential behaviours for individuals and groups, and to introduce an innovation in which single-case design principles can be applied to group interventions. The paper will explain the key methodologies of single-case designs, notably time-series single-case data, the use of baseline logic to identify experimental effects, visual analysis of experimental effects, and the use of replication to justify causal claims. Recent innovations extending these designs to group situations will be described. These employ scatter-plots for visual analysis of experimental effects, where data falling above or below the diagonal (zero change) line indicate intervention effects. Effect-size and other quantitative target information can also effectively be displayed. The paper will illustrate the successful use of single-case designs such as reversal and multiple-baseline designs as they have been applied in
environmental intervention research, and demonstrate these innovations for the analysis of group interventions. Single-case research designs are a useful tool to evaluate interventions designed to alter environmentally important behaviours both for single-case situations and where groups of individuals participate in the intervention.

Keywords: environmental psychology, single-case research designs, environmentally friendly behaviour, group intervention

Action research to promote a “sustainability culture” at a high school

HARRÉ, N. (University of Auckland), BLYTHE, C. (University of Auckland)

The New Zealand Enviroschools experience has suggested it is harder to make sustainability progress at high schools than primary schools. The aim of this project was to promote a “sustainability culture” at one high school in Auckland, New Zealand. This was an action research project in which a university team worked alongside the school’s student environment leaders. We had five working principles derived from community psychology. First we worked with the strengths of the school, primarily the student leader team and the school’s reputation in the visual and performing arts; second we attempted to empower the young people, so they took ownership of the project and learnt about the process of creating sustainability; third we role-modelled sustainability practices; fourth we measured our progress and provided tailored feedback to the school; and finally we placed high priority on communication. The student leaders chose to focus on the creation of new waste stations that would allow better waste management and be a visual symbol of the school’s commitment to sustainability. The events included: a photography and mapping workshop showing the waste situation at the school, waste and litter audits, a competition to paint murals for the new waste stations, an eco-day to teach students about waste separation, and a film to demonstrate use of the new waste stations. The researchers took notes at all meetings and events, and conducted interviews with the members of the school community before and after the project. All events were successful, being well attended and producing high quality artist outputs. The interviews also suggested the student leaders were empowered by the project and an emerging sustainability culture was evident from the post-project interviews with students and staff. The impact of the project on waste production and littering will be measured in early 2010. By working with a school’s strengths, role-modelling sustainability practices and measuring and communicating findings, considerable progress can be made towards encouraging a sustainability culture at a high school.

Encouraging sustainable food consumption: the role of identity

ABRAHAMSE, W. (University of Otago)

There is an increased awareness of issues related to our daily food consumption. Meat consumption in particular has been linked to various environmental issues (e.g. climate change), as well as health risks (e.g. coronary disease). Tailored information is emerging as a fruitful approach to encourage consumers to adopt healthier and more environmentally friendly lifestyles. However, much less attention has been devoted to examining why such tailored approaches are effective. The paper aims to address this issue by examining the effectiveness of tailored versus non-tailored information about meat consumption and the role of identity. A questionnaire study was conducted (N = 262), using a 2x2 between-subjects design. Respondents either read a message about meat consumption that matched their identity as a meat eater, or that did not match their identity. Subsequently, respondents were asked to evaluate the information in terms of its persuasiveness, and they were asked about their attitude towards eating meat. The results indicate that attitude towards eating meat were most strongly related to identity, in that respondents who more strongly identified with being a meat eater also expressed more favourable attitudes towards eating meat. Health identity was
positively related to attitudes towards eating meat too. Additionally, respondents tended to evaluate information that matched certain characteristics of their self-concept (identification with being a meat eater) as more positively than when it was not matched. The results suggest that the identity concept plays an important role in the evaluation of information about meat consumption. Policy implications of these findings are discussed.

A national, longitudinal study of climate change beliefs in New Zealand

MILFONT, T. (Victoria University of Wellington)

Discussion of issues related to global warming and climate change are increasingly frequent in public discourse. A Gallup survey in the early 90s showed that the majority of lay persons in four of six nations rated “global warming’ or the ‘greenhouse’ effect” as a very serious problem. A 2007 public opinion survey from Yale University also showed that 71% of the American public is convinced that global warming is happening. However, to our knowledge, no previous study has used a longitudinal design to examine people’s beliefs and attitudes toward these issues. The objective of this longitudinal project was to understand New Zealanders’ attitudes toward global warming and climate change. A nationally-representative list of 3,000 potential participants was randomly selected from the electoral roll, and a questionnaire packet was posted to participants. Wave I had a total of 581 valid questionnaires and was posted in June 2008. A second questionnaire was sent to Wave I participants about six months later (November 2008), and a total of 377 valid questionnaires were returned in this Wave II. The final questionnaire was posted one year after the first questionnaire (June 2009) and a total of 355 valid questionnaires were returned in Wave III. Participants were asked to indicate whether they agree with several statements, and consistent findings emerged across time. More than 60% of the participants believe that humans are responsible for global warming and climate change, and that their actions have an influence on these issues. However, less than half believe that their actions to reduce the effects of global warming and climate change in their community could encourage others to reduce these effects through their own actions. Participants were also asked to indicate the trustworthiness of information on global warming and climate change provided by different media and groups. The most trusted groups were scientists, university academics and environmental groups, and the least trusted group was government agencies. Understanding possible consistency in people’s beliefs about global warming and climate change has implications for climate change communication and for actions tackling denial and judgmental discounting. These implications will be discussed.

What comes before leadership?
The role of motivation and career supportive leadership

Chair(s): KOREK, S. (University Leipzig), STIEHL, S. (University of Siegen)
Discussant(s): FELFE, J. (Helmut-Schmidt-University)

One important issue in leadership research is the investigation of personal and organizational preconditions which foster the striving for of a leadership position in the first place. This symposium will shed light on leadership motivation as a personal factor and on career supportive leadership behaviour as an organizational condition. In particular, the first two speeches give special attention to women’s underrepresentation in high-hierarchy leadership positions. They investigate leadership motivation and the assumed gender differences in it, which have usually been used as an explanation for women’s underrepresentation. The first contribution presents results of a qualitative research study in which 50 leaders were asked about their motivation to lead (MTL) and about appeals of leadership positions. Results showed concern for others and the organizational progress to be the most important appeal. No gender differences were shown in the self-reported motivation to lead. The second contribution presents the construction of a gender-sensitive instrument to assess leadership motivation. Two studies with a total of 1080 students and employees reveal the expected 3-factor structure (affective, calculative and social-normative) and – as expected – no gender differences. The third presentation focuses on research on personality and the motivation to lead, showing that a facet approach to measuring the Big Five yielded improved and more specific patterns of the relationships between the Big Five and the 3 factors of the motivation to lead construct. The final contribution will turn to an organizational factor: the assessment of leadership behaviours that are supportive to career advancement. They developed and tested an instrument with facets like delegation or trust which showed substantial relationships with career-relevant outcomes. In conclusion, this symposium expands research on motivational and organizational conditions for leadership and career development and reveals that gender, personality and leadership behaviours are promising research fields. Furthermore, knowledge of motivational and personal preconditions or supportive leadership behaviour can be valuable to organizations to improve their leadership development.

The development of motivation to lead. An interview study.

STIEHL, S. (Helmut-Schmidt-University), GATZKA, M. (Helmut-Schmidt-University), ELPRANA, G. (Helmut-Schmidt-University), FELFE, J. (Helmut-Schmidt-University)

Women’s underrepresentation in leadership positions is being discussed at large, but little research has addressed motivational differences in men and women striving for leadership. Prior to the construction of a new, gender sensitive instrument to measure motivation to lead (MTL) an interview study was conducted to test the plausibility of the following assumptions: (a) MTL is relevant in order to attain leadership positions (b) Male and female managers are equally motivated to take over leadership (c) Early indicators for MTL can be found in most leaders’ biographies. (d) The power motive plays an important role in developing MTL. (e) We further explored which appeals of leadership positions are most relevant to managers. The semi-structured interview consisted of open questions (e.g. “Looking back in your history, would you say that you have always liked to be a leader?”) and ratings on 5-point-likert-scales The one-hour-interview was conducted with 29 men and 21 women in different leadership positions and branches throughout Germany. It was found that: (a) as expected, the majority of the managers (71%) found MTL to be important for attaining leadership; (b) Both male and female managers reported to have a rather strong MTL, confirming the relevance of a new, gender sensitive MTL measure, which contrasts the fact that the managers themselves believed in midsized motivational differences between men and women.; (c) biographical results are not entirely consistent, but many
leaders’ biographies do show proof of early indicators for MTL, such as having shown steady commitment in sports clubs or church, however, others have realized their own potential rather late; (d) nearly all managers denied that exerting power over others was relevant to them, when asked explicitly, though they did insinuate a definite relevance for managers in general; (e) the majority of the managers further explained that taking over responsibility, a pronounced concern for others, as well as for the company's progress are the most relevant appeals of a leadership position. The results of the present study mirror the need for a new, gender sensitive measure for MTL, which should take into account biographical indicators as well as the appeals of leading positions. To detect hidden motives, e.g. power, a projective approach should be considered.

**Keywords:** women's underrepresentation, leadership, motivation, gender differences, power

Are women motivated to lead? Measuring motivation to lead from a gender perspective

ELPRANA, G. (Helmut-Schmidt-University), STIEHL, S. (Helmut-Schmidt-University), GATZKA, M. (Helmut-Schmidt-University), FELFE, J. (Helmut-Schmidt-University)

Women are underrepresented in leadership positions. Above all, in the past, social context reasons and gender typed socialization were used to explain the underrepresentation. Little attention has been given to motivational gender differences. So far, there seems to be some empirical evidence that women's MTL is in fact not as pronounced. However, these results are based on measures which were not designed to be gender sensitive. Therefore a new measure of MTL following a multimodal approach, including self-report, biographical, and situational items (5-point-likert-scales) was developed. The instrument includes leadership experience in the past, personal significance of the appeals of leading positions, occupational goal setting, self-rated competencies, and the 3 basic motives (power, affiliation, achievement). All constructs were based on the 3-dimensional conception of an affective, a non-calculative, and a social-normative factor extending the instrument of Chan and Drasgow (2001). The items were partially based on results of an interview study, undertaken with 49 male and female managers throughout Germany. For the first time, leadership motivation is also assessed from a projective angle, involving the evaluation of photography. In order to examine the psychometric properties and the validity of the new instrument two studies were conducted with a total of 1080 high school and university students, majoring in economics, social sciences and natural sciences, as well as employees from different branches and organizational levels. As expected, we confirmed the 3-dimensional factor structure of MTL, including an affective, a calculative, and a social-normative factor. Internal consistencies were medium to high. In contrast to previous measures, descriptive analyses showed equal means for both sexes, proving the gender sensitivity of the new MTL instrument. Practical implications of this instrument lie in the identification of one’s own potential MTL which is likely to influence vocational choices. Differences in MTL between men and women in certain companies or branches can be analyzed in more detail. Risk and facilitating factors can be identified to improve equal job opportunities.

**Keywords:** women’s underrepresentation, leadership positions, motivations, gender differences, occupational goal setting

Towards better understanding of personality and the motivation to lead: A facet-level study

CHAN, K. (Nanyang Technological University), CHERNYSHENKO, O. (Nanyang Technological University), HO, R. (Nanyang Technological University)

The aim is to report the findings of an empirical study conducted to examine the relationships between facets of the Big Five personality factors and the motivation to lead (MTL; Chan & Drasgow, 2001). The objective was to determine if facet level measures of the Big Five personality factors can provide a better understanding and prediction of the three factor-MTL construct over the Big Five personality factors. 249 undergraduate
psychology students completed facet-level measures of the Big Five personality factors derived from Stark, Drasgow & Chernyshenko’s (2008) Tailored Adaptive Personality Assessment System (TAPAS) item pool and Chan & Drasgow’s (2001) measure of MTL. Correlation and regression analyses showed that personality facets provided improved prediction of the MTL factors over the Big Five personality factors. More importantly, the facet-level data provided important insights on the specific relationships between personality antecedents and MTL. For example, we better appreciate the importance of dominance and sociability facets of extraversion as antecedents of affective-identity MTL while a combination of Dominance, Cooperation (facet of agreeableness) and Responsibility (facet of conscientiousness) act as antecedents to social-normative MTL. The original study by Chan & Drasgow (1999) did not report any significant relationship between Conscientiousness and non-calculative MTL. However, the present study using the TAPAS facets showed that combination of Virtue (facet of Conscientiousness) and Generosity (facet of Agreeableness) are related to Non-calculative MTL. This was possibly because of the improved content coverage of Conscientiousness in the TAPAS measure over that originally measured by Chan & Drasgow (2001) using the Big Five personality markers from the International Personality Item Pool generated by Goldberg which mainly consisted of the “Order” facet in the TAPAS. Advances in conceptualizing and measuring personality structure at the level of facets can provide important insights to the trait approach to leadership. Future leadership research should go beyond the Big Five factors to examine and better explain relationships between personality traits and different leadership outcomes at the facet-level.

**Keywords:** big five model of personality, motivation, leadership, conscientiousness, virtue

Career supportive leadership behaviour - construction and validation of a new instrument

Careers and taking leadership positions are contingent upon factors like career opportunities or motivation. The impact of leaders' behaviour for the career of their followers has rarely been investigated. Leaders play a relevant role, because they are responsible for assigning tasks with opportunities to learn leadership skills, promoting careers, and are relevant role models for their followers. Thus, the aim of this study is to develop and test an instrument for the assessment of career supportive leadership behaviours. Based on theoretical considerations as well as interviews with "high potentials", leaders, CEOs, and members of workers' council, an item pool of 74 items was constructed, covering 11 dimensions of career supportive leadership behaviours. An online study (N = 158) was conducted to test for factorial and construct validity of this instrument. After a sequence of factor and reliability analyses, five factors remained to assess career supportive leadership behaviour, namely delegating meaningful tasks (5 Items), trust (4 Items), flexibility (3 Items), social role clarity (9 Items), and direct promotion (8 Items). These factors could be confirmed in explorative as well as confirmative factor analyses, showing good model fit. Furthermore these leadership behaviours showed to be positively correlated to career relevant indicators like occupational self-efficacy, personal initiative, and career commitment. Additionally, evidence on incremental validity in relation to transformational leadership will be presented. The developed instrument to assess career supportive leadership behaviour proved to have good psychometric properties. Additional validation studies are conducted to further elaborate both the psychological construct, as well as the scales. But results of this first study are promising. Career supportive leadership might be an interesting tool for human resource management practitioners and organizational researchers alike.

Whistleblowing at work: What we know and the way forward

Chair(s): MATTHIESEN, S. (University of Bergen)

The aim of the symposium is to strengthen the interaction and collaboration between whistleblowing researchers across nations to improve the practical implications of academic research. Whistleblowing concerns the reporting of wrongdoing at work, for example an unethical or illegal treatment regime, bribery or corruption, workplace harassment, or safety violations. Blowing the whistle has been regarded as a kind of prosocial behaviour, even though many of those who voice their concerns are met with aftermath reprisals. This symposium with five presentations from USA, Norway, South Korea, United Kingdom and Australia will focus on important knowledge research has provided us with thus far, and how we may proceed further in making the knowledge practically valuable. Presentation 1 will investigate whistleblowing from a legal perspective and will focus on how law and academic theory may be combined in order to be effective. Presentation 2 will outline conceptual challenges and problems associated with how academics measure and define whistleblowing, which in turn may effect the estimation of prevalence. The role of the complaint recipient is the topic of the third presentation. The relationship between personality and attitudes toward whistleblowing is the subject for presentation 4. In the 5th and last presentation findings from three empirical studies and a four year PhD research project on the antecedents and consequences of whistleblowing will be summarized.

U.S. approaches to and research on Whistleblowing

MOREHEAD DWORKIN, T. (Indiana University)

In an effort to reduce corporate wrongdoing, governmental regulations have increasingly focused on rewards to whistleblowers who report the wrongdoing as a mechanism for detecting problems. In addition, the financial crises, both in the Enron era and the current one, have engendered a variety of laws and regulations to prevent recurrences. Unfortunately, recent studies show that the laws, particularly those without significant rewards, have not achieved their desired results. At the same time, researchers have looked at whistleblowing from a variety of theoretical perspectives including personality types (e.g., negative affectivity and proactivity), societal cultures, organizational environments, and reward effects, in order to build theories and models of effective whistleblowing policies. This report will examine the latest empirical studies and theories on whistleblowing, and examine the recent legislation including Sarbanes-Oxley and the TARP/False Claims Act. It will examine whether greater attention by legislators to the theoretical work would result in legislation that will achieve better results. Additionally, since significant rewards are not the norm outside the U.S., it will examine whether this approach might work elsewhere.

Keywords: United States, whistleblowing, legislation

The prevalence of whistleblowing - conceptual challenges

MATTHIESEN, S. (University of Bergen), BJØRKELO, B. (University of Bergen)

The state of the art definition of whistleblowing was coined by Near and Miceli in 1985, and declares that whistleblowing is the disclosure by organization members (former or current) of illegal, immoral or illegitimate practices under the control of their employers, to persons or organizations that may be able to effect action. This is however a theoretical definition, and is not included as part of most previous whistleblowing survey questionnaires that have been distributed to various groups of employees. This in contrast to workplace bullying research, in which the respondents almost exclusively are given a well established definition of the bullying construct, prior to the question if they are exposed to it or not is addressed. In this respect, it should be mentioned that a recent meta study on workplace bullying by Nielsen, Matthiesen and
Einarsen (2009) demonstrated that respectively addressing or not addressing a definition for the respondents influences the prevalence rates of bullying consistently. Is this also the case in terms of whistleblowing? A national survey study of whistleblowing in Norway was carried out in 2008 (1604 participants). Within this, the prevalence of whistleblowing was mapped with and without a given definition. Contrary to the workplace bullying findings, our present study demonstrates that the prevalence rate of whistleblowing experience seems to be higher when a definition is given, as compared with the mapping without a definition. The presentation will discuss possible explanations for this finding. Whistleblowing as a social construct is also elaborated.

Keywords: prevalence, definition, whistleblowing, social construct

Next please! Or why we should focus our research on the whistle-receiver instead of on the whistle-blower

VANDEKERCKHOVE, W. (University of Greenwich Business School), TSAHURIDU, E. (RMIT University)

The past 30 years, research into the whistleblowing process has focused on the person blowing the whistle. Psychologists have been trying to find out what kind of people blow the whistle, and when. Ethicists have been worried about whether or not someone should blow the whistle, about how to solve a loyalty dilemma, and about what kinds of wrongdoing are wrong enough to blow the whistle. This scholarly work has had a major impact in how we generally think about whistleblowers. For example, we now know they are concerned about the legitimate well-being of their organization, and they raise their concerns inside before disclosing to an outside entity. Academic discussions about whistleblowing seem to forget two things; one is that there is a lot of successful whistleblowing where people raise a concern and that is taken seriously without any retaliation, and secondly, whistleblowing legislation often does not work precisely because the focus is not on the message but on whether or not the whistleblower has followed the right procedure and hence is entitled to protection. This calls for a shift in research focus away from the person blowing the whistle towards the person to whom the whistleblower raises their concern. They are key actors when it comes to 1) the concern being taken seriously, 2) keeping the process free of retaliation. This paper offers by way of meta-analysis: 1) that trying to predict who will blow the whistle is hopeless, 2) that ethicists focusing on moral dilemmas of whistleblowers are missing the point. This paper builds on that to offer the argument that the ethical questions are with regard to the whistle-receiving person, not the whistle-blowing person. We offer a meta-analysis of very recent research in support of our argument. We also point out a number of research questions that would flesh out that research stream.

Keywords: whistle-receiver, whistleblowing, loyalty

Relationship between personality types and attitudes toward whistleblowing

PARK, H. (Chung-Ang University), PARK, M. (Chung-Ang University), BLEINKINSOPP, J. (Teesside University)

This study examines the relationship between personality types and attitudes toward whistleblowing. Personality type has been identified as a major influence on individuals’ attitudes, behavior, and communication styles, but few researchers have empirically tested the relationship between personality type and attitudes towards whistleblowing. The study sought to address the following key questions. What role does personality type play in determining attitudes toward whistleblowing? What type of personality is most closely related with positive attitudes towards whistleblowing? And what portion of the variation in attitude does personality type explain? Based on a review of the literature we generated several hypotheses as to the nature of the relationship between personality type and attitudes towards whistleblowing, and these were tested using data collected from university students in South Korea on an ongoing basis since March 2008. The survey instrument comprised two parts, a measure of personality type based on MBTI, and a section
assessing attitudes towards whistleblowing. Data gathering will be completed in December 2009, and the final sample will be over 400. ANOVA and regression analysis will be conducted to clarify the relationship among the variables, focusing on the effects of personality types on attitudes towards whistleblowing. This study offers two main contributions; firstly, it assesses what role personality types play in forming attitudes towards whistleblowing, while improving our understanding of the relationship between personality types and attitudes towards whistleblowing, and secondly, it provides insights for designing training programs aiming at nurturing ethical attitudes in an organization.

Keywords: whistleblowing, personality types, attitudes

Whistleblowing: antecedents and consequences

BJØRKELO, B. (University of Bergen)

This is a presentation of a four year PhD research project (2006-2010) about the antecedents and consequences of whistleblowing. First of all the research project shows that few employees blow the whistle and that most self-reported actual whistleblowers report internally and is relatively successful in terms of effecting change regarding the reported wrongdoing. On average whistleblowers report low levels of retaliation while they simultaneously report less job satisfaction and more bullying at work than their non-reporting colleagues. It is therefore needless for management to fear massive hordes of whistleblowers. Whistleblowers ask for more information about action taken by management after they have reported. Secondly, the results show that employed self-reported actual whistleblowers may be characterised by high extraversion and dominance and low agreeableness in social interaction. Thirdly, the results showed that a U.S. model of whistleblowing, developed by Donald Soeken, was valuable when analysing a Norwegian whistleblowing case. Further, repeated, long lasting retaliation that made the whistleblower in this case unable to defend himself could be defined as workplace bullying.

The consequences on health and wellbeing were severe, and included posttraumatic stress analogue symptoms. Characteristics of the situation, leadership style and type of organisation could have influenced the whistleblowing process. In addition to presenting the overall findings from the research project the presentation will also outline practical and clinical implications and academic challenges for future research in this field.

Workplace bullying and harassment: Incidence, consequences and solutions

Chair(s): BROUGH, P. (Griffith University)

This symposium focuses on the impact of two major types of anti-social behaviour in the work environment – bullying and harassment. These phenomena have received increasing attention in the organizational psychology literature in recent times, and are recognized as having substantial consequences for the health and well-being of workers, along with their work performance. It has also been recognized that there are serious implications of these anti-social behaviours for the overall productivity of organizations, as well as their reputation. Hence an understanding of (a) the nature of bullying and harassment, (b) their potential consequences, and (c) strategies for dealing with these counterproductive behaviours at work, is essential for changing work environments so that they are more conducive to employee psycho-social health and well-being. Management of anti-social and counterproductive behaviours is a key theme underlying the papers in this symposium. The symposium includes four presentations, two from a major study of bullying and stress in New Zealand organizations, and two from a nationally-funded investigation of stress and well-being within the Australian corrections industry. Following the four specific presentations, there will be a general discussion of the implications of the overall findings for the effective management and reduction of bullying and harassment in organizational settings. The key learning objectives of this symposium are: (1) Developing an understanding of the nature of work-related bullying and harassment behaviours; (2) Examining the psycho-social impact of bullying and harassment on individuals at work; (3) Reflecting on the effectiveness of personal efforts to reduce workplace bullying and harassment; (4) Considering the role of managerial and organizational initiatives to manage anti-social behaviours and their aftermath.

Bullying and stress in New Zealand organisations: The effectiveness of personal coping efforts

O’DRISCOLL, M. (University of Waikato)

The aims of this study were to explore the occurrence of workplace bullying and psychological strain in New Zealand organisations; to assess the relationship between bullying and psycho-social outcomes, including strain and overall well-being; to examine the effectiveness of targets’ personal efforts to cope with bullying and its consequences. This study represents the first systematic attempt to evaluate the incidence of workplace bullying in New Zealand. An online survey was conducted of employees (N = 1608) from 36 organisations in New Zealand. Bullying experiences were assessed via the revised 22-item Negative Acts Questionnaire (Hauge, Skogstad & Einarsen, 2007), along with a single item asking whether individuals felt that they had been bullied over the past six months. Psychological strain was measured with the 12-item General Health Questionnaire (Goldberg, 1972), and overall well-being with Warr’s (1990) 15-item adjective checklist. Three types of personal coping strategy were also assessed: problem-focused coping (4 items), selective coping (4 items) and resigned coping (2 items). Coping items were taken from the Copenhagen Psychosocial Questionnaire (Kristensen & Borg, no date). Other variables measured in the survey included: affective organisational commitment (6 items), turnover intentions (3 items) and self-reported absenteeism (1 item). Based on the criterion of experiencing at least two negative acts per week over the previous 6 months, the incidence rate for bullying in our sample was 17.8%. The NAQ and self-reported bullying were significantly inter-correlated (r = .62). Bullying was correlated with strain (.55), well-being (.60), affective commitment (.36), turnover intentions (.48) and absenteeism (.26). Personal coping strategies were generally unrelated to other variables. The reported rate of workplace bullying was somewhat higher in this research than that
reported in other international studies, and bullying was clearly associated with a range of negative outcomes, including heightened strain and reduced well-being. Personal coping efforts appeared to be ineffective in alleviating the negative impact of bullying, suggesting that more systemic organisational interventions may be necessary to reduce the incidence and aftermath of workplace bullying. The importance of proactive managerial intervention, and a focus on work environment factors which may alleviate bullying behaviours, will be discussed.

Bullying in healthcare settings: Why is it happening, and what is being done by organisations?

COOPER-THOMAS, H. (University of Auckland)

Employees in healthcare settings typically report high levels of bullying relative to other industries. Our research aims were to investigate bullying among healthcare employees in New Zealand, examine potential antecedents and consequences of bullying, and assess organizational initiatives designed to reduce or eliminate bullying. Data were gathered using the Survey of Work and Wellness. A total of 727 participants across nine healthcare organisations responded to a range of measures, including the Revised Negative Acts Questionnaire (NAQ-R; Hauge, Skogstad & Einarsen, 2007) and the General Health Questionnaire (GHQ; Goldberg, 1972). Respondents were also asked their perceptions of the effectiveness of 13 different organisational strategies to combat bullying. Participants reported bullying behaviours at the high end but within international norms (18.4% at least weekly for two or more items on the NAQ-R). Those experiencing bullying reported a poorer work environment, in terms of work climate, organisational support, supervisor support, and colleague support. These targets of bullying also reported worse experiences of work, including lower performance and emotional wellbeing, and higher levels of strain and turnover intentions. Targets also considered organizational strategies for dealing with bullying as less effective. However, the effectiveness of organisational strategies overall was significantly associated with lower bullying, strain, and turnover intention, and greater wellbeing. For those experiencing high levels of bullying, they rated “developing a workplace bullying policy” as the most effective organisational strategy, although all organisational strategies to address bullying had mean scores in the ineffective range (“very ineffective”, “ineffective”, or “somewhat ineffective”). Our results confirm the organizational-level antecedents of bullying (e.g., poor leadership) and the negative consequences for individuals and organisations (e.g., poorer performance). The picture with regard to the effectiveness of organisational strategies is mixed. While perceiving organisational strategies as more effective is associated with better outcomes, targets of bullying perceive all organisational strategies as ineffective. These results highlight the ethical and practical imperative of finding more successful approaches for dealing with workplace bullying behaviour.

“This is the culture you are working in – you are supposed to be tough!” A case-study of harassment and bullying in corrections

BIGGS, A. (Griffith University)

Correctional workers experience a high degree of exposure to workplace aggression while working in a dominant masculine culture. The purpose of this study was to investigate the impact of harassment and bullying upon levels of burnout and job engagement reported by a sample of Australian correctional officers. Both qualitative and quantitative methods were employed to identify issues surrounding the existence and reporting of workplace bullying. This paper presents results self-reported by 324 Australian Correctional Officers. The results showed that harassment significantly mediated relationships between work characteristics and burnout and engagement. Supervisor harassment was the strongest predictor of work-related burnout, and
engagement; co-worker harassment was the most significant predictor of personal burnout; and offender harassment was the most significant predictor of burnout. No moderating effects for gender were observed. Qualitative feedback identified five key issues: (1) Harassment and bullying policies are ineffective if not genuinely supported by organisational members; (2) Awareness of bullying has reduced occurrences of overt and ritualistic bullying, but has had less impact on covert bullying; (3) Mistrust, lack of communication, and breakdown of community exacerbate bullying and harassment; (4) Bullying and harassment complaints are typically made after the situation has escalated beyond a point where resolution is possible; and (5) A definite stigma is still attached to bullying and harassment complaints within a ‘tough’ culture. This research demonstrates the importance of the organisational context in bullying and suggests that inadequate support for policies and lack of equity may be as damaging as the actual bullying experience. A number of implications for organisational-level intervention strategies are discussed, which also addresses a major criticism that intervention strategies are limited due to an individual-level focus. Finally, this research demonstrated that harassment/bullying from co-workers more significantly impacted perceptions of well-being than manipulation or harassment from offenders.

The long-term implications of co-worker initiated harassment and bullying

BOROUGH, P. (Griffith University)

Workplace aggression comprises a wide range of counter-productive workplace behaviours, including harassment, bullying, incivility, mobbing, and hostility. Despite the existence of substantial research focusing on workplace aggression, theoretical and empirical development has been impeded by a number of limitations associated with this literature. For instance, research has focused on individual-level predictors of aggression, neglecting the wider role of the organizational context; there has been a lack of agreement as to whether aggression sits within the stressor-strain framework; and research has overwhelmingly adopted cross-sectional methodologies. Within these limitations in mind, this research investigated longitudinal relationships amongst harassment/bullying, job demands, work-related social support, job control, turnover intentions, engagement, and work-related burnout. The research employed a repeated-measures, cross-lagged design, with a time-lag of six months. Longitudinal analysis was conducted with structural equation modeling. The sample consisted of 324 employees from an Australian State Corrections Department. Invariance testing indicated that the factor structure of the model was invariant across the two phases of research, which increases the validity of the longitudinal results. The results indicated that Time One demands, control, supervisor support, equal opportunities, and mentoring predicted Time One harassment/bullying from managers. Plus Time One demands, control, and equal opportunities predicted Time One harassment/bullying from co-workers. Furthermore, harassment/bullying from managers predicted job satisfaction, equal opportunities, mentoring, and supervisor support over a period of six months. However, harassment/bullying from colleagues did not predict any outcomes over a period of six months. Time One harassment/bullying from managers also mediated many of the relationships between Time One work characteristics and Time Two outcomes. In addition, the potential moderating effect of social support and a culture that promotes gender equity were also evaluated. Although cross-sectional moderating effects were demonstrated, these were not maintained over-time. This research demonstrated the importance of considering alternative forms of causation; the longitudinal impact of harassment on well-being outcomes; the greater effect of harassment from managers on outcomes; and the impact of work-related variables on harassment and bullying.

Young career researchers present: Critical perspectives on postmodern career concepts

Chair(s): DRIES, N. (Vrije Universiteit Brussel)
Discussant(s): SAVICKAS, M. (Northeastern Ohio Universities College of Medicine)

This symposium focuses on postmodern careers and, more specifically, on “hyped” concepts such as boundaryless and protean careers. While boundaryless careers imply not being bounded to a single organization, domain or specific career path, protean careers highlight freedom, self-direction and personal choice. Postmodern career theory advocates two assumptions: first, that most individuals nowadays follow non-linear, unpredictable career paths inadequately explained by existing models of career development; and second, that more and more people are thinking like “free agents”, and consequently, traditional career types are no longer wanted by employees. However, both assumptions are contradicted by recent studies. Reservations have been raised about the portability of the above assumptions beyond the US, the cultural importance people attribute to security and the syndicalization of organizations being at the heart of the discussion. Promotions, long-term loyalty, job security, upward mobility and material success are still greatly valued by employees worldwide. The discourse on postmodern career fits all too well within a “ruthless economy”, in that it is only advantageous for those employees who were formerly also privileged in traditional career settings (i.e. highly motivated, high-skilled white-collar employees), while at the same time, the role of this economy in dictating the shape of career is obscured or glorified. Therefore, we argue that careers researchers need to take up their responsibility and build theory based on actual facts about modern-day careers rather than develop new dogmas. Protean and boundaryless careers, although concepts introduced long over a decade ago, have only just recently emerged as popular topics for empirical research. This symposium presents the recent work of five junior researchers in the field of careers who seek to specialize in exactly this domain. The discussion, led by an established careers scholar, will tackle the following learning objectives: (1) gaining insight into the interplay of organizational-strategic and individual-psychological factors in shaping contemporary careers; (2) understanding what possible implications of postmodern career discourse are for researchers, employees and organizations; (3) examining how career theory could take employee well-being into account more explicitly by acknowledging the need for a more diversified view of careers and career success.

Integrating the talent management paradox into postmodern careers literature

DRIES, N. (Vrije Universiteit Brussel)

When examining the talent management literature, a twofold paradox emerges: talent management is simultaneously considered as outdated, and as more pivotal than ever to organizational survival; furthermore, talent management practices aim to retain exactly those employees most likely to leave. We examined the dynamics between individual career antecedents leading to organizational talent categorization and the subsequent effects on individual career outcomes. By doing so, we contribute to the literature: first, by integrating the careers literature with the talent management literature, thus creating a comprehensive framework for understanding talent management within a postmodern conception of career; second, by building on data coming from employees assigned to different talent categories themselves; and third, by examining cross-level effects, where organization-level variables (i.e. talent categorization) are related to individual-level variables (i.e. career antecedents and outcomes). A large-scale online survey was conducted. Employees from three organization-assigned talent categories participated: high potentials (n = 250), key experts (n = 230) and average performers (n = 461). The study findings indicate that talent category can be predicted by supervisor-rated performance, and to a much lesser extent, by career orientation. As for objective career
success, we found that high potentials receive more internal promotions, and at a higher speed, than key experts and average performers; we did not find effects of talent category on current salary or on salary increase. Conversely, we did not find significant differences in terms of subjective career success. High potentials were found to be less inclined to change employers under high boundaryless mobility preference, where we expected them to report the highest mobility. These findings might point to aspects outside of mobility preference in determining expected future mobility, such as the psychological contract and the organizational support and commitment related to being assigned the high potential label. It appears that the traditional model of career success is still alive, specifically for high potentials. Researchers are encouraged to clearly distinguish conjectural from empirically supported ideas about postmodern careers; organizations are recommended to allot a more central role to career orientation in the design and implementation of talent management programs.

Career transitions and their outcomes in the light of new career theory: An empirical study of business graduates

CHUDZIKOWSKI, K. (Wirtschaftsuniversität Wien)

Career transitions are an integral part of working life, and hence an important topic in careers research and practice. Transitions involve moves within the social space of an organization, occupation or career field. Postmodern career theory suggests that as traditional-organizational career patterns disappear, new career types emerge (with catchy labels such as “boundaryless”, “protean” or “post-corporate”), fostering different transition dynamics. In turn, different career transition dynamics might lead to different career outcomes. In this study we examine career transitions and their effect on objective (income) and subjective (satisfaction) career success. Our contribution to the current debate is twofold. First, we bring two aspects of career together by linking career transitions to career success. Second, we reflect on new career concepts by presenting results from two cohorts of graduates, one representing employees from the traditional, and one from the contemporary career context. The analyses were based on a sample of two cohorts of business school graduates, from 1970 and 1990 respectively. In terms of age and gender, the cohorts are representative of the respective graduation year for the whole university. The data for the study were collected by questionnaire interviews, plotting the graduates’ careers based on a curriculum vitae-type list of their jobs. The analysis uses mixed linear models, examining the effect of different forms of career transition on objective and subjective career success. The results indicate that overall, graduates from 1990 went through more job transitions during the first 15 years of their careers, although the types of transition did not change radically. In regards to objective career success, there were differences for certain types of transition; for instance, 1990 graduates experienced less increase in average income than graduates from 1970. With respect to subjective career success we did not find significant differences, except for hierarchical advancement. It appears that the different types of desired career transition still mirror aspirations in line with more traditional career paths. It is suggested that the underlying assumptions of new career concepts should be put into question, or at least nuanced.

Career stage and generational differences in psychological contracts

HESS, N. (University of New South Wales)

There has been a recent escalation of research exploring the psychological contract, driven by the need of researchers and practitioners to define the 21st century employment relationship. Organizations are required to manage an increasing number of older workers alongside younger workers in organizations with flatter structures and often, fewer career paths. No longer can it be assumed that an older, supposedly “baby boomer” worker is more advanced in their career than their
younger generation X or generation Y colleague. Using the colloquially popular generational cohort distinction for age, this paper examines the impact of age and career stage on the employee’s psychological contract. A survey of 345 working adults included psychological contract obligations, incentives and importance and the cognitive responses of job satisfaction, affective commitment and intention to leave. Super’s (1988) Adult Career Concerns Inventory measured career stage. Significant differences between individuals’ psychological contract perceptions were based on both career stage and generational cohort: higher levels of balanced obligations and fulfillment were found than either relational or transactional obligations and fulfillment; relational and transactional obligations were significantly higher for Baby Boomers than Generation Xers; a stronger negative relationship was found between transactional fulfillment and intention to leave for Generation Xers than Generation Yers; higher balanced fulfillment had a significantly stronger positive relationship with (a) job satisfaction for exploration than other career stages and (b) commitment for exploration than maintenance stages. Despite widespread colloquial use of generational cohort groupings such as Baby Boomer, Generation X and Generation Y, small effect sizes were found. Implications from the small effect sizes suggest that neither generational cohort nor career stage generalizations are likely to be effective in predicting responses in individual employees, irrespective of their age, cohort or career stage. A key theoretical contribution made by this study is to suggest the need to further investigate if the protean career concept is operating within employees’ perceptions of their PC terms.

A contingency perspective applied to psychological mobility

VERBRUGGEN, M. (Katholieke Universiteit Leuven)

Increasingly, the boundaryless career model and discourse are being criticized. The assumed prevalence of boundaryless careers can be countered by pointing to the ongoing dominance of traditional, bounded employment contracts. The claim that most workers would benefit from having a boundaryless career is, in turn, riposted by the argument that many boundaryless workers do not freely choose such careers but rather, are forced into them, through lay-offs and other types of involuntary turnover. Remarkably, most critiques are concerned with claims concerning physical aspects of the boundaryless career. Psychological mobility, another important aspect of such careers, has been largely preserved from criticism. In this study, we want to examine whether this is justified or not. In particular, we examine the prevalence and the outcomes of having a boundaryless mindset in a sample of young business alumni. Young, highly educated individuals are generally believed to benefit from having a boundaryless career. We hypothesize, however, that even for this population, psychological mobility may be bounded as well, and does not necessarily lead to benefits for the individual. We collected data from 477 business alumni graduated between 1997 and 2005. The average respondent was male (60%), 30 years old and had changed employer at least once (62%). Though most respondents were found to have a boundaryless mindset (92%), the strength of this mindset was strongly determined by personality. As personality traits are believed to be largely immalleable in adulthood, this finding indicates that there may be dispositional boundaries to people’s psychological mobility. In addition, we found that not everybody benefited from having a boundaryless mindset. Only when the working environment was congruent with this mindset, psychological mobility positively affected well-being. Our results indicate that psychological features of the boundaryless career, as well, are not as widespread as often assumed, nor do they generate only positive outcomes. Having a boundaryless mindset seems to be no common “necessity”, but rather one of many possible career drives.

"Who fertilized the egg???: Claiming discrimination through gendered constructions of responsibility"

HASTIE, B. (University of South Australia)

While discrimination is widely recognised as a serious problem with negative social consequences, little research has considered how people understand particular acts to be instances of (non)discrimination. This research aims to examine in practice understandings of discrimination, focusing on how these are worked up and countered in discourse. This paper examines 285 online comments in response to an article about gender disparities in pricing of health insurance in the US, applying a critical discursive analytical method. A number of gendered discourses are drawn on in order to investigate claims of discrimination. The focus here is on how constructions of men and women as (ir)responsible are linked to fairness, thereby refuting justifications for the pricing disparity. This research provides insight into how events are understood to be instances of (non)discrimination, and how discourses justifying such discrimination as ‘fair’ can be undermined. Such findings have implications for how those fighting discrimination, based on gender or other social categories, can resist claims that unequal treatment and outcomes are justified.

Keywords: discrimination, gender differences, responsibility, fairness

"Knowing me, knowing you": An exploration of the mother-daughter relationship

KATSIKITIS, M. (University of the Sunshine Coast), MUSCAT, M. (QLD Health and Drug Arm Australasia), JONES, C. (University of the Sunshine Coast), CRAWFORD, K. (Eviva Pty Ltd)

Young adolescent females are increasingly engaging in risky behaviors. Family connectedness, specifically the mother and daughter relationship, is associated with reduced adolescent risk taking behaviours. Mother and daughter relationships are considered the most significant of intergenerational relationships. It is important to understand a mother’s personal experiences, emotions and cognitions with the objective to create a positive relationship with their daughter(s). In particular, little is known of the effect of mothers’ resilience and self esteem and how these factors impact on their daughter’s self esteem and resilience to risk taking behaviours. This study explored the relationship between mothers and their 12 year old daughters. The information obtained from this study will inform a state-wide communication strategy which aims to increase resilience to risk-taking behaviours so often associated with adolescence. The data was collected in two stages. Firstly, two separate focus groups were conducted: (1) a mothers’ focus group and (2) one with their 12 year old daughters. These groups were conducted concurrently. Stage Two of the data collection comprised of a survey targeting attachment, self esteem, resilience and risk taking behaviours in both samples. Preliminary results from the focus groups demonstrated that data were consistent with the literature in the field and suggested that the basic themes emerging from other research also apply to mothers and daughters in the South-East Queensland Region. The survey data extends these findings and implications for the development of a multi-media communication strategy will be discussed. This study targets mothers’ self esteem and resilience as protective factors for risk taking behaviour among pre-adolescent females. It will be argued that designing activities that acknowledge the influence of family relationships and facilitate positive mother-daughter relationships will reduce risk-taking among pre-adolescent females. These themes will be discussed in light of the quantitative survey data. Communication strategies involving multi-media applications will be considered.

Keywords: adolescents, resilience, risky behaviours, family connectedness, self-esteem

"Me, myself, and the others": The influence of personal values on psychological contracts

GOMES, J. (CIS-ISCTE/IUL), COELHO, F. (University of Coimbra), SOUSA, C. (University College Dublin), COLAÇO, C. (University of Coimbra)
Despite all the advancements regarding psychological contract, it still remains largely unexplored how individual, social and organizational factors shape the way people establish these psychological links with their organizations. The current study explores this void by investigating how individual values shape psychological contracts in several of its dimensions (i.e. tangibility, contract scope, stability, time frame, exchange symmetry, and contract level). Using Schwartz’s personal values framework, two hypotheses were tested: 1) collectivistic-oriented values are positively related to psychological contract dimensions; and 2) individualistic-oriented values are negatively related to all psychological contract dimensions. The sample consisted of 217 frontline employees in a large services organization. Individual values were measured with the Schwartz Value Survey (SVS), which comprises 57 items (Schwartz, 1992; Schwartz & Sagiv, 1995). Psychological contract was measured using the scale developed by Sels, Janssens and Brande (2004). Results show a good support for hypothesis 1 (collectivistic human values are positively related to all psychological contract dimensions), and a moderate support for hypothesis 2 (individualistic human values are negatively related to the same psychological contract dimensions). In particular, results show that personal values have an impact on how employees perceive reciprocal duties in the relationship with their employer. We observed that certain values are associated with certain relational obligations, whilst others relate with transactional obligations. For instance, personal values such as stimulation and self-direction are often associated with employees’ perceived transactional obligations towards the organization as well as with employers’ transactional obligations perceived by the employees. Employees who emphasize value types as conformity and security – carrying out their behaviors seeking the acceptance and maintenance of institutionalized rules and norms and valuing the group’s harmony and well-being – tend to appreciate relational obligations in the employment relationship. Our work also shows that mutual obligations as perceived by employees affect their individual performance. Employees’ performance is higher when they accept and conform to hierarchical and status differences (exchange asymmetry), when they commit to organization’s purposes (flexible/broad scope) and when they adopt flexible and tolerant behaviors towards changes in the organization (flexibility). Similarly, employees’ performance is higher when they expect the employer to offer the opportunity to renegotiate contract terms whenever circumstances change (flexibility) and to use a rewards’ system based upon individual performance (individual regulation).

Keywords: personal values, psychological contract, collectivistic-oriented values, individualistic-oriented values

"Two-hit" hypothesis of schizophrenia and the auditory evoked potentials in the rat

Reduced mismatch negativity (MMN) is a robust finding in schizophrenia. It is correlated with other cognitive impairments in patients and with grey matter loss in frontotemporal regions. The goal of the present project is to establish a rodent model based on the "two-hit" hypothesis of schizophrenia and assess the success of the model by the extent to which it produces a reduction in MMN and other auditory evoked potentials (AEPs). However, the first step for this project is to assess whether MMN-like activity and other AEPs can be recorded in our experimental set up. Event related potentials to 3 kHz tones were measured over auditory cortex in freely moving Wistar rats (n = 3). The stimulus paradigms allow (1) control for stimulus attributes and extraction of long (100 ms) and short (50 ms) duration MMN and (2) for checking whether the MMN-like activity, if observed, is due to a memory based component. Event related potentials to clicks were also
measured to investigate other AEPs with different stimulus onset asynchronies. Preliminary data indicate that event related potentials have been recorded. In addition, we observed AEPs in non-deviant event related potentials. The amplitude of AEPs increased with longer stimulus onset asynchronies. This pattern was similar to the pattern in humans with longer stimulus onset asynchronies. While the preliminary data are encouraging, data need to be analysed further. We also need to collect data from more animals.

A cluster analytical approach of gender, impulsivity, expectancies, self-efficacy and self-esteem on drinking and eating behaviours in young people

GILMARTIN, T. (Australian Catholic University), WITENBERG, R. (Australian Catholic University)

This study aimed to examine the drinking and eating behaviours of Australian young people using cluster analysis to identify groups of like-minded young people. In particular, past research has identified that increased alcohol consumption is related to an increase in binge eating, and that impulsivity, expectancies, self-efficacy and self-esteem have an influence on both problematic drinking and eating behaviours. However, few studies have explored these relationships in a non-clinical sample. The sample consisted of 170 participants (48 males and 122 females) aged between 18 and 30 who were recruited using social networking websites, online survey methodology. Participants completed measures to assess alcohol consumption, eating attitudes and behaviours, impulsivity, drinking expectancies, eating expectancies, self-efficacy and self-esteem. A hierarchical cluster analysis was performed to form groups of like-minded participants based on drinking behaviours, eating behaviours, impulsivity, expectancies, self-efficacy and self-esteem. The cluster analysis revealed five distinct clusters. The clusters were compared and contrasted based on the factors of the study and revealed two clusters characterised by impulsive episodic drinking and eating behaviour, and another a cluster characterised by controlled drinking and eating, as well as two further clusters. The cluster analysis provided valuable insight into the drinking behaviours, eating behaviours and underlying psychological processes that characterise young people. In particular, the results contributed to the previous understanding of the psychological factors that underlie and protect against problematic drinking and eating behaviours. The cluster analysis highlighted a number of avenues for future research and the findings can be applied to education and treatment programs.

Keywords: impulsivity, self-esteem, drinking behaviours, eating behaviours, self-efficacy

A comparative study of styles of coping with work-stress in 16 different national contexts: Towards a culture centric approach

BHAGAT, R. S. (University of Memphis), SRIVASTAVA, B. N. (Indian Institute of Management Calcutta), BILLING, T.K (Rowan University), SINGH, K. (Indian Institute of Management)

In this investigation with 16 countries, we sought to examine the distribution of problem-focused and emotion-focused coping styles in professional managers and other occupational classes in a sample of over 5000 individuals. The objective of the study was to examine as to whether problem-focused coping was more frequent as a method of dealing with work induced stresses in managerial samples in all countries regardless of their standing on the individualism-collectivism continuum. Another objective was to examine the preponderance of emotion-focused coping in samples which were not necessarily classified as managerial or professionals in all the countries. Data were collected from US, Canada, Australia, France, Germany, Poland, Japan, China, India, South Korea, Malaysia, Indonesia, UAE, Chile, Brazil, and Venezuela. Some of the countries were clearly more individualistic in their orientation and others were more collectivistic. Using Singellis et al.’s (1995) scale of horizontal and vertical individualism and collectivism, we also correlated the scores of VI, VC, HI, HC with problem-focused and emotion-focused coping
scales of the 5341 individuals in our sample from 16 countries. The results are interpreted in terms of cultural variations as well as variations individual propensities to cope with work-stresses as a function of occupational cultures (Schneider, 2008). The results show a pattern of vertical individualism to be a better predictor of problem-focused coping styles compared to horizontal collectivism and vertical collectivism. The professional classes tended to favor a more distinct pattern of coping with work stresses by using a problem solving and an active intervention kind of style. Managers from all the countries regardless of their locations in the economic development or cultural orientation in terms of individualism-collectivism continuum tended to prefer an active problem-solving style for coping with work and organization induced role stresses. Other occupational classes below the managerial class, however, were more predisposed towards engaging in an emotion-focused style in dealing with work and organizational stresses in their work roles. The conclusions of the study are interpreted in terms of their implications for extending the role of cultural variations in human stress and cognition in work organizations. It is important for the field of international applied psychology to be concerned with improving coping effectiveness of people at work by exploring the kinds of patterns or styles they prefer in dealing with work stresses that are associated with performing work related duties and responsibilities.

Keywords: problem-focused coping, emotion-focused coping, stress, individualism-collectivism continuum, professional managers

A comparison between the self-assessed and instructor-assessed driving skills of a sample of Japanese driving school students

NAKAI, H. (Kobe University / Osaka University), USUI, S. (Osaka University)

This study was conducted to examine the accuracy of the self-evaluated driving skills of Japanese novice drivers by comparing the self-assessments with those made by a driving instructor. In addition, we tried to examine the relationship between the extent of overconfidence—defined as the difference between the drivers’ self-rating and the instructor’s rating—and the drivers’ characteristics, such as gender and age. A sample of Japanese driving test candidates (n=2021) completed a self-assessment on a five-point scale, shortly after clearing a practical driving test conducted at a driving school. The examiner also rated the candidates’ performance on the same scale. The assessed 19 items were categorized into five skill sets, namely, “turning indicators,” “vehicle handling,” “speeding,” “safety confirmation,” and “social skills.” The comparison between self-assessment and examiner-assessment revealed that the majority of Japanese driving school students had a tendency of overestimating their own driving skills, especially in “vehicle handling,” “social skills,” and “safety confirmation.” Furthermore, the results indicated that males displayed higher levels of overconfidence than females, while older candidates (over 25 years) realistically assessed themselves in contrast to the younger ones. However, most candidates were not found to overestimate their skills in the areas of “turning indicator” and “speeding.” To conclude, the result from comparing the drivers’ self-assessment with the instructor’s assessment for Japan is consistent with the common findings of similar studies focusing on Europe—that young male drivers overestimate their skills more than female and older drivers. This study highlighted the need of improving the accuracy of self-assessments at driving schools before issuing licenses.

Keywords: driving skills, self-assessment, Japan

A comparison of three personality trait models and the implications for selection into the medical and allied health professions

BORE, M. (University of Newcastle), MONRO, D. (University of Newcastle), BRIDGE, P. (University of Newcastle), DOUGLAS, H. (University of Newcastle), POWIS, D. (University of Newcastle)

Personality assessment is used widely in selection procedures in the business sector, the armed services and police services. However, medical and allied health sector educators and
employers are only recently considering the use of non-cognitive variables in selection. For some 10 years Bore, Munro and Powis have been developing a three-domain model and self-report measure of interpersonal personality specifically targeted at the interaction between practitioners and their patients/clients (e.g., Bore, Munro & Powis, 2009). The three domains are Involvement (empathy, confidence with others) vs. Detachment (aloof, narcissistic), Resilience (emotional stability, capable under pressure) vs. Reactivity (anxious, moody, volatile) and Control (high self-control, orderly, conscientious vs. low self-control, disorderly, disregard for rules). We compared the predictive validity of this Involved, Resilient and Controlled (IRC) model against two other trait-based personality models: the Big 5 measured using the 30 facet IPIP inventory, and the 11 DSM-based traits of the Hogan Development Survey (HDS). The criterion variables were self-report measures of problematic personality styles (Psychopathy, Machiavellianism, and trait Aggression), two measures of psychological distress (the Kessler 10 and Global Severity Index scores from the Brief Symptom Inventory) and two measures of psychological wellness (Subjective Well-Being and Hope). The battery was completed by 236 first year psychology students. Factor analysis results supported the theoretical structure of each of the three models. Using regression analysis the IRC and Big 5 were found to account for a significant proportion of variance in each of the criterion variables with R-Squared (adjusted) values ranging from 38% to 65%. The HDS R-Sq (adjusted) values ranged from 24% to 38%. Both the IRC and the IPIP Big 5 strongly predicted Psychopathy. The implications of the findings in using the models and measures for selection will be discussed. Of specific note is that the results suggest that both the IRC and the IPIP measures could help to detect potentially psychopathic medical practitioners at an early career stage.

Keywords: personality assessment, problematic personality styles, psychological distress, psychological well-being, psychopathy

A cross-cultural comparison of the reliability generalization studies on the Eysenck Personality Questionnaire and its implications

ZHANG, J. (South China Normal University), JIAO, C. (Shenzhen University), ZHANG, J. (South China Normal University), ZHANG, M. (South China Normal University), ZHANG, W. (University of Canberra)

This paper attempted to study the reliability generalization on the Eysenck Personality Questionnaire (EPQ) in China. The analysis was done through descriptive statistics and hierarchical multiple regression with data from seven Chinese major psychology journals for ten years. The findings were compared with those of the analogous study on EPQ in other countries, which was conducted by Caruso et al. Comparing the results at home and abroad, the similarities lie in: 1) the sampling characteristics do affect the reliability coefficients; 2) A low proportion of articles report reliability coefficient or its range from the data at hand; 3) P scale owns a low reliability coefficient; 4) standard deviation of scores in subscales is the main predictor variable for the reliability coefficients of P, N, E and L subscale. Differences in the studies are also discovered: 1) 84.82% of researches in China do not report reliability coefficient from the data at hand, comparing with 62.51% of researches in the other countries, 2) Variables such as the number of items, the mean of scores, standard deviation of age, sample type have different predictive functions on the reliability for EPQ in China and in other countries. The prediction from mean of scores to P, N and L subscale as well as the prediction from number of item to P, E and N subscale are found to be statistically significant in China, but not in Caruso’s study. On the other hand, the prediction from standard deviation of age to P, and L subscale as well as the prediction from sample type to P subscale are found to be statistically significant in Caruso’s study, but not in China. The analysis and comparison demonstrate that 1) “reliability induction” is inappropriate when using questionnaires available, and it is necessary to report the reliability coefficient of the samples at hand; 2) a certain heterogeneity of samples may enhance the reliability in the use of EPQ; 3) the increase of item numbers which does not follow the psychometric rules will not improve the reliability of scores necessarily.
A decisional hierarchy in interactive ad-hoc-evaluation of desktop software by end-users

ZIMMERMANN, J. (University of Rostock), NERDINGER, F. (University of Rostock)

The aim of this study is to understand how end-users decide when choosing from a set of software programs. The study’s context is today’s commonplace practice of satisfying one’s computer software needs by downloading demo versions or freeware from distributive internet portals. This means that individuals frequently do not base their evaluations on attribute lists or expert reviews, but upon trying out the software interactively without any introduction, advice or tutoring. In an exploratory approach, 20 individuals were confronted with a set of three programs. Before their final task of drawing a given flowchart as quickly and as nicely as possible, they were told to pick the program that suited them best. The think-aloud method was used for accessing their cognitions during the process. The participants’ individual interactions with the software as well as their utterances were analysed for critical incidents (e.g. excitement about a feature or failure to produce certain effects). These incidents were interpreted in connection with the individual’s decision, thus deriving hypotheses explaining why certain decisions were reached. Across individuals, a consistent hierarchy emerged, suggesting a Satisficing approach to decision making: the most important aspect appears to be an individual’s ability to produce the required function. Once this has been secured, the option producing the best results is chosen. The ease of using a program was relegated to third place. Soft features such as optical appearance, familiarity, etc. came in last place. This result can be fitted into the Technology Acceptance Model (TAM), enhancing it in regards to the non-tutored evaluation of software. The most important extension is that TAM’s “ease of use”-construct seems to work on two levels, with the novel feature that it moderates the effect of external variables on the perception of “utility”. With respect to the fact that individuals frequently failed to produce certain effects but would not use traditional help mechanisms, we find that novel approaches to recognising what a user intends to do and to providing proactive and unobtrusive help must be developed. This could significantly improve the chances of software which is to be evaluated without tutoring or introduction.

Keywords: end-users, desktop software, decision making

A family-centred interdisciplinary service model to address challenging behaviour of children and young adults with developmental disabilities

MCIVER, C. (Disability Services Commission), MCVILLY, K. (Deakin University)

This paper describes the implementation and evaluation of a family-centred behaviour support team (Positive Behaviour Team) developed to support individuals (aged 6-25) with a developmental disability who engage in behaviour that is challenging (e.g. Physical and verbal aggression, self-injury, destruction to property). The team was developed in recognition that discipline specific therapeutic interventions were often insufficient to meet the needs of families and that both clinical and systemic strategies are necessary to facilitate effective and lasting positive change for individuals and families. The Positive Behaviour Team was developed in the context of a sector-wide review of behavioural services for people with a disability in Western Australia. A multi-disciplinary team was formed consisting of experienced clinical psychologists, speech pathologists and social workers supported by a clinical team leader and manager. Clinicians from all disciplines were trained in a variety of evidence-based approaches, including Positive Behaviour Support/Applied Behaviour Analysis, functional communication interventions and family systems models. Individual and peer supervision processes were developed to support consistent implementation of the service model as well as to safeguard team health. Key features of the service model included a referral process consisting of periodic calls for referrals, rather than a wait-list approach; services provided within the family
home to multiple family members; allocation of multiple clinicians from different disciplines to every family; an intensive assessment designed to help families understand drivers of challenging behaviour holistically and equipping them with the information necessary to develop their own goals in partnership with clinicians; supportive implementation of strategies during intervention; an emphasis on helping families to plan for the future (maintenance of change) prior to closure. Outcomes were measured using a combination of quantitative and qualitative measures which are currently being collated at the time of preparing the current abstract. Quantitative measures included indicators of behavioural problems, parental functioning, family coping, quality of life and staff health. Qualitative measures included interviews with family and staff concerning their experience of the intervention process and their satisfaction with goal attainment. Challenging behaviour is best addressed taking into account not only the specifics of the behaviour, but the family context. Interdisciplinary practice implemented using a coherent service model and drawing on a combination of evidence-based approaches provides optimal and potentially sustainable outcomes for individual with a disability and their families. This model of service also appears to provide staff with a positive and fulfilling working environment despite the intensity of the challenging behaviour and family issues.

Keywords: family-centred behaviour support team, developmental disorders, behaviour problems

A formative versus reflective analytical approach to work ability measurement

KARIMI, L. (La Trobe University)

In the last few decades discussions around formative models have gathered speed. The literature in psychology and management pays growing attention to formative measurement models for operationalising construct variables (Diamantopoulos, Riefler, & Roth, 2008). Despite the appropriateness of using formative indicators in many circumstances, these are often either neglected or miss-specified in empirical studies. Using unsuitable reflective measurement models undermines the validity of the constructs, misrepresent the structural relationship between them and lower the value and validity of the findings. Building on theoretical and empirical considerations, the present study primarily employed Partial Least Square (PLS) analysis and Structural Equation Modelling (SEM) to validate and design both formative and reflective measurement models on a large data set from a workplace survey. The results of the study have significant theoretical and empirical implications for the areas of psychology, management and other related disciplines.

Keywords: formative approach, construct variables, validity, reflection

A longitudinal study of the determinants and consequences of career change

CARLESS, S. (Monash university), ARNUP, J.

Career change refers to movement to a new occupation or profession that is not part of a typical career progression. This can be distinguished from job change which is movement to a similar job or a job that is part of a normal career path. The first aim of this study was to understand the determinants of career change. It was hypothesized that age, gender, marital status, job satisfaction, job security, occupation tenure, intent to change and personality would influence career change. The second aim of the study was to examine if key variables improved after career change, specifically, these were job satisfaction, job security, salary, hours worked and life satisfaction. Data from the Household, Income and Labour Dynamics in Australia (HILDA) survey were used to examine the determinants and consequences of career change. This Australian government sponsored data set has collected annually an extensive range of information about individuals and their families. We accessed two sub-samples of the data set. To assess the first aim we selected individuals who were working full-time in Years 5 and 6 of the data collection (N = 4547). The predictor variables were obtained from Year 5 and the dependent variable of career change was obtained one year later (Year 6). The second aim
examined only those individuals who had changed careers in Years 2 – 6 (N = 1,467). The findings showed that age, sex, education, occupation tenure, job security, previous job search, quit probability, extraversion and openness to experience were significant predictors of occupation change. Also that after career change, individuals had better job security and job satisfaction and worked less hours; their salary and overall life satisfaction remained constant. Theoretical and practical implications of the findings will be discussed.

Keywords: longitudinal study, career change, determinants, job satisfaction, job security

A model of the promotion of health and well-being in hospital staff: The relationships linking organisational culture, stress and change

MCCARTHY, E. (University College Dublin), CLIFFORD, I. (University College Dublin)

This research focuses on the relationship between leadership/mission, the policies and organisational culture of a large Dublin hospital, and outcomes such as job satisfaction, health and well-being, stress and coping, and desired future change. A cross sectional random sample of 179 staff, including nurses, medical and allied staff and administrators were studied, adopting a systems model of change. Attitude scales were developed using bottom-up and top down research methodology and tailored to the demands of the particular hospital. Results, including descriptive statistics, qualitative analysis of focus groups and interviews, factor analysis, and multiple linear regression analysis, will be presented. Challenges and priorities for the population will be discussed and outcomes for future change mapped out.

Keywords: leadership, job satisfaction, health, well-being, stress

A multidisciplinary approach to measuring spatial performance in novice designers

SUTTON, K. (The University of Newcastle), WILLIAMS, A. (The University of Newcastle)

Design Cognition is a relatively new domain and as such there are gaps in our understanding of the cognitive implications of the design process. Spatial ability is not well understood in the domain although it’s very role in the understanding of shapes and relations of objects to each other is potentially important to Design. The ability to improve design thinking and understanding is desirable and hence the potential of spatial ability is significant. The ability to effectively and efficiently manipulate imagined objects as a thought process is valuable to most design domains. Spatial ability could be considered a fundamental skill in design disciplines. This paper reports on a study conducted with 194 novice designers that investigated spatial performance across gender and several design disciplines. The study was a collaborative project between design and applied psychology and central to the study was an online test of 3D ability (3DAT) that measured choice accuracy and reaction time. The 3DAT was developed in accordance with psychometric test construction standards and the analytical procedures were based on the rigour normally applied to experimental psychology research. The 3DAT consisted of 12 subtests with 6 test items in each and was developed as part of an Australian Learning and Teaching Council (ALTC) funded project. Spatial ability can be defined as the performance on tasks that require the mental rotation of objects, the skill to understand how objects appear from different perspectives, and the skill to conceptualize how objects relate to each other in space. The study examined differences in gender performance and differences between three design disciplines on the 3DAT and each of the 12 subtests. Consistent with the literature, a significant gender difference favouring males was found for the 3DAT and most of the subtests. Architecture students consistently outperformed participants from construction management and technology teaching. We report individual differences and focus on the implications for students studying graphical communication courses in the higher education sector. This project provides a good insight into the potential of applied psychology and what it can offer to other disciplines. Details of the collaboration are also reported.
Keywords: spatial performance, novice designers, design cognition, gender, mental rotation

A multivariate strategy for the prediction of vigilance

MATTHEWS, G. (University of Cincinnati), WARM, J. (Air Force Research Laboratory), FINOMORE, V. (Air Force Research Laboratory), SHAW, T. (George Mason University), LANGHEIM, L. (University of Cincinnati), REINERMAN-JONES, L. (University of Central Florida)

Vigilance and sustained attention are important in many operational environments including industrial inspection, transportation, medical monitoring and military surveillance. However, standard psychometric instruments, including personality tests are only weak predictors of vigilance. This presentation aims to provide a brief overview of three recent studies that support a multivariate approach, based on attentional resource theory. Predictors included measures of ability and psychophysiological and subjective response to a cognitive challenge. The studies reviewed used a two-phase design. Participants performed, first, a short high-workload task or tasks, and, second, a longer task requiring sustained attention. Different sets of predictors were explored across three studies (N = 210, 462, 294). All included the Dundee Stress State Questionnaire (DSSQ), which provides an assessment of task engagement. Two studies also included standard personality and ability tests and a short vigilance task. The third study assessed a psychophysiological response to cognitive load, bilateral cerebral bloodflow velocity (CBFV), which was measured using Transcranial Doppler Sonograph (TCD). Longer vigilance tasks included those requiring attention to an air traffic control display, decoding alphanumeric sequences, and monitoring military tactical displays. Durations of these tasks ranged from 36 – 60 min. Multiple regression and structural equation models were used to assess the predictive validity of personality, ability, stress response and CBFV. The most robust predictor was subjective task engagement. The engagement response to the initial short task(s) reliably predicted subsequent vigilance. The CBFV response was also predictive, and added to the variance explained by subjective measures. Ability measures, including a short vigilance task, also correlated with longer-duration vigilance performance. Multivariate modeling confirmed that predictive validity is maximized by including multiple measures. Up to 30% of the variance in performance was explained by the models. Data fit the resource model of vigilance, which attributes loss of sustained attention to depletion of a general processing resource. The strongest predictors – subjective engagement, CBFV and ability – may all be conceptualized within a resource model. However, no single measure may be used as a ‘gold standard’ index of resource availability. Effective prediction in operational environments requires integrating information from multiple indirect markers for resources.

Keywords: vigilance, sustained attention, measurement, performance

A national survey of multicultural counselling competency in Malaysia: Preliminary analyses

AGA MOHD JALADIN, R. (Monash University)

Multicultural counselling is a rapidly emerging profession in most developed countries such as the United States of America, Britain, and Australia. However, in the specific cultural context of Malaysia, neither understandings nor practices of multicultural counselling have been fully explored. This research in progress aimed to determine the extent to which practising professional counsellors perceive themselves as multicultural competent when counselling clients who come from different cultural backgrounds in Malaysia. A national survey study was conducted targeting 1500 registered practising counsellors at various states in Malaysia. A 32-item questionnaire, the Multicultural Counselling Survey – Malaysian Version, was developed based on the existing research literature to assess the self-reported multicultural counselling competency of Malaysian professional counsellors when counselling clients in the Malaysian context. More than 300 counsellors responded to this questionnaire via mailed survey, while 170 responded via online survey. Preliminary
findings from the mailed survey data regarding participants’ self-perceived multicultural counselling competency are reported. Results showed that, although Malaysian counsellors reported good understanding regarding multicultural counselling, they scored low in some multicultural skills areas such as counselling gay and lesbian clients in the Malaysian context. These results highlight the importance of understanding specific cultures and contexts to become multiculturally competent when working with minority clients from different cultural backgrounds. Multicultural counselling competency needs to be integrated into all counselling in Malaysia. Implications of this research for the education and training of counsellors in the specific cultural context of Malaysia are discussed.

Keywords: multicultural, counselling, Malaysia, minorities

A naturalistic study of executive function and problem-solving in mathematics

KOTSOPOULOS, D. (Wilfrid Laurier University), LEE, J. (Wilfrid Laurier University), PIQUETTE, M. (Upper Grand District School Board), HEIDE, D. (Waterloo Region District School Board), WHITE, J. (Wilfrid Laurier University)

Few studies on executive function (i.e., inhibiting, shifting, and updating) and problem-solving in mathematics have isolated the type of executive function that contributes to cognitive challenges for students during the different stages of problem-solving. The aim of this research was to examine the relationship between executive function and six proposed stages of problem-solving in naturalistic settings, while students completed mathematics homework at home. Modified talk- and think-aloud protocols were utilized to examine “mathcam video diaries” completed by students at home (Ericsson & Simon, 1993, 1998). The data set included select episodes where students were either describing or having difficulties in their problem-solving (n = 342). Episodes were transcribed and coded twice to identify when in the problem-solving sequence challenges were experienced, and what appeared to be the related executive function. Descriptive statistics, as well as Fisher Exact Tests of significance, Cramer’s V, and Kendall’s Tau-b were computed to estimate predictive relationships. Updating may be the most significant challenge faced by students at the onset of the problem-solving task, and shifting at the conclusion of the problem-solving task. Inhibiting was found to present the most significant challenge only during the carrying out stage of the problem-solving. Statistical analysis confirmed a relationship between executive functions of inhibiting, shifting, and updating, and the six stages of problem-solving (i.e., understanding the problem, devising a plan, carrying through the plan, looking back, generalizing, and problem posing) (P < 0.05, two-sided Fisher’s Exact Test). Cramer’s V and Kendall’s Tau-b were found to be significant but weak and very weak, respectively, suggesting neither an ordinal or nominal relationship. This research provides an extension to existing studies (predominantly experimental) by showing that different executive functions may be implicated at different times during problem-solving. Results suggest that perhaps different experimental designs need to be explored to investigate multiple stages of problem-solving. Teachers should implement different pedagogical interventions depending on where in the problem-solving stages the student is experiencing difficulty and depending on which executive function is implicated.

Keywords: executive function, problem-solving, mathematics, students

A pilot of psychorationalist based therapy with 10 injured workers demonstrating large effect sizes for anxiety, depression and trauma

PHILLIPS, P. (Psychorationalist Institute), WINKS, T. (Allianz Insurance)

Psychodynamic therapy has been accused of being too lengthy and lacking an evidence base to be used in the management of worker injuries. Thus cognitive behavioral therapy and applied relaxation therapy have been used instead. However, recent evidence from American psychiatric studies of psychoanalysis for anxiety (twice per week for 12 weeks) achieved a 73% symptom remission rate with only 7% dropouts (Milrod, et.al. 2007). These
results are impressive when compared with applied relaxation therapy results of only 39% remission and 34% dropouts. In this article we report on a trial of psychorationalism, a form of psychodynamic therapy, with 10 injured workers (6 female, 4 male). All workers had a soft tissue injury more than 52 weeks previous yet remained at reduced hours of work or unemployed. People were seen once per week for 12 weeks. Various psychometric tools were used to assess anxiety, depression, self-efficacy, self-esteem, defence styles and trauma. The tools were administered at baseline, week 6 and week 12. As there was no control group to compare results, an effect size calculation was used. The initial results indicate an effect size (Cohen’s d) of 1.84 for anxiety, 2.13 for depression, and 1.08 for trauma. When Cohen’s d is above 0.8 the effect size is considered large. Therefore, these effect sizes demonstrate the effect of psychorationalist therapy in this sample to be large. The initial results indicate that Psychorationalist therapy offers an effective form of treatment to injured workers. Further clinical trials will establish if the above effect sizes are typical. Given the current data further trials are encouraged.

Keywords: psychorationalism, worker injuries, depression, trauma, anxiety

A profile of the young tennis player at risk of burnout

STYNES, J. (Australian Catholic University), ADAMSON, B. (University of Sydney), COVIC, T. (University of Western Sydney)

Four empirical studies were conducted to examine the change over time in perfectionism, trait anxiety, motivation, and coping, and the impact these variables have on burnout. This research was guided by Smith’s (1986) Cognitive Affective Model of Athlete Burnout with the aim to identify a profile of the young tennis player at risk of burnout. Young tennis players between the ages of 10 and 17 years were assessed on burnout, perfectionism, trait anxiety, motivation, sources of stress and coping behaviour over 25 months. The tennis players were competing at the school, state and/or national level. Since burnout is considered to be a fluid construct that builds up slowly, the longitudinal analysis allowed for the development of burnout to be measured over time. Perfectionism, trait anxiety and motivation remained stable over the testing period. The use of ineffective coping strategies (i.e., non-productive) increased and effective coping strategies (i.e., productive) decreased over time. Age and components of perfectionism (i.e., positive perfectionism), coping (i.e., non-productive), and motivation (i.e., amotivation) were found to be significant predictors of burnout in the young tennis players. Positive perfectionism was identified as a protective factor and non-productive coping, amotivation and age as risk factors for burnout. The results show that the relationship between personality, motivation and coping variables and burnout is multifaceted. The results reported in this research have significant implications in the understanding, prevention and intervention of burnout in young tennis players. Coaches, parents and others working with young tennis players must be mindful of amotivation and the use of non-productive coping strategies particularly during the middle stages of adolescent development. Vigilance and continuous assessment of coping behaviour, motivation and burnout symptoms during the youth sport experience is recommended.

Keywords: perfectionism, trait anxiety, motivation, coping, tennis player burnout

A prospective study of time perspective and well-being: Present focused time perspectives predict change in depression

HAROS, M. (Danila Dilba Health Service), DADDS, M. (University of New South Wales)

There is general consensus that we all see the world differently and that this is an important element in understanding human behaviour. How we see the world is considered a factor influencing illnesses such as depression (Beck, 1976). But what does seeing the world differently mean? It is literally true with regard to vision. No two people share exactly the same vantage point and even if they did, eye-tracking experiments indicate that they would perceive
Abstracts of the 27th International Congress of Applied Psychology

Individual Oral Presentations

different information, depending on their objective, rather than the entire visual field (e.g., Yarbus, 1965). It is less obvious that the experience of time is a subjective one and is integral to seeing the world differently, perhaps contributing to a range of illnesses. In this study, the construct time perspective was used to operationalise the concept that the way individuals see the world affects their well-being. The Zimbardo Time Perspective Inventory (ZTPI; Zimbardo & Boyd 1999) was validated on an Australian sample of 449 undergraduate students in order to be used in a prospective study of time perspective and well-being. The subjective nature of time perspective – one’s view of the past, present and future - including how time perspective can become biased was reviewed. Previous relations between time perspective and well-being were replicated and extended: time perspective was found to be predictive of well-being during a challenging event. Sixty-five participants took part in the study in which well-being was measured prior to and during a university exam period. Biasing the present focused ZTPI time dimensions present-hedonistic and present-fatalistic was predictive of greater depression symptomatology. Bias towards the present-fatalistic dimension approached significance in predicting increased anxiety and stress, and diminished happiness. Present focused time perspectives involve the individual being susceptible to features of their current situation. The thread of past, present and future is interrupted as well as means-end processes. The possibility that time perspective confers a vulnerability or resilience to psychopathology in different contexts was considered.

Keywords: vision, depression, well-being

A psychological perspective on god-belief as source of well-being and meaning

VAN DER MERWE, K. (North-West University), VAN EEDEN, C. (North-West University), VANS DEVENTER, H. (North-West University)

This paper reports on a qualitative exploration of the well-being and meaning that second- and third-generation Christians from an African context experience because of their integration of religion in their life and being. A case study design, which is ideally suited to an in-depth study, was used. Individual interviews were conducted, digitally captured, transcribed and reflected upon in the light of the research questions. Twelve participants, eight male and four female, ranging in age between twenty five and sixty five years were individually interviewed. A total of fourteen hours of audio material was transcribed for detailed analysis and interpretation. The differences and similarities in the God-image and God-concepts in traditional African religion and Christian beliefs and how these influence adherents’ philosophy of life form a core part of the study. Participants, who can all be described as intrinsically religious, create meaning in the light of the tenets of African and Christian religion they accept and individually forge into an integrated worldview or system of meaning. The power of this system to frame understanding and make sense of experiences is explicated, highlighting the crucial role of feeling individually significant and safe. The insights gained in this study of the role that religion plays in the creation of meaning and the contribution of religion to the psychological well-being of Christians from an African context, could be translated into psychological practice. The practice fields of pastoral counselling and trauma counselling can base therapeutic interventions and/or guidance on the fact that religious beliefs and practices can provide a basis for a transcendent sense of personal growth, efficacy, mastery and purpose in life. The findings of this study suggest that religious beliefs and experiences may provide an important source of personal strength that promotes psycho-social well-being, mental and physical health and positive emotions such as joy, gratitude, forgiveness, hope and optimism – all building blocks of psychological well-being.

Keywords: religion, Christian, African, well-being, case study

A psychometric evaluation of career decision self-efficacy scale-short form with Turkish undergraduates

IK, E. (Selcuk University), IK, E. (Selcuk University)
Abstracts of the 27th International Congress of Applied Psychology

Since the Career Decision Self-Efficacy Scale-Short Form (CDSES-SF) developed by Betz, Klein, and Taylor (1996) is one of the most used instruments within the career counseling field, there have been many attempts to assess its reliability and validity with different languages, cultures and ethnic minorities (Creed, Patton, & Watson, 2002; Gushue & Whiston, 2006; Hampton, 2005, 2006; Watson, Brand, Stead, & Ellis, 2001). However, especially in non-English speaking countries, the use of CDSE-SF is still unknown. Therefore, this study examines the reliability and validity of CDSE-SF with Turkish undergraduates. Participants were 368 Turkish undergraduate students from a large state university. Internal consistency, test-re-test reliability and item total correlations were calculated for reliability studies. A principal component factor analysis was employed for structural validity, age and gender differences were tested for criterion validity, and Vocational Outcome Expectations Scale and Rotter Locus of Control Scale (RLOCS) were used for convergent validity. Values of coefficient alpha indicated high reliability ($r = .88$), a seven week test-re-test reliability coefficient was $r = .81$, and item total correlations ranged between .34-.62. Even though there is little support for a five factor structure as in the original form, the CDSES-SF is a generalized instrument for assessing career decision self-efficacy. The convergent validity of CDSE-SF was supported by a high correlation with VOE and a moderate correlation with (RLOCS). Besides, as in the previous literature, the older group (20 and below) scored higher than the younger group (21 and above) and no significant difference was found in terms of different age groups. CDSES-SF is a reliable and valid measure when used with Turkish undergraduates. As a single factor measure, most of the findings of the current study support the previous findings. The implications of these findings are discussed and some recommendations were given.

Keywords: Career Decision Self-Efficacy Scale-Short Form, career counselling, Turkish, undergraduate students

This study aimed to examine the psychometric properties of the Satisfaction with Life Scale (SWLS) in terms of factorial validity and measurement invariance across gender, age and residential region (city/county town/rural) with a general population sample in China. The stratified multi-stage random sampling method was used to obtain a nationally representative sample of 4,795 respondents from ten capital cities, eleven county towns and eleven rural areas in Mainland China. Face-to-face interviews were conducted to gather respondents’ evaluation of life satisfaction using the SWLS. Confirmatory factor analysis (CFA) was used to examine the factor validity, and multi-group CFA was employed to demonstrate the measurement invariance of SWLS across gender, age, and region. Results showed that the SWLS has a high internal consistency reliability, a one-factor structure with a wording effect on Items 4 and 5, strict invariance across gender, and partial strong invariance across age (Items 1, 2 and 3) and residential region (Items 1 and 2). Specifically, people from different age or residential region groups had the same perceptions of the items tapping present life satisfaction (Items 1, 2 and/or Item 3), but not of the items tapping past life satisfaction (Items 4 & 5). Authors concluded that time frame effect existed in the evaluation of life satisfaction for Chinese using the SWLS, and the effect was not invariant across different age or residential region groups. It was speculated that this effect was related to the differences of life experiences of respondents from different groups due to the rapid economic and societal change of China during the past three decades. However, more research is needed to address how social transition would influence people’s subjective well-being.

Keywords: satisfaction with life scale, China, well-being, social transition

A psychometric evaluation of the satisfaction with life scale in a general population sample from China

A psychometric study on college student’s creativity in China
The aim of this study was to develop a Creativity Scale for college students in China, and to examine its reliability and validity. Based on interviews and experts’ evaluation, a previous questionnaire with 50-item version was developed. After a pretest in 285 college students for determination, a 40-item version of formal questionnaire, a random sample of 800 college students completed it; reliability and validity of College Student’s Creativity Scale were analyzed. Firstly, after exploratory factor analysis, a 40-item version of questionnaire including seven factors was established. These seven factors could explain 59.18% of the total variance, and were confirmed by confirmatory factor analysis (X2/df=2.48; NFI=0.98; CFI=0.99; GFI=0.97; AGFI=0.94; RMSEA=0.078). Secondly, the internal consistency of the scale was good (α=0.902), and the retest reliability was 0.897. Thirdly, the reliability and validity of College student’s Creativity Scale were corresponded with psychometric standard, and could be used as an effective and reliable tool for assessing college student’s creativity in China. Under the condition of this research, we could make these conclusions: the Questionnaire of College student’s Creativity Scale corresponded with psychometric standard in reliability and validity, and could be used as an effective and reliable tool for assessing college student’s creativity in China.

A randomised controlled trial of the ABCD Parenting Young Adolescents Program: Post treatment outcomes

BURKE, K. (Parenting Research Centre), BURKE, K. (Parenting Research Centre), BRENNAN, L. (Monash University), CANN, W. (Parenting Research Centre)

Parenting programs delivered to parents during their child’s transition to adolescence offer a potentially effective approach to reducing engagement in dangerous risk-taking. The aim of this study was to examine the efficacy of a parenting program that combines a behavioral family intervention (BFI) approach with acceptance-based strategies to promote positive parenting practices, parent-adolescent relationships, and parent and adolescent outcomes. A total of 180 parents of young adolescents were randomly allocated to either intervention or wait-list control conditions. Parents allocated to the intervention condition participated in the ABCD Parenting Young Adolescent Program, a six session group BFI program that incorporates acceptance-based strategies. The program aims to promote parenting factors associated with positive child outcomes, thereby addressing many of the risk and protective factors likely to have a preventative effect for adolescent risk taking and problem behavior. Assessments of adolescent behaviour and conflict, parenting practices, and parenting stress and depression were completed prior to, and immediately after, the intervention. Post-intervention questionnaires were returned by 114 (63%) participants. Both completer and intention-to-treat analyses were conducted. After controlling for pre-intervention differences, parents in the intervention condition reported that their adolescent had significantly higher prosocial (F(1, 113) = 5.57, p = 0.020, partial η2 = .048) and significantly lower conduct problems(F(1, 112) = 3.99, p=0.048, partial η2=.034) and total difficulties scores (F(1, 110) = 4.29, p = .041, partial η2 = .038) compared to the control condition. Intervention parents also reported significantly lower stress associated with adolescent moodiness (F(1, 111) = 4.74, p=0.032, partial η2 = .042) and parent life restriction (F(1, 90) = 13.73, p < 0.001, partial η2 = .135), adult relations (F(1, 82) = 28.99, p < 0.001, partial η2= .266), social isolation (F(1, 110) = 6.56, p = 0.012, partial η2 = .057), incompetence/guilt (F(1, 109)=14.54, p<.001, partial η2=.120), stress in the parenting domain(F(1, 110) = 22.88, p < .001, partial η2 = .175) and overall stress (F(1, 113) = 9.11, p = 0.003, partial η2 = .076) relative to the control condition following the intervention period. No other statistically significant differences were evident (p < .05). The current study revealed a number of positive effects for parents participating in the ABCD program that suggest that the program may have benefit to parents of young adolescents in assisting them to promote or maintain protective factors in their families such as improving their own...
wellbeing and reducing parent perceptions of child behavioural difficulties.

A socially-oriented perspective on emotional processing: building on Greenberg’s formulation of therapeutic weeping

MCVEA, C. (Queensland University of Technology)

Emotional release during the enactment of a corrective interpersonal experience in psychodrama group therapy has been identified as therapeutically helpful for healing painful emotional experience. Greenberg argues that therapeutic weeping is an indicator of allowing emotional pain, and is a transformative process which has general application across therapeutic modalities. This current research investigates the fit between protagonists’ experiences in psychodrama and the allowing and accepting painful emotional experience model, as operationalised by Foerster and Greenberg (1996). The verification phase of task-analysis method was applied to the psychodrama enactments of nine protagonists (7 female & 2 male, aged 35–60 years). In-session performances were coded using Foerster and Greenberg’s (1996) measurement criteria for the four components of their model: articulating maladaptive beliefs, acknowledging secondary bad feeling, allowing emotional pain and accessing needs. In-session performances were charted and these actual performances were compared to Foerster and Greenberg’s (1996) hypothesised performance. Resolved (6) and not-resolved (3) cases were compared, using Fisher’s exact test (1954). Resolved cases met all Foerster and Greenberg’s (1996) criteria and, consistent with their model, only resolved cases met the criteria for therapeutic weeping. However, the sequence of protagonists’ actual performances differed from that proposed by Foerster and Greenberg. Furthermore, the emotional release which occurred during the enactment of a corrective interpersonal relationship, which had previously been identified by participants as therapeutically significant, did not typically meet Foerster and Greenberg’s (1906) criteria for therapeutic weeping. These findings offer qualified support for Greenberg’s model. However, the variation in the sequence of protagonists’ in-session processes suggests that there is an intervening dynamic not described in their model, which facilitates the transition from awareness of secondary bad feelings and maladaptive beliefs, to the process of releasing emotional pain. Possible intervening factors are considered. The findings also support the proposition that the therapeutic agency of emotional release during psychodrama is primarily as a catharsis of integration linked with the experience of a corrective interpersonal relationship, rather than being primarily an indication of allowing emotional pain.

A structural model linking commitment to organizational change and change success

MACHIN, T. (University of Southern Queensland), FOGARTY, G. (University of Southern Queensland)

This research examines the linkages between employees’ commitment to organizational change and their perceptions of change success and job satisfaction whilst controlling for their tenure in the organization. The organization involved had undergone significant structural reform over a number of consecutive years involving thousands of staff. The nature of the change involved a large number of employees moving into new roles so we expected that job tenure may also influence their perceptions of change success. Using the three-component model of commitment to organizational change, we analyzed the ability of the three commitment to change variables (affective, continuance, and normative) to directly and indirectly explain perceptions of change success in three successive organizational surveys. The data were obtained from a large public sector organization that established as a result of a restructuring and amalgamation of corporate services within a State Government. The number of respondents
varied each year from 2549 in the first year, to 2737 in the second year and 2595 in the third year. A structural model was specified using Amos with three models estimated simultaneously in which all parameters were allowed to vary. The strongest predictor of change success across all three years was job satisfaction followed by affective commitment to change. Continuance commitment to change and normative commitment to change were only very weakly related or not related to change success. Tenure was negatively related to change success at all three times. Job satisfaction partially mediated the link between affective commitment to change and change success. The structural model was reasonably stable across the three years and highlights the important role that job satisfaction plays in the process of implementing large-scale organizational change. Other issues to be considered include the potential moderating role of tenure, job level and gender as these have been proposed as moderators of the way employees respond to and cope with organizational change.

Keywords: organisational change, commitment, job satisfaction, change success

A survey of Chinese college students’ career planning

CHI, L. (Beijing Sport University), ZHOU, X. (Beijing Sport University), YE, H. (Beijing Sport University)

This study tries to reveal characteristics of Chinese college students’ career planning, and to find factors affecting their career exploring behaviors. 336 college students attended the survey (male = 130, female = 206; mean age = 20.56), and they were from four grades. College Students’ Career Development Inventory was utilized, consisting of four subscales: career action, career exploring, career decision making, career estimation and regulation. Multivariate analysis showed that main effect of grade is significant. Scores of fourth grade on estimation and decision making are higher than that of second and third grade. On career behavior, scores of first grade was higher than other grades. Scores of fourth grade on career exploring is higher than other grades. Students majored in liberal arts had high scores in career estimation and regulation than majored in natural science. The students who have been trained in career planning had high scores in career behavior. The students who came from rural areas had high scores in career behavior than those from urban area. Those who had working experiences had high scores in career exploring than those having no experiences. It was concluded that: differences of career planning are significant between grades; significant differences of career planning also existed among students who are different in majors, working experiences, and career trained experiences.

A systems approach to analysis of sheep farming accidents

LOBB, B. (The University of Auckland), ATKINSON, C. (The University of Auckland), IM, R. (The University of Auckland)

Farm accidents have major human and financial costs. While much research worldwide has identified numerous risk factors contributing to these accidents, farming work and contexts vary widely. According to systems theory, different combinations of factors are likely to predict different accidental injury outcomes. Thus more detailed understanding of the links between accidents and their specific task and associated system factors would enable development of interventions targeted directly at the relevant risk factors and so less wasteful of resources and more meaningful to farmers, increasing likelihood of safety compliance. This study aimed to identify the specific risk factors for accidents in North Canterbury sheep farming by providing a systematic description of the work, identifying the nature and incidence of accidental injuries, linking these accidents with specific tasks and identifying contributing system factors according to Sanders and Shaw’s (1988) Contributing Factors to Accident Causation (CFAC) model. Interviews with experienced farmers informed a hierarchical task analysis of the work. Further interviews with 26 owner-operator sheep farmers then sought information about
accidents occurring during each of the identified task types and about contributing factors. Results were analysed qualitatively and quantitatively. Sheep farming was found to involve four main tasks (feed provision, property/equipment maintenance, stock trading and stock management). Most of the reported accidents (27/35) occurred during just nine of the 47 identified subtasks. The majority of accidents involved motor vehicles or stock but not all task types involving stock or vehicles resulted in accidents. Injury type was also clustered according to task. When the contributing factors identified were mapped to the CFAC model, the most frequent were worker/coworker factors (n=24), work factors (n=20) and management factors (n=12). The findings of this study provided the first systematic description of New Zealand sheep farming work and contributing factors to accidents during specific tasks, suggesting targeted, meaningful interventions to improve safety compliance.

A talent retention strategy framework for retaining graduate interns in a South African information, communication and technology Company

BARKHUIZEN, N. (University of Pretoria), POP, C. (University of Pretoria)

Talent retention is an important topic of debate in the Information, Communication and Technology (ICT) sector in South Africa, given the context of a skills shortage, the relative scarcity of specialist employees and the mismatch between the supply from higher education institutions and the demands of the ICT workplace. As a result, organisations invest in graduate internship programs to attract and retain high calibre graduate interns. The main objective of the research was to determine whether a graduate internship program, as a national skills development strategy, contributed to the retention of graduate interns in a South African Information, Communication and Technology (ICT) Company. An exploratory, ex post facto research design was followed using a combination of quantitative and qualitative data gathering techniques. Surveys were administered among a purposive selected sample of graduate interns (N=79) and mentors (N=39) in a South African ICT company. The surveys measured soft and technical skills training, mentorship role, turnover intention and general program information. Open ended questions were used for the triangulation of results. Results overall showed that the graduate internship program contributed to the employability and retention of graduate interns. On average, the graduate interns indicated that the program training contributed most to business etiquette, conflict management, problem-solving, self-management and goal-directedness soft skills. Combined, the participants identified verbal communication, self-motivation, teamwork and goal directedness as the most important soft skills for graduate employability. Results further showed that the technical skills training contributed to a large extent to the employability of the graduate intern. Practically significant relationships were found between technical skills training, mentorship, program need and the graduate intern’s intention to quit the internship program. Practically significant relationships were also found between mentorship, program need and the mentor’s intention to employ the graduate intern. The research concludes with a retention strategy framework in guiding the implementation of a graduate internship programme in the ICT sector. It is of great value for companies to put strategies in place to ensure that they retain new graduates if they are suitable, skilled and respond to on-the-job training.

A virtual tabletop workspace for upper-limb rehabilitation in traumatic brain Injury (TBI): A within-group evaluation

WILSON, P. (RMIT University), MUMFORD, N. (RMIT University), THOMAS, P. (Griffith University), SHUM, D. (Griffith University), DUCKWORTH, J. (RMIT University)

The aim of this study was to evaluate the effectiveness of a table-top virtual reality (VR)
based system (called Elements) for rehabilitation of upper-limb function in patients with Traumatic Brain Injury (TBI). Participants were nine patients with severe TBI (5 male, 4 female), aged from 18 to 48 years \( (m=33\text{ years}) \). All were recruited at the Epworth Hospital, Melbourne. The median PTA was 70 days (range 28 to 630 days). The VR system consisted of a large 42-inch tabletop LCD, camera tracking system, tangible user interfaces (i.e., graspable objects of basic shape), and software. There were two modes of user interaction—goal-directed and exploratory, both using augmented feedback. The former were reach and place tasks, cued from within the virtual environment, while the exploratory tasks were a suite of tools for composing with sounds and visual feedback, via object manipulation. A within-group research design was employed with three time points: Pretest-1 and Pretest-2, conducted four weeks apart, and a Post-Test. Training consisted of 12 one-hour sessions. All patients maintained normal physical therapy throughout the study. Upper-limb performance was assessed using both system-rated measures, recorded automatically (movement speed, accuracy, and efficiency), and standardized tests (Box and Block Test, MAND nut threading, and Neurobehavioral Functioning Inventory—NFI). Results of planned comparisons revealed little change in performance over the pre-test period; the only significant change was an increase in movement speed. Comparison of (average) pre-test and post-test performance showed significant training effects (each \( p<.01 \)), with large effect sizes on all measures with the exception of nut threading on the MAND. The present findings support an earlier case-study assessment, further demonstrating that training on the Elements system can facilitate motor learning in TBI patients. These results suggest that VR-based techniques are a viable adjunct to conventional physical therapy in the rehabilitation of TBI.

Keywords: traumatic brain injury, rehabilitation, virtual reality

**Absence makes the heart grow fonder: A study into the possible causes of increasing absenteeism in part time flight attendants**

ALLAN, M. (Livuingstones Australia), COOGAN, J. (University of East London)

Full time longhaul flight attendants for a major international airline, who voluntarily moved to part time contracts, have a higher sickness and absenteeism level than their full time colleagues. The unique employment conditions of the cohort enabled a reduction or elimination of confounding variables identified in previous part time employee research. This mixed methods research utilised thematic analysis and Q methodology to investigate the differing lifestyle priorities of a group of longhaul flight attendants. The epistemological debate regarding mixed methods was investigated as part of the research, with thematic analysis used to gain an in depth understanding of full time and part time employee perspectives. Thematic analysis also generated 69 statements for the Q methodology \( (N=21) \) with PCQ computer software utilised for factor analysis. Four factors were identified. Results indicate that the full time flight attendants within the cohort have stronger commitment and engagement with the organisation dependant on their seniority, length of service and level of autonomy, in line with the literature. Indications are that the most engaged full time employees also invested the most effort in remaining connected to the organisation during their days off. All of the established part time employees identified onto one factor indicating significantly different priorities within their psychological contract and differing attitudes towards the provision of emotional labour. The analysis indicates that the length of time disconnected or detached from the organisation may well contribute to the higher levels of absenteeism with the anticipated or perceived effort involved in providing emotional labour being a significant factor. This research gives an in depth understanding of the possible causes of absenteeism within part time employees delivering emotional labour, raising the question of the necessity for a differing management style, contracting and level of engagement to meet differing expectations. This research raises the question that, contrary to the literature, part time employees may have a different priority order within their psychological contract and employers may need a different approach when trying to engage and motivate these employees.

**Abusive leadership and hostile personality. Do leaders high on trait anger target subordinates low on trait anger?**

EINARSEN, S. (University of Bergen), KANT, L. (University of Bergen), SKOGSTAD, A. (University of Bergen), TORSHEIM, T. (University of Bergen)

Both individual traits and situational stressors have been theorized as antecedents of destructive leadership behaviors, going back to the inevitable person-situation debate in psychology. Yet empirical studies investigating why leaders expose subordinates to abuse and intimidation are scarce. The aim of the present study is threefold, 1) to investigate if trait anger and trait anxiety of leaders predict abusive supervision as reported by subordinates, 2) if destructive leaders target subordinates being either low on trait anger or high on trait anxiety, and 3) to investigate if the predicted relationship between personality and abusive leadership stands when controlling for situational influence in the form of role stressors. A survey was conducted in 89 crews (n= 180) working on Norwegian coastal ferries where captains reported their own trait anger, trait anxiety and experienced role stressors, while their subordinates evaluated their captains leadership behaviors as well as describing their own trait anger, trait anxiety and experienced role stressors. Data was analyzed with multilevel analysis, analyzing both within and between level variance and with gender and tenure in crew as control variables. The results showed that abusive leadership as reported by subordinates was related to trait anger as reported by the captain. In addition, subordinate trait anxiety and experiences of role conflict was related to their reports of exposure to abusive leadership. In addition, an interactive effect was found between trait anger in captains and trait anger in subordinates. Combinations of high trait anger in captains and low subordinate trait anger is related to more reports of exposure to abusive supervision. The present study shows that leaders who expose their subordinates to abusive supervision are characterized by high levels of trait anger, while the situation influence did not matter much. Furthermore, some subordinates seem to be more in danger of such experiences than are other. Particularly exposed subordinates are those who themselves are low on trait anger, indicating that angry leaders may target subordinates who are unable or unwilling to retaliate in kind. In addition, distressed and anxious subordinates seem to be particularly vulnerable. Prevention should therefore address both leaders and subordinates, as well the combination of the two.

**Keywords:** individual traits, situational stressors, destructive leadership, trait anxiety, trait anger

**Academic wear-down and attitude toward school among Iranian university students**

HAMEEDY, M. (Alzahra University), FAKHAAREE, E. (Alzahra University)

From a social constructivist perspective, learning is a life-long activity of construction, and effective educational programs and processes are those rooted in the psycho-socio-cultural realities constructed by the individual. Nevertheless, in formal education the learner may experience a sense of wear-down, because of some misconstructions that may have occurred in his/her attitudes toward school. The learner may wear down physically, cognitively, affectively, and behaviorally, and in doing so, the attitudes, with three cognitive, affective, and behavioral dimensions, can play a determining role. The aim of this research has been to find a way of predicting and preventing the wear-down from taking place by initially showing the relationship between the two constructs and paving the way for a program of reconstructing attitudes. Given the nature of the inquiry, each of three groups of participants will be measured once on the two constructs in an academic setting. Participants would be junior year university students in the Arts, Social Sciences, and Sciences at an Iranian University in Tehran where competition to attend university is high. The measures used in the study include an attitude scale consisting of items in three subcategories, and a questionnaire on the academic wear-down (AWD) consisting of four sets of items. These are being constructed based on the
theoretical basis of the study, and will be tested for reliability with the help of other groups of students. The data, once gathered, will be assumed to be interval in order to pave the way for their processing using Pearson's method of assessing the correlation between two constructs and Fisher's analysis of variance. It is expected that the correlation between academic wear-down and attitude toward school would be positive and high, while the difference between three groups of participants in both characteristics would be significant. Furthermore, there may be differences between different dimensions of both variables giving hints as to how to intervene and remedy the problem. The problem of academic wear-down in Iranian universities can be reduced if the learners' attitude towards school is checked and reconstructed to a level of positivity that would enable the students to pursue their academic goals more enthusiastically and productively.

Keywords: academic wear-down (AWD), Iranian students, attitudes

Acceptance and commitment therapy for psychosis: avoidance, fusion, preoccupation and delusional distress

THOMAS, N. (La Trobe University / Monash Alfred Psychiatry Research Centre), FARHALL, J. (La Trobe University), SHAWYER, F. (La Trobe University)

In spite of advances in pharmacological and psychological treatments for schizophrenia, it can be difficult to eliminate psychotic symptoms such as hallucinations and delusions. This has led to an important therapeutic aim being the reduction of symptom-related distress. Cognitive Behavioural Therapy (CBT) has targeted distress by modification of the content of delusional and associated beliefs. However, belief modification, especially with delusions held with strong conviction, is not always successful. An emerging alternative psychological therapy is Acceptance and Commitment Therapy (ACT; Bach & Hayes, 2002; Gaudiano & Herbert, 2005). Designed to be applied across a wide range disorders, ACT aims to reduce symptom-related distress by targeting cognitive processes which perpetuate the dominance of distressing thinking over desired behaviours. These include cognitive fusion, ruminative preoccupation and attempted experiential avoidance. ACT aims to help the person detach from these maladaptive thinking processes by taking their thoughts less literally, developing skills in mindfulness, and undermining experiential avoidance. These therapeutic strategies appear primarily to be targeting delusional preoccupation, as opposed to delusional content. This paper reports on pre-therapy data from a randomised controlled trial of an ACT intervention for psychosis to examine the role of these cognitive processes in determining delusion-related distress. 40 participants with a diagnosis of schizophrenia and medication-resistant positive psychotic symptoms were recruited from mental health services. Measures completed included symptom severity (Positive and Negative Symptom Scales); delusional content, preoccupation, conviction and distress (Peters Delusion Inventory); cognitive fusion (Thought Action Fusion Questionnaire); and experiential avoidance (Acceptance and Action Questionnaire). A model was tested in which delusion-related distress is determined by delusional preoccupation and conviction, moderated by experiential avoidance. Cognitive fusion was hypothesised to be predictive of delusional conviction. Data supported this model, finding that delusion-related distress was more strongly associated with delusional preoccupation than delusional content or conviction, and that this relationship was moderated by experiential avoidance. Cognitive fusion predicted the degree of delusional conviction. These results support delusional preoccupation as a target of psychological intervention in schizophrenia, and suggest that the cognitive processes specifically targeted by ACT are important in contributing to the severity of delusions.

Keywords: psychotic symptoms, distress, acceptance and commitment therapy, schizophrenia

Accidental risk judgements and choices between private and public transportation

RUNDMO, T. (Norwegian University of Science and Technology), NORDFJÆRNL, T. (NTNU)
The core aim of the present study was to examine the role of risk perception related to accidents and injuries in choices between private and public modes of transportation. An additional aim was to examine the relative importance of perception of risk related to transportation with other risk-related factors. The results are based on a mailed self-completion questionnaire survey carried out amongst a representative sample of the Norwegian public aged from 18 to 65 years ($n = 1864$). The data collection was carried out during October to December 2008. The results have shown that perceived control related to private modes of transportation, knowledge about safety and trust in authorities seem to be more important for choices between private and public modes of transportation than risk perception. Severity of consequences was found to be insignificant for transport mode choices. It may be that conclusions of previous research about the role of consequence judgement for precautionary action and demand for risk reduction may be misleading.

Keywords: risk perception, transport

Acquiring two new languages: Comparing a picture-mediated method and a word-mediated method

JOB, R. (University of Trento), TONZAR, C. (University of Urbino), LOTTO, L. (University of Padova)

In this study, we aimed at evaluating the effects of two learning methods (picture-mediated vs. word-mediated) on the vocabulary acquisition of two foreign languages: English and German. In addition, we investigated the effects of word status (cognates vs. non-cognates) and test sessions (immediate vs. delayed). 40 concepts were presented both in English and German (in different learning sessions) to 229 Italian children from fourth and eighth-grades. Half of participants were exposed to the “word-mediated method” (Italian words paired with the corresponding foreign words), while the other half were exposed to the “picture-mediated method” (pictures paired with the corresponding foreign words). For each language, participants performed 4 test sessions: Immediate Test 1 at the end of the first learning session; Immediate Test 2 at the end of the second learning session. Delayed Tests were administered one week after Immediate Test 1 (Delayed Test 1), and one month after Immediate Test 2 (Delayed Test 2). The picture-learning method produced a better performance than the word-learning method, but this effect was modulated by cognate status, age of learning, and test session. In particular, a stronger superiority of the picture-learning method in the latter than in the first session indicated that the effects of the picture-mediated learning method may be fully appreciated when the learning sessions were spaced in time. Furthermore, cognate status interacted with the learning method for older children, indicating that the word method was particularly effective for cognate words. Finally, for both languages and for both age groups, cognates status interacted significantly with test sessions. The superiority of the picture-mediated method compared to the verbal one suggests that the link between the structural description of an object, its visual representation, and its name is more efficient than the link between the corresponding L1 and L2 names. From an educational perspective, this study suggests that a) reliance on, and strengthening of, the link between the concepts presented as pictures or real objects and their names may help in vocabulary learning, and b) cognate and non-cognate words should be should be taught differently to maximize vocabulary acquisition.

Keywords: picture-mediated learning method, word-mediated learning method, vocabulary acquisition, foreign languages, performance

Acting upon dynamic speed limits: Is change blindness involved?

HARMS, I. (Rijkswaterstaat Center for Transport and Navigation), BROOKHUIS, K. (University of Groningen)

Dynamic speed limits are the latest traffic management pilot in the Netherlands. Being dynamic they can vary during the day. Previous studies showed difficulties with noticing small changes, also called change blindness. These change blindness studies have mainly been
conducted using static scenes or changing irrelevant objects or changing objects that are perceived as static. But what happens if the information changed is relevant for the task, is perceived as dynamic and continuously in a dynamic scene? On a Dutch freeway dynamic speed limits were tested that increased from 100 km/u to 120 km/u at moderate traffic conditions. They were shown on rotation signs next to the road and varied several times a day. Loop data was used to measure average speeds of passing cars every minute and compared with the dynamic speed limits displayed. To minimize side-effects only data from speed limit increases for over an hour were used. The average speed before a switch is 107.7 km/u, meaning that drivers are driving on the pilot route for approximately three minutes before passing the detector loop. Drivers passing the loop did not react immediately on an increase in speed limit. On average it took three to four minutes before car drivers increased their speed. After that driving speed starts to increase significantly. Drivers in the middle and left lane are quicker to act on new speed limits than drivers on the right lane. Three minutes of non-response equals the amount of time it would take the last car driver that could have seen a 100 km/u sign to pass the detector loop. This may mean change blindness is involved. Drivers who may still have seen 100 km/u signs before the switch do not act upon the new speed limit. Subsequent drivers of information that changed. It is suggested that the observed quicker reaction of drivers in the middle and left lane may be due to their more active driving styles, where these drivers are often seen overtaking other vehicles. This driving style may increase situation awareness making them more sensitive to changes in their environment.

Keywords: dynamic speed limits, traffic management, change blindness

Activity restriction as a mediator of the relationship between ageing-related physical decline and mental health: A report from the New Zealand longitudinal study of aging

Prior research indicated that restriction of normal activities is an important factor in poorer mental health outcomes (Williamson, 2000). The present study aims to investigate the relationship between ageing-related physical decline in mental health, and how this relationship is mediated by restricted routine activities. Data were drawn from the New Zealand Longitudinal Study of Aging (2006-2008), with complete data available for 2170 participants (Mean age = 61.24 years; SD = 4.56). Self-rated health as compared to last year was used to assess ageing-related physical decline and mental health was measured by the SF 36. Activity restriction was assessed by the 16-items attributed to restricted normal activities adapted from the Physical Component of the SF-36. Several sociodemographic factors were also measured. Mediational analysis using multiple regression equations indicated that ageing-related physical decline was a significant longitudinal predictor of decrements in mental health, after statistically controlling for various sociodemographic factors and baseline scores of the outcome variable. Results also indicated that this relationship was partially mediated by restricted activities (Sobel's test: Z = 8.72, p<0.01), suggesting that ageing-related stressors such as physical decline undermines mental health by disrupting routine normal activities. Our findings suggest that activity restriction is a major factor in poorer mental health outcomes in older adults. As ageing-related physical decline increases, so does activity restriction which, in turn, results in decrements in mental health over time. Interventions focusing on promoting manageable activities considering individual differences in psychosocial resources and/or using compensatory control strategies can be developed to reduce activity restriction. For example, programs designed to foster strategies such as social support resources and social integration (e.g., free or low-cost bus service to visit friends and family, more participatory activities arranged in community halls etc.) may improve mental health among the elderly with perceived low social support.

Keywords: ageing-related physical decline, activity restriction, mental health, stressors
Adaptive personality assessment for unsupervised pre-screening

Conventional Big Five orientated personality inventories (normative and ipsative) have proven their effectiveness for applicant screening under supervised conditions. However, these types of instruments are very prone to targeted biased responses which make them less effective in unsupervised conditions. Furthermore, in order to establish sufficient reliability these instruments are very time-consuming for participants which causes problems in acceptance under various circumstances. With adallocTM a new method is presented which enables an adaptive personality assessment online. It is demonstrated how the adallocTM method allows bias-robust assessment in a fraction of the test time of conventional methods. Results from an international deployment of the adallocTM method for unsupervised online pre-screening of undergraduates (N=95,314) are presented along with results from in vitro studies on the effect of targeted biased responses.

Keywords: big five model of personality, applicant screening, biased responses

Adolescent girls’ responses to partner abuse prevention training: risk-sensitivity, perceived self-agency, and victim-blaming

MURPHY, K. (RMIT University)

This study formed part of an evaluation of a group-based training program designed to reduce adolescent girls’ vulnerability to chronic emotional, social, and physical partner abuse. The objectives of the program are to equip girls with the motivation and self-efficacy to resist the development of three “slippery-slope dynamics” in their current and/or future couple-relationships. Participants are given opportunities to predict possible harmful outcomes of each dynamic and then to explore ways in which five types of “warning-sign behaviour” can lead to the establishment of one or more of these dynamics. Participants also prepare and rehearse scripts for non-aggressively discouraging warning-sign behaviour by a partner. The study employed a repeated-measures design involving 15 groups of adolescent girls aged 13 to 17 years; 147 girls in total. This paper reports on attitudinal shifts observed during the program, as gleaned from measures taken immediately prior to the commencement of the training, immediately following the awareness-focused component, and immediately following the skills-focused component. Overall, risk-sensitivity increased for all categories of warning-sign behaviour, most substantially for dominance-seeking and possessive behaviours, following the awareness-raising component; it further increased following the skills-training component. Perceived importance of monitoring partner behaviour and self-confidence to positively influence treatment by a partner both increased after each component, but a small number of participants reported lower self-confidence following the skills-focused component. Similarly, while victim-blaming attributions decreased for most participants, some reported stronger victim-blaming attributions following the program. Through follow-up focus groups and subsequent hypothesis-driven analyses, a number of insights were garnered relevant to youth-targeted partner abuse prevention. These include the importance of (a) looking beyond self-confidence as an indicator of girls’ capacity to resist abusive dynamics, (b) promoting harm-minimising options other than relationship termination for responding to warning-sign partner behaviours, in order to minimise attitudinal resistance and maximise risk-sensitivity, (c) allowing ample time to practice assertive responses to a variety of real-life scenarios, in order to maximise self-efficacy, and (d) continually emphasising the logic of personal accountability only for harms perpetrated by oneself.

Adolescents vocational indecision and problem solving

FERREIRA, J. (University of Coimbra), SANTOS, E. (University of Coimbra), FERREIRA, L. (EB2/3 Cantanhede)

The purpose of the present study was to investigate the relationship between vocational (in)decision and problem solving. The study involved different variables (e.g., vocational, personality and demographic). Specifically we refer to anxiety, self-esteem, locus of control, vocational identity, generalized indecision, gender, and grade in school. The present research is a non-experimental correlational study, based on a sample of 357 students, attending the 9th and 11th grade, both public and private middle and secondary schools of the center region of Portugal. The instruments used were: A demographic questionnaire; the Indecisiveness Scale (IS; Frost & Shows, 1993); the Rosenberg Self-esteem Scale (RSES; Rosenberg, 1965); the My Vocational Situation (MVS; Holland, Daiger & Power, 1980); the Trait Scale of the State-Trait Anxiety Inventory (Spielberger, Gorsuch, Lushene, Vagg & Jacobs, 1983); The Vocational Certainty Scale (ECV; Santos, 1997); the Internal-external Locus of Control Scale (IE; Rotter, 1966); and the adaptation of the Problem Solving Inventory (PSI; Heppner, 1988). Results of the hierarchical regressions revealed that the best predictors for Vocational Certainty were Vocational Identity followed by the problem solving variables (with particular emphasis on the Confidence in Problem Solving). Results also suggest that personality variables such as self-esteem, anxiety, and generalized indecision, constitute factors that explain a considerable part of the variance on the three dimensions of problem solving (confidence, approach/avoidance, and personal control). Vocational variables also have a significant contribution to the explanation of problem solving, with the exception of the approach/avoidance dimension. It is noteworthy to point out that from all the studied variables, problem solving dimensions were the ones that showed most explicative power of the variance on vocational indecision. Implications for vocational counseling were taken and were suggested future studies to deepen the knowledge on the interface between vocational (in)decision and problem solving in adolescents.

Keywords: problem-solving, vocational indecision, anxiety, self-esteem, adolescents

African-American male athletes: An examination of a conflicted sense of masculinity as a source of psychological distress

SPEARMAN-TEAMER, C. (The University of Kentucky), SPEARMAN-TEAMER, C. (The University of Kentucky), JACKSON, C. (Tennessee State University)

This study explores both masculinity and gender role expectations in African American collegiate level male athletes and ways in which masculinity and athletic identity are potential sources of distress/conflict across roles. Gender role conflict has been significantly correlated with lower self esteem, higher anxiety and depression, psychological distress and negative attitudes toward help seeking. Literature suggests the experiences of African American male athletes are unique and include inadequate educational preparation and racial isolation in the collegiate setting. Also, they include difficulty negotiating multiple roles in the family, academics and workplace, athletics, and relationships. Consequences include decreased sports performance, potential conflict regarding bridging various cultural dynamics (including those associated with AA culture as well as the dominate culture), and adjusting their identities across situations (dualism) to maintain their perception of masculinity and athletic identity to receive acceptance from peers, coaches, parents, and their community. Participants were chosen from a Historically Black, College/University (HBCU) athletic department and were members of an identified varsity athletic team. The following assessments were completed: MARS, GRCS, RCS, BSI-18, and AIS. Pearson r correlations were conducted to calculate the degree to which these variables (dualism, GRC, and masculinity) represent significant relationships. Multiple regression analyses were then performed to ascertain additional data regarding relationships between dualism, gender role conflict, and perceptions of masculinity as predictors of psychological
Abstracts of the 27th International Congress of Applied Psychology

Individual Oral Presentations

(distress in African American male athletes. Results from this project suggest strong relationships regarding socio-cultural factors and gender role conflict as contributing to the psychological distress of African American male athletes. Conclusion data specifically address interventions and counseling models that will support increased sensitivity regarding the intersection of masculinity, athletic identity, gender role conflict, and sources for distress in this and other male collegiate level student-athlete populations.

Afterschool predictors of behaviour in young school-aged children

SIMONCINI, K. (James Cook University), CALTABIANO, N. (James Cook University)

There is growing recognition that the hours after school are an important context for children’s social, physical and cognitive development. While there has been considerable research into adolescent’s time use, there has been much less interest in school-aged children’s experiences. These experiences after school afford children opportunities for development and can also influence their behaviour. Children’s behaviour is an important predictor of their future successes or failures. Adaptive behaviour allows children to form better relationships with peers and teachers, participate more in classrooms and do better in school while problem behaviour in young children is a main predictor of school failure, school dropout and later delinquency. This study examined the relationship between children’s after school care arrangements and extra-curricular activities and behaviour to help uncover factors that promote positive children’s behaviour. Both teachers and parents of children in Prep to Year three from seven schools in middle to high socio economic status (SES) areas in a regional city were asked to provide responses for this study. Mothers of 906 children gave details of their child’s current care arrangements, extra-curricular activities as well as other demographic details. The Strengths and Difficulties Questionnaire (SDQ) (Goodman, 1997) was used to measure children’s behaviour and the Raising Children Checklist (Shumow, Vandell & Posner, 1998) was used to measure parenting style. Low scores on the SDQ indicate normal behaviour, while high scores indicate borderline or abnormal behaviour. Teachers provided behaviour ratings using the SDQ for 693 children. However, only 337 teacher surveys could be matched to the parent surveys. Agreement between teacher and parent behaviour reports was moderate $r=.34$. According to parent reports, lowest behaviour scores were associated with participation in two or more extra-curricular activities for duration of 90 to 180 minutes, parental care before entry to school and authoritative parenting. According to teacher reports the lowest behaviour scores were associated with parental care after school and before entry to school. While extensive early childcare centre care and full-time afterschool care were associated with the highest behaviour scores the majority of children with these care arrangements were still within the normal range of behaviour.

Age group differences in self-reported road rage perpetration and victimization

WICKENS, C. (Centre for Addiction and Mental Health), MANN, R. (University of Toronto), STODUTO, G. (Centre for Addiction and Mental Health), LALOMITEANU, A. (Centre for Addiction and Mental Health), SMART, R. G. (Centre for Addiction and Mental Health)

This study examined whether the predictors of self-reported road rage perpetration and victimization vary across age groups. Based on data from a general-population telephone survey conducted from July 2002 through June 2005, three groups of drivers were examined: 18-34 year olds ($n=1522$), 35-54 year olds ($n=2726$), and 55 years of age or older ($n=1883$). For each age group sample, logistic regression analyses examined self-reported road rage perpetration and victimization in the last 12 months by measures of driving exposure, binge drinking, cannabis use, and drinking-driving, while controlling for demographic factors. The prevalence of road rage perpetration within the past year was highest for the youngest age
Individual Oral Presentations

group (51%), followed by the middle-aged group (37%), and then the oldest age group (18%). The same pattern of results was found for prevalence of road rage victimization (54%, 47%, and 31%, respectively). Controlling for demographic factors, the predictors of perpetration were generally consistent across the age groups. The logistic regression model for the youngest drivers revealed that those who reported stressful driving, binge drinking, and cannabis use had significantly increased odds of reporting road rage perpetration. For middle-aged and older drivers, stressful driving, driving on busy roads, cannabis use, and driving after drinking were associated with perpetration. In addition, increased mileage contributed to perpetration in the oldest group. The findings for road rage victimization were similar. The logistic regression model for the youngest age group identified stressful driving, cannabis use, and higher annual mileage as being associated with victimization. For the oldest age group, these same variables were significant predictors of victimization, in addition to driving on busy roads. The logistic regression for the middle-aged group identified the same predictors as that of the oldest age group; however, interestingly driving after drinking was found to predict lower victimization among middle-aged drivers. Although the prevalence of road rage perpetration and victimization declined with age, the factors that contributed to road rage remained generally stable across the lifespan. The results suggest potential areas for intervention that may prove effective across all age groups.

Aggression Replacement Training (ART): An Australian youth justice evaluation

CURRIE, M. (Swinburne University of Technology), WOOD, K. (Swinburne University of Technology), BATES, G. (Swinburne University of Technology), WILLIAMS, B. (Swinburne University of Technology)

Aggression Replacement Training (ART) is a multimodal, cognitive-behavioural intervention for aggressive youth. Outcome studies from the US, UK, and Europe indicate that ART is one of the most effective anger management programs in treating aggressive youth. The aim of this evaluation study was to investigate the effectiveness of ART among aggressive juvenile offenders (aged 17 to 22 years) at an Australian youth justice custody centre. The results of an initial pilot study with 5 young offenders indicated overall support for the effectiveness of ART. Participants in the main study were 20 young offenders from the same youth justice centre. A repeated measures design was used with pre, post-, 6-month, and 24-month post assessments. Measures included social problem solving, aggressive behaviours and thoughts, criminogenic cognitive distortions, and impulsivity. Results showed clinically and statistically significant reductions in self-reported aggression, cognitive distortions, and impulsiveness and improved social problem solving skills with moderate to large effect sizes. Contrary to expectations, custody worker reports of participants aggressive/antisocial behaviours did not vary significantly at the six month follow-up. This measure also failed to reach clinical significance at any time point, suggesting issues with scale validity. Despite efforts, a waitlist comparison group was not obtained. Notwithstanding the methodological limitations, the present study provided strong support for the application of ART with aggressive Australian youth. Some of the key implications of these results include the cultural suitability of an American based training program to an Australian youth justice population and the apparent maintenance of treatment gains at 2-year follow-up, beyond the treatment setting. The results also supported the social-learning principles and cognitive-behavioural procedures underpinning ART for this group of high risk youth.

Aggressive children at school: Communication patterns and styles of responses to frustration

ARMAS-VARGAS, E. (Universidad de La Laguna (Spain))
In the investigation related to the field of communication skills in the family and school situation, (mother/father and child relationship; peers and teachers), we studied the patterns of communication and of conflict resolution that are related to certain variables of adaptation and styles of response to frustration in Spanish children. The sample comprised 124 adolescents (65 boys and 59 girls) of between 12 and 15 years old, with an average age of 13. The aim of the study was to examine the relationship between the factors of the Patterns of Communication and Resolution of Conflict Questionnaire (CPC-RC) (Armas-Vargas, E., 1996-1998) among peers and teachers, with the three styles of response to frustration of the PRF test (Resolutive, Self-Punishing/Self-Harming and Aggressive). Questionnaire A (CPC-RC teachers) assessed five factors of communication on how students perceive communication with their teachers: 1) Facilitative and Resolutive; 2) Reasoned and Empathetic; 3) Explicative and Taking into Account Opinions and Decisions of Others; 5) Difficulty in Reaching Agreements. Questionnaire B (CPC-RC peers), assessed four factors of communication on how students perceive communication between themselves: 1) Explicative and Empathetic; 2) Active Listening and Allowing Others to Speak; 3) Reasoned and Understanding; 4) Difficulty in Reaching Agreements. The students who scored higher in solution to conflict tended to be those who perceived their teachers with a facilitative and resolutive style of communication \( r = .43; p \leq .001 \). Conversely, difficulty in reaching agreement with their teachers correlated positively with aggressive responses \( r = .30; p \leq .001 \) and self-punishing \( r = .28; p \leq .01 \) among the children. In communication among peers, difficulty in reaching agreements also correlated positively with the aggressive \( r = .29; p \leq .01 \) and self-harming \( r = .24; p \leq .025 \) response styles, and negatively with the resolutive response \( r = -.36; p \leq .001 \). Children that tend to score higher in resolving conflict are those that perceive their teachers and peers with the ability to communicate (helping to reason, giving and asking for explanations, taking into account opinions and decisions of others, listening and allowing others to speak and reaching agreements).

Alexithymia in Somatoform Disorders

KAUR, H. (Punjabi University)

The aim of the present study was to determine Alexithymia in patients suffering from somatoform disorders, and in their matched normal controls, in the Indian context. Therefore, study examined the effect of age, gender, and education on Alexithymia in an Indian sample. Adult patients \( (N=102) \) diagnosed as Somatoform disorder (ICD-10, WHO, 1992), by a qualified psychiatrist were included in the study. Normal controls \( (N=116) \) were statistically comparable with patients on age, gender, education, occupation, marital status, family income, and residential area; and scored less than three on GHQ-12 (Goldberg et. al, 1997). The two groups were assessed on 20- item Toronto Alexithymia Scale (Pandey, Mandal, Taylor, Parker, 1996), and rendered to analysis using t-test and ANOVA on the total as well as sub-factors scores. Somatoform patients were significantly more Alexithymic than the matched controls, and the difference persisted on all the three factors. Female patients were more Alexithymic than males; exhibiting specific difficulty in identifying (factor 1) and in describing emotions (factor 2). There were no gender differences in Alexithymia in the normal controls. Alexithymia was equally prevalent in the four age categories, while educational based differences were present in both the patient as well as the normal group. In patients Alexithymia was more evident in joint families as compared to nuclear families, but controls showed no such differences. Alexithymia as a personality construct characterized by difficulty in differentiating and describing subjective feelings, and by a cognitive style which is externally oriented rather than expressive of inner fantasies and drives (Nemiah, 1977), has found repeated theoretical and empirical validity. Somatoform disorders are marked by personal morbidity, and immense burden on family and health care facilities. By establishing Alexithymia as one of the core aspects in somatic symptoms, psychological interventions for enhanced emotional sensitivity and communication in client can be planned to enhance self reliance.
and independence in thought and action. Consequently, reliance on physical symptoms as a mode of communication is likely to reduce or even disappear.

Keywords: Alexithymia, somatoform disorders, age, gender, education

Alterations in different types of memory in poliaddicts

FLORES, D. (Benemeritus University Autonomous of Puebla), INÉS, R. (Benemeritus University Autonomous of Puebla), SILVANA, T. (Benemeritus University Autonomous of Puebla), VANESSA, V. (Benemeritus University Autonomous of Puebla), LIZET, A. (Benemeritus University Autonomous of Puebla), JACOBO, B. (Benemeritus University Autonomous of Puebla), ALEJANDRA, S. (Benemeritus University Autonomous of Puebla), EDSON, P. (Benemeritus University Autonomous of Puebla), CYTHIA, T. (Benemeritus University Autonomous of Puebla), MAURICIO, T. (Benemeritus University Autonomous of Puebla)

In past years, consumption of addictive substances is increased considerably in a world level. Our interest consists in study and analyzes the alterations that produced the combined use of different groups of poliaddicts. The aim of the current study was to analyze the neuropsychological disorders in different types of memory in poliaddicted population. The study was exploratory, descriptive and transversal. A total of 200 subjects were selected, 99 of whom were poliaddicts. Both groups were gender and age matched (between 18 and 77 years of age). The poliaddicts were classified according to the type of substance used. Thus three subgroups were formed: 1) Cocaine, amphetamine and hallucinogen users; 2) Alcohol and hallucinogen users; 3) Alcohol, hallucinogen, cocaine and amphetamine users. They also were classified according to the type of substance used. The statistical analysis show significant differences in the neuropsychological evaluation tests. The analysis of the results contributes significantly to the understanding of the organization of cognitive skills. Consumption of addictive substances causes alterations in different types of memory. Neuropsychological alterations are related with type and with long years of consume of addictive substances.

Keywords: substance use, poliaddicts, neuropsychological disorders, memory, addiction

An application of rTMS: The role of the anterior temporal lobe in associative stereotypes

Brain stimulation via repetitive transcranial magnetic stimulation (rTMS) is yielding interesting results in diverse cognitive domains. Inhibiting the anterior temporal lobe (ATL) via rTMS appears to have deleterious effects on people’s semantic conceptualization. A negative outcome of conceptual association is the overgeneralization or stereotyping of social groups. The aim of this study was to investigate if inhibition of the ATl via rTMS could reduce implicit prejudice towards Arab people. Forty participants were randomly allocated into 4 groups: right ATL stimulation; left ATL stimulation; control site stimulation; and sham. Participants completed an Implicit Association Test (IAT) that measured the association between Arab people and terrorism, and then underwent 15 minutes of inhibitory rTMS (1Hz) or sham stimulation. They then completed a parallel form of the IAT and a self-report questionnaire including questions about explicit prejudice. On average participants had positive scores indicating a moderate-high implicit bias to associate Arab names with terrorist attributes. Analyses revealed significant differences in scores from pre to post stimulation between the 4 groups (F3,36=3.57; p=0.02). Both left and right ATL stimulation decreased prejudice scores on the IAT significantly compared to the control stimulation and sham groups (t=3.19; p=.003). Paired t-tests confirmed that both the RATL and LATL group had significantly lower IAT scores.
after stimulation (RATL: $t=3.16$, $p=.01$; LATL: $t=3.42$, $p<.01$). The sham and the control site group had no change in IAT scores post stimulation. The results of the current study demonstrated that LATL and RATL rTMS stimulation was capable of reducing prejudice scores on an IAT. The association of Arab people and terrorist is a current example of an overgeneralization being applied to a people group is the association of Arab and terrorist and is arguably a ‘learned’ prejudice that may exist without any direct experience. When this concept was weakened via rTMS inhibition of the ATL, people completed the IAT with less bias and therefore produced lower prejudice scores. These findings are consistent with the view that the ATL may be one of the brain areas involved in prejudicial biases, and to conceptual processing more generally.

Keywords: repetitive transcranial magnetic stimulation (rTMS), anterior temporal lobe, stereotypes, prejudice, implicit association test

An application of the theory of planned behaviour (TPB) to the speeding behaviour of young drivers

FERGUSON, C. (Edith Cowan University), COHEN, L. (Edith Cowan University), POOLEY, J. (Edith Cowan University), GUILFOYLE, A. (Edith Cowan University)

Young drivers are proportionately over-represented in traffic crashes in which death and injury are reported. This fact is reported internationally and consistently over time. Driving in excess of the posted speed limit has been associated with crash involvement, and the higher the speed, the more severe the outcomes when a crash occurs. As theory based interventions have proven successful in different behavioural domains, this research used the Theory of Planned Behaviour (TPB) to produce some understanding of speeding behaviour in young drivers and to identify potential bases for interventions. Participants were vocational education students (both male and female) aged 18 to 24 years ($n = 75$). This research investigated the beliefs and core Theory of Planned Behaviour variables (attitude, norms and perceived behavioural control) in relation to the speeding behaviour of young drivers. Several additional variables were included in the research. These variables were moral norm, self identity as a safe driver, and a short driving style questionnaire from Deery and Love (1996). A prospective design which enquired about TPB variables up to behavioural intention and expectation at first presentation, and self reported behaviour three weeks later was used to determine the validity of the theory for speeding behaviour. Behavioural beliefs which had been determined in a prior study in a similar population were also measured. Both logistic and standard regressions were used to analyze the data. Logistic regressions revealed significant differences between those that speed and those that do not on a variety of dimensions with satisfactory overall prediction rates compared to other research in this domain. Standard regressions were used to measure expectation to speed as this variable was measured on a Likert scale. The TPB provides a suitable model upon which to base the investigation of speeding behavioural intention/expectation and self-reported behaviour in young drivers with attitude, control and moral norm producing significant increases in the accounted for the variance in intention/expectation. Differences in the beliefs between those that do speed and those that do not speed provide information for the design of road safety media campaigns/interventions aimed at this vulnerable driving population.

Keywords: theory of planned behaviour, driving behaviour, speeding, young drivers

An attempt on semiotic analysis of work-motivation theories

KOLMAN, L. (Czech University of Life Sciences)

The paper presents an analysis of the succession of work-motivation theories which reveal a shifting pattern of underlying meanings and ideas. This pattern might be informative on the ways psychologists think about and deal with the immensely complex field of work-motivation. The analysis presented is dubbed as semiotic, as it deals with the meanings of the core concepts of the theories in question. At the same time, it might be understood, as well, as an analysis of ideological foundations of the theories.
questioned (for the most part the ideologies considered are the humanistic conception, protestant ethic and man-as-a-machine approach). Through the second part of the twentieth century there arrived a number of work-motivation theories. All of them were, in due course, tested in laboratories and in the field alike, and all of them got some empirical support in the process. Through the years, though, the older theories became gradually less accepted and researched on and the attention of scientists moved to newer conceptions, even if the older ones were not disproved or falsified unequivocally. This succession of work-motivation theories shows a shifting pattern of underlying meanings and ideas. The analysis was commenced upon because of a survey results which contradicted some of the expectations of the more recent work-motivation theories. The pattern of shifting meanings and ideas in the theories of work motivation might be informative on the ways psychologists think about and deal with the immensely complex field of work-motivation. Findings concerning this pattern might be helpful in the future theoretical developments of the field. The semiotic analysis of the theories in question will help to determine, among other things, if the field of work motivation should be studied as a single area or rather as several sub-fields for anyone of which specific theories should be developed.

Keywords: work-motivation theories, semiotic

An evaluative synopsis of four related TEACCH-based tertiary preventive outcome studies for Autism Spectrum Disorders

PROBST, P. (University of Hamburg)

Research literature indicates that there is urgent need for more tertiary prevention studies in the field of autism worldwide. While the TEACCH approach has shown promising validity there is still a clear lack of controlled international studies. In this study, a synopsis of four TEACCH-based tertiary prevention studies for children and adults with Autism Spectrum Disorders, carried out in Germany, is presented. Study 1 describes the outcomes of a controlled single-subject social communication training study with a 7-year-old girl living in a residential home; study 2 analyzes the outcomes of a 3-year TEACCH-based intervention in a residential and vocational setting with 3 male adults; study 3 includes the outcomes of a three month follow-up, three full day education and skills parent group training study with 23 parents of 24 children; study 4 evaluates the outcomes of a home program intervention study with a 5-year old boy and his family. The outcome measures of the four studies embrace standardized questionnaires, behavioral observation instruments, and semi-structured interviews. The key results include: (a) the training of social-communicative skills in study 1 resulted in reduced challenging behaviors, enhanced alternative communication skills and improved toilet skills; social acceptance by staff was high; (b) the outcomes of study 2 on average showed a substantial reduction of behavior problems and increased social skills, and a high degree of social acceptance of the TEACCH approach by educational staff; (c) in study 3, the follow-up outcomes of the parent group training were based largely on the perspectives of parents; the training resulted in enhanced parental skills, improved parental health and higher family functioning; (d) the 2-year evaluation of the parent and child home intervention program resulted in enhanced language, communication, and social functioning and improved classroom adjustment of the child, and very positive acceptance of the training by his parents and teachers. Overall, the results suggest some further evidence for clinical and social validity of the TEACCH-approach and are largely consistent with the international literature. Cross-cultural implications for educational and health care sectors are discussed.

An examination of the influence of perceived job threat, job pressure and work-life balance/conflict among Australian academics

BELL, A. (Monash University), RAJENDRAN, D. (Swinburne University of Technology), THEILER, S. (Swinburne University of Technology)
Abstracts of the 27th International Congress of Applied Psychology

Research evidence suggests that the psychological strain and work-home conflict increased among academia, where work pressure remains high in a changing academic environment (see for example Winefield, et al, 2008). This innovative research explores the impact of job-stress on work-life balance practices among Australian academics. Drawing on Zedeck’s (1992) spill over theory, it was hypothesised that high levels of job stress (job threat stress and job pressure stress) would predict increased levels of work-life conflict, and decreased levels of work-life balance. A further aim was to examine gender differences in work-life balance practices given the limited research in this area. A sample of 139 academic staff employed in Australian universities (higher education and TAFE) participated in this study by anonymously completing an on-line a self-report questionnaire. The instrument used contained measures of work-life balance, work-life conflict and job stress (job threat stress and job pressure stress) that were rated on a five point Likert type scale. A strong, negative correlation was reported between work-life balance and both job threat stress and job pressure stress, where these were also strongly and positively correlated with work-life conflict. Multiple regression analyses demonstrated that job threat stress made the strongest unique contribution to work-life balance and work-life conflict scores, when the variance explained by job pressure stress was controlled. There were no gender differences for work-life balance or work-life conflict. In conclusion, job stress demonstrated a detrimental influence on academics’ abilities to balance their personal and work lives, and contributed to increased conflict between their work and personal lives. In order to combat the increasing job stress and work-life problems amongst academics, we suggest that universities consider implementing stress management components (particularly for job threat stressors) into Human Resource Management employee work-life balance programs, and also encourage academics to make use of these initiatives.

Keywords: work-life balance, job stress, academics

An examination of the relationship between personality, emotional intelligence, and occupational stress: Results from UAE police

ALALI, O. (Abu Dhabi Police), GARNER, L. (Sheffield Hallam University), MAGADLEY, W. (Sheffield Hallam University)

Most employees experience stress as a normal part of their job but, some workers experience stress more than others, suggesting a role of individual difference in perceiving and dealing with occupational stress (Cimbura, 1999). In the United Arab Emirates (UAE), however, little research has been conducted regarding the validity of personality traits and emotional intelligence in predicting job stress. For instance, the level of job-related stress that police officers working at Abu Dhabi Police feel was found to be high (Tawaiha, 2004). Therefore, the aims of the present study are: (1) to explore the relationship between personality, emotional intelligence and perceived job stress among a sample of police officers; and (2) to identify coping strategies that employed by officers to manage job stress. The sample consisted of 310 officers working at Abu Dhabi Police. Personality was measured using the Arabic version of NEO-FFI (Costa and McCrae, 1992). Emotional intelligence was measured by the Arabic version of Self-Report Emotional Intelligence Test (Schutte et al, 1998). Occupational stress was measured by perceived stress scale (Cohen et al, 1983), and the Brief Cope scale developed by Carver (1997) was used to assess participants’ coping style. Results show that Conscientiousness, Neuroticism, Extraversion, and emotional intelligence were all significantly correlated with perceived job stress. Data from regression analysis revealed that three variables namely Neuroticism ($b$=.401, $p<.01$), emotional intelligence ($b$=.266, $p < .01$), and Conscientiousness ($b$= -.143, $p< .05$) predicted perceived job stress, and together explained 33% of its variance. Regarding coping strategies, results demonstrate that the most frequently used strategies were turning to religion and instrumental social support. On the contrary, substance use was found to be the less used strategy among the sample. Moreover, conscientiousness, extraversion, and emotional intelligence show significant positive correlations.
with adaptive coping strategies (e.g., planning, active coping, emotional social support) and significant negative associations with maladaptive coping strategies (e.g., self-blame, substance use, behavioral disengagement). In contrast, Neuroticism correlated negatively with adaptive coping strategies and positively with maladaptive coping strategies. The implications of these findings for practice and future research will be discussed.

Keywords: personality, emotional intelligence, occupational stress, coping strategies

An examination of the relationships between elements of the psychological contract (i.e., type and fulfillment), careerism and employee turnover intentions

JOHANSEN, S., VON TREUER, K. (Deakin University), GERBER, T.

To date, existing research on the psychological contract has predominantly focused on contract breach rather than examining its contents. The mechanisms through which the psychological contract affects employee retention attitudes and behaviour are also not well understood. Therefore the present study aims to investigate the relationships between elements of the psychological contract (i.e., contract type and fulfillment) and an employee’s intention to leave (ITL) their current organisation, and to explore the role of careerism as a mediating and moderating variable. 202 Allied Health Professionals completed a questionnaire containing measures of the psychological contract, careerism and turnover intentions. As expected, correlational analyses revealed that ITL is positively related to transactional obligations and negatively related to relational obligations and employer balanced obligations. A strong positive association between contract fulfillment and ITL was also found. As predicted, path analyses conducted via Structural Equation Modelling demonstrated that careerism partially mediates the relationship between psychological contract types and ITL. These findings suggest that employees with transactional contracts are more careerist, resulting in higher ITL, while employees with relational contracts are less careerist, resulting in lower ITL. Contrary to expectation, Multiple Linear Regression analyses revealed that careerism failed to moderate the relationship between perceived contract fulfillment and ITL. The results were consistent with the proposition that psychological contract type and fulfillment predict employee turnover intentions. Moreover, it appears that careerism is important in shaping the contract type - ITL relationship. Organisational awareness and understanding of employee psychological contracts and career motives is needed.

Keywords: psychological contract, contract type, fulfillment, careerism, employee turnover intentions

An examination of the role of efficacy in intention to mitigate climate change: Self-efficacy, response efficacy, collective efficacy and collective response efficacy

TRUELOVE, H. (Vanderbilt Institute for Energy and Environment)

The nature of climate change (CC) dictates that it can only be solved through the collective action of millions of people. Surprisingly, few studies have examined the role of efficacy beliefs in predicting intention to act to mitigate climate change (CC intention). Drawing on Bandura’s efficacy theory, this study conceptualized efficacy as consisting of four separate constructs (self-efficacy, personal response efficacy, collective efficacy, and collective response efficacy) and tested the role of efficacy beliefs (along with personal norms) in predicting CC intention. The present study used Stern’s Value-Belief-Norm theory as a framework and hypothesized that beliefs (in this case efficacy beliefs) would lead to CC intention via their effect on personal norms (feelings of moral obligation to mitigate CC). Participants were 461 students at a Northwestern University in the United States. Participants completed measures of personal norms, efficacy beliefs, and a CC intention scale that tapped dimensions related to travel behaviors and household energy use. Structural regression modeling was used to evaluate the model. The final model provided an excellent fit to the data. Personal norms partially mediated the relationships between self-efficacy
and CC intention and response efficacy and CC intention, and fully mediated the relationships between collective efficacy and CC intention and collective response efficacy and CC intention. Personal norms had the largest total effect on CC intention, followed by personal response efficacy, self-efficacy, collective response efficacy, and collective efficacy (whose effect was negative). Overall, the model explained 33% of the variance in personal norms and 36% of the variance in CC intention. As hypothesized, increases in efficacy beliefs (except for collective efficacy) resulted in increased personal norms and CC intention. The results underline the importance of assessing efficacy beliefs when predicting CC-related behaviors and suggest that researchers using Stern’s Value-Belief-Norm theory may benefit from incorporating efficacy beliefs in their research. This study also has implications for those who design behavior change campaigns and suggests that bolstering people’s efficacy beliefs may be an effective strategy.

Keywords: climate change, efficacy

An individual approach to work-life balance: Support for the big 5 predicting individual work-family coping through structural equation modelling

RASMUSSEN, L. (Department of Transport and Main Roads), BROUGHS, P. (Griffith University)

Balancing work and other responsibilities is a common concern among most adults, yet research has suggested this experience varies across individuals. Personality has been shown to influence different work-family outcomes; however, the means by which individuals manage life roles is unclear. Preliminary research by the authors has evidenced that Big 5 personality traits (i.e., neuroticism, extroversion, openness to experience, agreeableness and conscientiousness) predict use of work-family coping strategies (e.g., active role management, partner support, tension reduction, cognitive restructuring, friend and relative support, workplace support, and reducing personal role demands). The present study aims to validate these results through Structural Equation Modelling (SEM). Of interest was whether the 5-factor personality model would be supported through Confirmatory Factor Analysis (CFA), as previous CFA analyses have failed to support the a priori structure. A convenience sample (N = 327) was used to confirm the 5-factor personality (NEO-FFI) and the 7-factor coping (Individual Work-family Coping Questionnaire) models through CFA, and test the influence of the Big 5 on work-family coping through SEM. An independent sample of 725 employees from a public service agency was used to validate the structural model. CFA produced revised models of 5-factor personality and 5-factor coping (reducing personal role demands and workplace support were deleted); these comprised the structural model. However through SEM, the neuroticism and openness to experience traits did not explain the use of work-family coping strategies, therefore were eliminated. Conscientiousness predicted use of active role management. Agreeableness predicted use of tension reduction, while extroversion predicted use of partner support, cognitive restructuring, and friend and relative support. The structural model was supported in the independent sample. Results suggest that strategies to facilitate work-life balance among employees should be diverse in recognition of dispositional factors. Implications for organisations include developing a suite of strategies targeted to the individual level, and for managers to gain an understanding of individual employee preferences. Revised models based on Big 5 Personality and Individual Work-family Coping fit for SEM were produced, however, the significant reduction in items and low numbers of items measuring factors are of concern and prompt suggestions for future research.

Keywords: work-life balance, big five model of personality, work-family coping strategies, Structural equation modeling, individual approach

An integrated model of health services and employment placement: An empirical evaluation

THORNTON, A. (MaximusSolutions Australia), BURKE, T. (MaximusSolutions Australia)
The use of an integrated model for the delivery of employment services to clients, whereby evidence based health and psychological interventions, with theoretical bases in cognitive and behavioral therapeutic and brief therapeutic traditions, are provided to overcome severe psycho-social barriers to employment, are not commonly used. This organization is one of the few commercial enterprises to develop and use such a model. It is a model favored currently by government and increasingly other practitioners are beginning to copy it. However, at present, little has been done to evaluate its efficacy. This paper presents data in support of such an evaluation. The aim is to establish the relationship between the data collected by psychological staff who assess the health and psychological condition of applicants and who employ psychological interventions to overcome barriers to successful employment and the nature and duration of the employment placement of that client by employment service officers subsequent to the interventions. The design is a large scale cross-sectional analysis of a sample of job seekers across the entire country of Australia, ensuring a representative sample of clients who have significant barriers to employment, barriers which stem from histories of mental illness, physical and sexual abuse and drug and alcohol use. Psychologists systematically gather General Health Questionnaire (GHQ-12) and Depression Anxiety and Stress Scale (DASS) data over the course of three sessions with clients. Change scores on these variables, reflecting the impact of psychological interventions in the sessions, are related to measures of the employment of the client after the release of the client to employment consultants (EC). Measures of work capacity, including full versus part time status, salary level, nature of job, nature of employer and duration of employment are collected. These data are routinely collected over several months in the organization’s offices, situated in over 80 offices across Australia. Data collection, using 100 psychologists in their regular duties has commenced. The analysis of the data will comprise multivariate analysis of the relationships between the psychological test data and the employment outcome, examining the impact of prior condition and degree of change duration the psychological interventions. Sample size will enable estimation of the impact of the interventions upon outcomes and will also enable the identification of any significant psychological barriers that continue to preclude successful employment outcome, by examination of sub-groups of clients within the sample. The evaluation of the data will demonstrate, with a large representative sample of job seekers in Australia, the efficacy of a theoretically driven integrated model in enabling successful job placement and will also enable the identification of further barriers to employment.

**An intergroup and intragroup approach to workplace bullying: Patterns of bullying from ingroup versus outgroup sources**

GULYAS, A. (Deakin University), ZINKIEWICZ, L. (Deakin University)

Bullying in the workplace is a prevalent and pervasive behaviour that affects health, well-being, and performance. Research has predominantly examined individual and organisational factors that promote bullying in the workplace, despite evidence that bullying is frequently an intergroup phenomenon, occurring between members of different groups or levels, and is also normative in certain professions and organisations. As such, this study introduces an innovative theoretical framework that explains workplace bullying as a function of social identity processes. To support this approach, this study examined patterns of relationships between types of bullying, sources of bullying from higher, lower or equal level employees, level of employees, and employment status (full-time/part-time). A sample of 179 nurses from a large hospital in Victoria completed a questionnaire. Patterns of relationships emerged between types and sources of bullying, which suggested that relationships between and within groups may underlie types of bullying behaviours. Specifically, it was found that derogation (e.g. criticism, threats and intimidation) is a predominantly aggressive intergroup behaviour.
used by higher levels towards lower levels to maintain intergroup distinctions. Additionally, it was found that social exclusion (e.g., being ignored/left alone socially, insulted or offended) is predominantly used by bullies either as an intragroup behavior in order to ostracise deviating ingroup members and maintain ingroup member conformity and homogeneity, or as an intergroup behavior which is used by members of higher level groups toward those in lower level groups to maintain intergroup distinctions and emphasise lower group members’ relative lack of power in the workplace. Work-related bullying (i.e., misuse of power) emerged as an intergroup behaviour that could either be used by higher levels to separate their group from lower level groups, or to highlight ‘superior’ characteristics of the ingroup. These patterns of relationships between types and sources of workplace bullying support an intergroup and intragroup approach to workplace bullying. It was concluded that, compared to individual and contextual explanations, the social identity approach to workplace bullying best explains why the type of workplace bullying appears to differ depending on whether it occurs from a higher level group, lower level group, or from a member of the same group. Further research on this approach is needed, across industries and professions, and interactions between individual, contextual, and group-related factors predicting workplace bullying should also be explored.

Keywords: intergroup and intragroup approach, workplace bullying, social identity, bullying, aggressive behaviour

An investigation into stress-induced analgesia and pain during self-harm

DYKES, K. (University of Tasmania), HAINES, J. (University of Tasmania)

All existing stress theories propose stressor-strain effects, but several authors suggested that reversed effects of strain on stressors might also explain their empirical relation. We propose that both effects exist, but they rest on different mechanisms that require different amounts of time. Reversed effects of strains on stressors should involve changes in job tasks, which are frequently caused by job changes: Employees under strain either drift towards high stress jobs (drift hypothesis), or employees are attracted by low strain jobs (refuge hypothesis). Such drifts/flights take some time to happen. On the other hand, we propose reversed effects to dominate in long term panel studies, whereas stressor-strain effects should dominate in short term panel studies. Hypotheses were tested by meta-analyses of existing panel studies ($k= 68–93; n= 25.985–39.882$). Population correlations for 2-Variable 2-Wave matrices were estimated using the Raju et al. (1992) validity generalization approach, and then further analyzed using structural equation modeling. Simultaneous meta-analyses of all studies did not provide evidence for causal effects in either direction. With length of time lag as a moderator, however, hypotheses were confirmed. Long-term (> 1 year) studies showed evidence for reversed causation (refuge hypothesis), whereas short-term panel studies yielded evidence for effects of stressors on strains. Despite the weak effects discovered, we conclude that stressors impact on strains. Panel studies covering much shorter time intervals are necessary to provide stronger evidence. When reversed causation hypotheses are tested, long time intervals are necessary. Finally, we conclude that results from cross-sectional studies are unlikely to yield inflated stressor-strain effects due to reversed causation. The reason is that our results support the refuge hypothesis of reversed causation, and the refuge process reduces rather than increases strain-stressor correlations.

Keywords: stressors, job changes, job satisfaction

An investigation of delusion-like beliefs in anorexia nervosa

MOUNTJOY, R. (La Trobe University), FARHALL, J. (La Trobe University / Mental Health Research Institute), ROSSELL, S. (Mental Health Research Institute)

Anorexia Nervosa (AN) is a disorder characterized by irrational beliefs about body weight and shape. While these cognitive
features play a significant role in the formation and maintenance of the disorder, little is known about their phenomenological characteristics, and whether such beliefs could be characterized as delusional. The current research aims to investigate the similarities and differences between unusual and body-related beliefs in individuals with AN, beliefs of body image dissatisfaction in healthy controls, and delusional beliefs in schizophrenia. Participants completed the Brown Assessment of Beliefs Scale (BABS), and the Psychotic Symptom Rating Scale (PSYRATS-Delusions) in relation to a dominant belief regarding body weight/shape (AN sample and healthy controls) or a current delusion (schizophrenia sample). All groups completed the Peters Delusions Inventory (PDI) to assess a wide range of delusion-like beliefs. The AN sample endorsed higher levels of preoccupation and distress in relation to their dominant belief (PSYRATS), but were comparable to the schizophrenia sample on belief conviction and the degree of life disruption experienced. The BABS found the AN sample to have better insight into their belief than the schizophrenia sample. On the PDI, the AN sample endorsed a greater number of unusual beliefs than healthy controls, but fewer than the schizophrenia sample, and displayed greater distress and preoccupation for these beliefs than the other groups. The body-related beliefs of the AN sample displayed phenomenological similarities to delusions in schizophrenia. High degrees of distress and preoccupation in the AN sample were the major points of difference, which might be accounted for by better illness insight in this group.

Keywords: anorexia nervosa, delusional beliefs, body image, schizophrenia

An investigation of Lebanese students’ reactions, cognitive processing, and quest for meaning following the 2006 war in Lebanon

MERHEJ MOUSSA, M. (Swinburne University of Technology), BATES, G.

The overarching aim of this study is to account for negative and positive outcomes of traumatic events in a Lebanese student sample by investigating: the role of distress and posttraumatic growth as co-existing mechanisms; the interplay of key variables in the model of posttraumatic growth and cognitive processing as put forward by Tedeschi and Calhoun (1995; 2004) and Janoff-Bulman (1989; 2004); the role of rumination in response to traumatic events; and the validity of posttraumatic growth reports and their potentially illusory nature. 295 students from four universities based in Lebanon participated in the study. Students completed self-report questionnaires relating to their direct and indirect exposure to the 2006 Lebanon war which lasted for 33 days. Measures consisted of self-report measures of positive and negative outcomes including posttraumatic growth, changes in outlook, and distress; cognitive processing measures including measures of intrusion, rumination, and reflection; and measures of mood and social desirability accounting for covariate variables. Good reliability results supported the use of Western-based measures in a Lebanese student sample. In relation to the first two aims, findings provided support for the co-existence of growth and distress suggesting a catalytic role of distress in initiating growth; and for the validity of the use of Tedeschi and Calhoun’s growth model in a Lebanese context. A refinement of the construct of rumination, as set in the third aim, was put forward through factor analyses and the role of intentional rumination as a mediating variable was established as a determining factor in the relationship between posttraumatic growth and trauma exposure. Findings were consistent with the theoretical models by Tedeschi and Calhoun and Janoff-Bulman and supported the key role played by cognitive processing and active meaning-seeking attempts in finding potential growth following traumatic events. Additional findings contributed to data on the validity of growth as set in the fourth aim, and showed mixed findings pointing to a potentially illusory, as well as a potentially veridical, account of growth. Results suggest that while distress may still remain, active cognitive attempts to grapple with the meaning of traumatic events may lead to posttraumatic growth.

Keywords: cognitive processing, traumatic events, distress, posttraumatic growth, Lebanese students
An investigation of the factors predicting organizational identification in new staff

SMITH, L. (University of Queensland)

In the first few months of their employment, what makes one employee want to stay, and another to resign? Researchers have argued that once an individual is identified with a social group, and self-categorized as a group member, they will be committed to their group. This is obviously desirable within organizations. Yet, we are still unclear on the process through which individuals become identified with their new organization or work team, and which level of identification is important in predicting turnover. Guided by insights from social, organizational, cognitive and development psychology, this study investigated (a) the factors which predicted identification with both the work team and the organization, and (b) the relationship between both levels of identification and turnover intentions. 569 new staff who had been employed at a large, public-sector organization for less than 6 months completed a questionnaire about their experiences. Based on a model of identity integration (Amiot et al, 2007), the questionnaire measured social factors (e.g., social support), individual perceptions (e.g., identity conflict, procedural justice) and organizational outcomes such as turnover intentions, and subcomponents of identification at both the team and organizational level. Preliminary structural equation modeling (SEM) analyses on the subcomponents of identification revealed that group-level satisfaction negatively predicted turnover intentions at both the team and organizational level. Subsequent SEM analyses demonstrated that social support by team members and the team leader predicted greater satisfaction with both the organization and the team, but to different degrees. Perceptions of procedural justice also positively predicted organizational satisfaction, but not team satisfaction. Experience of identity conflict in new employees negatively predicted both organizational and team satisfaction and was directly positively related to turnover intentions. It is concluded that both support by colleagues, and perceptions of procedural justice at work, combined to socialize newcomers both within their work team and the organization.

Significantly, both levels of identification were independently important in predicting turnover intentions. The multi-level facilitators and inhibitors of the identification process are discussed, alongside the implications for social-psychological theory of the development of identification and its impact on workplace turnover.

Keywords: organisational identity, group membership, staff turnover, procedural justice

An observational survey of driver distraction in Austria

SULLMAN, M. (University of Hertfordshire), METZGER, M. (University of Hertfordshire)

The main aim of the present study was to identify the proportion of Austrian drivers who were engaged in secondary tasks while driving. The study also investigated the types of distracting behaviours along with demographic differences. Road side observations were used to collect the data at ten randomly selected sites in Salzburg. All ten sites were observed twice, resulting in 20 hours of data collection. In total 10,767 drivers were observed, with 91.3% of them driving only, while 8.7% were also engaged in a secondary task. The most commonly observed secondary tasks were using a handheld mobile phone and smoking. There were also demographic differences, with younger drivers being more likely to engage in a secondary task than older drivers. In addition younger drivers were more likely to use a mobile phone while driving. Drivers were also more likely to be eating and drinking while driving in the morning and on main roads (cf residential roads). Finally, drivers were also more likely to be distracted on a Monday. A relatively large proportion of the observed drivers were engaged in secondary tasks while driving, which is concerning. Furthermore, many of the results support previous research findings using different methods of data collection. This indicates that road side observation can be a useful technique for collecting data on driver distractions.

Keywords: drivers, distracting behaviours, demographic differences, secondary task, road side observation
Antecedents and outcomes of idiosyncratic deals: Including deals that never happened

Idiosyncratic deals (i-deals) are personalized arrangements of a non-standard nature, negotiated between individual employees and their employer. Special arrangements are frequently sought out to customize conditions of work and employment, thus increasing fit with personal needs, preferences, and aspirations. I-deals are authorized by employer agents (e.g., managers, supervisors), possessing legitimate power to grant the resources bargained for. The present study examines differential antecedents and outcomes of two previously distinguished forms of i-deals: a) special flexibility in working times (flexibility i-deals), and b) customized professional development opportunities (development i-deals). Survey data were collected from 159 medical doctors in two German hospitals. Using a refined version of a previously validated scale, participants rated the extent to which they had successfully negotiated special conditions (i-deals). Alternatively, they could indicate that they had not tried to negotiate for the respective content (not asked for) or were turned down (denied i-deals). Antecedents refer to characteristics of the: a) individual (e.g., gender, age), b) job (e.g., interdependence, position), c) leadership situation (e.g., LMX), and d) organization (e.g., perceived transparency). Examined outcomes are a) work-family conflict, b) work engagement, and c) career satisfaction. Structural equation modeling was used to test hypotheses on the differential antecedents and outcomes of the two types of i-deals. Hierarchical position and LMX were the best predictors for both forms of i-deals. Organizational transparency limited the use of development i-deals, whereas flexibility i-deals were restricted by job interdependence. As expected, flexibility i-deals related negatively to work-family conflict, whereas development i-deals showed positive associations with both work engagement and career satisfaction, but also appeared to increase the risk of work-family conflicts. Denied developmental opportunities related negatively to work engagement, whereas denied time arrangements aggravated work-family conflict. Results highlight the individual and organizational benefits of customized development opportunities as well as tensions regarding work-life balance. Flexibility i-deals by themselves seem neither beneficial nor detrimental for employee engagement. Findings also call attention to the potential costs of the “deals that did not happen”. We conclude that the negative side-effects of discouraging or denying desired i-deals may be substantial and have not received sufficient attention.

Keywords: idiosyncratic deals, flexibility, professional development, career satisfaction, work-family conflict

Antecedents, correlates and consequences of entrepreneurs’ risk taking

PINES, A. (Ben-Gurion University), DVIR, D. (Ben-Gurion University), SADEH, A. (Holon Institute of Technology)

The present study is the fourth in a series of studies on the risk taking propensity of entrepreneurs, a topic that generated great controversy in the literature. It aimed to test three hypotheses. Firstly, entrepreneurs’ risk taking is correlated with psychological antecedents including: entrepreneurial traits (e.g. love of challenge) but not managerial traits (e.g. love of management); regulatory focus of promotion but not prevention; secure attachment but not insecure attachment (avoidant and anxious ambivalent); openness to experiences, Inventor Type (perceiving and intuition) and Investigative vocational type. Secondly, entrepreneurs’ risk taking is correlated with the risk related aspects of the new venture: Novelty and Technological uncertainty. Thirdly, entrepreneurs’ risk taking is correlated with certain dimensions of ventures’ success: including meeting business goals and creating new technological and market opportunities. 88 Israeli entrepreneurs and 77 new ventures participated in the study. All ventures were in their early stages and mainly High Tech. The
ventures were chosen randomly by students who were collecting data for their final project in college and as such can be seen as representative. A self report questionnaire that included three parts: (a) provided information about the new venture, including the novelty and technological uncertainty; (b) assessed seven features of the entrepreneurs’ personality and (c) assessed the ventures’ success. The results provided strong support for all three hypotheses. The findings indicate that risk-taking is a major entrepreneurial characteristic that differentiates entrepreneurs from managers. They findings contradict studies that argue that entrepreneurs are risk avoidant or that risk-taking propensity is not be one of their distinguishing traits.

Keywords: entrepreneurship, risk taking, antecedents

Anticipatory cognitions and innovation performance: The value of contextual fit

BLEDOW, R. (University of Giessen), ROSING, K. (University of Giessen), FRESE, M. (National University of Singapore)

An improved understanding of the mental processes from which innovation emerges may help individuals to successfully innovate (Bledow, Frese, Anderson, Erez, & Farr, 2009). Towards this goal, the present study focuses on two forms of task-related cognitions which we hypothesize play a key role for innovation performance: anticipation of success and anticipation of barriers. Task-related anticipatory cognitions imply an intense mental engagement with one’s work task. Based on self-regulation theories, we argue that both anticipation of success and anticipation of barriers have important and distinct self-regulatory functions. Moreover, their relative importance depends on the demands of the work context. If there is contextual fit between cognitions and the demands of the work context, we expect that performance is highest (e.g., Higgins, 1997; Kuhl, 2000; Oettingen, Mayer, Thorpe, Janetzke, & Lorenz, 2005). The relative importance of these two forms of cognitions depends on the work context. If there is contextual fit between cognitions and the demands of the work context, we expect that performance is highest (e.g., Higgins, 2005). If personal initiative is demanded by the work context, anticipation of success is related to performance, whereas anticipation of barriers is related to performance if the work context demands close adherence to rules and guidelines. Hypotheses were tested with a sample of 110 employees of 48 R&D project teams. Team members provided self-ratings on success and barrier anticipations and evaluated the demands of the work context. Project leaders assessed performance of each team member. Due to the nested nature of the data, hierarchical linear modelling was used to test hypotheses. In line with the hypotheses, barrier anticipations ($γ_0 = 0.17, p < .05$) and success anticipations ($γ_0 = 0.11, p < .10$) were positively related to performance. Furthermore, barrier and success anticipations interacted with the demands of the work context supporting the contextual fit hypothesis. The study provides support for propositions derived from self-regulation theories: anticipation of success and anticipation of barriers have important and distinct self-regulatory functions. Moreover, their relative importance depends on the demands of the work context. Due to the cross-sectional design and the partly marginally significant findings unequivocal practical implications on stimulating success or barrier anticipations require further research. Finding the right balance between success and barrier cognitions for a given context appears to be of primary importance. We argue that this line of research has the potential to be of significant applied value because success and barrier anticipations can be influenced by self-regulation and leadership to promote success at innovating.

Keywords: innovation, anticipatory cognitions, success, barriers, contextual fit

Applicability of learner driver research to learner motorcyclists

HAWORTH, N. (CARRS-Q), ROWDEN, P. (CARRS-Q)

Learner driver research has identified a large range of psychological factors which contribute to the over-involvement of novice drivers in crashes. These include a range of factors related to the youthfulness of learner drivers (e.g. susceptibility to peer influences, higher propensity for risk taking) as well as factors related to inexperience (e.g. restricted ability to
divide attention between different tasks, poorer hazard perception). These research findings have informed changes in the graduated driver licensing systems in many countries which have often been paralleled in changes to motorcycle licensing. This paper compares the characteristics of learner drivers and motorcyclists and examines the applicability of the findings of learner driver research to learner motorcyclists in order to provide guidance for improving learner motorcyclist safety. The review of the international literature examined academic journal publications, industry specific training documentation, government and non-government documentation relevant to motorcycle licensing. Crash data analyses were also examined. A number of differences were identified. Learner motorcyclists are not protected from the risks of the on-road environment to the same extent as learner car drivers. They are far less likely to receive immediate feedback and instruction from a supervising rider in order to avoid risky situations or address technical deficiencies (e.g. braking). Such differences in supervision between car drivers and motorcyclists are reflected in crash statistics during the learner phase, where learner drivers are relatively safe, but learner motorcyclists are not. Many of the factors associated with youthfulness are less relevant because most learner motorcyclists in developed countries are aged over 25. Despite the differences, many factors related to inexperience are common to learner car drivers and motorcyclists. The potential for training to contribute to overconfidence, optimism bias and the problem of risk taking are all relevant for learner motorcyclists. The lack of robust evaluations of measures to improve the safety of learner motorcyclists prevents firm conclusions being drawn, but the differences in the nature of motorcycling and in those attracted to it, compared to car driving, need to be considered in developing measures to improve the safety of learner (and all) motorcyclists.

Keywords: learner drivers, motorcycle, safety, risk taking

Applying self-determination theory to the development of burnout in humanitarian health workers

TASSELL, N. (Massey University)

The aim of the present study was to examine the effects of motivation on the development of burnout or experience of vitality in humanitarian health workers. It was expected that the Self Determination Theory (SDT) motivations of introjection and identification would have differential effects on burnout or vitality. Introjected motivation would be positively related to burnout and negatively related to vitality, while identified motivation would be positively related to vitality and negatively related to burnout. The passion for activities construct was hypothesized as mediating the role in these relationships. An online quantitative questionnaire assessed motivation and the experience of burnout and vitality in a sample of 82 humanitarian health workers, of different nationalities, working for different humanitarian organizations. The sample derived from individuals working in different humanitarian situations around the world. Path analyses revealed neither introjected nor identified motivation were significantly related to vitality, but both had direct effects on burnout, albeit in the opposite direction to that hypothesized and observed in previous SDT research. Additional path analyses showed the passion for activities construct played a mediational role between motivation and the three aspects of burnout. Obsessive passion mediated the path between identified motivation and emotional exhaustion and depersonalisation. Harmonious passion mediated the path between identified motivation and diminished personal accomplishment and depersonalisation. Results imply motivation is related to the development of burnout in humanitarian health workers. The mediational role of the passion for activities construct determines which aspect of burnout is more prevalent with regard to a specific motivation type. The findings are applicable to humanitarian organizations seeking ways to enhance employee motivation, and design and implement burnout prevention programs.

Keywords: burnout, humanitarian health workers, self determination theory
Applying social cognitive understanding to peer relations in school: Issues for children with deafness, autism and typical development

PETERSON, C., PETERSON, C. (University of Queensland)

An important problem for applied developmental, educational and counseling psychologists concerns children's popularity, friendships and peer relations in school and how problems in these areas can be overcome. Theory and past research suggest that peer problems are sometimes related to delayed social-cognitive development of a “theory of mind” (ToM: awareness that beliefs, both true and false, shape people's behavior). Children with deafness or autism are often unusually slow to develop ToM. This study aims to see how such cognitive delays may relate to their friendships, peer popularity and social skill in school. 80 children aged 6 to 12 years (20 each with deafness, autism, Asperger syndrome (AS) and typical development) took part. Batteries of standard ToM tests other measures of social cognition were individually administered and teachers rated children's peer popularity, social behaviour, social maturity and group relations skill using well-validated published instruments. The typically developing primary-school children outperformed their age-peers with deafness and autism on the social-cognitive ToM tests as well as on most of the behavioural social measures. Furthermore deaf children outperformed those with autism on most social maturity and social skills measures, despite scoring equally on ToM. Conversely, those with AS scored as highly as typical developers on ToM but as poorly as those with autism in popularity and social skills. ToM scores were not closely related to social skills measures in this sample, in contrast to some previous research. As well as raising interesting theoretical questions about the developmental underpinnings of peer social relations and cognitive awareness of others’ minds in the context of atypical development, these findings also raise important applied questions about how to intervene therapeutically to boost children’s everyday peer communication and social interaction skills. Explanations for the relative independence of social relations versus cognitive understanding of ToM for children with autism and AS will be considered and implications of the findings for applied intervention to assist children with delayed ToM development will be discussed.

Keywords: children, deafness, autism, theory of mind

Are employability dimensions related to the quality of university graduates’ job insertion?

GAMBOA, J. (University of Valencia), GONZÁLEZ, V. (University of Valencia), PEIRÓ, J. (University of Valencia)

Employability has been one of the main goals to be achieved with the creation of the European Higher Education Area (EHEA) from the very start. The underlying assumption is that employability enhances the quality of university graduates’ job insertion. However, this assumption still has to be tested. Therefore, the aim of this study was to ascertain whether employability dimensions were related to a number of indicators of the quality of university graduates’ job insertion. Employability was conceptualized according to the psychosocial model proposed by Fugate, Kinicki and Ashforth (2004), which comprises three different dimensions: human and social capital, career identity and personal adaptability. The quality of job insertion was measured by means of the following criteria: job qualification fit, job-university degree relatedness, occupational status, pay and general job satisfaction. The study’s general hypothesis was that employability dimensions are positively related to the quality of job insertion because they enable people to find better jobs. The study sample was composed of 6640 Spanish young graduates from different fields of study. Hierarchical multiple regression analysis was used to investigate the hypothesized relationships. After controlling for some demographic variables (gender, social class and years after graduation), results confirmed the positive relationship between employability and the quality of university graduates’ job insertion. However, differential results were found depending on the job quality indicator. The three employability dimensions were
significantly related to job qualification fit, job-degree relatedness and occupational status. Only human capital and personal adaptability (generalized self-efficacy) were related to pay and job satisfaction. Taken into account these results, employability seems to be a multidimensional construct and a new key predictor of the quality of university graduates job insertion. Therefore, results have theoretical and practical implications in the context of the new labour relationships.

Keywords: employability, university graduates, job insertion, job satisfaction

Are the determinants of the maintenance of hard-to-change behaviours fundamentally different to those that determine trying: Findings from smoking cessation

BORLAND, R. (The Cancer Council Victoria)

Quitting smoking is a difficult task. The vast majority of cessation attempts end in failure, even when accompanied by the best available help. This paper reviews evidence that the factors that predict the making of quit attempts are quite different to those that predict the success of attempts, once initiated. The evidence reviewed includes currently unpublished data on wave-to-wave prediction of quitting attempts and success from the International Tobacco Control (ITC) surveys that follow cohorts of smokers in a range of different countries. Motivational variables, such as outcome expectancies and explicit reports of how much they want to, strongly predict making attempts. However, when assessed at pre-quitting, these variables are typically not predictive at all and, at times, can be negative predictors of success in countries with long histories of anti-smoking activity. This does not seem to apply in countries that have only recently discouraged smoking, suggesting a hard-core of smokers who have little or no volitional control over success, beyond trying. An attempt is made to develop a new theoretical framework based on the differing roles of expectancies and experiences in the determination of various phases of behaviour change. It is argued that such models are required for understanding the maintenance of behaviour changes that people find difficult to maintain and thus that these models may be useful in areas beyond changing addictive habits.

Keywords: smoking, cessation attempts, success, Motivational variables, behaviour change

Assessee profiles, assessors’ judgment policy and construct validity in assessment centers

LI, D. (Zhejing College of Administration)

The present study aimed to integrate the two aforementioned research streams by imposing structure on simulation tasks and experimentally manipulating both dimension ratings and assessee-related factors to more completely understand the design and validity of assessment centers. The second primary purpose was to focus on the way in which assessors use available information to form judgments of candidates. Risky-choice and time-pressure task designs were used. Fifty assessors evaluated 10 hypothetical candidates for a high level managerial position in a software company whose dimensional ratings were experimentally manipulated. We analyzed our data by performing multivariate generalizability analyses. Multivariate generalizability analyses indicated that construct validity evidence was established for only some assessee profiles. The results also showed that each of assessee profiles by task situations, assessee profiles by dimensions, and assessee profiles by assessors’ interaction effects contributes large proportion of variance in assessment ratings. The results revealed substantial relationship between dimensions and task situations in assessors’ ratings. A dimension’s salience may vary as a function of a particular assessee’s profile because certain actions or features of an assessee often stood out thereby affecting inferences. Assessors probably tended to notice that some pairs of dimensions were highly related in a particular situation but that other pairs of dimensions were not. The practical implications and future directions for research were also discussed.

Keywords: assessment centers, validity, judgement, assessee profiles
Assessing a measure of driving anxiety

SULLMAN, M. (University of Hertfordshire), TAYLOR, J. (Massey University)

The present study investigated the psychometric properties of the Driving and Riding Avoidance Scale (DRAS) to investigate its applicability to samples other than crash survivors. The participants were undergraduate university students completed the DRAS, along with a number of demographic and descriptive questions (e.g. age, gender, accidents), in class. All participants were drivers and had a current licence. Two months later the same group of participants were again asked to complete the DRAS. Of the 301 participants who completed the first questionnaire, 219 also completed the DRAS a second time. Internal consistency for the DRAS was 0.89 and temporal stability over the two month period was 0.71. In addition, the factor structure of the DRAS supported the use of some subscales but not others in this nonclinical sample. Furthermore, while some narratives provide by participants indicated that their driving avoidance was related to driving anxiety, others gave more practical reasons for avoiding driving. Therefore, although the DRAS had strong internal consistency and temporal stability there are substantial questions regarding what the scale is actually measuring. In addition to avoidance which is due to driving anxiety, some items may be rated highly for practical reasons, such as the increasing cost of fuel. Suggestions for improving the scale are also discussed.

Keywords: psychometric properties, Driving and Riding Avoidance Scale, internal consistency, temporal stability, driving avoidance

Assessing positive irrational beliefs

COLLARD, J. (Deakin University)

The aim of the current study was to create a measure for directly assessing different types of positive irrational beliefs in an attempt to overcome the theoretical shortcomings of previously used inferential assessments of such beliefs. In line with Taylor and Brown’s (1988) theoretical division of positive illusions into three distinct areas, a list of questions to directly assess such beliefs was developed. In two separate studies, these items were utilised and factor analyses were conducted to determine whether they represented separate constructs. Furthermore, in the second study, a set of indirect items representing those used in the literature was also created. The responses to both the direct and indirect assessment of positive irrational beliefs were then compared. It was found in both studies that the items directly assessing positive irrational beliefs could be divided into four separate types. The grouping of such results across both studies was largely identical. The four types of beliefs were categorized as self enhancing beliefs, beliefs rejecting imperfection about oneself, irrational beliefs of control and irrationally optimistic beliefs. Together, these beliefs contributed to a super-ordinate factor. In the second study, the items indirectly assessing such positive irrational beliefs were found to relate to a single construct, however, and the relationship between the two sets of items was weak-moderate. It is concluded that future research can be enhanced by distinguishing between different forms of positive irrational beliefs. Adding to this, it appears that direct assessments of positive irrational beliefs may have a greater utility for identifying the presence of such beliefs than indirect or inferential assessments.

Keywords: positive irrational beliefs, assessment

Assessing school readiness using multi mode assessment system

PURWONO, U. (Universitas Padjadjaran, Bandung, Indonesia), SYAHRATU, M. (Universitas Padjadjaran, Bandung)

Children readiness to start formal schooling has been a primary concern for parents and educators as well as researchers and policy makers. Given the multidimensionality of the construct, the use of a multi mode standardized measure is warranted. This paper reports the results of a two-stage study to design and develop a standardized assessment to assess children’s school readiness. In the first stage of the study, a survey questionnaire derived from
the five domain of school readiness identified by the National Educational Goal Panel (NEGP) was developed and distributed to 63 experienced elementary school teachers in Bandung to inquire the typicality of each of the indicators. The teachers came from 46 public and private schools randomly sampled from all elementary schools in the city of Bandung. Based on the results of this first stage of the study, in the second stage of the study a multi mode paper and pencil based assessment consisting of 15 different instruments grouped into three assessment formats: tests, observational checklist for teachers, and a standardized playing activity were developed. The system was field tested to 63 pupils attending 4 kindergarten in Bandung sampled using a multi stage random sampling procedure. Item and Test analyses were performed using the perspective of Classical Test Theory. After analysis and revision, the system was used to assess school readiness of 69 children attending kindergarten in the city of Bandung. Out of the 141 indicators of school readiness, 105 indicators were retained to be used in the second stage of the study. The results confirmed the 5 domain of school readiness: health and physical development, social and emotional development, approaches to learning, language development and communication, and cognition and general knowledge. Overall, the system has an acceptable reliability (Alpha = 0.79). The observation checklist has the highest internal consistency (Alpha = 0.82). The results of the assessment correlate highly with the observation of the teachers. The School Readiness Assessment System has acceptable psychometric properties. The concurrent validity evidence was also encouraging for the use of the system to assess school readiness.

Keywords: school readiness, multidimensionality, multi mode assessment system, standardized assessment, children

Assessing stigma among psychiatric patients in Singapore – Psychometric evaluation of King’s Stigma Scale

YUEN, W. (National University of Singapore), SO-KUM TANG, C. (National University of Singapore), CHUN, R. (National University of Singapore)
schizophrenia. The stigma level was found to be different among mental illness labels.

Keywords: stigma, Singapore, psychiatric patients, stigma

Asylum seeking in Australia: The mental health consequences and their determinants

HOCKING, D. (Victoria University), KENNEDY, G. (Victoria University), SUNDRAM, S. (Mental Health Research Institute of Victoria)

Asylum seekers (AS) frequently undergo a protracted refugee determination process in Australia, which may compound trauma experienced in their country of origin and/or during transition to Australia. It is well established (Silove, 2002) that refugees experience higher rates of post-traumatic, depressive and anxiety symptoms and this may also apply to AS (Silove, 1993). It is unknown if a protracted process of refugee determination contributes to this psychological and psychiatric morbidity. ASs were recruited through case-workers at the Asylum Seekers Resource Centre. Demographic information was gathered and 4 questionnaires were administered: the Harvard Trauma Questionnaire-R, the Hopkins Symptom Checklist-25, the PERI-D and the Post-Migration Difficulties Checklist. 74 ASs (63 males) from Afghanistan (n=4), Iraq (n=3), Pakistan (n=19), Sri Lanka (n=39) and Zimbabwe (n=9) were recruited. 31% (n=22) had been granted permanent protection (PR) whilst the remainder (non-PR) awaited the outcome of their application (n=52). The two largest sub-groups of the non-PR group were those on Bridging Visa (BV) E (33.8%) and BVA (18.3%). Sri Lankans (62.6 ±67.1) spent a significantly longer time awaiting refugee determination than those from Pakistan (17.7 ±39.4) and Zimbabwe (10.2 ±2.6). Compared with the PR group, the non-PR group had significantly higher scores on all clinical scales: depression (28.0 ±9.8 vs. 39.4 ±10.9), anxiety (17.1 ±7.11 vs. 21.2 ±8.6) and trauma (79.2 ±25.8 vs. 102.2 ±28.2). Post-Migration living difficulties scores were also greater for the non-PR group, as were demoralisation scores (which did not reach significance). Linear regression with demoralization as DV and demographic and other symptoms as factors, demonstrated that 60% of variance was accounted for by anxiety, depression, trauma and number of times the individual had been to the Refugee Review Tribunal (RRT). People seeking asylum in Australia have high levels of anxiety, trauma and depressive symptoms. Those who have not been granted permanent protection have significantly higher levels than those who have; this was not significantly influenced by the type of temporary visa. Demoralisation was significantly influenced by the number of times the person had presented to the RRT, indicating that the asylum seeking process in Australia contributes significantly to the mental health of AS.

Keywords: asylum seekers, trauma, Australia, mental health, depression

ATRAMIC: Lying and personality

ARMAS-VARGAS, E. (Universidad de La Laguna (Spain))

ATRAMIC (compiled by Armas-Vargas, 2007) is a multifactorial test of personality measures designed to assess self-deception and verbal behaviour which affirms or acknowledges, knowingly and intentionally lying to others. ATRAMIC tries to describe and explain what relationship exists between the reported behaviour of lying, to what extent it is recognised and affirmed. It aims to study the relationship that such conduct has with other attitudinal and personality measures such as: guilt, self-criticism, insecurity, mistrust, hypercontrol, control, transparency, coherence, consistency, social desirability, extreme caution, selective privacy, assertiveness, fear of rejection and criticism, empathy, lack of awareness, attitudes of acceptance and rejection of self-deception and lying, failure to make adjustments for lies told, self-control when lying, honesty and admission that one has lied or deceived oneself. Thus, to study the behaviour of lying, by means of these other variables and measures, enables us to understand and approach a possible behavioural pattern of a person who lies. The sample consisted of 306 adults (193 men; 113 women) with an average age of 37. 157 single, 101 married, 48 divorced. The participants
belonged to four groups: control (78 people); clinical (48), forensic population of persons charged with domestic abuse (62) and forensic population of persons convicted of domestic abuse (118 men). Objectives were to (1) examine whether there are differences between the different groups with the 22 variables of the ATRAMIC questionnaire, and (2) identify the predictive factors of the variables of the ATRAMIC questionnaire, by conducting a discriminant analysis. In using the discriminant function, 83% of the control group and the convicted forensic population were correctly classified. The variables that showed the highest discriminant power were: honesty and admission that one had lied, selective privacy, assertiveness, guilt, self-criticism, empathy, mistrust, social desirability, control, coherence, being consistent and insecurity. 84% of the cases in the control and clinical groups were correctly classified. The variables with the highest discriminant power were: failure to make adjustments for lies told, assertiveness, self-criticism, hypercontrol and control. On the basis of the samples used in this study, the differences found are sufficient to support a model that permits differentiation using ATRAMIC instruments.

Keywords: ATRAMIC, lying, personality measurement, behavioural patterns

Attentional bias to gambling and smoking cues in a non-dependent and non-problem gambling population

JORDAN, M. (SCU), PROCTOR-BROWN, C. (Southern Cross University), BOWN, R. (Southern Cross University), PROVOST, S. (Southern Cross University)

This study was designed to determine whether smokers who are not nicotine dependent and individuals who are non-problem gamblers would show evidence for attentional bias to smoking and gambling related stimuli. 37 volunteer participants completed a modified version of the Canadian Problem Gambling Index, the Fagerstrom Nicotine Dependence Scale, and Barratt’s Impulsivity Scale. They then participated in an attentional allocation task (AAT) based upon that described by Fox et al., (2001). Target stimuli, consisting of a cross (x) and a plus sign (+) were identified 250ms following the presentation of a pictorial cue either on the same side of the computer screen as the target (validly cued trials, 80% of trials), or on the other side of the screen (invalidly cued trials, 20% of trials). The pictorial cues were either neutral, gambling related or smoking related. As reported by Fox et al. (2001) in their study of social anxiety, gambling and smoking related cues resulted in slower target identification on invalidly cued trials (so-called “attentional hold”), but had no effect on validly cued trials (“attentional capture”). However, the relationship between participants’ smoking and gambling behavior was not consistent with Fox et al.’s data. There were insufficient participants who smoked to make assertions regarding this factor, but non-problem gambling behavior was negatively correlated with attentional hold of gambling cues (b=-.42), as was impulsivity (b=-.47). These results suggest that participation in gambling, even at low-moderate levels, is associated with desensitization to cues associated with this behavior. Possible theoretical accounts for this loss of attentional effect include habituation, evaluative conditioning and direct compensatory conditioning of incentive motivational properties of the gambling behavior.

Keywords: smoking, gambling, attentional bias, cues

Attentional control of executive function in elderly working memory: An fMRI study

OSAKA, N. (Kyoto University), OTSUKA, Y. (Kyoto University), KINOSHITA, Y. (Osaka University), YAOI, K. (Kyoto University), OSAKA, M. (Osaka University)

Using fMRI, the effect of training on inhibitory control of attention was investigated in the elderly, with special reference to executive function of working memory. We employed 26 elderly volunteers (12 males & 14 females; age range = 64-78 years, mean = 70.1) using two kinds of working memory task, i.e., focused and non-focused reading span tests (RSTs). In RST, the elderly were requested to memorize the target words while they read a few sentences under the dual task. Focused-RST (F-RST).Target
word was the focus word of the sentence under focused RST (F-RST), while target word is the other word of the sentence under non-focused RST (NF-RST). Focused-word was defined as “the most important word to comprehend a sentence” (Osaka et al., 2007). We used an fMRI to investigate whether ACC (anterior cingulate cortex) related the inhibitory processes. We measured fMRI activations were serially measured while elderly participants performed F- and NF-RST, before and after a training period. After training, behavioral data showed that recognition accuracy increased and reaction time decreased only in NF-RST but not in F-RST. In NF-RST condition, fMRI data showed that there were significant activations in the left dorsolateral prefrontal cortex, ACC, left inferior parietal lobule (IPL) and para-hippocampal gyrus in post-training session compared with that of pre-training. However, there was no such significant activation increase in the elderly groups without training. The findings suggest that inhibitory training in the elderly leads to improve attentional control and increase the activations which underlie executive functions of working memory.

Attitudes of seatbelt non-users in the car’s front-seat: An application of the theory of planned behaviour

More than 90% of the front-seat car occupants (drivers and passengers) in Japan are reported to use seatbelts. Seatbelt offence is regarded as a minor offence and has attracted, to date, scarce attention. Is it a trivial violation, needing little extra care? This study aimed to examine psychological determinants of seatbelt use within the framework of Theory of Planned Behaviour (TPB), and to discuss its implications for interventions. We conducted a field study at a large shopping centre in the suburbs of Tokyo. Seatbelt use behaviour of all occupants seated in incoming cars through one of the gates was unobtrusively observed (N=3000). Of them, adult occupants were approached by an interviewer in the parking area and invited to a questionnaire survey. Self-reports of seatbelt users (n=211) and non-users (n=76) in the front-seats were obtained, along with their observed behaviour. Two focus groups (N=11) were separately interviewed. Seatbelt users and non-users were homogenous as to age, gender and driving distances. Non-users were more likely to have received a ticket due to seatbelt offence, more likely to report positive attitudes towards/less subjective control over drink-driving and red-light running. Hierarchical regression analysis showed that intention to use seatbelt was predicted by attitudes (explaining 41% of the variability in intention), and to a lesser degree, by behavioural control (10%), subjective norm (5%) and habit (2%). Perceived effectiveness of seatbelt, risk of contact with the police and discomfort were not significant predictors. Self-reported behaviour and intention were considerably correlated, but a significant gap was found between observed and reported behaviour. Discriminant analysis showed that TPB constructs moderately discriminated the observed use/non-use (R2=.25, correctly classified: 69% of non-users and 81% of users). Results of focus groups indicated that non-users had unrealistic illusion of control and negative attitudes towards seatbelt use, but this could be remediable. Some seatbelt non-users can be characterized as deliberate, consistent offenders, unconvinced of the efficacy of seatbelt use. This suggests a need for targeted remedial intervention. Self-reported behaviour and intention were well explained by TPB constructs. However, further research is needed to explain the gap between observed and reported behaviour.

Keywords: seatbelts, psychological determinants, theory of planned behaviour, attitudes

Attitudes toward information technology careers: Competing theories for understanding gender issues

MAJOR, D. (Old Dominion University), MORGANSON, V. (Old Dominion University)
Since women are underrepresented in information technology (IT) and other high tech fields, there is considerable interest in understanding the factors that influence commitment in this field, especially among women. Two competing theories shed light on this issue. Inclusion theory is directed toward ensuring that all employees feel a sense of belonging, participation, and influence in the workplace and describes a common set of characteristics and processes for developing inclusion. In contrast, gender theory argues that women have unique experiences in male-dominated environments and that factors contributing to women’s career and organizational commitment may differ from those predictors for men. Applying these theories, the goals of this research were to: 1) examine the predictors of organizational commitment, turnover intentions, and career commitment among information technology professionals, and 2) to examine any differences in the relative strength of these predictors for women and men. Web-based survey data were obtained from 1,229 information technology workers (38% women) who responded to established measures of the three outcomes as well as a set of theoretically determined predictors, which included job stress, satisfaction with pay, growth opportunities, job security, and work-family culture. Relative weights analysis was used to examine the research questions. The results for predicting organizational commitment and turnover intentions followed the same pattern: the importance of work-family culture, job stress, and pay satisfaction in predicting both organizational commitment and turnover intentions did not differ between women and men. However, growth satisfaction was relatively more important for women and satisfaction with job security was more important to men. The relative weights analysis for career commitment showed that work-family culture, growth satisfaction, and pay satisfaction predicted a larger proportion of variance for women than for men. However, compared to women, job stress was relatively more important in predicting career commitment for men. Our results demonstrate the relevance of both inclusion theory and gender theory for understanding career outcomes. The inclusion model was supported in predicting organizational outcomes (i.e., organizational commitment and turnover intent). Yet, our analysis predicting career commitment favored the gender-specific model. Implications for organizations and the IT workforce will be discussed.

Keywords: Inclusion theory, information technology, gender theory, job stress, work-family culture

Attitudes toward organizational change, change perception and the impacts of organizational changes in the social networks of a public agency

NEIVA, E. (University of Brasilia), VIEIRA, S. (University of Brasilia)

The present study’s objective is to verify the impacts of organizational changes in the intra-organizational social networks of a public agency and to relate the changes in the organizational social networks with the change perception and the attitudes toward organizational changes during a change program implementation. In order to attain this objective, a mapping of the friendship and communication networks of the agency was conducted, through the application of a questionnaire to the 194 employees at two distinct moments: during the implementation of the change, and 11 months after the first application, when the change was already settled. The change perception scale and the attitudes toward organizational change scale were also applied. The instrument of social network was composed of four parts with some information about the research and open questions that asked the subject about people of his/her friendship and communication networks. The answers were inserted in matrices and analyzed with the software Ucinet. The results allowed the analysis of the microstructures to graphically represent the two types of investigated networks. The data reveal a positive impact in the friendship network: even with a reduction of the network it became denser and the average distance between actors was reduced. The change has caused little impact on the communication network. The employees have showed opposition attitudes toward organizational changes and they have perceived
few changes in the organization. The organizational unit has predicted the attitudes toward organizational and the attitudes toward change have predicted the social network cohesion and the centrality of social network actors. These results are contrary to previous literature which affirms that in change processes, the intra-organizational network of communication shows greater differences, as it is essential for the functioning of the organization, and is transformed to better adapt to the new organizational reality.

Keywords: organisational change, attitudes, change perception, social networks

Australian baby boom career women: A conceptual model of psychosocial wellbeing

COURTNEY, L. (James Cook University), CALTABIANO, N. (James Cook University), CALTABIANO, M. (James Cook University)

Worldwide attention is focused on the massive baby boom cohort as they transition into their retirement years. With the dramatic demographic shift of women into career roles, baby boom career women (women born 1946 to 1964) are the first cohort of career women to approach retirement age. Traditional male models of life satisfaction in retirement are insufficient to encompass the needs and expectations of women. Therefore, it is crucial to develop a conceptual model of psychosocial wellbeing for Australian baby boom career women. This model will inform policy so that strategies can be developed; thereby ensuring that these women continue to contribute to society and have fulfilling and productive lives in their later years. An extensive national survey was undertaken with 1,051 respondents. The survey was comprised of three well-established wellbeing scales: Ryff’s Psychological Wellbeing scale; Keyes’ Social Wellbeing scale; and the International Wellbeing Group’s Personal Wellbeing Index. The survey also included the Life Orientation Test – Revised, a measure of optimism/pessimism, as well as six questions derived from content analyses of focus group interviews. Confirmatory Factor Analyses were utilized to validate the three wellbeing scales and, where appropriate, their sub-scales. None of these provided a good fit for this sample; however, aspects of all three measures did fit. Structural Equation Modelling was then employed to fit a hypothetical structural model through path analysis with latent variables, providing tests of goodness-of-fit for the theoretical model. The effect of optimism/pessimism, as a mediating variable of subjective wellbeing, was also explored in the structural model. Additionally, there was compelling evidence that the Australian baby boom career women cohort consists of at least two distinct groups; early and late baby boomers, suggesting a dynamic model is required. This research elucidates the factors that Australian baby boom career women identified to be essential for psychosocial wellbeing in their retirement years. The preliminary conceptual model will be refined and validated in the next stage of this project. Upon validation, this model is expected to contribute to the development of effective social strategies to improve the capacities, productivity and independence of these women in their later years.

Keywords: baby boom, career women, psychosocial well-being, retirement, life satisfaction

Authentic leadership and self-awareness: A developmental intervention experiment

WERNSING, T. (IE Business School)

The field of leadership development is undergoing rapid growth. More leadership development programs are being offered by universities at all levels, and more degrees are being designed that specialize in leadership (Doh, 2003). Yet, at the same time, leadership scholars point out the atheoretical nature of leadership development practices used today (Avolio, in press; Day, Harrison, & Halpin, 2009). Day et al. (2009) suggest that without theory, we cannot make scientifically grounded decisions as to how to develop leaders and leadership and how to advance research in a systematic way (p. xii). One emerging theory in this area is called authentic leadership development, and it has its
theoretical basis in self-determination theory (Deci & Ryan, 1985). Presented as a self-based model of leader and follower development, Gardner et al. (2005) proposed that self-awareness of one’s values, strengths, and purpose serve as central basis for internalized self-regulation and authenticity. A study was designed to translate the theory of authentic leadership to an online leader development program and test its effectiveness. In this field experiment, two leadership interventions were compared in effectiveness for developing authentic leadership and related emerging theory of leader self-awareness. One intervention was designed to focus on all components of authentic leadership, whereas the second intervention was focused only on leader self-awareness. A total of 86 managers were randomly assigned and completed pre and post survey assessments. Other factors related to leader development including developmental readiness and leader identification were also quantitatively measured. Results show that the both interventions successfully raised participants’ self-reflection, leader self-awareness, and self-rated authentic leadership, but did not raise external ratings of authentic leadership. The effect size varied based on developmental readiness levels. Qualitative data provided insight into what aspects of the intervention were most effective. Implications for future research and practice are considered.

Keywords: authentic leadership development, self-awareness, interventions, self determination theory, self-regulation

Automaticity and sport performance: Emotion, attentional focus and automatic skill execution

VAST, R. (Flinders University), YOUNG, R. (Flinders University), THOMAS, P. (Griffith University)

This study used the framework of explicit monitoring theory to examine the effect of emotions and attentional focus instructions on golf putting performance. In doing so, the benefits of an emotional control versus an attentional control strategy for performance were compared while athletes were experiencing negative and positive emotions. A 2 (group: high skilled, low skilled) x 3 (emotion: negative, neutral, positive) x 3 (instructions: no instructions control, emotion focus instructions, analogy focus instructions) mixed group design was used. Emotion was a repeated measures factor with all participants performing the task under negative, neutral and positive emotion conditions. Instruction was a between group factor where participants were randomly assigned to one of the three instruction conditions. A median split was also performed on handicap to categorize athletes as high skilled (≤ 10) or low skilled (≤ 11). As hypothesized, all athletes putted more accurately when experiencing positive than negative emotion. In relation to putting consistency, low skill athletes putted more consistently in the positive than the negative and neutral conditions while high skill athletes did not differ in putting consistency between conditions. Emotion focus instructions had a small but non-significant impact on increasing the beneficial effect of positive emotions and the detrimental effect of negative emotions on performance. This was mirrored in episodic memory protocols for movement mechanics, where athletes reported fewer execution steps on average in the positive than the negative and neutral conditions. Contrary to expectations, analogy instructions did not improve performance over the no-instructions control condition. The results provided strong support for explicit monitoring theory through demonstrating the benefit of positive emotions for performance. Overall, the findings suggest that controlling emotions, and attentional focus toward emotions, during competition may be a more effective strategy to encourage automaticity and improve performance than using analogy or metaphoric instructions.

Keywords: emotions, attentional focus, sport, automaticity, episodic memory

Awareness and perceptions of the health risks of exposure to radon in homes

POORTINGA, W. (Cardiff University), BRONSTERI, B. (Cardiff University), LANNON, S. (Cardiff University), PIDGEON, N. (Cardiff University)

The project aims to link people’s attitudes and behaviors to the geography of radon occurrence.
in the area, the history of radon testing initiatives, as well as the socio-economic context. More specifically, the project will examine whether: (1) people’s awareness and perception of the risks of radon vary according to exposure; (2) Recent radon awareness and testing initiatives, such as the radon roll-out program, have had an effect on people’s radon-related perceptions and testing behavior; and (3) The effectiveness of radon policy and communication initiatives is mediated by social factors, such as social capital and trust. A representative sample of 1,578 residents aged 16 and older living in radon-affected areas of 15 local authorities in England and Wales. The interviews were conducted in 214 sampling points that were randomly selected from a total of 428 output areas that were identified as being affected by radon. As a multistage sampling technique was used, the data was analyzed from a multilevel perspective using the MLwiN software package. This study found that awareness of radon is high in radon-affected areas in England and Wales, but that people are generally not aware of the potential adverse health effects. Participants living in local authorities that had participated in the radon roll-out program had higher levels of awareness, felt better informed, and were more likely to have tested their home for radon than participants living in non-participating local authorities. Similar results were found for participants living in ‘actionable’ areas as compared to those living in ‘non-actionable’ areas. The study further found that where awareness of radon was high in Southwest England, it was lower in the rest of England, and in particular in Wales. This study suggests that the radon roll-out program has been effective in raising awareness of radon, and that residents of participating local authorities have formed a better idea whether they are personally affected by radon or not. A similar pattern was found for people living in actionable and non-actionable radon-affected areas, probably also partly reflecting the impact of the program and other previous radon awareness campaigns. The results also show that in particular in Wales there is scope for further radon awareness and testing campaigns.

Keywords: radon exposure, awareness, health risks

**Beating the blues after cancer: A randomised controlled trial of a tele-based psychological intervention for high distress patients and carers**

HUTCHISON, S. (Cancer Council Queensland), SARGEANT, H. (Cancer Council Queensland), CLUTTON, S. (Cancer Council Queensland)

The diagnosis and treatment of cancer is a major life stress such that approximately 35% of patients experience ongoing clinically significant distress (Zabora et al., 2001). Distress amongst carers is often greater than that amongst patients (Cliff & MacDonagh, 2000). Psychological disorders such as anxiety disorders, depression, post-traumatic stress disorder and sexual disorders are prevalent among those coping with cancer, and yet access to evidence-based psychosocial care is the exception rather than the norm in many settings (Chambers et al., 2009). Access to psychosocial support is largely limited to patients at the time of diagnosis or hospitalisation, and is often limited to those living in major metropolitan centres. To this end, a cancer counselling service was established by a peak state-based non-government cancer control organization in 2004 to provide high-quality, evidence-based psychological support for all people in Queensland affected by cancer. In 2009, a two arm randomised controlled trial, Beating the Blues After Cancer, was initiated to investigate the benefits of this type of psychosocial intervention. The trial involves patients and support people who have elevated psychological distress as measured by the Distress Thermometer at point of contact with one of two community-based cancer help lines. The trial compares two telebased interventions including (1) minimal contact self management introduced by nurse counsellors and (2) individualised tele-based cognitive behavioural five-session intervention delivered by psychologists from the cancer counselling service. This paper will provide preliminary descriptive data on participants in the Beating the Blues After Cancer trial. The paper will also describe the psychological interventions utilized in the trial, including a number of evidence-based approaches for use with clients affected by cancer. This study will help determine the efficacy of population based strategies for
promoting optimal psychosocial adjustment and mental health for people affected by cancer who are at risk.

**Keywords:** cancer, stress, counselling service, helpline

### Behavioural gerontology and clinical practice: a critical review and implications for clinicians and researchers

**TURNER, J.** (University of Sydney), **MATHEWS, M.** (University of Sydney)

To critically review recent (2005-2009) behavioural gerontology literature on managing challenging behaviours of older adults and compare published findings with reasons for referral to a clinical service. Based on this review and comparison, this paper will offer recommendations for clinicians and researchers interested in providing assistance to care staff or family carers in managing older people who exhibit challenging behaviour. Criteria for inclusion comprised research articles published in the last five years which: included older adult participants (> 64 years) provided a direct measure of a socially relevant behaviour, provided a clear description of environmental or psycho-social intervention procedures, used an experimental design (either single subject or group), and manipulated either antecedent or consequent events or conditions. Results of the review are compared and contrasted with recent (2007-2008) reasons for referral of 26 older adults to a specialist behaviour assessment and intervention clinical service. Seventeen articles from six Journals met criteria. These addressed seven problem areas including engagement (47% of articles); depression (18%); independence in ADL (12%); safety belt use (6%); sleep (6%) agitation (6%); and cognitive function (6%). The literature review results contrasted with the reasons for referral to the clinical service which included physical and verbal aggression, disruptive vocalizations, resistiveness to care, chronic psychotic behaviours; intrusiveness; and other idiosyncratic behaviours. The underlying causative factors of these behaviours include depressed mood, chronic pain, sensory deprivation, social isolation, cognitive problems (including disorientation and communication impairments), and inadvertent reinforcement by staff. The differences between behaviours as clinical reasons for referral (as observed and described by carers) and as areas of study selected by researchers, are discussed and reconciled with reference to the causative factors. Evidence-based practice recommendations and suggestions for future research based upon the clinical reality will be discussed. Overall, clinicians and researchers need to document long term follow up in cases, researchers need to include more detail about their interventions or combination of interventions in research publications, and better objective measures of outcome are needed.

**Keywords:** behavioural gerontology, challenging behaviour, caregivers, older people

### Beliefs, distorted thoughts and aggressive behaviour in men who abuse their partners

**ARMAS-VARGAS, E.** (Universidad de La Laguna (Spain), IML of Santa Cruz de Tenerife, COP de Tenerife ( Spain )), **IMLCOMO-HERNÁNDEZ, I.** (Instituto de Medicina Legal), **MARTÍN-CABALLERO, R.** (Universidad de La Laguna), **BETHENCOURT-PÉREZ, J.** (Universidad de La Laguna)

Men who abuse their partners tend to be affected by numerous cognitive biases, related, on the one hand, with mistaken beliefs about gender roles and the inferiority of women and, on the other, with distorted ideas about the use of violence as a form of conflict resolution in the couple (Echeburúa et al., 1998). In this work, we show the results of a questionnaire containing 109 items that we selected at random to measure distorted beliefs and thoughts about women, the use of violence in the couple and the relationship that such beliefs and thoughts have with the aggressive behaviour of men who abuse their partners. The sample comprised 94 men who had abused their partners. The sample comprised 94 men who had abused their partners. The Beliefs and Distorted Thoughts Questionnaire (CREE, Echeburúa et al., 1998) was utilized, obtaining four factors: (1) Distorted Thoughts about Women (P.D.M.), (2) Distorted Thoughts about the Use of Violence (P.D.V.), (3) Distorted
Thoughts about Relationships. (P.D.P.), (4) Control Items. Then the Aggression Questionnaire (AQ, Buss and Perry, 1992) was used to measure four factors: Physical Aggression, Verbal Aggression, Anger and Hostility. We present the results of the factorial analysis for each factor, internal consistency (Cronbach Alpha) and the correlation between the measures of different factors of the CREE and AQ questionnaires. From the Beliefs and Distorted Thoughts Questionnaire (109 items), we obtained 2 sub-questionnaires, each with 2 factors: (A) Questionnaire A: Distorted Thoughts about Women (21%; \( r = .80 \)), Distorted Thoughts about Violence (13%; \( r = .82 \)); Explained Variance = 34%, and (B) Questionnaire B: Distorted Thoughts about Relationships (23%; \( r = .79 \)); Control Items (12%; \( r = .64 \)); Explained Variance = 35%. From the Aggression Questionnaire (AQ), we obtained two sub-questionnaires, each with two factors: (A) Physical Aggression (33%; \( r = .78 \)) and Anger (16%; \( r = .71 \)); Explained Variance = 49% and (B) Hostility (30%; \( r = .81 \)) and Verbal Aggression (20%; \( r = .67 \)); Explained Variance = 50%. From the correlation analysis we found that all the factors of the aggression questionnaire (AQ) positively and significantly correlated with all the factors in the beliefs and distorted thoughts questionnaire. For example, hostile behaviour correlated with distorted thoughts (P.D.) about women \( (r = .36; p < .001) \), about violence \( (r = .44; p < .001) \), about relationships \( (r = .49; p < .001) \). The data we found in this work significantly support the convergent validity for the combination of the variables of the Aggression Questionnaire (AQ) with the factors of the Beliefs and Distorted Thoughts Questionnaire (CREE).

Best interests of the child: A national Australian survey of experts and legal professionals

HARMER, A. (Charles Sturt University), GOODMAN-DELAHUNTY, J. (Charles Sturt University)

In all jurisdictions, including Australian courts, in decisions about children, the paramount consideration is the "best interests of the child". Courts often rely on an assessment by a psychologist in making this determination. The absence of any clear definition of "best interests" or professional guidelines to inform the methodology or interpretation of findings leads to challenges for scientist-practitioners to effectively assist the court. The study examined the gaps in our knowledge of expert practices in interpreting this standard. To determine how experts and legal practitioners interpret "best interests of the child", an on-line survey was administered nationwide to psychologists and legal practitioners involved in child and family court proceedings in Australian jurisdictions. Qualitative and quantitative questions explored respondents’ views regarding the best interests of children in custodial disputes and issues impacting expert assessments in that context. Participants ranked the relative importance of legislative criteria relevant to children’s best interests and indicated their temporal considerations—whether decisions were made according to the child’s best interests in the short- or long-term. Preliminary findings from the first Australian survey of family court psychological experts and legal practitioners highlighted differences and some similarities between psychologists and legal professionals in applying the statutory criteria. Groups of legislative factors considered most important for children of different ages were identified. Questions on information about the limitations of current expert assessment practices yielded information of interest to law reformers and policymakers. Variability observed in the meaning of "best interests of the child" and interpretive differences applied by practitioners underscored the vagueness of this concept. A greater awareness of practitioners’ views and of differences between approaches of psychologists and legal practitioners can enhance cooperation between these two professions and improve the use of psychological evidence in the courts. Recommendations are made on ways to assist courts make better use of psychological expert evidence in the context of the legislative framework that guides legal judgment.

Best practices for best agers? The influence of knowledge of ageing and age climate on human resource management

STAMOV ROßNAGEL, C. (Jacobs University), THEISEN, S. (Stepstone AG), LÜKE, L. (Expertia GmbH)

Human Resources Management (HRM) is critical for organisational performance (Combs, Yongmei, Hall, & Ketchen, 2006). In an ageing labour force (e.g., Alley & Crimmins, 2007), HR management will have to become age-differentiated. Therefore, an update of the hitherto prevailing “age-free” (Griffiths, 1999) theories underlying HRM is needed (Korff, Biemann, Voelpel, Kearney, & Stamov Roßnagel, 2009) and insights are required into the levers of age-differentiated HRM. Our study was intended to yield such insights by addressing the perceptions of HR managers. We posited that HR managers’ knowledge of objective changes in older workers’ capacities influences their choice of age-differentiated HR practices and that this influence is moderated by a company’s age climate. In a survey of 991 Heads of Personnel from German, European, and international companies from a good mix of industries, participants completed items from Palmore’s (1988; Harris & Changas, 1994) Facts on Aging Quiz to assess objective knowledge of older workers’ physical health, performance capacity, work motivation, and work-related attitudes. Participants also gauged their company’s age climate, i.e. the company-wide perception of older workers’ capacities and attitudes. Finally, participants indicated for a list of age-differentiated personnel development measures whether a given measure was used or if, and when, its future use was planned. Knowledge accuracy was positively associated with age-differentiated HRM and with age climate. Knowledge was highest in the production industries and in companies with mean worker ages above 40 years old, whilst biased images prevailed in the service industries and companies with lower mean ages. Less accurate knowledge was linked to a more pessimistic view of an age-diverse workforce’s productivity. Our findings might support the development of trainings for HR managers and supervisors. Rather than aiming at an overall “feel-good” age climate that might impede age-differentiated HRM, such trainings would tackle specific knowledge deficits and thus contribute to age-adequate HR management (see Hedge, Borman, & Lammlein, 2006). Accurate knowledge could not only help correct inadequately pessimistic views on ageing that support negative age discrimination. Appropriate knowledge might also avoid overly optimistic views that might lead to a neglect of age-differentiated HRM and involve positive age discrimination.

Better or worse: Mental health status and PTSD symptoms of elderly survivors after the 512 Earthquake

HAN, B. (Chinese Academy of Sciences), WANG, T. (Chinese Academy of Sciences)

Mental health state and the post traumatic stress disorder (PTSD) symptoms of elderly survivors after the Wenchuan Earthquake (May 12nd, 2008) were explored. The authors used time sequence methodology to survey 146 older adults (55+ years) lived in relocation houses in Beichuan county and 233 older adults (55+ years) in Mianyang city around where both are directly affected by the 512 Earthquake. Assessed tendency is about mental health (CMHI – E) and post-traumatic stress disorder (IES-R) symptom level with the extension of time. Older adults in Beichuan reported no decreasing tendency in PTSD symptoms and five aspects of mental health, while level of PTSD symptom of elderly in Mianyang decreased, mental health status reduced too. Positive emotion, self-evaluation, social support and interpersonal skills are less than before in Mianyang victims. Although earthquake has passed nearly one year, elderly survivors in serious disaster-hit area are in high PTSD symptom level and lower mental health states. Elderly survivors in hardly disaster-hit area had less PTSD, but their mental health state decreased with the extension time either.

Keywords: mental health, post-traumatic stress disorder, elderly, survivors, earthquake
Beyond the PhD: Encouraging the ongoing development of higher education researcher capabilities

DEBOWSKI, S. (University of Western Australia), DEBOWSKI, S. (University of Western Australia)

This paper describes a development project aimed at increasing the research capabilities of university staff and testing the suitability of a collaborative learning design. A qualitative study of thirty Australian researchers (early career, mid and senior) identified a range of learning needs that required ongoing support and development as researchers progressed in their careers. Following the study, a Framework for Researcher Development was devised to map the various capabilities required to undertake effective research. Following this gap analysis, a comprehensive program of nine blended learning modules was developed, piloted, trialled and implemented. The program focused on the early career phase of research work, supporting the initial induction of staff into universities and the development of more sophisticated research project management and knowledge management capabilities. Pre-test and post programme measures of research capability were collected, along with feedback on the programme delivery and content. Case studies were also undertaken in each university to review the impact of the intervention on the internal culture and practices. Over 1,000 researchers participated in the programme, with 232 participating in the pre and post-test data collection. Over 30% of the participants reported a growth in research capabilities in the areas of financial and business management skills, financial reporting compliance, quality of business management and grant productivity and efficiency. In total, 141 (60.5%) of the respondents noted that they had been able to apply the learning into their existing work roles and 196 (84.4%) noted that the learning would be of value in their future research work. Participation in the programme was rated worthwhile by 82% of the respondents. The institutions generally noted an improvement in their practices and coordination of support, although the political context was notably influential in some cases. The program illustrated the value of undertaking a detailed capability analysis and building learning support around that research. The results highlight the difference that effective learning programmes can make to staff capabilities, and the need for careful design of the learning programme to match the learner context. The project also highlighted the challenges of working across various portfolio holders and institutions to increase the effectiveness of organisational support.

Bias towards anxiety related words among college students as related to self-reported tobacco and alcohol consumption

HERNANDEZ-POZO, R. (UNAM), MATA, A. (UNAM, National Autonomous University of Mexico), CASTILLO, P. (UNAM, National Autonomous University of Mexico)

This study explores three different indexes of anxiety, from a behavioral perspective, in order to comprehend the role that different levels of anxiety, fears and worries play as precursors of tobacco and alcohol consumption among college students, given the major role these behaviors play in Public Health concerns for this segment of the population. 660 college students from three public universities participated were subjected to verbal behavioral and physiological assessment of anxiety. Students responded to a 28-item Checklist of Fears, previously administered to a Spanish speaking population (Alpha=.967, and 68.06 % explained variance) with a four factors structure (fear of affective loss, fear to become a victim of non contingent negative events, fear of vulnerability, and fear of death). The behavioral measure for anxiety consisted of a computerized discriminative 8-minute test based on the emotional version of the Stroop task where positive, negative and neutral words were used as sample stimulus. Interference was computed by subtracting latencies to neutral words from latencies to negative or positive words, of the same length and lexical probability. Before and after the Stroop task, blood pressure and heart rate were monitored. Additional self-report measures of tobacco and alcohol consumption were
recorded. Results showed a significant relationship between Stroop performance, fear to become vulnerable and fear of death, independent of gender. Both tobacco and alcohol consumption were directly related to verbal scores of fear for males, but they failed to associate in the same manner to negative interference scores. Gender produced significant differences only for verbal fear scores, with females scoring higher than males and the opposite tendency for pretest-systolic blood pressure, however no gender difference was found for behavioral scores. We concluded that the gap between reacting with apprehension and “talking about being anxious” is gender sensitive, and both behavioral and physiological reactivity should be taken into account to understand human fears and worries.

Keywords: anxiety, tobacco consumption, alcohol use, college students, gender

Biased language in description of domestic violence incidents

KWIAKOWSKA, A. (Helena Chodkowska University of Management and Law)

The aim of this paper was to explore biased language use in family violence discourse. Theoretical framework is provided by the Linguistic Category Model (LCM) developed by Semin and Fiedler (1991). The LCM makes a distinction between four different levels of abstraction: descriptive-action verbs (DAV) as the most concrete terms; interpretative -action verbs (IAV), which refer to a general class of behaviors; state verbs (SV) describing an emotional state, but not a specific event; and the most abstract adjectives (ADJ), which generalize across specific events and objects, and describe only the subject. People can choose between these four levels of abstraction to express their beliefs, expectancies and stereotypes. When they use a more abstract language to describe a specific event, they suggest that behaviors are due to some inherent and enduring qualities of acting persons, not to some situational fluctuations or factors outside of the their control. Describing behaviors in more concrete terms means that these behaviors are incidental and due to situational circumstances rather than to some dispositional tendency. The following hypotheses have been formulated: (1) There is a general tendency to prefer more abstract terms to depict an oppressor’s behavior; (2) Women are more prone to use more abstract terms in comparison to men; (3) The higher the level of sexism against women, the higher the tendency to use concrete terms in description of an oppressor’s behavior. 136 participants took part in the study: men (n=82) and women (n=52) of mean age of 31 years. They read four stories about domestic violence incidents, where oppressors and victims were either men or women. They were then asked to assess to what extent, in their opinion, four proposed statements might serve as valid and reliable title to each story. Statements represent four levels of abstractness. Additionally, the Ambivalent Sexism Scale was administrated in order to measure the participants' level of sexism. Results confirmed Hypotheses (1) that abstract terms were preferred in description of incidents; and (2) that women tended to use more abstract terms than men. As regards relationships between sexism and language abstractness (Hypothesis 3), this was proven only for benevolent sexism. The study indicates that a negative behavior, as in case of domestic violence, is attributed to dispositional traits of an actor rather than to situational factors. This tendency is more pronounced in women than men, probably due to their stronger disapproval of violence, and/or empathy toward victims (women are more likely to be victims). Relationships between benevolent sexism (i.e. positive attitude toward stereotypical women, but negative when women transgress their stereotypical roles) and usage of more concrete terms (i.e. attribution to non-dispositional causes of violent behavior) can be explained as the tendency to justify actions of perpetrator who might be provoked by a transgressed victim.

Keywords: biased language, domestic violence, behaviour, sexism

Black racial life narratives: A transnational reinterpretation of black racial identity

NEVILLE, H. (University of Illinois at Urbana-Champaign)
Over the past four decades, there have been considerable theoretical, measurement, and methodological advancements in research on Black racial identity. However, there has been little exploration of the experiences of people outside of the U.S. or on process issues (i.e., how and under what conditions people develop their racial beliefs over time). In this project, I explore the context of racial identity themes among self-identified Black men and women in Australia, Bermuda, South Africa, and the U.S. I am using a (racial) life narrative methodology to examine the common and diverging themes among 60 participants (83% of the in-depth one-on-one interviews have been completed thus far). Approximately equal numbers of men and women are participants and there is an equal representation of participants across sites (e.g., Australia, Bermuda, etc.). The format of the interviews is based on Dan McAdams’ life narrative interview protocol. Interviews are conducted at a location of the participant’s choice and typically last between 2-4 hours. The taped interviews are transcribed verbatim, double checked for accuracy, and sent to the interviewee for feedback and approval. I am using dimensional analysis to conduct the constant comparative, iterative, and line-by-line analysis of the text. Thus far, a quest for humanity has emerged as a core theme. The initial theme emerged from my interviews in Bermuda. A number of people expressed a desire to be viewed as human [both in a raced and non-racial view]. I reworked this restricted concept of a quest for humanity in situations typically last between 2-4 hours and double checked for accuracy, and sent to the interviewee for feedback and approval. I am using dimensional analysis to conduct the constant comparative, iterative, and line-by-line analysis of the text. Thus far, a quest for humanity has emerged as a core theme. The initial theme emerged from my interviews in Bermuda. A number of people expressed a desire to be viewed as human [both in a raced and non-racial view]. I reworked this restricted concept of a quest for humanity after conducting several interviews with Aboriginal people in Australia. Participants in this context also talked about humanity as being connected to freedom from external and internal constraints of racial oppression. Colorism and its influence on identity is another dominant theme that is emerging in the data. I am examining the ways in which gender, class, and nationality intersect in the expressions (or not) of the themes. I plan to complete data collection by March and am in the process of analyzing the interviews now.

Keywords: black racial identity, racial identity themes, life narrative methodology, quest for humanity, Colorism

Black Saturday: Treating trauma and loss in the aftermath of the 2009 Victorian bushfires

JACKSON, C. (Mitchell Community Health Service)

This paper will address treatment approaches and outcomes for those traumatized and bereaved as a result of the 2009 Black Saturday Bushfires in Victoria. The paper will present an overview of the clinical presentations of bushfire affected residents in an area where 106 people perished, 1397 homes were destroyed and 40% of the Shire burned. The ferocity of the fires and the loss of life and property have created particularly devastating traumatic outcomes for many of those present on Black Saturday. The paper will examine treatment approaches employed, and treatment outcomes, including psychometric measures of post-traumatic stress disorder (PTSD), depression and anxiety, pre and post treatment. Particular and distinguishing issues and implications for trauma treatment in post disaster settings (compared with traumatic material commonly presented in the course of regular psychological practice) will be discussed. Further, issues of practitioner self care in light of the nature, the severity and the immediacy of the traumatic material presented by clients will be addressed.

Keywords: trauma, bushfires, post-traumatic stress disorder, depression

Body image and reasons for exercise in young adult gym users

DANDO, A. (Deakin University), KING, R. (Deakin University)

Exercise as a body change behaviour and the variables that impact on this have not been extensively examined. This is of concern as ‘at risk’ groups such as gym users demonstrate higher negative body image issues compared with non-gym users. This is of particular importance when considering the number of gym memberships are increasing. Therefore, the current study aims to develop a theory driven model to explain gym-specific exercise as a body change behavior based on relevant variables identified by prior research such as
internalisation, body dissatisfaction (BD), drive for thinness (DT), muscularity (DM) and leanness (DL), and motivations for exercise. 103 (65 females, 38 males) young adult (18-29 years) current gym users recruited through gyms, social networking sites and personal contacts, completed an anonymous online self-report questionnaire. In addition to demographic information, the frequency and duration of gym exercise behavior that was either cardio or weights-related was assessed. The questionnaire also comprised of measures examining internalisation, BD, DT, DM, DL and motivations for exercise. As hypothesized, internalisation of the General and Athletic ideal correlated with dissatisfaction with thinness and muscularity, respectively. Additionally, as hypothesised, females demonstrated higher levels of DT and males higher levels of DM, with both genders illustrating DL to similar degrees. Further, these drives were significantly related to motivations for exercise; DT associated with appearance and weight-management exercise motivations, and DM correlated with weight-management and strength and endurance motivations. Path analysis indicated the variables contributed to a well fitting model of exercise behaviour. The model provided pathways from internalisation to muscle or thinness-related BD, resulting in either DT or DM, which, in turn, predicted motivations for exercise, which were associated with engaging in weights as an exercise behaviour. Motivations for exercise did not correlate with engaging in cardio-based exercise. Young adults attend the gym for reasons of toning and strength building with the primary motivation of weight management for both genders. Further, negative body image and associated drives can influence the degree, type and intensity of exercise. This is of relevance when considering obligatory and unhealthy levels of exercise and associated health problems such as disordered eating and use of performance enhancing substances. Therefore, these combinations of variables predict the use of gym exercise as a body change behaviour, warranting further examination of the model.

Keywords: body image, exercise, body change behaviour, gym users, motivations

Breaking the change – cynicism cycle: A role for HR?

BROWN, M. (University of Melbourne), KULIK, C. (University of South Australia), CREGAN, C. (University of Melbourne), METZ, I. (Melbourne Business School)

Organizational change programmes are usually intended to bring about positive outcomes such as organizational survival and profitability. The attitudes and reactions of employees to change initiatives, however, can have an impact on the success of the change programme. Employees become cynical about organizational change when they have experienced multiple rounds of change initiatives. Organisational change cynicism (OCC) is defined as an employee view that change is futile and management is to blame for the failure of change programmes. In this paper we investigate the role of Human Resources (HR) in mitigating employee reports of OCC. We use HLM to investigate two roles of HR: as an administrative expert (focus on the efficiency of the day to day operations) and as a change agent (focus on people and strategy with a view to overcoming resistance to change). Our level 1 data is from approximately 1800 employees: from this data we generate our dependent variable (OCC) and our independent variable (quantity of organizational change). Our level 2 data is from the HR managers of our employees in 70 Australian organisations (minimum of 5 employees per organisation). From these data we generate two role variables (change agent and administrative expert) to determine if the relationship between the quantity of organizational change and OCC is affected by the role taken by HR. We find that the greater the quantity of organizational change, the higher the level of OCC. However, when HR works as an administrative expert, the relationship between the quantity of organizational change and OCC is strengthened. When HR performs a change agent role the relationship between the quantity of organizational change and OCC is weakened. Our findings suggest new ways to prevent the development of OCC. HR managers who adopt a change agent role can disrupt the change-cynicism cycle and keep employees engaged with organizational change efforts.
Burnout in Brazilian organizational context: A study with university professors

MENDONÇA, H. (Catholic University of Goiás), SOUZA, I. (Catholic University of Goiás), ZANINI, D. (Catholic University of Goiás)

The university question in Brazil has been suffering great changes. These changes reflect on the cultural, political and economical history of Brazil and can affect the university professor’s health by the manifestation of acute stress and burnout syndrome. This study aims to analyze the socio-demographic characteristics of these professors, such as sex, grade and knowledge area that are involved in the development of burnout. Besides that, the study also analyzes the predictive power of affective organizational commitment on burnout. The participants were 233 university professors of the West-Central area of Brazil. The instruments included the Maslach Burnout Inventory which has 22 items divided into three dimensions: emotional exhaustion (9 items); cynicism (5 items) and personal accomplishment (8 items). To measure the affective organizational commitment variable a Brazilian version of the Organizational Commitment Questionnaire (OCQ) was used. It is a one factor scale. The participants of the study were also asked some socio-demographic information such as sex, grade and knowledge area. The data were analyzed at two different times. On the first one, t-tests and ANOVAs between the socio-demographic variables, affective organizational commitment and burnout were used. On the second one, a stepwise regression was used to verify the predictive power of the socio-demographic variables and the affective organizational commitment on burnout. It was shown that sex is a differential factor for affective organizational commitment and that the knowledge area and grade are antecedent variables of affective organizational commitment. It was observed that the higher the grade, the less affective organizational commitment was found along with higher emotional exhaustion. In conclusion we can postulate that the demands the university professors are submitted to make them more involved with their personal career and less involved with their institution.

Keywords: Brazil, stress, burnout, affective organizational commitment, gender

Can drivers ignore disturbing news?

SHIGEMORI, M. (Railway Technical Research Institute), SATO, A. (Railway Technical Research Institute), SHINPO, Y. (Gakushuin University), OHTA, N. (Gakushuin University)

The aim of our study was to examine whether passive listening to the news or conversation on the radio affect recollection of prospective memory. Authors randomly divided participants (undergraduates) into three groups and all of them engaged in prospective memory task like which Einstein et al. (e.g., Einstein & McDaniel, 1990) developed. In this kind of task, participants were asked to do recognition memory task or lexical decision task concurrently with reaction (e.g., pressing a key) for the specified words. Group 1 completed the task while listening to news of interest, while Group 2 listened to news of no interest, and Group 3 listened to no news. Results of comparison of mean accuracy rates of prospective memory tasks among groups showed that participants who did task with listening to news of interest tend to have lower accuracy rate than those of other groups although accuracy rates of participants who did it without listening to news. Those results indicate that people don’t ignore news of interest even if they are listening to it passively and that such an involuntary dedication causes absent-minded failures of remembering things intended to do. Car or train driving demand us some kind of prospective memory. Therefore, we call attention to listening to the radio news while driving.

Keywords: passive listening, prospective memory

Can internet-based interventions influence long-term efficacy of trainings?

KAPS, S. (Technical University of Braunschweig)
In clinical psychology and psychotherapy, internet-based interventions (IBI), such as online-therapy, follow-up e-mails and chats have been shown promising for consolidating therapy effects (e.g. Ott, 2003). These approaches, however, are barely used to enhance effects of trainings. This is even more surprising since today there is a substantial imbalance between investment costs and training outcome with only 10 percent of the training-contents being effectively transferred (Georgenson, 1984). The current study investigated whether the long-term effectiveness of a cognitive-behavioral social skills training (Hinsch & Pfingsten, 2007) could be perpetuated using IBI during the four following weeks. Therefore a specific IBI was developed and evaluated with questionnaires measuring self-efficacy, social behavioral habits and attributional styles. The IBI used cognitive-behavioral tasks and elements which were created based on the training contents. These tasks were provided twice a week via Moodle. Participants posted reports about the realization of the tasks in forums and had the opportunity to get assistance by a trainer. The effectiveness of the IBI after training was evaluated over 12 months and compared to no IBI after training, IBI alone and training alone. Results show evidence that IBI can sustain effectiveness of training. Training combined with IBI was superior to the other conditions in a 9-month follow-up. That implies that IBI is one approach to increase long-term efficacy. Based on these findings, ongoing research aims to further clarify the causal role of single elements of the IBI for its effectiveness.

Keywords: internet-based interventions, training, cognitive-behavioral social skills, effectiveness

CDSM training: Health professional uptake in daily practice

LINDNER, H. (Australian Psychological Society), FULLER, T. (Australian Psychological Society)

The burden of chronic illnesses and lifestyle risk behaviours is well established. Psychologists and other health professionals have a major role to ensure effective client adherence to recommended client-managed treatments for chronic illnesses, such as arthritis, heart disease, diabetes, obesity, and asthma. Additionally, health professionals can contribute significantly to client self-management changes in health risk behaviours, such as smoking and alcohol abuse. There is a growing requirement around the world for medical, nursing and allied health professional training programs to include strategies, such as motivational interviewing and interdisciplinary models of care, to enhance patient adherence to recommended treatments. The current research aimed to investigate the effectiveness of a training program trained for health professionals. Approximately 200 health professionals across four geographical regions of Australia that represented metropolitan and rural environments, and communities with a high population of Aboriginal people. The health professionals undertook a self-directed 3-hour CD-based training program in chronic disease self-management skills, including motivational interviewing and readiness to change assessment and intervention techniques, early intervention skills for dysfunctional self-talk and emotions, and models of interdisciplinary professional local care. Participants were required to complete an online assessment following completion of the training program. Data on training outcomes, implementation of skills and interdisciplinary meetings will be finalised by May 2010.

Keywords: chronic illness, risk behaviours, training programs

Change management and trust in safety critical environments: Small plane safety culture

KABI, R. (University of Newcastle), CHALMERS, K. (University of Newcastle)

Safety culture and safety management practices in commercial and military aviation operations have been based on human factors research evidence for over four decades. However, this is not the case in the small plane environment. Australian small plane operations were completely reviewed in the past decade and the ensuing new or amended rules and recommendations are currently being implemented. Pilots and organizations are expected to manage required change in a timely manner. Management of small plane operations
is quite different to that of large plane operations. Additionally, there is great diversity within the small plane sector itself. Mandatory change management presents particular problems for those who themselves may have limited appreciation for the evidence underpinning incoming changes. There is little direct evidence of current small plane safety culture and safety management knowledge, attitudes and practices. The aim of this project was to assess and report on the state of current safety culture and safety management practices and planning within this sector. An online survey was made available to Australian small plane pilots in Sept-Oct, 2008, about current and incoming safety management requirements and readiness for change management. 426 pilots responded to the survey, mainly from three subcategories: fixed wing VH registered recreational aircraft and balloons. Pilots were asked to rate their own, other pilots, and club or organizational awareness and planning for safety management requirements. Pilot responses were matched against a recognised model of change management stages. Results indicate that knowledge, attitudes and levels of trust correlate with age group, flying experience and aircraft type. These variables are shown to be associated with attitudes to change management and implementation readiness. The findings are consistent with previously established models in which attitudes and knowledge correlate with changes in behaviour, confirming that change management in safety critical environments requires careful planning and adequate inclusion of ‘changees’ in change management processes.

Changes in observed driver behaviour following extended use of in-vehicle backing aids

The popularity of larger vehicle types such as sport utility vehicles (SUVs) for transporting families, combined with the aging of the driving population, may be causing an increase in the incidence of back-over crashes. The aim of the study was to determine whether experience using a backing (or reversing) aid over an extended period would be associated with changes in driver behaviour. Forty-two parent-aged (25-50 years) drivers drove their own vehicle for a period of two months, throughout which it was equipped with one of three types of backing aid: ultrasonic, dash-mounted video, or rear view mirror-mounted video. Before and after this period, driving performance was observed while performing a series of backing manoeuvres, both with and without the use of the backing aid. At the ostensible conclusion of testing, an ‘unexpected obstacle’ was placed behind the participant’s vehicle without their knowledge, and they were asked to reverse out of the parking spot with their backing aid activated. Following the eight week period, drivers made significantly fewer glances to rear view and side mirrors, and made fewer shoulder checks while backing, when they used the devices compared to when performing the same manoeuvres unassisted at the beginning of the study, $F(1, 38) = 34, p < .001$). This difference persisted even when the backing aids were turned off, $F(1, 38) = 20.4, p < .001$), suggesting that experience with the backing aids caused drivers to adapt their visual search behaviour in a potentially safety critical manner. Finally, regardless of backing aid type, the majority (80-93%) of participants collided with the unexpected obstacle, a finding that is consistent with previous similar research (Llaneras et al., 2005; McLaughlin et al., 2003). The high rate of collisions observed in this scenario may have been due to a delay in system activation (for the video-based systems) or because of the unexpected nature of the event, which caused drivers to ignore warnings from the ultrasonic device. Collectively, results indicate that driver behaviour changes in safety critical ways following exposure to backing aids over an extended period of time. Backing aids should not, therefore, be promoted as safety equipment for drivers.

Charting psychology’s progress in demonstrating relevance to the needs of Indigenous Australian people: A review of literature and experience from 1992-2009

GARVEY, D. (Curtin University of Technology)

Following a meeting in 1992 to discuss a proposal to develop a four year psychology program for Indigenous Australian students, Reser (1993, 1994) identified several issues, barriers and opportunities regarding the roles and relevance that the profession might have with Indigenous students and Indigenous people generally. Reser outlined not only the structural and practical ramifications of such a proposal, he also made reference to the milieu, or ‘contested cultural space’ in which such a proposal would need to be considered. This paper outlines aspects of this context, placing particular emphasis on discursive elements of the debate surrounding the proposal at the time, and the consideration of Indigenous issues by the profession since. A literature review was conducted focusing on Australian Psychological Society (APS) policy and guidelines relating to Indigenous people during this period. Journal articles and other commentary on the topic were also sourced. Interviews with persons involved with psychology and Indigenous Australian people were conducted. Participants included Indigenous and non-Indigenous psychologists, students and clients of psychological services. A Causal Layered Analysis (Inayatullah, 2004) was conducted with a view to identifying the varied and interconnected layers of discussion. Activity has been predominant in the ‘political sphere’ with emphasis placed on validating and entrenching an Indigenous presence in the contested cultural space of Australian psychology. The emergence of bodies, such as the Australian Indigenous Psychologist’s Association (AIPA) in 2008/2009, are indicative of a renewed imperative to organize and mobilize Indigenous voices and presence within the profession. Furthermore, an emphasis on professional development under the rubric of cultural competence has become increasingly apparent, seeking to address in a conceptually rigorous manner what has been an enduring demand for practical skills enhancement amongst psychologists working with Indigenous Australian people. Discourses of ‘ongoing struggle’, and ‘reconciliation and partnership’ seem to characterize and underpin these developments in recent times. The paper concludes by outlining issues that stand to confront those interested in negotiating psychology’s relevance to Indigenous Australian people in this generation and beyond. These will include the structural and apparent parameters that define service delivery and how less apparent discursive underpinnings determine these.

Keywords: Indigenous Australians, barriers, reconciliation

Children’s categorization of objects: Developing from a conceptually to a perceptually based process?

CHANG, J. (The Chinese University of Hong Kong), TAI HAU, K. (The Chinese University of Hong Kong)

Past research on how children categorize objects has resulted in inconsistent findings. Some studies suggest that children use non-obvious properties that can only be identified on the basis of prior-conceptualizing (conception-driven, e.g., both can hold water) or causal characteristics (e.g., both have eyes and can see). In contrast, other studies suggest that children primarily use perceptual (perception-driven; e.g., both round) and other distinctive features (e.g., both have wheels). However, there is still no clear consensus on whether children’s categorization is mainly a conceptually or perceptually based process, or whether these two processes operate in tandem. The present research consisting of four experimental studies attempted to understand factors affecting children’s categorization process. Considerable effort has been exerted to determine conditions that would facilitate young children’s use of the conception-based mechanism, particularly when they have little prior knowledge about the conceptual attributes of the targeted objects (Gentner & Markman, 1995b; Mussweiler & Gentner, 2008). More recently, it has been suggested that children tend to categorize attributes and compare their functions and conceptual characteristics when they have enough conceptual knowledge and experience.
about these objects (Gentner, Loewenstein, & Hung, 2007; Namy & Gentner, 2002; Uttal et al., 2008). The current study proposed that the basis of children’s categorization varied developmentally from a conceptual to perceptual preference with the increase of their knowledge about the objects in the world. In four experiments, we modified tasks from earlier studies (e.g., Namy & Gentner, 2002; Uttal et al., 2008) and investigated the categorization mechanism of a total of 116 four-year-old children. These four experiments investigated with (i) tasks that were conceptually-matched, but not perceptually matched, (ii) tasks of different familiarity, (iii) tasks with different familiarity with the relationships among them, and (iv) tasks with manipulation on their visual hints and background information. The results suggest that young children can actively use the conceptually driven mechanism during the comparison process if there are opportunities for them to focus on these conceptual properties. Young children could also categorize unfamiliar objects in the presence of familiar objects on the basis of their conceptual information.

Keywords: children, categorization, conceptual processing, perceptual processing

Chinese entrepreneurs’ motives: Pushed or pulled?

NGUYEN, H. (California State University, Long Beach), YANG, J. (Jiangxi University of Finance and Economics), SZE, N. (Michigan State University), LIAO, J. (Jiangxi University of Finance and Economics), ZHOU, M. (Jiangxi University of Finance and Economics), XIONG, X. (Jiangxi University of Finance and Economics)

We conducted a field survey with a sample of actual Chinese entrepreneurs in Jiangxi and Hong Kong (N = 86). One research goal was to examine the multi-dimensionality of entrepreneurs’ motives: whether Chinese business owners opened their own business because they were “pulled” or attracted to advantageous factors associated with entrepreneurship, or because they were “pushed” or trying to escape undesirable factors surrounding their previous employment, or both. We also investigated the personality correlates of entrepreneurs’ perceived business success and satisfaction. This study utilized the survey method with two convenient subsamples of actual entrepreneurs from Hong Kong (n=26) and Jiangxi, China (n=60). Participants were recruited from the authors’ local networks and were instructed to return completed surveys to the researchers by mail. The response rates were satisfactory (65% in Hong Kong and 83.33% in Jiangxi). Participants were mostly male and were, on average, over 40 years of age. Most of them owned small and medium enterprises (69.6%). The survey consisted of a constructed entrepreneurial motives, a constructed perceived business success scale, Bass’ (1997) entrepreneurial satisfaction scale, Triandis et al.’s (1986) individualism-collectivism scale, Goldberg’s (1999) big-five personality dimensions, and a demographic questionnaire. Most measures were translated into Chinese and back-translated by bilingual researchers. Most measures yielded at least adequate internal consistency levels. In terms of Chinese entrepreneurial motives, consistent with qualitative findings by Nguyen and Nguyen (2008), factor analyses showed that participants endorsed four categories of “pull” motives (e.g., to have a challenging and meaningful career) and four categories of “push” motives (e.g., to escape stress and/or heavy workload in previous employment). A majority of participants also endorsed an altruistic motive (i.e., to help family or community members in need of employment). In terms of the correlates of perceived business success, the Big-Five personality traits were significant predictors, with Openness to Experience explaining the highest percentage (19.2%) of the variance accounted by personality. Whether participants were more collectivistic and less individualistic also predicted perceived success, with (the lack of) Self-Reliance explained the most (12.4%) of the variance accounted by individualism-collectivism. In terms of participants’ satisfaction with their enterprise, the variance was also explained by personality, some individualism-collectivism dimensions, and the endorsement of several entrepreneurial motives. Number of years in business, business size, participants’ age, and number of work hours correlated with either perceived business success or overall satisfaction. The present study provided empirical evidence to support Nguyen and
Nguyen’s (2008) grounded theoretical framework of entrepreneurial motives and their correlates. The results revealed a complex pattern of motives with some unique characteristics (altruistic; collectivistic) that may distinguish Asian entrepreneurs from their western counterparts. Future cross-cultural, comparative research may shed further light on these findings. Theoretical and practical implications were discussed.

Chronic disease management in the community: The nurse educator programme

PHOON, W. (Health Promotion Board), LOH, H. (Health Promotion Board), THILAGARATNAM, S. (Health Promotion Board), KHOO, G. (Health Promotion Board)

The National Health Survey 2004 showed the prevalence of diabetes, high blood pressure and high blood cholesterol among Singaporeans aged 18–69 years to be 8%, 25% and 19% respectively. This prevalence is considerably higher in persons aged 40 years and above. In all, an estimated 1 million Singaporeans suffer from one or more chronic conditions such as diabetes, high blood pressure and high blood cholesterol. The Survey also showed that 27.6% of those with diabetes had unacceptable blood glucose control and 50.5% of hypertensives had poor blood pressure control. Patients with uncontrolled blood glucose and blood pressure are likely to suffer complications such as stroke, heart disease, renal failure and amputations. Besides medications, lifestyle changes e.g. exercise and diet is critical for the patients to control their conditions. The majority of patients with chronic disease(s) are managed by doctors in polyclinics (government clinics) and private practices. However, feedback has shown that the doctors often do not have the time to educate their patients on the holistic management of their conditions, in particular, the necessary lifestyle changes e.g. nutrition, exercise. To close this gap, the Nurse Educator (NE) program was developed. Participants attend three group psycho-educational sessions with the NEs that include a health risk assessment, creating action plans with achievable goals, identifying barriers to achieving these targets and methods to overcome these barriers. The workshops are conducted in English, Mandarin and Malay. Working closely with the Wellness Program, a community-based program with health and social inclusiveness as its focus, participants are also referred to physical activity and nutrition program within the community. Pre- and post-workshop evaluation questionnaires are administered to measure learning outcomes. NEs conduct follow-up with participants through phone calls at 6 and 12 months post-workshop. Participants’ lipid levels, blood pressure and/or HbA1c test results will be recorded at the end of 12th month. The pre- and post-workshop evaluation on knowledge and attitudes showed a 45.6% improvement. At the 6-month telephone follow-up, 51.4% of participants showed an improvement in their confidence in making lifestyle modifications (i.e. in relation to physical activity, medication compliance, weight control and healthy eating) and 48.6% of participants reported adopting healthy lifestyle practices. The one-year data will be ready in April 2010. This is a three-year community-based program that focuses on lifestyle modifications that will assist with the management of chronic disease patients. Working with GPs, and through empowerment and education, individuals are taught ways to better manage their health through lifestyle changes.

Civic competence development of 9-13 years old Dutch youth

SKLAD, M. (Roosevelt Academy), RIGTER, J. (Hague University, the Netherlands), DIEKSTRA, R. (Hague University, the Netherlands)

This study has followed the development and individual differences in the domain of civic competence during the last three classes of primary education. Civic competence was
assessed using a civic competence questionnaire (Dam, Geisel, Ledoux & Reumerman, 2009). Four components of civic competence were assessed separately: knowledge, attitude, skill, and reflection. In turn, each component was divided into four social functions: social responsibility, conflict resolution, democratic behavior and dealing with differences. 265 secondary school pupils of 9 to 13 years old took part in the study. To strengthen the conclusions concerning the changes in civic competence, these changes were assessed both cross-sectionally and longitudinally: three age groups were compared and one group of students was followed for three years. The results have shown a significant improvement between 6th and 8th grade in terms of knowledge, but not regarding the other three components. There were also significant differences between genders, in favor of girls. The results suggest that pupils experience an increase of civic knowledge between 6th and 8th grade, but this increase does not seem to be accompanied by analogous improvement of the other three components of civic competence (i.e., attitudes, skills, and amount of reflection).

Keywords: civic competence, Dutch, young people, education

Client threats as experienced by West Australian psychologists

HYDE, P. (Edith Cowan University), ALLAN, A. (Edith Cowan University), ALLAN, R. (Edith Cowan University)

Researchers found that psychologists experience threatening behavior from clients in their professional practice. No published research has been undertaken in Australia to determine what the local situation is. A feature of the published research is that researchers have generally used surveys to collect the relevant data. The data therefore do not indicate exactly what type of behavior psychologists experience as threatening. The aim of this stage of a more comprehensive project was to explore what type of client behavior Australian psychologists experience as threatening. This data will be used to develop an instrument that can be used to examine Australian psychologists' experience of threats. This qualitative study was guided by a phenomenological approach. Semi-structured interviews were used to collect data from 15 Western Australian psychologists. Participants were recruited by using a purposeful sampling method to ensure that they varied in terms of gender, experience, therapeutic modality they use, clientele, and workplace characteristics. The data collected from these interviews were analysed using thematic analysis. Psychologists’ experiences of client threats could be categorised into nine types: Physical Aggression, Threat of Physical Aggression, Stalking, Threats to Loved Ones, Indirect Acts of Aggression, Verbal Aggression, Emotional Manipulation, Boundary Violations, and Threats to Competence. The level of threat in each of these categories can differ on a continuum. These findings suggest that Western Australian psychologists’ definition of threatening client behavior is broader than that typically used by researchers who survey psychologists about client threats. Psychologists reported that they constantly experience a range of client behaviors as threatening, but with different levels of intensity that range on a continuum. Psychologists’ responses to these threats differ depending on their perception of the level of the threat.

Keywords: threatening behavior, Australian psychologists, thematic analysis, intensity, perceptions

Clients’ understanding of professional boundaries in psychological services

HAMMOND, S. (Australian Catholic University), VAN MEGCHELEN, T. (Australian Catholic University), HAMMOND, S. (Australian Catholic University)

The aim of this study was to examine perceptions of boundaries, boundary blurring, and boundary crossings in embedded and non-embedded communities among clients of psychology services. Utilising qualitative and grounded theory research methods, 29 psychology clients aged between 20 and 64 years from both non-embedded (urban) and embedded (e.g., rural; and gay, lesbian) settings participated in in-depth interviews. Seventeen grounded theories were identified. Three key findings are presented here. Firstly, many clients
found it difficult to define boundaries, and had low awareness of boundary issues or how to deal with potential boundary crossings. Second, beliefs about boundary crossings were socially constructed and varied significantly according to the context of the situation. Third, there was similarity in how clients from embedded and non-embedded communities understood and dealt with boundary issues; however, the rural embedded sample deemed boundaries harder to manage. These results have implications for professional practice. There is a need to educate clients about boundaries and how to deal with boundary crossings and violations. Additionally, clients need to be supported to develop an ‘informed client identity’ that is conducive to their expectations of handling boundaries in treatment.

Climate, politics, and performance of public organizations: a cross-level analysis of public schools’ biosphere

VASHDI, D. (University of Haifa), VIGODA-GADOT, E. (University of Haifa), SHLOMI, D. (University of Haifa)

Public organizations highly depend on building constructive environments and encouraging a healthy climate that leads to higher performance. Throughout the years, questions about organizational climate, organizational performance and their mutual relationships have been studied extensively and from multiple perspectives such as management, public administration, organization studies, psychology and sociology. This study builds on accumulated inter-disciplinary perspectives to examine the contribution of multiple climates to organizational performance both on the Micro-individual level and on the Macro-organizational level. It is suggested that examination of multiple climates (participative, innovative, leadership, and service), as well as organizational politics, can improve our understanding of micro and macro level performance of public organizations. A field study of 2102 teachers from 108 public schools and 3 major districts in Israel was conducted between November 2004 and June 2005. The teachers answered the climate questionnaire and archive data about school and students achievements, socio-economic rank of the schools, school size, level of teachers’ self-reported absenteeism, and reports on group level OCB was also collected. Data was analyzed on the basis of Random Coefficient Modeling as this approach allows for testing the nesting of teachers within schools. The findings indicate that multiple climates in the school environment are positively related with micro-level performance and this relationship is mediated by organizational politics. In addition, both organizational climate and micro-level performance are related with macro-level performance. Our findings emphasize the impact perceptions of organizational politics have in explaining the relationship between climate and performance in public organizations. Additional theoretical, methodological and practical implications are discussed. The paper supports further investigation of multiple climates in public organizations and exploration of their complex relationship with politics and with multi-level performance indicators.

Keywords: climate, politics, performance, organisations, micro-individual/macro-organisational levels

Clinical features in the children’s psychological assessment

SILVA, R. (Santa Cruz do Sul University), SILVA, M. (Santa Cruz do Sul University)

Children and adolescents develop mental disorders due to emotional, environmental or developmental stress situations. Psychological evaluation by managing specific instruments provides comprehension of possible causes for these disorders. This study identifies clinical symptoms of a sample of children referred for psychological evaluation, as well as demonstrates statistical association between the symptoms with their age and sex. In this study 849 children protocols have been analyzed aged between five and 12 years old, which included data from medical history interview or from CBCL (Child Behavior Check List). The
information obtained were imputed into a database on SPSS version 11.5 for Windows and analyzed by scanning frequencies of the variables and by the association of measures using the chi-square test. The predominant age group in this evaluation was between 9 and 10 years (34.2%), having more male children (66%). Through interviews of anamnesis, the most frequent symptom was learning disabilities (23.8%). According the CBCL, internalizing symptoms had higher occurrence (55.5%). Through the association between child’s age and clinical symptoms, learning difficulties showed a significant association \((p = 0.000)\), as well as age and presence of seizures \((p = 0.000)\). It’s also found a significant association between sex and anxiety symptoms, insecurity and fear \((p <0.05)\). Across the protocols evaluated it is possible to conclude that the treatment search is so late for children between 9 and 10 years. Learning disability was the prevalent symptom, proving that the school is the place where the child expresses his cognitive, personal and family difficulties. Moreover, age is relevant to the onset of symptoms linked to learning and to the presence of seizures. Furthermore, sex means to be the most relevant factor related to the internalizing disorders according to the CBCL’s proposal. The importance of this identification is to promote stimulation to the mental health professionals to work in a preventive manner, helping families to identify symptoms in their children earlier.

Clinical, comorbid, and psychological characteristics associated with HIV across decade of life

VANCE, D. (University of Alabama at Birmingham), MUGAVER, M., WILLIG, J., RAPER, J., SAAG, M.

Of the 1.1 million adults infected with HIV in the United States, those adults 50 years of age or older made up 15% of all new HIV diagnoses, 24% of those living with HIV, 29% of those diagnosed with AIDS, and 35% of those who died of AIDS. Similar trends have been found in Australia and Europe. With the increasing number of older adults with HIV, healthcare professionals will need to know what to expect as this population ages. This cross-sectional study examined the medical records of 1,478 HIV patients from a university clinic from May 2006 to August 2007. Clinical characteristics and patterns of comorbidities were examined across each decade of life. Data reflected that older adults with HIV were more compliant with medical appointments; this suggests an opportunity to reach older adults and educate them about successful aging with HIV. Meanwhile, younger adults with HIV were less compliant to medical appointments which indicate an area of need. In addition, older adults with HIV had lower HIV viral loads but had more comorbidities in many cases several fold higher. Such comorbidities included hypertension, hypogonadism, hypercholesterolemia, coronary artery disease, and diabetes. The increase in these comorbidities can have detrimental effects on brain health and cognition; this may help explain some of the cognitive problems observed in older adults with HIV. Interestingly, there were no differences in the prevalence of depression (38% to 45%) or anxiety (12% to 20%) across age groups. Implications for practice and research are provided.

Keywords: HIV, clinical characteristics, patterns of comorbidities

Coach impact in a process of managerial coaching: A case study

ORTEGO, J. (Universidad de Burgos), GARCIA, C. (University of Burgos), SAN JUÁN, C. (University of Basque Country)

Executive Coaching theory is relatively new, consequently there are very few empirical studies in the field linking Coaching and managerial abilities development. The most relevant research in the field refers, to the analysis of job performance and productivity (Genger, 1997; Mc Gouvern et al., 2001; Miles & Huberman, 1994), Individual learning factor, (Harris, 1999; O’Brien, 1997; Witherspon & white, 1996), Self-Awareness and Developmental Goals (Kampa-Koesh, 2001; Laske 1996), Leadership Effectiveness and Coaching (Kampa-Koesh, 2001), Coaching
effectiveness amount customer perspective, (Gwynne Dawdy, 2004), and Coaching and stress (Gyllensten & Palmer, 2006). This research aimed to evaluate a coaching program that analyses perceptions around participants’ performance, their superiors and collaborators performance, and organizational development. In order to analyse the impact of coaching several issues have been incorporated into the analysis, such as seniority, type of post, time on managerial post and kind of coach. The study was a quantitative analysis that makes uses of survey data on a sample of 108 managers (out of a population of 143) from a financial services cooperative in the Bask Country, Spain. The questionnaire for evaluating the process of training in managerial tasks and abilities were designed by the research team. The level of analysis were perception of superiors’ development, own development, collaborators development and organizational development at 9 different levels: leadership, definition and planning of strategy, personal development, alliances and resources, processes, clients outcomes, peoples outcomes, society outcomes and key outcomes. For participants, the organization has progressed considerably from 2007 in central issues as leadership (20%), Strategy definition (26%), people’s development (27%), Alliances and Resources (21%), processes (18%), clients outcomes (17%), peoples outcomes (19%), society outcomes (18%), key outcomes (20%). Coaching Effect has an important impact on respondents’ perception of own professional performance, above-managers performance, collaborators performance and Organizational Development. The above-mentioned impact of Coaching Effect on Organizational Development is, however, limited (around 7% of explained variance). Variables such as type of post (central or provincial office); seniority (time in the organization); time on post, and type of coaching (team and methodology) has proved to be not influential on coaching, in this study.

Keywords: executive coaching theory, managerial competence, organisational development

Cognitive and motivational predictors of achievements of gifted students in math, humanities and music

SEKOWSKI, A. (John Paul II Catholic University of Lublin)

The paper presents results of a study on the psychological conditions of school achievement of gifted students. The study was based on Renzulli’s theory of giftedness and Sternberg’s theory of successful intelligence. Experiments were conducted in Poland and Germany. School achievement of gifted individuals enables diagnosis of underachievers as well as optimization of the achievement of other gifted students. The participants were secondary school students. They were divided into groups of students with outstanding school achievements and those with average school achievements. Also the type of achievements, including achievements in math, humanities and music, was taken into account. The following testing tolls were used: Raven Matrix Scale, Rokeach Value Scale, Costa and McCrae’s NEO Five-Factor Inventory (NEO-FFI), Urban and Jellen’s Test for Creative Thinking-Drawing Production, and Sears’ Self-Esteem Inventory. The results point to significant differences in the psychological functioning of gifted and average students. The differences concern the level of intelligence, creative abilities, the system of preferred values and self-esteem. This also refers to the type of achievements. Students with outstanding esteem achievements in math had a high level of intelligence, a high level of creative abilities, a high self- regarding their functioning at school, and a low self-esteem regarding their social functioning and their fitness in sports. Students with outstanding linguistic achievements had a high level of intelligence, a high level of creative abilities, a high self- regarding their functioning at school, and a low self-esteem regarding their social functioning and their fitness in sports. Students with outstanding linguistic achievements had a high level of intelligence, a high level of creative abilities, and a much higher self-esteem regarding their social functioning than mathematically gifted students. Musically talented students had a high level of creative abilities, a high general self-esteem, and a preference for artistic and esthetic values. The paper presents a comparative analysis of scores obtained by the examined groups of students for all the tested variables. The results indicate a significant dependence of school achievement on intellectual factors, as well as on self-esteem and preference of values. Underachievement of
gifted students is mainly associated with low self-esteem and impairments of social functioning.

Keywords: gifted students, cognitive predictors, motivational predictors, school achievement, intelligence

Collective affective identity: The Paradox of sustainable membership

PRINCE, K. (Monash University)

The question as to what motivates professionals to participate in and contribute to professional membership associations is challenging to all associations’ executive committees. Arguably, such professional communities invite member participation in: professional development events; committee meetings; advisory groups; and selected projects. However feedback from such executive committees is that of the continual need to address issues of return on investment for membership subscription. This research uses two theoretical frameworks to understand what motivates professionals to participate, exploring: socio-emotional motivational differences; and dual psychological processes. Theoretically, socio-emotional selectivity theory argues that older adults are motivated by more positive emotional experiences and are selective with social networks; whereas younger adults are motivated by seeking knowledge, information and meaningful participation. Furthermore, a social movement framework posits that a collective identity process; and a cognitive process are responsible for participation. Consequently a three dimensional construct, Collective Affective Identity emerged based on: micro, meso, macro levels of identity; social and affective needs; and is analogous of the affective half of the dual process. Similarly a Return on Investment construct emerged to complete the cognitive dual process analogy. A professional psychological association was examined, with participants being members of the College of Organisational Psychologists. One hundred and ninety nine members participated at Time 1; one hundred and fifty members participated at Time 2; which included eighty four members who provided longitudinal data. There was an eighteen month interval between the two identical questionnaires, and these were advertised on-line through the college. Results indicated that Collective Affective Identity both mediates and moderates the relationship between Return on Investment and three levels of participation: Co-production; Organisational congruence; and Intention to stay. Furthermore results revealed a career life-span effect, consistent with motivational differences between younger and older generations. Paradoxically collective affective identity, rather than return on investment, was found to be the primary motivator for sustainable membership levels. This exploratory research contributes to areas of: socio-emotional literature; collective identities; generational diversity and professional membership participation. These findings conclude that Collective Affective Identity shows potential for manipulation in individuals to encourage professional and personal growth, leading to: increased collaboration; and membership sustainability.

Keywords: professional membership associations, participation, motives, collective affective identity, membership sustainability

Collectivistic and individualistic value orientation, coping style, and trauma symptoms following life adversities among adults in Singapore

TANG, C. (National University of Singapore)

Studies on Western samples have found that individuals who place more emphasis on individualism tend to use more direct coping strategies, which are in turn related to better adjustment following life adversities. The present study aimed to determine associations between individualistic and collectivistic value orientation, coping style, and trauma and depression symptoms. A community sample of 947 adults residing in a multi-cultural and non-Western country of Singapore. It also investigated the influence of the interplay between value orientation and coping style on trauma and depression symptoms. A community sample of 947 adults in Singapore who had experienced various life adversities were recruited. Participants were invited to complete anonymous questionnaire consisting of
psychological scales on life adversities, cultural and value orientation, coping style, and trauma and depression symptoms. Bivariate correlations were conducted to delineate associations between variables. Hierarchical regression analyses were also performed to investigate whether coping style moderated the association between value orientation and trauma symptoms. Results of bivariate correlations indicated that trauma and depression symptoms were associated with experiences of life adversities at a younger age, female gender, being single, without employment, individualistic value orientation, and negative coping style. After controlling for demographic characteristics and age of life adversities, intrusive symptoms were best predicted by negative coping. Significant individualistic orientation x negative coping 2-way interaction effects were found for arousal and avoidance symptoms. In particular, the association between individualism and arousal and avoidance symptoms were found among participants with high levels but not low levels of negative coping. For depression symptoms, a significant collectivistic orientation x positive coping 2-way interaction was found. Among participants with low collectivism, depression symptoms were related to low levels of positive coping. Among participants with high collectivism, depression symptoms were related to high levels of positive coping. Prevailing literature may not accurately reflect associations among value orientation, coping, and adjustment of individuals from non-Western countries with varying degrees of collectivism and individualism.

Keywords: individualistic value orientation, collectivistic value orientation, non-Western culture, coping styles, trauma

**Colour psychology and colour therapy: Ancient knowledge or new age nonsense?**

O'CONNOR, Z. (University of Sydney)

Colour psychology and colour therapy, which is part of an alternative therapy industry with an annual turnover of $620m in Australia, rests on the assumption that colour prompts a range of cognitive, affective and behavioural responses. Colour therapy as a practice exists outside the jurisdiction of a regulatory body or the Therapeutic Goods Act. This research sought to determine the veracity of the link between colour and human response. This research incorporated a critical review of literature relating to colour and human response from academic/scientific sources. A meta-analysis was also conducted to examine studies that focus on cognitive, affective and behavioural responses to colour, and studies relating to the practice of colour therapy. In addition, a critical review of colour psychology and colour therapy claims and assertions commonly found in non-academic, non-scientific sources (such as popular media and the Internet) was included. The results indicate that an association between colour and cognitive, affective and behavioural responses is less than weak. A range of factors such as individual differences (such as screening ability) and cultural variations as well as perceptual, contextual and temporal factors influenced the interface between colour and human response. In addition, substantial variation was found in terms of the methodological rigor of studies relating to colour and human response. Furthermore, many of the claims and assertions commonly found in non-academic, non-scientific sources relating to colour psychology and colour therapy were found to be baseless and unsubstantiated. Providing benchmark research into colour psychology and colour therapy, this research highlighted the alarming disconnect between academic, scientific literature relating to the interface between colour and human response, and the lack of an evidence-based foundation common to the colour psychology and colour therapy industry. Further research will endeavour to identify the size, extent and nature of the industry in Australia, the quality of information provided to patients, and determine the extent to which colour psychology and colour therapy are used to treat serious conditions.

Keywords: colour therapy, cognitive responses, affective responses, behavioural responses, evidence-based research

**Combating wood smoke pollution using behavioural and technological solutions: a case study of Armidale, a regional town in NSW, Australia**
BHULLAR, N. (University of New England), HINE, D. (University of New England)

Winter levels of air pollution in Armidale regularly exceed the national standard for airborne particulate matter. Most of these winter emissions come from wood heaters, the main source of heat for about one third of all households in the city. The present study evaluated the effectiveness of two strategies: the first involving education materials and the second involving a technological intervention using SmartBurn canisters, which are designed to help fires burn more efficiently and reduce emissions. 316 participating households (Participants’ Mean age=48.80 years, SD=14.64) were randomly assigned to one of the four experimental conditions: (1) Education only, (2) SmartBurn only, (3) Education and SmartBurn, and (4) No intervention (control group). Household wood smoke emissions were assessed at pre- and post-intervention. A 2 (Education/No Education) x 2 (SmartBurn/No SmartBurn) analysis of covariance (ANCOVA - with pre-test scores of smoke emissions used as a covariate) was conducted to examine the effectiveness of two wood smoke reduction strategies. Results indicated statistically significant main effects for both education and SmartBurn interventions ($p<.05$). Contrary to our prediction, education by SmartBurn interaction failed to reach statistical significance. However, there is a trend for households in the education and SmartBurn condition to produce lowest smoke emissions than that of all three conditions (education only, SmartBurn only, and control group). In first of its kind experimental trial of comparison of two wood smoke reduction strategies, our findings suggest that either strategy was effective in significantly reducing household smoke emissions. An important finding is that a cost-effective strategy such as providing information about best practices related to firewood purchase and storage and wood heater operation can be as effective as using a technological solution in reducing smoke emissions.

Keywords: air pollution, wood heaters, SmartBurn canisters, smoke emissions

Community perceptions of older child victims of child sexual abuse in comparison to adult rape victims

KLETTKE, B. (Deakin University), S., SOPHIE

The aim of this study was to investigate community perceptions of older children in comparison to adult victims of child sexual abuse (CSA). It was hypothesised that a 15-year-old victim of child sexual abuse would be perceived similar to a 20-year-old rape victim with regards to (a) victim credibility, (b) victim culpability (c) cognitive competence, and (d) that a 15 year-old female will be perceived as a “quasi-adult”. 173 participants were randomly allocated to one of two versions of the Knowledge and Perceptions of Child Sexual Abuse Questionnaire. This questionnaire was comprised of 28 items assessing participants’ perceptions of credibility, culpability and cognitive competence of either a 15 year-old or a 20 year-old female who had been sexually abused. Participants comprised 53 males and 120 females, aged 18 to 60 years ($M=30.1, SD=13$ years). The results indicated that a significant proportion of participants perceived a sexually abused 15 year-old female to be similar to a 20 year-old sexually abused female. A series of Chi-Square tests of independence revealed support for all predictions. That is, a 15 year old victim of child sexual abuse was perceived similar to a 20 year-old rape victim with regards to victim credibility, victim culpability and cognitive competence. The hypothesis that 15-year old child sexual abuse victims are treated as ‘pseudo-adults’, was also supported. According to Australian law, there are legislative differences between child sexual abuse and adult rape allegation. For example, consent does not constitute a defence in child sexual abuse cases; which includes 15 year-old victims. Yet, the current results indicate that 15 year-old child sexual abuse victims are perceived more similarly to 20 year-old adult rape victims. Thus, the perceptions of older children are not in congruence with current legislation. The legal implications of these findings will be discussed.

Keywords: community perceptions, victim credibility, child sexual abuse, rape, cognitive competence
Comparative effects of the use of sad induction procedures and music on driver's performances

PÊCHER, C. (CLLE-LTC, University of Toulouse), CÉLINE, L. (CLLE-LTC, University of Toulouse), JEAN-MARIE, C. (University of Toulouse)

Contrary to anger and aggression, sadness is not inherent to the driving situation and researchers face methodological limits to investigate its impact on performances. This study therefore aims to explore the effects of the use of imagery inductions, i.e. autobiographical recall and combined vignettes and music procedures, as well as the use of sad music to generate and maintain driver's sadness and assess its effects on behavior. Thirty-three participants were divided into three groups: (a) controls which were neutrally induced, (b) “autobiographical recall” participants which were invited to recall eight sad personal events and (c) “imagery” participants which had to imagine eight dramatic described situations with sad music in background. After it, participants drove for 15 minutes on a static simulator. During this session, neutral and sad music extracts were presented in background to reinforce the induction effects. At the end of the experiment, participants were interviewed about their feelings and performances. Analyses of scores on the PANAS X (subjective scale to assess mood changes) showed a high increase of sadness and a decrease of joy only when participants were negatively induced with the imagery procedure. Additionally, they drove faster (114 km/h) than the two other groups (controls = 99 km/h, autobiographical recall = 101 km/h). This increase of mean speed was reinforced when sad music was presented during the driving task. In post-interviews, “imagery” participants said they were conscious of their sadness and were in a favorable situation for ruminations. As a consequence, they voluntarily focused on their driving task to inhibit the induction and music effects. The imagery procedure seems to be the most efficient way to induce sadness and affect emotional state, leading to a deterioration of driving performances. The effects were strengthened with music during driving which appears to be a relevant tool to promote a sad and gloomy environment, propitious to ruminations. This procedure is relevant to assess the effects of inattention due to ruminations while driving.

Keywords: sadness, driving behaviour, imagery, music

Consumer psychology: Personality profiling to forecast consumer demand

PARDO, N. (California Southern University), PARDO, N. (California Southern University)

Applied psychology in the area of consumer psychology is used to create models for predicting consumer demand for products. Traditional economic models used in forecasting are based on linear regression, with a limited number of variables to predict consumer demand for a product line. However, artificial intelligence techniques including neural networks and embedded systems are used to analyze data with a larger number of variables and larger data sets to examine trends and predict consumer demand to a more efficient level than ever before. Data will be examined from several applications used in a retail environment in Asia, the US and Australia, comparing traditional statistical methods using linear techniques to non-linear neural network outputs. Cognitive Science as a specialized field of Psychology, combining many disciplines, is now providing the foundations for more effective models to predict consumer behavior in the area of consumer psychology. The industrial applications of such software to help managers with both human and fiscal resources in their companies is exciting.

Keywords: consumer psychology, consumer demand, forecasting, cognitive science

Co-occurring health complaints: The cumulative impact on employee productivity

LEWIS, K. (University of Wollongong), LEWIS, K. (University of Wollongong), IVERSON, D. (University of Wollongong), CAPUTI, P. (University of Wollongong), KNOPSE, S. (Health Development Partners)
Although the literature on the indirect costs of health conditions on worker productivity has developed considerably over the past 10 years, no studies have examined the co-occurrence of related conditions and their impact on productivity. Acknowledging that physical and mental conditions rarely occur alone, this study sought to explore the underlying factor structure of 13 psychological and physical conditions frequently observed in the workplace, and to examine the relative contributions of condition factors on productivity. A total of 667 employees from a large international commercial manufacturing firm in Hamburg, Germany completed a self-report questionnaire addressing 13 common health complaints, and their impact on productivity. Exploratory Factor Analysis (EFA) was performed to determine whether the underlying factor structure was theoretically sound. Confirmatory Factor Analysis was subsequently performed to obtain parameter estimates and model fit indices. The analyses yielded support for three underlying condition factors: (1) psychological/mental, (2) episodic/acute, and (3) medical/chronic. After adjusting for the effects of self-report bias and co-variance, the psychological/mental factor accounted for over 50% of productivity lost due to absenteeism and presenteeism in the organisation. Given the relatedness of the health complaints within the three factors, the development of workplace interventions that address multiple health complaints may be more efficacious, cost-effective and manageable for the organisation than multiple single condition interventions.

Keywords: worker productivity, health conditions, Germany, health complaints, workplace interventions

Coping behaviour and quality of life of a sample of women who experienced sexual abuse in childhood

WILLIAMS, H. (North-West University), VAN EEDEN, C. (North-West University)

The article aims to determine what women who experienced sexual abuse in childhood coping behaviour’s are and how these impact on their quality of life in adulthood. A case study design was used. Individual interviews were conducted with ten randomly selected women with abusive experiences in their childhood. The participants were women ranging between ages 18 and 55 years. The transcribed data from the interviews were analyzed and reflected upon in light of the research questions. The life outcomes of women who experience childhood sexual abuse are generally adverse, yet some of these victims manage to overcome the abusive relationship and experience posttraumatic growth and through this are able to survive, prevail and even experience health, well-being and overall quality of life. Positive changes occurred in these women’s experience of their struggle with childhood trauma. Protective factors which affect psychological adjustment in the face of sexual assault are positive subjective experiences, positive individual characteristics, positive communities and positive social relationships. The potential mediator of the posttraumatic growth link is that of coping behaviour. Trauma can provide the impetus for personal and social transformation. The different protective factors identified in the study have played a definite role in the adjustment and quality of life of these women survivors of childhood sexual abuse. These factors make a valuable contribution to the development of an intervention program aimed at reducing adverse risk behaviours and promoting psychological well-being (coping and quality of life) in these women.

Keywords: coping strategies, quality of life, women, child sexual abuse, trauma

Core self-evaluations and core other-evaluations: Their roles in organizational behaviors

WU, T. (National Taiwan University of Science and Technology)

Core self-evaluations (CSEs) is the fundamental assessment of an individual’s value, effectiveness, and capacity as a person (Judge, Erez, Bono, Thoresen, 2003, p304). This super trait is included in Judge, Lock, and Durham’s (1997) core-evaluations system and has attracted a lot of research attention in the field of organization psychology for the last decade.
In spite of this, another super trait in the core-evaluations system, core other-evaluations (COEs), is neglected by researchers. COEs can be defined as one’s basic evaluation about the human nature of others (e.g., trust, cynicism). Given that social perception and interpersonal judgment is an important part of organizational life, COEs also deserves academic concern in addition to CSEs. Therefore, the purpose of this study is to untangle the roles that CSEs and COEs play in organizational behaviors by exploring their differential relationships with other personality traits (five factor models, narcissism, and altruism) and work satisfaction (job satisfaction and supervisor satisfaction). Using questionnaire survey, this study collected a sample of 340 respondents from different occupations. To reduce common method bias, this study distributed CSEs and COEs questionnaire first (time 1), followed by another questionnaire including other personality traits and work satisfaction to the same respondent one month later (time 2). Regarding the relationships of CSEs and COEs with other personality traits, the results of partial correlation showed that conscientiousness is positively correlated with CSEs, and this relationship is stronger than conscientiousness-COEs correlation. Neuroticism is negatively correlated with CSEs and COEs, but these two correlations are not significantly different. Extraversion is positively correlated with CSEs but not COEs. In addition, narcissistic personality is positively correlated with CSEs but negatively correlated with COEs. Altruism is not correlated with both CSEs and COEs. Regarding the relationships of CSEs and COEs with work satisfaction, the results of hierarchical regression revealed that the predictive effect of CSEs on job satisfaction is greater than that of COEs, whereas the predictive effect of COEs on supervisor satisfaction is greater than that of CSEs. This study not only extends our understanding of the nature of COEs which is seldom explored in past literature, but also adds to the evidence regarding the nomological networking of CSEs and COEs.

Keywords: core self-evaluations, core other-evaluations, organizational behaviors, personality traits, work satisfaction

Oil Industry generates the least desirable impacts on environment, especially in the developing countries, according to International public opinion. Against this background, this research aims at showing the efforts made by all involved actors in developing countries, in order to achieve a more sustainable development of our ecosystems. This research describes a negotiation process among indigenous communities, municipalities, petroleum companies and the Bolivian State, working through social conflict to a viable and sustainable agreement in the frame of the policy of corporate responsibility of one of the most important oil companies in Latin America. The methodology is two-fold: firstly, in-depth interviews of principal actors of the process are gathered, and secondly, focal groups developed for the search of agreed by consensus solutions. The principal result of the study is a sustainable environmental and social proposal, replicable in similar contexts in the frame of the Human Sustainable Development. More concretely, the creation and developing of the second indigenous oil distribution company in Latin America. The first conclusion is the development of Social Corporate Responsibility with a high economic, social and environmental commitment, even in the most adverse socio-environmental conflict. The second conclusion is the need for an agreement within the Oil Company before attempting to reach an external agreement with other stakeholders involved in the conflict.

Counselor education in United Arab Emirates: A 'SWOT' analysis

AL DARMAKI, F. (UAE University), HASSANE, S. (UAE University), AHAMMED, S. (UAE University), ABDULLA, A. (UAE University)
The counseling profession in the United Arab Emirates (UAE) is relatively new. As a new field in the Gulf region, it encounters a lot of challenges that needs to be carefully addressed, so as to promote awareness about the value and application of the field among scholars, professionals, practitioners, and the population in general. Despite this, the need for the discipline cannot be underscored enough, due to the ever increasing number of individuals and groups needing counseling services in the background of a society that is under tremendous social change. Added to many other benefits, is the fact that in a traditional setting, counseling serves as an alternate, less stigmatizing method compared to psychiatric or social work services. This paper delineates the current state of Counselor education in UAE in terms of a SWOT (Strengths, Weaknesses, Opportunities, and Threats) analysis. Some of the strengths identified are the ever increasing levels of recognition and acceptance of the discipline by the current generation and significant research attempts by professionals. Weaknesses include the socio cultural barriers in reaching out and lack of professional bodies guiding the discipline. Opportunities in the external environment include the social changes in the Emirati society, increasing levels of diversity set in by the forces of globalization and an ensuing need for wellbeing and psychological health. Important among the threats are turf issues with other disciplines and socio cultural barriers preventing the progress of the discipline in the region. At the core of the SWOT analysis is the understanding that counseling in UAE is a discipline which is struggling to establish its identity in the midst of the many internal and external challenges that it faces. Based on the analysis, the paper also presents and recommends certain strategies to advance the discipline in the Middle East region. The imperative for relevant and culturally indigenous conceptualization of counseling to promote the discipline in the region is one among those suggestions.

Cross cultural validation of the sensation-seeking construct: Development and validation of a new Spanish-language sensation seeking scale

VELEZ-PASTRANA, M. (Universidad Carlos Albizu), BRADLEY, G. (Griffith University)

This cross-cultural study aims to: 1) document the psychometric properties of a new Spanish-language sensation seeking scale, the Escala de Busqueda de Sensaciones (EBS; Velez-Pastrana et al., 2009) and 2) study the equivalence of an English-language version of the existing EBS scale. The EBS was developed in 2009 based on the conception of sensation seeking that had been developed by Zuckerman (1994, 2007) and later revised by Arnett (1994), while addressing advantages and limitations of such scales. The 36-item EBS includes a 7-item sexual sensation seeking subscale. Preliminary research indicates that this subscale has .74 reliability and correlates significantly (i.e., .39 to -.25) with sexual risk behavior items, which is comparable to the 11-item Kalichman sexual sensation seeking scale (i.e., Gaither & Sellbom (2003) report correlations of .49 to .18). A total of 300 Puerto Rican and Australian adults complete Spanish/English versions of the EBS. The Puerto Rican participants also complete Arnett’s Inventory of Sensation Seeking (AISS; Arnett, 1994) and Zuckerman’s Sensation Seeking Scale V (SSS-V; Zuckerman, 1994). All participants completed a questionnaire assessing sexual risk behaviours. Concurrent validity will be assessed by correlating the Spanish-language EBS with Arnett’s AISS and Zuckerman’s SSS-V. A comparison of the factor structure of the Spanish-language EBS with the AISS and SSS-V will explore validity of the sensation-seeking construct as measured by the scale. Spanish and English-language versions of the EBS will be compared to assess equivalency. The psychometric properties of the English EBS will be explored. Results are discussed in the context of previous research on Spanish-language versions of the SSS-V and the AISS (Carretero-Dios & Salinas, 2008; Ferrando & Chico, 2001). These studies had suggested that the two instruments measure essentially the same construct. Clinical and research implications are discussed.
Cross-cultural assessment of attention level of Israeli and American university students

LUFI, D. (Emek Yizreel Academic College)

The study of attention level and itspsychopathological aspects is very extensive, mostly when it is concerned with children and adolescents with Attention Deficit Hyperactivity Disorder (ADHD). Attention is considered more as a psychobiological ability not bound by cultural aspects. Some researchers hypothesized that cultures with consistent attitude toward children may have fewer children with attention difficulties. Others postulated that poor child behavior management in early childhood may be the reason for attention deficit. No clear findings have been found thus far that connect attention level to any specific cultural trait. The present study is a comparison of attention level between first year university students in Israel and first year university students in the United States. Seventy-one first year students in Israel were compared to forty four first year students in the United States with the following two measures of attention: (1) MATH-CPT, a computerized Continuous Performance Test (Luﬁ, 2006), and (2) d2 Test of Attention, a paper and pencil cancellation test constructed by Brickenkamp in Germany in 1962 and validated again in 1998 by Brickenkamp and Zillmer (Brickenkamp & Zillmer, 1998). The two tests were administered to both populations in a counterbalanced order (half took one test ﬁrst while the other half took the second test ﬁrst). The results showed that the American students scored signiﬁcantly better in the main measure of the MATH-CPT (indicating higher sustained attention level), and in another four main measures of the d2 Test of Attention. The results indicate that ﬁrst year student in the United States performed better in various measures of attention in both instruments used in the study. These results were unexpected. As attention level is considered as ability inﬂuenced a little by cultural aspects. It is possible that differences in temperament between the cultures when people in Middle Eastern cultures tend to be more impulsive and short tempered or differences in the level of sluggish cognitive tempo (SCT) may explain these results. The author discusses the results and other possible explanations for these unexpected differences.

Cross-cultural moral reasoning about sacred values: East and west, same values but different rationale

WAGLAND, P. (Macquarie University), WASTELL, C. (Macquarie University), EBRAHIMI, W. (Macquarie University)

This study examined moral reasoning concerning sacred values in Western and East Asian populations. Responses to a moral dilemma in which a decision was made to spend a considerable amount of money in order to either (a) save the life of one child via an expensive operation or (b) improve hospital resources more generally. These dilemmas were initially framed in the context of the cultural dimension; individualism or collectivism. Expectations were that East Asians, with their more collectivistic mindset, would place higher value on improving hospital resources rather than on saving the life of one child. The results indicated that East Asians were as outraged as Westerners at the prospect of improving hospital resources rather than saving the life of one child. The results are interpreted within a universalist approach to moral reasoning with recognition of shared scared values across cultures and yet emphasizing the different explanatory frameworks used cross culturally to account for the common values.

Cross-national investigation of positive youth development

RENATI, S. (K B P College), RENATI, S. (K B P College), TOMBOU, J. (Deakin University)

The study aims to explore the prevalence of adolescent volunteering in three nations. It
Abstracts of the 27th International Congress of Applied Psychology

Individual Oral Presentations

776

examines cultural and contextual factors in a cross-national comparison of volunteering. The study also aims to update our understanding on universal theories of development. The total sample of the study is 4,638 adolescent school students in the age range of 16-17 years drawn from Mumbai, India (n = 802) Victoria, Australia (n = 1929) and Washington, United States (n = 1907). The student survey protocol consisted of a self-report instrument. The International Youth Development Study (IYDS) survey was used in Australia and the United States and the Adolescent Health and Wellbeing questionnaire (AHWQ) was used in India. The study reports on risk and protective factors associated with volunteering and smoking and alcohol behavior that may influence youth volunteering. Meta analysis of data revealed findings relevant to cultural differences. Highest rate of volunteering was reported in Washington State (19.0 percent), lowest in Victoria (6.9 percent) and intermediate in Mumbai (13.6 percent). Females (63.8 percent) were found significantly more likely than males (53.4 percent) to report volunteering. The multivariate logistic regression figures indicate that in Mumbai late adolescents reported less volunteering. Compared to Washington and Victoria smokers and tobacco users in Mumbai reported more volunteering. The study indicates that several protective factors are associated with positive youth development. The findings also suggest that family, school, peer and neighbourhood context are important determinants of positive youth development. Although understanding the development of problematic behaviour has been the focus of much research attention until recently, it is crucial that the factors that promote positive youth behaviour are also understood. Interventions for problematic behaviours no longer simply strive to reduce problem behaviours, they also seek to promote positive behaviours to replace the problematic ones. To ensure that these interventions are appropriate and maximally effective, we need to understand how positive behaviour such as volunteering develops. It is recommended that future research should examine these important differences by using more closely matched survey designs. Examining predictors of youth behaviour in internationally comparative longitudinal studies can establish whether India can borrow similar population change strategies from other nations.

Keywords: volunteerism, adolescents, The International Youth Development Study, youth development, cross-national comparison

Cultural similarities and differences in perceived affordances of situations for big five behaviors

CHURCH, T. (Washington State University), KATIGBAK, M. (Washington State University), DEL PRADO, A. (The Wright Institute)

Consistent with efforts to integrate person and situation approaches, we conducted a cross-cultural study of the perceived “affordance” or conduciveness of situations for behaviors associated with the Big Five traits (i.e., neuroticism, extraversion, openness to experience, agreeableness, and conscientiousness). Drawing on existing theory, we hypothesized that situations will vary in their perceived affordance for Big Five behaviors and that the perceived links between situations and trait-relevant behaviors will be similar across cultures. We also hypothesized that respondents in different cultures will construe situations along similar general dimensions, but that some situations will be construed differently along these dimensions. Using a five-point scale, American (N= 188) and Filipino (N= 215) college students rated, for each Big Five trait, the likelihood that behaviors associated with that trait (e.g., extraverted behaviors) would be displayed by a person in each of 29 situational contexts. Example situational distinctions included the pleasantness of the situation; the status of interaction partners; various relationship categories and physical settings; intellectual and social demands of the situations; and whether the situations were freely chosen or imposed. As hypothesized, we found greater cultural similarities than differences in the perceived links between situational contexts and Big Five behaviors. Situational effects were large in both cultures in ANOVA results, and in most cases the perceived situation-behavior patterns did not differ significantly across cultures. In addition, in a multidimensional scaling analysis, Americans and Filipinos construed or
differentiated the situations along similar general dimensions (i.e., positive vs. negative situations, challenging vs. easy situations). We also found some meaningful cultural differences that were plausibly attributable to differences in cultural values and practices. Certain features of situations are cultural universals and are perceived to have similar effects on trait-relevant behavior across cultures. The findings contribute to renewed efforts to reconcile person and situation approaches. The finding of similar perceived links between situations and behaviors across cultures also has positive implications for inter-cultural social interactions.

Keywords: cross-cultural, affordance, big five model of personality, personality, situational contexts

Cultural variations from the perspective of Hofstede [1991] and House [1994]: A comparative evaluation of the dimensions in 16 countries

BHAGAT, R. (University of Memphis), SRIVASTAVA, B. (Indian Institute of Management Calcutta)

The dimensions of Cultural Variations by Hofstede and those of Robert House have been guiding theoretical and empirical research in the area of Cross Cultural Applied Psychology for the past 15 years and more. There are hardly any empirical investigations that have analyzed the conceptual and empirical overlaps of the dimensions from these two well known and well researched theoretical perspectives. Using the data from over 5000 professional managers and other occupational categories we compare and contrast the overlap of the dimensions in 16 countries. The results are discussed for their future implications in the area of applied psychology. Data were collected from US, Canada, France, Germany, Poland, Australia, Japan, China, India, South Korea, Malaysia, Indonesia, UAE, Chile, Brazil, and Venezuela. The total sample was over 5000 individuals. We compared the empirical overlap from the dimensions for the overall sample and then for each of the countries analyzed separately. The countries were from North and South America, Europe, Australia, and Asia. The results varied according to the clustering of the countries in terms of regions. The dimension of Individualism and Collectivism had the most overlap from both the theoretical perspectives of Hofstede and House. It seems clear that this dimension is the most fundamental dimension of cultural differences that one should seriously consider in future investigations across national and political boundaries in different geographical locales of the world. We suggest implications of the study for various area of applied psychology including scheduling of tasks, technology transfer, organizational Knowledge Management, and work stress and coping etc. There is no doubt that while there has been an important advance after House broadened the nature of cultural differences, Hofstede Study still should be regarded as a fundamental breakthrough in understanding variability of Cultural Differences in work and organizational settings in different countries of the world and in different continents.

Keywords: cultural variability, theory, empirical overlaps, applied psychology

Culture, motivation, and occupational decisions

JUNG, J. (The University of New South Wales), MCCORMICK, J. (University of Wollongong)

The purpose of this investigation was to test a new model of the cultural and motivational perspectives associated with the occupational decision-making processes of senior high school students. A model that was developed by integrating theories from the culture, motivation, and vocational decision-making literatures (i.e. concepts/theories including individualism/collectivism, long term orientation, expectancy-value theory, and the theory of reasoned action) was preliminarily tested by administering a newly developed questionnaire to a sample of 492 Grade 11 students attending a stratified random sample of 6 Independent high schools located in the Sydney metropolitan area (Australia). The questionnaire was subsequently revised, and a refined version of the model was then re-tested using 566 Grade 11 students attending a stratified random sample of 16 government high schools in the Sydney metropolitan area.
Structural equation modeling was used for both phases of analysis. The major findings of the investigation included the development and confirmation (after modifications) of a model of vocational decision-making processes. The model provided empirical support for relationships between cultural orientation, occupation-related values, and attitudes/intentions toward occupations. Two of the main path sequences in the final model suggested that the more students were idiocentric (individualistic) toward the future or allocentric (collectivistic) toward the family, the more they would value occupational interest/enjoyment. In turn, the more students valued occupational interest/enjoyment, the more positive would be the attitudes toward their putative occupations, and the stronger would be their intentions to pursue these occupations. The findings of the investigation may be used by psychologists, career advisors, educators, and families to advise and assist senior high school students faced with the occupational decision. In particular, these groups may need to modify their guidance, and/or understanding of the associated issues, in response to the finding that cultural orientation may be an important consideration. Moreover, reflecting the prominence of occupational interest/enjoyment, they may need to place a greater focus on what occupation-related activities or subject matter are considered the most interesting or enjoyable by senior high school students. From the perspective of marketing, the research may provide occupational and professional groups with valuable marketing information that may be used to attract future candidates. For example, the final model suggested that target groups for marketing campaigns may be classified according to cultural orientation. The investigation may contribute to reducing the gap in the literature on the roles of culture and motivation in the occupational decision-making processes of senior high school students.

**Damaged identities narrative repair: Investigating emotional cycles of employees undergoing organisational change**

SEHGAL, S. (University of Delhi), PRAKASH, A. (University of Delhi)

The present paper explores the human side of the contemporary economic reforms through narratives generated in the context of change initiatives introduced by organizations. The focus of the present paper is on the way that individuals understand and make sense of the organizational change and this research examines various emotions experienced by organizational members situated at different levels of hierarchy. The present research is grounded in the qualitative genre of conducting organizational research which is driven by the principle of plural existence of realities. Our understanding of the organization wide processes can be best captured by the stories and narratives generated by employees. In-depth interviews followed by narrative analysis was carried out to decipher the making of the psychological world of the participants. The investigation of the narratives revealed that organizational reality is rooted in the interpretive framework, which is locally constructed and defined rather than existing as an independent or objective entity. As indicative by the data, an organization played a vital role in the self-images of the employees dependent on their levels of congruence with the organizational reality. The paper is organized around various emotional themes related to constitution of personal and professional identities. It is asserted through this paper that in the evolution of the management thought, the identity of an employee as a conscious being needs to be recognized and attended to by the organization. Narrative analysis offers a coherent framework to integrate the ‘fragmented’ identities of the individuals amidst the change process. Change cannot be treated as a linear shift from one modus operandi to the another rather the present research suggests that understanding the emotions that are generated during the process of change play a pivotal role in making any change initiative a success or failure.

Keywords: organisational change, emotions, narrative analysis, identity, self-images
Dealing with disasters: Impact of occupational stress in journalists’ well-being

MONTEIRO, S. (CeFIPsi)

Recent studies have considered journalists as first responders as well as policemen, firemen and health personal (Osofsky, Holloway & Pickett, 2005; Law, 2007). This inclusion is due to the fact that journalists are exposed to the same stressors as the emergency professionals and so they can exhibit the same emotional answers and vulnerability levels. There are still very few studies regarding occupational stress of journalists, either on potentially traumatic situations (as war conflicts and natural disasters) or on their daily work. The main focus has been on distress and pathological coping strategies associated. The main goal of this study is to provide a better understanding of the stress process of journalists to better help them dealing with occupational stressors. According to the Holistic Model of Nelson and Simmons (2002), in order to also analyze the positive experiences of stress, savoring strategies and positive outcomes after being in a disaster scenario, we interviewed 25 Portuguese journalists from television, radio and newspapers. All the journalists have more than 15 years of experience and are well renowned in the media field. Following it, we started the application of a set of questionnaires in order to gather information from as many journalists as possible. There is more positive stress than distress among journalists in disaster fields. They perceive their daily work with higher distress. Natural disasters cause higher emotional impact than war conflicts. In their opinion there seems to be some evidence for post traumatic stress disorder (PTSD) signs but also for PTSD growth among journalists that work in disasters. Psychological support after distressing experiences is seen by these journalists as a useful and needed tool to overcome the possible downsides of that same experience. We will be presenting some cues for therapeutic intervention that promote occupational the well-being of journalists (in order to prevent distress and promote positive emotional experiences).

Decision making strategies and self-regulation of driving behavior

DOGAN, E. (University of Groningen)

Driving performance is thought to be guided by satisficing decision making strategies. This refers to not striving for the optimum level of performance but being satisfied with the good enough performance. Less is known about whether there are conditions under which drivers would try to reach an optimal performance level and self-regulate to reach their goals in accordance with a performance feedback. The aim of the current study was to investigate decision making process behind self-regulation of driving behavior. We used eco-driving task and fuel saving as a goal. We hypothesized that drivers would aim an optimal performance level when told to drive environmentally friendly and to save fuel; however, this would not be the case if drivers were under time pressure. Driving performance was measured in a driver simulator. We created six different situations that would require participants to accelerate and decelerate but leave room for different patterns of acceleration and deceleration. We had two experimental groups: one with time pressure manipulation and one without. We recorded drivers’ behavior and later on we had interviews with the participants asking detailed description of their behaviors and decision making process. Participants were forty university students who had a valid driver’s license at least for one year and had at least two thousand km of annual mileage. Initial results revealed that participants in the time pressure and no time pressure groups showed different patterns of acceleration and deceleration both in terms of gas and brake use and slow-down & speed-up distances. Moreover, interviews revealed different thinking patterns for two groups. Additionally, participants in the no time pressure condition were more likely to take into account the fuel consumption feedback in choosing their behaviors. Data collection is still in progress. Drivers’ self-regulation and reliance on performance feedback were guided by different decision making strategies under different conditions.
conditions. Drivers showed more optimizing strategies when they were not under time pressure.

**Keywords:** driving performance, decision making, eco-driving, driver simulator

**Delayed reentrant processing impairs visual awareness: an object substitution masking study**

DUX, P. (University of Queensland), VISSER, T. (University of Queensland), GOODHEW, S. (University of Queensland), LIPP, O. (University of Queensland)

In object substitution masking (OSM) a sparse, common-onsetting mask impairs conscious target perception if it temporarily trails the target and spatial attention is dispersed. Di Lollo et al.’s (2000) Reentrant Processing Model explains OSM as reflecting the interaction of feed-forward and feed-back processes in the brain. Specifically, upon presentation of a target and mask a coarsely coded representation of both stimuli progresses from V1 to anterior brain regions (feed-forward sweep). Due to the low resolution of this information feedback/reentrant processing is employed to confirm the identity of the visual stimulation. According to this model, dispersing spatial attention delays feed-forward processing, increasing the likelihood that only the mask remains visible once reentrant processing is initiated. Therefore, the mask will substitute the target in consciousness. Notably, the Reentrant Processing framework predicts that OSM will be elicited when either feed-forward or feed-back processing is delayed/impaired as both will increase the probability that only the mask remains visible once reentrant analysis begins. Thus, it should be possible to observe OSM for spatially attended stimuli if feedback from anterior regions is delayed. We presented subjects with a standard OSM paradigm (Landolt C target, four-dot mask) while they performed a difficult arithmetic task known to engage brain areas involved in reentrant processing (prefrontal and parietal cortex). All stimuli appeared in the same spatial location and, employing a standard dual-task protocol, the arithmetic and OSM tasks had either a short (100ms) or long (800ms) stimulus onset asynchrony (SOA). Increased OSM was observed at the short relative to the long SOA and this was more pronounced when subjects performed, rather than ignored, the arithmetic task. The results support a key prediction of Di Lollo et al.’s Reentrant Processing Model: if feedback processing is delayed then OSM can be observed for spatially attended objects.

**Keywords:** object substitution masking, reentrant processing model, feedback, visual awareness

**Deliberate practice, feedback and learning of complex tasks**

WONG, M. (University of New South Wales), WOOD, R. (University of Melbourne)

Deliberate practice is considered the single most important determinant of the development of deep knowledge that leads to expert performance e.g. Ericsson, Krampe & Tesch-Romer, 1993. However, this conclusion is based on retrospective analyses and is yet to be examined experimentally especially during the early phases of knowledge development. Deliberate practice theory also identifies feedback as a means of developing deep knowledge, but the relationships between deliberate practice and feedback remains unexplored. We tested the hypothesis that deliberate practice plus high feedback specificity would lead to the best learning outcomes using a complex computer-based management simulation. A 2 (high/low feedback specificity) x 2 (high/no deliberate practice) x 12 (practice and transfer trials) between-and-within-subjects experimental design (n=117) included an initial practice phase and a transfer phase conducted five days later. As predicted, deliberate practice improved both practice and transfer performance, and the improvement was greater under high rather than the low feedback specificity. The effects on transfer performance remained significant after controlling for individual differences in fluid intelligence, positive affect, negative affect and self-efficacy; and were partially mediated by practice performance. Contrary to the findings of Goodman and Wood’s research program on feedback specificity and transfer of training (e.g.,
Goodman & Wood, 2009), we found high compared to low feedback specificity resulted in better transfer performance, however this main effect was no longer significant when the interaction term (deliberate practice x feedback specificity) and individual differences were included in the hierarchical regression models. Findings show that deliberate practice is highly beneficial for learning of a novel complex task, and that the high guidance of specific feedback facilitates learning when accompanied by the conscious processing required by deliberate practice. Implications for the design of effective training interventions include building in practice sessions to develop the metacognitive skills required for deliberate practice, and for trainers to balance specific feedback and other forms of guidance with opportunities for deliberate practice.

Keywords: deliberate practice, feedback, learning, complex tasks, expert performance

Demographic differences and students’ preferential helper

SETIAWAN, J. L. (Universitas Ciputra)

Students experience various concerns during their time in the university. Numerous studies have been carried out to examine students’ preferred helpers. The aim of this study was to investigate whether there are differences on preferential helpers among students with different gender, ethnic backgrounds, modes of living and years of study. A questionnaire consisting of 14 areas of concern and 14 choices of helpers was distributed to 1,279 students. Respondents were asked to imagine themselves to experience serious problem relating to the area presented in each item of questionnaire and to choose one of the 14 choices of sources of help. The study found that there were high positive correlations of chosen sources of help between the groups with different gender, ethnic backgrounds, modes of living and years of study. Friends, self-help, and mothers were the popular choices in any groups. The percentage for Self was significantly higher in males than females. The percentages for Father and Brother tended to be higher in male students than in female students, whereas the percentages for Mother and Sister were significantly higher in females than males. The percentages for family members were significantly higher in students living with their family than in those living outside the family. The percentages for helpers outside family members were higher in students living outside the family than in those living with their family. Students from different gender, ethnic backgrounds, modes of living, and years of study showed no important differences in the preferential sources of help. Friends and mothers are the most preferred sources of help, apart from self-reliance. There is a universality of human experience that people are more likely to seek help from close relations. This confirms the help-seeking theory proposed by Margaret Clark (1983).

Keywords: students, university, preferential helpers, gender, ethnic backgrounds

Depression, anxiety and quality of life (QoL) among HIV and AIDS patients attending a public health clinic in South Africa

NAIDOO, P. (University of the Western Cape), MWABA, K. (University of the Western Cape), LOONAT, N. (University of the Western Cape), MAJOZI, N. (University of the Western Cape)

To ascertain baseline measures of depression, anxiety and quality of Life (QoL) as mental health indicators of individuals infected with the HI Virus and receiving health care within the public health sector in a disadvantaged area in the Western Cape Province in South Africa (SA). This study used a quantitative research design and was cross-sectional in nature. A purposive sample was recruited from a single public health clinic and comprised 70 male and female adult participants with a male to female ratio of 3:7, a mean age of 31 years ($SD = 8.7$). The participants were either on anti-retroviral (ARVs) treatment or being prepared for ARVs. Self-report questionnaires which included the Beck Depression Inventory (BDI II), Hospital Anxiety and Depression Scale (HADS) and the Quality of Life Satisfaction and Enjoyment Questionnaire (Q-LES-Q) were administered. The prevalence of depression and anxiety were found to be 36.8% and 28.6% respectively. On the Q-LES-Q the general (overall QoL), feelings,
school/coursework, and social relations measures were above average (58.4%, 52.7%, 59.4%, and 59.4% respectively) as compared to the physical, house-duties and work measures which were below average (48.6%, 45.8%, and 10.3% respectively). It was concluded that young adults, especially females, were found to be the most vulnerable to HIV infection, the prevalence of depression and anxiety was extremely high as compared to national and international rates in the general population, and while the general QoL was found to be average, the physical and work domains were not satisfactory. This study, therefore, highlights the importance of assessing the mental health aspects of HIV/AIDS. The most important recommendation that will be made to the relevant health authority is to develop a health management plan for HIV infected patients that is holistic and includes the biological, pharmacological and psychological/social treatment components.

Keywords: quality of Life, HIV, South Africa, depression, anxiety

Determinants of car users’ switching to public transport

ERIKSSON, L. (Karlstad University)

The general aim of the present paper was to investigate the determinants of car users’ switching to public transport when driving to work. Since the quality of services is particularly low in medium-sized cities, making the car a much more attractive option, the focus is on car-use in such cities. A combination of web-based survey and experimental simulation was used. The participants were given the task of planning their travel to and from work, including the performing of additional activities according to predetermined agendas. Four agendas varying in their number of additional activities were compared. The participants were randomly assigned to four groups of approximately the same size (high vs. low car costs and good vs. bad access to bus stops). The main results were that shorter travel times and good access to bus stops led to greater bus use while constraints imposed by a busy daily agenda led to greater car-use, in particular if car costs were low. The conclusions of this paper are that a public transport system must appear attractive, not only to its present users, but also to prospective users who currently use their cars. To appear attractive, it must not be too expensive and must have timetables and routes that allow users to travel in an efficient manner. One measure that can be used to force commuters out of their cars is higher car-use costs; however, car-use costs may need to be substantially higher than the cost of using public transport in order to be effective. As indicated, the perceived difficulty of using public transport is also an important factor. Raising car-use costs will thus be insufficient unless changes are made to public transport services. A factor complicating this is activity patterns, which are often complex. As has been indicated in the present research, the more complex the activity pattern - the more the car is used as a means of transport.

Keywords: car use, public transport

Developing tools to facilitate personal reflection in the journey to achieve personal development

SETIAWAN, J. L. (Universitas Ciputra)

The degree of helpfulness found in the counseling process is largely influenced by the person of the counselor (Cormier and Hackney, 1987). The personal quality of helpers is more essential than their specific skills or knowledge. The essential requirement for an effective helper is awareness. Arguably, counseling courses should not only equip students with academic knowledge and counseling skills, but also help students be aware of themselves in order to achieve personal growth (Setiawan, 2010). The aims of this study is to elaborate and evaluate teaching methods or assignments in Counseling Psychology course in the efforts to assist students in the personal reflection journey in order to achieve higher self-awareness and better personal quality. Qualitative approach was chosen as the research method. Focus group discussion and open ended questionnaire were chosen as the data collection tools. A total of 30 students participated in the focus group discussions (FGD-s) and 14 students volunteered in filling in the open ended questionnaire. The participants were undergraduate students in
Psychology who just completed the counseling course. Results showed that participants benefitted from personal reflection assignment. However, they lacked of experience in conducting personal reflection, so that personal reflection should be facilitated by some tools to make the reflection processes more focused. Workbook to be completed by students and buddy sharing were regarded as helpful tools. The use of self-assessment tools or workbook with clear structure to be completed by students is strongly recommended as this will facilitate reflection processes. The method of group sharing or buddy sharing is also suggested as buddy sharing contains conducive climate to help an individual develop and accommodate the need of objectivity and accuracy to reach better self-awareness.

Keywords: counselling, effective helper, awareness, counseling psychology, personal reflection

Development and testing of an instrument to measure the concept of human resources strength

The current research presents a set of studies in order to develop a new instrument to measure the meta-attributes as proposed by Bowen and Ostroff (2004) in their model of human resource strength. Human resource (HR) strength is the degree to which the HR function is capable of conveying a common set of messages regarding the HR function. The research is composed of two studies. In the first study, a first pool of items was created, following psychometric theory (e.g. Nunnally & Bernstein, 1996). This pool of items was next submitted to expert scrutiny (including academic fellows and HR practitioners), which led to item purification and selection. A final pool of items was translated into meaningful sentences. A first application in five companies (n= 91 cases), and a second application, with a larger number of items, in two companies (n= 198) allowed to refine, select, and generally improve the initial pool of items. The analysis included common techniques, such as reliability, exploratory and confirmatory factors analysis, as well as less popular techniques, such as the Rasch model for item analysis. The second study was carried out in a large multinational company within the hospitality industry, and was based on 511 questionnaires. Confirmatory factor analysis, amongst other techniques, was used to test the empirical structure of the data. Although results from the first study suggested that the theoretical proposals by Bowen and Ostroff (2004) were not entirely met, results from the second study showed a considerable improvement, both in terms of reliability and validity. All the nine constructs initially proposed by the authors (visibility, understandability, consistent HR messages, relevance, legitimacy of authority, instrumentality, validity, agreement among principal message senders, and fairness of the HR system) were supported by the data, although some of the dimensions revealed better results than others. Despite the theoretical interest of Bowen and Ostroff’s (2004) proposals, few studies have looked at ways to measure the key constructs in their model. The current investigation presents interesting results, which are compared to other works in the field, such as Sanders, Dorenbosch and Reuver (2008), and Delmotte, Gilbert and Winne (2010). Key results include the confirmation of Kelley’s (1973) model of attribution theory, in which Bowen and Ostroff (2004) based their nine new constructs.

Keywords: human resources, psychometric instrument, reliability

Development and validation of a Chinese worldview scale

LAI, J. (City University of Hong Kong), LO, N. (La Trobe University), BRENNAN, A. (La Trobe University), WAN, K. (City University of Hong Kong)

The aim of the study was to develop and validate scales to measure major worldviews present in Chinese populations, and to investigate the association between those worldviews and environmental attitudes and behavior. Worldviews were defined in terms of beliefs: a worldview is a set of beliefs that provides a metaphysical account of what the world is like, how the sources of meaning can be found, and
which provides, on the basis of these, general guidance for most of a person’s attitudes and actions. By means of literature review and expert consultation, it was determined that four major worldviews were likely to be present in all Chinese populations: monotheism (Christianity, Islam), Confucianism, Buddhism, and Daoism. By submitting provisional lists of conceptually significant items to a selection of philosophers and psychologists, a final set of survey questions was developed amounting to 46 items. Together with a number of other scales, measuring anthropocentrism, ecocentrism, ecologically conscious consumer behavior, endorsement of environmental policy, the 46 items representing the aforementioned worldviews were administered to 430 Hong Kong Chinese with 341 valid responses. A principal component analysis with Varimax rotation and Kaiser normalization was run and two factors were extracted which explained 35% of the variance of the 46 worldview items. Nine items pertaining to monotheism loaded onto the first factor, while 15 items associated with Buddhism, Daoism and Confucianism loaded onto the second factor. The former was labeled Monotheism and the latter Chinese Worldview. The result of a confirmatory factor analysis provided support to the validity of this two-factor structure: RMSEA = 0.06, NNFI = .92, CFI = .92. The impact of the two worldviews on attitudinal and behavioral variables was tested using path analysis. Results showed that Monotheism and Chinese Worldview exert their effects on pro-environmental behaviors mainly via ecocentrism. In particular, lower Monotheism and higher Chinese Worldview was associated with higher ecocentrism which in turn predicted pro-environmental behavior and endorsement of pro-environmental policies. Results of the present study provided preliminary support to the structure of worldviews present in the Chinese people and how these worldviews are related to environmental attitudes and behaviors. We demonstrated clearly that worldviews are theoretically important antecedents to pro-environmental attitudes which have been reported repeatedly in the West to be predictive of environmentally relevant behaviors. However, as present findings were generated from a sample Hong Kong Chinese, further research is warranted to demonstrate the generality of the construct of Chinese worldviews and their behavioral consequences in different contexts or Chinese populations.

Keywords: Chinese worldviews, environmental attitudes, beliefs

Development and validation of the alliance psychological contract (APC) model and instrument

SALICRU, S. (PTS Consultants / Curtin University)

The aim of the present study was to describe the development and validation of a new instrument - the APC (Alliance Psychological Contract) Questionnaire, which is designed to measure and diagnose the health of relationships, and predict performance outcomes, in project alliances. A sequential mix method design (qualitative/quantitative) approach was utilized. Semi-structured interviews were conducted with 24 industry experts performing different roles in various industries across Australia, the purpose being to validate the APC model and corresponding constructs, which are based on Guest’s (1998) model of the psychological contract (PC). NVivo 8 qualitative analysis package was used to store, manage, code and analyze the data. A hybrid content analysis approach (inductive and deductive) was used. Next, a pilot was conducted in order to develop the psychometric properties of the APC questionnaire, using a sample of 16 Australian project alliances and including a total of 400 individual responses. The APC questionnaire appears to have acceptable psychometric properties and some predictive power regarding performance. Feedback from participating alliances indicates the application of the model and survey results as useful to industry. The APC model and associated instrument provide the means to reliably measure and diagnose the health of alliance relationships, and predict performance outcomes.

Keywords: validation, alliance psychological contract questionnaire, relationships, performance outcomes
Development of an admission test for a newly-established university: the case of Pelita Harapan University in Surabaya, Indonesia

ADI, F. (Pelita Harapan Surabaya University)

The aim of the paper is to develop a valid and reliable admission test that can be used to select students who are seeking admission to Pelita Harapan University in Surabaya (UPHS). Specifically, the study will undertake item analysis that will be used to generate information about the quality of each item based on psychometric properties. Secondly, the results will be used to determine the reliability of UPHS admission test itself. The UPHS admission test was designed for three subjects, namely mathematics, physics, and general knowledge. Each subject consisted of several components. Lecturers from the different departments were identified to generate 100 items for each of the subjects so that the content validity could be achieved. The test was a multiple-choice type with five choices of possible answers. The items were administered to 315 senior high school students in Surabaya. Item analysis was conducted based on item discrimination, item difficulty and distracter effectiveness. The selected items must have an index of item difficulty from 0.2 to 0.7 and an index of item discrimination ≥ 0.2. All of the distracters for each item were selected by the respondents. Since each subject consisted of several components, the selection of the items also considered the proportion of the components as written on the initial blueprint. Thereafter, the reliability was conducted based on selected test items. The study was able to select 50 items for each of the three subjects. Each item in the UPHS admission test was assessed based on psychometric properties. The reliability ranged from 0.764 to 0.877. Results showed that the UPHS admission test is reliable. Thus, it can be used to select students who are seeking admission to the newly-established university. A valid and reliable admission test can be used to select students who are seeking admission to Pelita Harapan University in Surabaya (UPHS). Items that met the selection criteria were selected as admission test questions. Subsequent assessments, however, must be conducted as the UPHS admission test is used. This will ensure its reliability in the long-run.

Keywords: admission test, psychometric properties, reliability, validity

Development of the gender harassment scale

TANAKA, K. (Graduate School of Nihon University), KOBAYASHI, A. (Graduate School of Nihon University)

In Japan, workers are treated differently according to their gender in the workplace, whereby men are perceived as having important roles while women are perceived as having subordinate positions by their supervisors or coworkers in their organizations regardless of their abilities. In this study, we define Gender Harassment as behaviors which treat workers according to their gender in organizations. Our focus was on gender harassment behaviors toward women. A scale for measuring gender harassment of women by men, as well as by other women at Japanese workplaces was developed. First, items related to gender harassment were generated through semi-structured interviews. And these items classified into two categories. Second, a questionnaire containing these items was administered to a sample of working Japanese males and females (n=354; 132 female, 222 male). Factor analysis was conducted on the responses to the questionnaire. Results indicated that gender harassment had the same two-factor structure in both sexes. The first factor consisted of items where women were not expected to do something; the second factor was constructed of items expecting women to do something. The former was named “omission” (α=.845); the latter was named “commission” (α=.848). To test of validity of the two-factor structure of gender harassment, we examined the relevance of the egalitarian sex role attitude, gender conception, and old-fashioned sexism. There were moderate correlations for each of them. Then, the relationship between gender harassment and sexual harassment on workplace incivilities, such as general forms of mistreatment was analyzed in the sample of men. Results suggested that gender harassment was linked to sexual
harassment; however, it is possible that the two concepts are different, at least in Japan. We discussed that these findings in two facets of gender harassment at Japanese organizations.

Keywords: gender harassment scale, discrimination, women, Japan, egalitarian sex role attitude

Developmental deficits in executive functions in children and adolescents with Asperger’s syndrome

SMYRNIOS, S. (RMIT University), TUCKER, A. (Victoria University)

This paper reports findings of a study of executive functions in children and adolescents with Asperger’s Syndrome in relation to mental age. A neuropsychological model of the characteristic deficits in Asperger’s Syndrome as expressing executive dysfunction has been influential in driving research. Challenges for investigations of this model include the prolonged developmental trajectory of executive control by comparison with other cognitive abilities and the relationship of test performance to real-life functioning. Reports of deficits on traditional measures of executive function in Asperger’s Syndrome are inconsistent, in contrast to autism, with differences between clinical groups often reflecting differences in mental age. 30 participants with Asperger’s Syndrome (AS) (mean age = 10 years, range = 6-15 years; mean FSIQ 98, VIQ 99) were compared with 30 nonclinical participants matched on age, gender, Full Scale and Verbal IQ. Three indices of executive function (EF) - planning (Tower of London; TOL), cognitive flexibility (Wisconsin Card Sorting Test, WCST - Perseverative Errors), and problem solving (WCST - Non-perseverative Errors) were employed. Within-groups analyses identified EF deficits operationalized as significant deviations from predicted EF scores for mental age as derived from the nonclinical group. Parent reports of daily living skills on the Vineland Adaptive Behaviour Scales (VABS) provided a measure of real-life adaptive functioning separate from diagnostic criteria for Asperger’s Syndrome. 85% of AS participants scored significantly below mental age prediction on one or more of the three EF indices. Type of EF deficit varied according to mental age, IQ profile, and severity of autistic-type maladaptive behaviours. 15% (4) of AS participants without deficits on EF indices showed significantly impaired daily living skills as did all AS participants. Findings supported an executive dysfunction model of Asperger’s Syndrome. Deficits in real-life adaptive behaviours were universal within the Asperger’s Syndrome group, including the four Aspergers participants with non-deficient scores on the three EF indices. Findings that the type of EF deficit differs according to developmental level would be consistent with failure to develop executive abilities in tandem with development of other cognitive abilities in Asperger’s Syndrome.

Keywords: executive function, Asperger’s syndrome, mental age, test performance

Difference between membership and pride in group identity: A multilevel view

OZEKI, M. (Kanazawa University), YOSHIDA, T. (Nagoya University)

Some recent group identity studies have taken on a multilevel perspective since the Interactive Model of Social Identity Formation (Postmes et al., 2006) was proposed. Treating group identity as multilevel would enable us to capture a situation within a group and members’ affect and behaviors brought by the enhancement of group identity within the whole group. Hence, this approach was expected to bring a new trend in group studies. However, there has not been consensus on the operational definition of group level group identity as of yet. In addition, group identity has remained uncertain at the group level. The aims of this study were to (1) compare two operational definitions by Swaab et al. (2008) and Ozeki & Yoshida (2009); (2) to identify the difference of two subscales of group identity, Membership and Pride, in both individual and group level, and (3) to signify Membership and Pride in group level using Multilevel Covariance structural Analysis. A total of 358 university students (161 Male, 190 female, 7 unidentified) evaluated their group identity with the department of their major and its group entity and ingroup value (Leach et al., 2008). They also answered how much they
thought students of their department shared a group identity with the department of their major, which was operational defined by Swaab et al. (2008). At the group level, Membership led to shared group identity mediating group entity. However, at the individual level, people with high Membership perceived that their ingroup was cohesive, and its members shared group identity tightly. At the individual level, perceived ingroup value predicted Pride leading to Membership. In group level, Pride was affected by ingroup value. Membership at the group level was considered to be an indicator of cohesiveness, and Pride in group level might reflect ingroup value. The result suggested that enhancement of Membership within the whole group (Membership at the group level) might be a source of ‘groupiness’ which made its members share group identity. The most interesting finding of this study was that the process of the group becoming cohesive seemed to be different from members’ perception of cohesiveness.

Keywords: group identity, members, pride

Differences in career choice development: General versus technical education

LACANTE, M. (Katholieke Universiteit Leuven), VAN ESBROECK, R. (Vrije Universiteit Brussel)

Vocational and technical education receives increasing attention worldwide. It is acknowledged more and more that these students follow a special track and show an own identity. Also, the career choice development profile is an issue. Is their profile specific and different from that of students in other educational tracks? A five-year longitudinal follow-up study in Flanders followed a cohort of 2,619 students (1,768 general education, 851 technical education) from the start of grade 9 till the end of the 1st year in HE. These students completed the Career Choice Development Questionnaire at the beginning and end of each school year. The scores were calculated on six career activities: sensitization (ST), exploration self (ES), exploration environment (EE), exploration relation self-environment (ER), specification (SP) and decision (DE). The development and differences in development between general and technical education students were analyzed via mixed models; t-test for paired samples and t-tests for independent samples. The scores for the six career activities increase in general between grade 9 and the end of grade 12. At the start of grade 9, technical education students score higher on ES, EE, SP and DE. At the end of secondary education, students from general education reach a significantly higher career development profile. The career development profile of general education students increases much more sharply than the profile of technical education students from the end of the penultimate year onwards. The way general and technical education students evolve to the career development profile at the end of secondary education differs significantly. The career development profile increases at moments of crucial career decisions and when professional career interventions are made available. The higher score of technical education students in grade 9 can be related to the early confrontation with the actual work environment. This confrontation is inherent to their schooling. The sharper increase among general education students’ towards the end of secondary education connects to more intensive career interventions than those made available in technical education.

Differences in risk perception, priorities, worry and demand for risk mitigation in transport among Norwegians in 2004 and 2008

NORDFJÆRN, T. (Drug and Alcohol treatment in central Norway), RUNDMO, T. (Norwegian university of science and technology, dept of psychology)

This study aimed to investigate differences in risk perception, the demand for risk mitigation, priorities and worry related to transport between the Norwegian public in 2004 and 2008. Age, gender, education, driver licence and number of injuries in transport were controlled for. The comparisons were carried out with questionnaire surveys consisting of validated measurement instruments among randomised
representative samples of the Norwegian public in 2004 (n = 1730) and 2008 (n = 1864). Both samples were obtained through the Norwegian population registry. Multivariate analysis of variance (MANOVA) showed that the perceived probabilities of transport accidents decreased, whereas the perceived severity of consequences increased during this period. Both samples estimated higher probabilities of accidents by private means of transport. The demand for risk mitigation and priorities related to transport safety increased significantly in the same period. The 2008 sample also reported more worry regarding accidents by private transport. Gender, age and education exerted individual main effects on the dependent measures. Due to investments in road infrastructure and safety campaigns probabilities of transport accidents have been reduced in Norway the last four years. The probability estimates by Norwegians in 2008 are fairly congruent with objective risk estimates. Safety campaigns which have focused upon the affective component of transport accidents have been intensified in the same period. This could be attributed to the higher ratings of the severity of consequences, worry, demand for mitigation and safety priorities among the public in 2008.

Keywords: risk perception, risk mitigation, transport, Norwegians

Different factors influencing driving limitation in young-old and old-old drivers

MATSUURA, T. (Jissen Women's University)

Driving limitations and subsequent cessation have much effect on the life and well-being of older people because of a reduction in mobility. The present study aims to identify the factors predicting driving limitations among the young-old (aged 69 - 74 years, n = 175) and the old-old (aged 75 - 87 years, n = 152). Active Japanese older drivers, who attended driving schools to take part in the Older Driver Program for license renewal, participated in the study. They completed a questionnaire about demographics (age, sex), traffic offence/accident in the last 3 years, anxiety while driving, necessity of driving, subjectively perceived oldness, and driving limitations. Driving behaviour was also evaluated by an in-car observation. Multiple regression analyses were conducted with each of the driving limitation variables (i.e. driving frequency, compensatory driving, and intention to stop driving) as the dependent variable because of small correlations between them, from $r = .08$ to $.13$. The analysis revealed that age, sex, perceived oldness, necessity of driving had significant influences on 2 or 3 driving limitation variables. However, the explanatory variables that significantly predicted driving limitations differed between young-old and old-old drivers when they were analyzed separately. Only drivers with a history of traffic offence/accident were more likely to report driving limitations for the old-old group. Old-old drivers exhibited more compensatory driving and showed stronger intention to stop driving than young-old drivers. The two groups, however, did not differ significantly in driving frequency and in the explanatory variables except driving behaviour after controlling for sex. The results support that older drivers adjust their driving in response to their increasing age and necessity of driving. Yet, some of the old-old drivers are more likely to continue to drive actively in spite of their declining ability and smaller necessity of driving, and some of them are more likely to limit driving while still fit to drive and need to drive. This suggests that other reasons such as cognitive impairment and low income may play a role in driving limitation among the old-old.

Keywords: age, drivers, reduced mobility, driving limitations, driving behaviour

Dimensionality of DSM-IV borderline personality disorder in Chinese psychiatric patients: a confirmatory factor analysis

LAI, C. (The Chinese University of Hong Kong), YOU, J. (The Chinese University of Hong Kong), FU, K. (The Chinese University of Hong Kong), LEUNG, F. (The Chinese University of Hong Kong), CHEUNG, F. (The Chinese University of Hong Kong)

Empirical efforts over the past decade have established its reliability and validity of the construct of borderline Personality Disorder (BPD) in the West. The Chinese Classification of
Mental Disorders (CCMD-III), however, raised doubt about the construct validity of BPD in the Chinese culture. The objective of this study was to examine the construct validity of the DSM-IV criteria for BPD among Chinese psychiatric patients. A total of 1419 Chinese adult psychiatric patients aged between 18 and 45 years old completed the Chinese Personality Disorder Inventory (CPDI) (Leung, 2004) and the Chinese Personality Assessment Inventory-2 (CPAI-2) (Cheung et al., 2003). We selected two highly relevant items from the two measurements to assess each of the BPD diagnostic criteria. Endorsement on both items will be considered as meeting a specific simulated BPD criterion. A confirmatory factor analysis (CFA) was then performed on the set of simulated diagnostic criteria to test (a) a unitary construct and three earlier-reported multidimensional models that included: (b) Sanislow et al.’s (2002) three-factor model; (c) Lieb et al.’s (2004) four-factor model; and (d) Leung and Leung’s (2009) four-factor model. Measurement invariance of BPD criteria across gender and age group was also assessed. DSM-IV BPD criteria set as assessed by the simulated diagnostic method demonstrated good internal consistency (α=.81). Although results of CFA suggested good fit for all the tested models, the latent structure of BPD was best represented by Leung and Leung’s (2009) four-factor model measuring correlated dimensions of affective dysregulation, impulsivity, self-disturbances, and interpersonal disturbances (NFI=.96, NNFI=.95, CFI=.97, RMSEA=.06). This model also demonstrated gender equivalence of the BPD construct, but not age group equivalence. BPD is a reliable and valid construct among Chinese psychiatric patients. However, future investigation on factorial equivalence of BPD construct across age groups is warranted.

Keywords: borderline personality disorder, Chinese psychiatric patients, construct validity, confirmatory factor analysis

Direct, indirect and interactive effects of self-control demands and emotional dissonance on indicators of strain and absence behaviour

Recently, self-control demands at work (SCD; demands on inhibiting spontaneous, impulsive response tendencies and associated emotions becoming manifest in huffiness or injudicious expressions) have been introduced as a source of stress predicting job strain. In explaining the adverse effects of SCD, we hypothesized that emotional dissonance (ED; perceived discrepancy between genuinely felt emotions and emotions required by the job role) mediates the relationship between SCD and job strain (hypothesis I). Moreover, as ED and SCD are assumed to draw on the same limited regulatory resource both variables were expected to interact in a predicting strain, such that ED and SCD mutually amplify each other in their adverse effects (hypothesis II). Emotional exhaustion, depersonalization, anxiety and one absence measure were introduced as outcomes. Our study draws on two German samples. The first sample consisted of 326 service employees of a health-insurance company, while participants of the second sample were recruited from a civil service institution (N = 324). Absence frequency of the 12 months following the survey was available (second sample). In order to test both hypotheses, structural equation analyses were conducted. In both samples, bootstrapping revealed significant mediator effects of ED in the relationship between SCD and burnout. The effect of SCD on anxiety was also fully mediated by ED in the second sample (hypothesis I). Finally, interaction effects between ED and SCD were found such that the relationships between one predictor and all outcomes (including absence behaviour) were amplified as a function of the other predictor (Hypothesis II). The mediator effect of ED is consistent with the argument that emotional job demands will only lead to job strain, if ED is experienced. The interaction effects are in line with the notion that ED and SCD trigger different self-control processes which consume a common limited resource capacity.

Discursive positioning during heated intergroup encounters: Contesting the social meaning of a peace agreement

MONTIEL, C. (Ateneo de Manila University), DE GUZMAN, J. (Ateneo de Manila University)

This paper used positioning theory to analyze the heated intergroup conflict over the failed 2008 peace agreement between the Government of the Republic of the Philippines (GRP) and the Moro Islamic Liberation Front (MILF). Data sources consisted of 220 news articles extracted from national and local newspapers, and the website of the MILF (Luwaran). Groups like the President’s Office, the government peace panel, local governments, the political opposition and the MILF are discursively positioned as each collectively unfurls their own storyline in a volatile political landscape. The findings from this research are presented in three parts. First, we look at the different storylines that were constructed and contested by the various stakeholders across analytical layers and across time periods. Second, we present the major positions that were taken up and negotiated by the key actors in this issue. Finally, the shifts in positioning patterns across time periods among the different stakeholders are illustrated through a positioning matrix. Results demonstrate the importance of detecting intergroup conversation patterns and shifts surrounding contentious peace agreements over long-standing protracted social conflicts.

Discussing women’s self-views and body images in intimate relationships: A role for verification or enhancement processes?

BARR, L. (La Trobe University), EVANS, L. (LaTrobe University), STUKAS, A. (LaTrobe University)

This research consisted of two parts examining whether Self-Verification theory (Swann, 1987), or Self-Enhancement theory (Murray, Holmes, & Griffin, 1996), best characterised actual interactions between intimate partners over women’s specific positive and negative self-views (Part 1), and women’s body images (Part 2). The study aimed to determine: (1) how women presented, and how men responded to, women’s self-views; (2) women’s feedback desires; and (3) whether women attempted to bring men’s views into alignment with their own self-views. 43 opposite-sex couples (72% had been in their relationship for more than two years) aged 18-62 from rural and urban Victoria, completed measures of self-views, body image dissatisfaction, relationship satisfaction and relationship intimacy. They were videotaped engaging in three counterbalanced four-minute interactions over women’s positive self-views, negative self-views, and body images, respectively. The recordings of these interactions were subsequently coded for verification and enhancement processes by objective raters. Women’s and men’s perceptions of the interactions were assessed using self-report questionnaires. Results demonstrated that verification processes characterised interactions over women’s positive and negative self-views, but enhancement processes characterised interactions over women’s body images. For both positive and negative self-views, women presented themselves in a self-verifying manner, desiring and receiving consistent feedback. Women attempted to bring their partners’ views into alignment with their own self-views. Verification effects were stronger for the positive than negative self-views (Part 1). Body image dissatisfied women, although providing self-verifying presentations, desired and received self-enhancing positive feedback, and did not attempt to change their partners’ views (Part 2). Objective ratings and self-reports were consistent. The findings of Part 1 validate Self-Verification theory, indicating that it applies to actual interactions of intimates over women’s specific self-views, and may explain how such self-views are shaped and maintained. Self-enhancement processes were found to be more characteristic of couple’s interactions over women’s body images in Part 2, indicating that self-verification processes may not explain the maintenance of women’s body image dissatisfaction. Body image may have special status as a self-view requiring enhancement due to being: (1) a socially scrutinised construct; (2) highly relationship relevant; and (3) related to
global self-worth. Implications for psychological interventions are discussed.

Keywords: self-verification theory, self-enhancement theory, women’s self-views, body image, intimate relationships

Dispositional hope to predict resilience after hereditary colorectal cancer genetic testing: a prospective outcome trajectories study

HO, S. (The University of Hong Kong), HO, J. (University of Hong Kong Medical Centre), BONANNO, G. (Columbia University), CHU, A. (Queen Mary Hospital), CHAN, E. (Queen Mary Hospital)

Genetic testing for hereditary colorectal cancer (HCRC) had significant psychological consequences for test recipients. This prospective longitudinal study aimed at investigating factors predicting psychological resilience in adults undergoing genetic testing for HCRC. A longitudinal study was carried out on Hong Kong Chinese HCRC family members recruited and offered genetic testing by the Hereditary Gastrointestinal Cancer Registry to determine psychological outcome after genetic testing. Self-completed questionnaires were administered immediately before (pre-disclosure baseline) as well as 2 weeks, 4 months and 1 year after result disclosure. Using validated psychological inventories, the cognitive style of hope was measured at baseline and psychological distress of depression and anxiety was measured at all time points. Seventy-six subjects participated among whom 71 persons (43 men and 28 women; mean age 38.9 ± 9.2 years) from 9 FAP and 24 HNPCC families completed the study including 39 mutated gene carriers. Four patterns of outcome trajectories were created using established norms for the specified outcome measures of depression and anxiety. These included chronic dysfunction (13% and 8.7%), recovery (0% and 4.3%), delayed dysfunction (13% and 15.9%) and resilience (76.8% and 66.7%). Because of the small number of participants, the chronic dysfunction and delayed dysfunction groups were combined into a non-resilient group to compare with the resilient group in all subsequent analysis. Two logistic regression analyses were conducted using hope at baseline to predict resilience with depression and anxiety as outcome indicators. Both regression equations were significant. Baseline hope tended to be a significant predictor resilience outcome trajectory for depression ($B = -0.24, p < 0.01$ for depression); and anxiety ($B = -0.11, p = .05$ for anxiety). The current findings suggest that hopefulness might predict resilience after HCRC genetic testing in Hong Kong Chinese. Interventions to increase the level of hope may be beneficial to psychological adjustment of HCRC genetic testing recipients.

Disruption to place attachment and the protection of restorative environments: A wind energy case study

DEVINE-WRIGHT, P. (University of Exeter)

Deepening understanding of public responses to energy projects is of both academic and practical importance, given policies to increase energy supply from renewable sources in many countries. Although the ‘NIMBY’ (Not In My Back Yard) concept is commonly used to explain public opposition to wind farms, the concept has been extensively critiqued. This study applies an alternative approach based upon theories of place and social representations, and the use of mixed methods. In particular, we focus upon the symbolic meanings associated with a proposed project and the places affected by it, and how the adoption of these meanings relates to place attachment. Empirical data is provided from a case study of a proposed 750MW offshore wind farm in North Wales, using in-depth interviews, group discussions and a questionnaire distributed to local residents in two coastal towns ($n=455$). Results indicate how opposition is based upon a symbolic contradiction between ‘nature’ and ‘industry’ - between a place represented in terms of scenic beauty, providing a restorative environment for residents and visitors, and a wind farm represented to industrialise the area, ‘fence in’ the bay and create an eyesore. The data suggests that the contradiction between project and place-related meanings was experienced as a threat to identity
for those with strong attachment to the place, leading to negative attitudes to the project and oppositional behaviour. The results provide further evidence of the role place attachment has in shaping so-called ‘NIMBY’ behavioural responses to proposed development projects and challenges the common assumption that offshore wind farms will prove less controversial than those onshore.

Distress and functional impairment associated with eating-disordered behaviour in a community sample of women

MOND, J. (University of Western Sydney), HAY, P. (University of Western Sydney), RODGERS, B. (Australian National University), OWEN, C. (Australian National University)

Distress and functional impairment associated with eating disorder attitudes and behaviours were examined in a large, general population sample of women aged 18 to 42 years. Participants (n = 5255) completed self-report measures of eating-disordered behaviour (Eating Disorder Examination Questionnaire, EDE-Q), general psychological distress (Kessler Psychological Distress scale (K-10) and impairment in mental health (Medical Outcomes Study Short Form Mental Component Summary scale, SF-12 MCS). Eating disorder features assessed included objective and subjective overeating, purging and non-purging weight-control behaviours, and key cognitive features, namely, concerns about dietary intake, concerns about eating, and concerns about weight or shape. In bivariate analysis, distress and functional impairment were most pronounced among participants who reported extreme dietary restriction and extreme weight or shape concerns, whereas excessive exercise was associated with minimal impairment. In multivariable analysis, in which scores on each outcome measure were regressed on all eating disorder features, while also controlling for age, BMI and physical health, each of the cognitive features assessed - concerns about food intake, concerns about eating, and concerns about weight or shape - showed strong, independent associations with both K-10 and MCS scores, whereas the occurrence of subjective overeating and extreme dietary restriction made small, but still statistically significant contributions. The associations between elevated weight and shape concerns and higher levels of distress and functional impairment were particularly strong (K-10: β = 0.35; MCS: β = 0.36). Hierarchical linear regression models confirmed that eating disorder behaviours accounted for a negligible proportion of the variance in both outcome measures when compared with weight and shape concerns and other cognitive features. From a clinical perspective, the findings are consistent with the importance given to the “undue influence of weight or shape on self-evaluation” as a core component of eating disorder psychopathology. From a public health perspective, the findings indicate the need to conceive of body dissatisfaction, weight and shape concerns, and related constructs, as targets in their own right, rather than as mere risk factors for the occurrence of “clinical” disorders.

Do age, achieved level of education and demands on personal time influence personal values, self attributes and approaches to learning?

MATTHEWS, B. (Flinders University), HALL, M. (Flinders University), LIETZ, P. (Australian Council for Educational Research)

The changing demographic characteristics of students in higher education are of concern to educators. This is particularly evident in the professional education of nursing students where the practical and theoretical aspects are combined in the pursuit of an academic qualification. A longitudinal study has been initiated to measure aspects of these characteristics. Two sets of measurements were taken to assess values using the Portrait Values Questionnaire (PVQ) (Schwartz et al., 2001), learning approaches using the Study Process Questionnaire (SPQ) (Biggs, 1987) and personal self concepts using the Self Attributes Questionnaire (Pelham & Swann, 1989) that are
extant in undergraduate nursing students at an Australian university. The pilot and second measurements done in the first and second years of the study have shown that (a) there are two distinct age groups present in almost equal proportion; (b) mature-aged students are more highly motivated despite their lower level of prior or pre-entry learning; (c) universal part-time employment leaves little time for academic endeavour; (d) Mature-aged students have personal self-concepts that are significantly different from younger students; and (e) older students show a greater incentive to succeed in the nursing education program. Personal values are statistically important precursors that motivate the ways in which students prefer to learn and have an influence on students’ self-esteem.

Do anger-congruent behaviours transfer across separate driving situations?

STEPHENS, A. (University College Cork (UCC)), GROEGER, J. (University College Cork)

It is unclear whether driver anger, and driving aggression, which seems to occur without provocation, arises because of events prior to those circumstances in which anger is experienced and aggression is exhibited. In this study, time pressure and enforced following of a slowly moving vehicle were used to manipulate drivers’ anger as a means of assessing whether prior mood would influence affect and behaviour during a subsequent, non-provocative, drive. Ninety-six drivers drove twice in a simulated urban environment. During the first drive oncoming traffic and a slowly moving lead vehicle required that the driver travelled far slower than they would choose. Unrealistic time limitations also imposed a sense of time pressure. During the second drive, drivers again followed slower drivers and were required to respond to events not encountered in the manipulation drive. Anger evaluations, arousal (heart rate) and behaviour (mean and variation of speed and lane positioning) were measured during both drives and driver mood was measured before and after each drive. Drivers exposed to slower lead vehicles and time pressures displayed reliable differences in anger, mood and behaviour during the manipulation drive when compared to control group drivers. Behavioral differences of speed and lane positioning carried over into the subsequent, unrelated drive and these effects were not limited to similar situations to what had been experienced during the manipulation drive. Drivers who had recently been pressured for time maintained more varied speeds and road positioning during uninterrupted periods of driving. Drivers impeded by a slower lead driver during the manipulation drive, approached road hazards with less caution and attempted more dangerous overtaking maneuvers in the general drive. It appears driving aggression may arise from events which have occurred in a previous drive. More research is needed to identify the extent to which these findings suggest a mood-related impairment in hazard detection.

Do perceptions of the use of humour in the workplace mediate the relationship between job insecurity and measures of job satisfaction and psychological well-being?

FINDLAY, B. (Swinburne University of Technology), DARLISON, N. (Swinburne University of Technology)

Given literature suggesting that humour buffers the effect of stress on aspects of well-being, the aim was to examine whether perceptions of the use of humour in the workplace would mediate the relationship between job insecurity and measures of job satisfaction and psychological well-being. One hundred and nine Australian workers (modal age 30-39) responded to an online questionnaire containing demographics and measures of job insecurity, perceptions of humour use at work, job satisfaction, depression, anxiety, stress, psychological well-being and social desirability. Hierarchical regression, controlling for social desirability, indicated that job insecurity predicted greater depression (but not anxiety or stress) and less job satisfaction and psychological well-being. An unpleasant climate of humour use in the
workplace predicted greater stress (but not depression or anxiety) and less job satisfaction. No mediation by the humour measure was evident. The effects of job insecurity and workplace humour appeared largely independent. Social desirability was always a uniquely significant predictor of all output measures. While it is unsurprising that job insecurity predicts aspects of well-being, it is useful to learn that specific aspects of workplace climate, such as perceptions of the sort of humour typically used, independently predict well-being. It is also important to control for social desirability when using self-report instruments in researching self-relevant constructs.

Keywords: humour, stress, well-being, job satisfaction, job insecurity

Do stressors cause strain or does strain cause stressors? Evidence from meta-analyses of longitudinal studies

DORMANN, C. (University of Mainz), HAUN, S. (University of Mainz)

While existing stress theories propose stressor-strain effects, several authors suggest, however, that the reversed effects of strain on stressors might also explain their empirical relation. We propose that both effects exist, but they rely on different mechanisms that require different amounts of time. Reversed effects of strains on stressors should involve changes in job tasks, which are frequently caused by job changes: Employees under strain either drift towards high stress jobs (drift hypothesis), or employees are attracted by low strain jobs (refuge hypothesis). Such drifts/flights take some time to happen. On the other hand, we propose effects of stressors on strain to require less time. Overall, we propose reversed effects to dominate in long term panel studies, whereas stressor-strain effects should dominate in short term panel studies. Hypotheses were tested by meta-analyses of existing panel studies (k= 68–93; N= 25,985–39,882). Population correlations for 2-Variable 2-Wave matrices were estimated using the Raju et al. (1992) validity generalization approach, and then further analyzed using structural equation modeling. Simultaneous meta-analyses of all studies did not provide evidence for causal effects in either direction. With length of time lag as a moderator, however, hypotheses were confirmed. Long-term (> 1 year) studies showed evidence for reversed causation (refuge hypothesis), whereas short-term panel studies yielded evidence for effects of stressors on strains. Despite the weak effects discovered, we conclude that indeed stressors affect strains. Panel studies covering much shorter time intervals are necessary to provide stronger evidence. When reversed causation hypotheses are tested, long time intervals are necessary. Finally, we conclude that results from cross-sectional studies are unlikely to yield inflated stressor-strain effects due to reversed causation. The reason is that our results support the refuge hypothesis of reversed causation, and the refuge process reduces rather than increases strain-stressor correlations.

Keywords: stressors, strain, job changes

Do we learn best from our own age?
Increasing the effectiveness of a behavior modeling based vocational training

BAUSCH, S. (University of Heidelberg), NOEFER, K. (University of Heidelberg), STEGMAIER, R. (University of Heidelberg), SONNTAG, K. (University of Heidelberg)

Demographic changes and lifelong learning necessitates differentiated vocational training concepts. Although Behavior Modeling Training (BMT - Bandura, 1986) is an acknowledged training method, there is little research about the interaction it has with age. Previous research also indicates that a higher similarity between model and learner is beneficial, but so far, no study examined the interaction of the observed model’s age and the age of the learner. In our study, we focussed on these interactions. As it is a well accepted training medium, we conducted the study in an e-learning context. 277 participants (18–75 yrs) finalized a 2.5h lasting BMT-oriented time and self-management e-learning program containing introduction, video and interactive task-modules. Three, otherwise identical, versions of the training were designed, showing a) a young, b) a middle-aged and c) an older model (25, 40, 55 yrs). Based on own age,
participants were divided into young, middle-aged and older learners and were randomly assigned to the three age-variations. The 3x3 design was analyzed comparing all 9 groups and focussing on the high- vs. low-congruence condition. The one-way ANOVA showed a superiority of the age-congruence condition: participants of all age-groups who learned with a model of their own age group showed a higher increase of applied knowledge ($p < .05$). Additional repeated measurement ANCOVA analyses showed a main effect of training gain, an interaction between learning success and pre-training knowledge and another between learning success and age-congruence. We further revealed a three-way-interaction between pre-training knowledge, age-congruence and learning success: learners who observe an age-congruent model benefit more than learners who observe a non-congruent model, and this effect is stronger for learners with a low level of previous knowledge than for those with a high level (all $p < .01$). Findings show that the effectiveness of BMT can be increased by observing an age-congruent model. This variation could easily be implemented in an e-learning training but might also be beneficial for other BMTs. Implications are discussed in terms of age adaptive vocational trainings.

**Keywords:** age, behavior modeling, vocational training

**Do you have better verbal memory if you have better musical ability and musical intelligence?**

AU, A. (James Cook University), MENG, W. (China National Institute for Educational Research), CALTABIANO, N. (James Cook University), CALTABIAN, M. (James Cook University), WALKER, A. (James Cook University)

The current study investigated whether better musical ability and better musical intelligence were related to better verbal memory, based on the findings that musicians have larger left Planum Temporale that is also involved in one's verbal memory. Forty-one undergraduates participated in a musical ability test that examined pitch discrimination, rhythmic and melodic patterns identification and music reading. Musical intelligence of multiple intelligence and verbal memory were also examined. Participants were then divided into high- and low-ability groups based on their overall musical ability, their ability to discriminate pitch, to identify music pattern, to read music, and their musical IQ. Results showed that participants with formal music training were better in pitch discrimination, music reading and musical IQ. However, they did not perform better than their counterparts who received no musical training in verbal memory. Further analysis illustrated that participants who had high ability in their overall musical ability, pitch discrimination, pattern identification, music reading and musical intelligence did not have better verbal memory than their low-ability counterparts. None of the musical abilities correlated significantly with verbal memory. It was concluded that music training, though can improve individuals’ musical ability and musical IQ, does not necessarily result in better verbal memory. The sensitivity of the music test used might provide insights on the current findings. The relationship between musical ability and verbal memory requires further investigation. Practical implications of music in various cognitive tasks were discussed.

**Keywords:** verbal memory, musical ability, musical ability

**Does increasing awareness promote changes in behavior? A study of injunctive normative influence on littering behavior**

The present experimental study examines the extent to which participants are persuaded to assume prosocial nonlittering attitudes, behavioral intentions and behavior following exposure to media with different injunctive normative messages. Initial attitudes towards littering, awareness of the littering “problem”, and demographic variables were collected to test for moderation. 204 participants were randomly assigned to view one of three
experimental public service announcements that displayed a) a descriptive norm of littering and a negative injunctive norm (a man with a tear); b) a descriptive norm of litter and a positive injunctive norm (happy faces); or c) a control condition (children playing in nature). In addition, participants completed an online survey prior to viewing the video, and a post-survey in the lab subsequent to viewing the video. For the post-survey, each participant was given a plastic covered pen. Attitudes toward the environment, awareness of littering as a problem, as well as demographic information were assessed. Intention to litter and actual littering behavior (of plastic in the lab) were dependent variables. Results indicated that awareness of littering as a problem was a strong moderator, such that those with high awareness were more sensitive to injunctive normative messages than those with low awareness. High awareness participants were more likely to litter when the injunctive norm communicated social approval for littering ($\chi^2 (1, N = 70) = 3.72, p<.05$), and they were less likely to litter when the injunctive norm communicated social disapproval for littering ($\chi^2 (1, N= 69) = 6.72, p<.01$). The control condition had no significant differences. Thus, highly aware participants, counter intuitively, littered more when they watched a video with people smiling in response to litter than when they watched a video with a negative response to litter. The opposite was true for those with low awareness. Prior environmental attitudes and demographic variables did not moderate the effect. We conclude that awareness of a problem affects the way in which a person attends to injunctive normative information. Consistent with previous research, our findings suggest that persons with high awareness use more controlled, central processing (Göckeritz et al., in press), which increases the effects of the injunctive normative message. We conclude that “effective” messaging to reduce littering may not be the same for those with prior awareness of a problem than for those who are not aware. Implications of these findings are discussed.

Keywords: prosocial nonlittering attitudes, behavioral intentions, media

Does information order influence financial decision-making?

TERRY, E. (Ryerson University)

How efficiently do individuals process information when making financial decisions? In particular, can financial decisions be influenced merely by altering the order in which the information used to make these decisions is presented? Serial order effects have been observed in a variety of situations that include: impression formation (Asch, 1946), evaluations of sequential information (Miller & Campbell, 1959), memory (Atkinson & Shiffrin, 1968), the arrangement of questions and responses on surveys (Schuman & Presser, 1981), consumer choices (Lohse, 1997), and portfolio selection (Levy & Levy, 2005). Two separate experiments were conducted by administering written questionnaires to over 1,000 undergraduate business students. In the first experiment, participants chose between two mutual funds on the basis of their reported past performance. In the second experiment, students chose between two capital investment projects on the basis of their computed net present values in three scenarios (base-case, worst-case, and best-case). For the first experiment, it was found that the fund with superior short-term results was chosen more frequently when short-term performance appeared last rather than being presented first. The magnitude of this effect was not sensitive to simulated market conditions for the two funds or to the time frame used for short-term vs. long-term performance. Furthermore, no significant differences were observed between finance majors and those students taking other business majors. For the second experiment, it was found that the riskier project was selected more often when the best-case scenario was presented last rather than being listed first. The magnitude of this effect was consistent across a series of hypothetical capital budgeting decisions. The two experiments demonstrate that financial decisions can be influenced by the order in which information about the available choices is presented. Specifically, the results of both experiments suggest the existence of a recency effect in which individuals tend to overemphasize the last piece of information that is presented to them. They are also consistent with Lee and Terry (2009), who found a recency
effect in which individuals choose riskier alternatives more frequently when potential outcomes are listed from worst to best than when they are listed from best to worst.

Does the activity restriction model explain depression in older adults with Osteoarthritis: A longitudinal study in Shanghai, China.

WANG, Q (Cancer Council, Victoria), WANG, K. (Cancer Council Victoria), JAYASURIYA, R. (University of New South Wales), HUA, F. (Fudan University, Shanghai)

Management of Osteo-arthritis (OA) requires attention to pain and functional disability. Higher levels of depression are related to functional disability in older adults. The reciprocal relationship of pain, functional disability and depression has been explained using the activity restriction model (ARM) (Williamson et al, 1995, 2000). This model has been contested by others (Parmalee et al, 2007). The aim of the study was to tease out the temporal associations between pain, functional disability and depression using a cohort of older adults with clinically diagnosed Osteo-arthritis in Shanghai, China. A cohort of OA patients was examined at baseline and after an interval of six months to collect data on pain, functioning and depressive symptom. Data analysis using partial correlation and multiple regression was carried out on 139 who completed both surveys. Mediation analysis was used to test the ARM. Internal consistency reliabilities of the scales for pain, function and depression were good (α was between 0.75 and 0.97). Partial correlations (controlling for socio-demographics) showed that depression at baseline (T1) was significantly related to pain at T1 (r=0.3); function at T1 (r=0.45). Depression at follow-up (T2) was significantly related to Depression at T1 (r=0.59); function at T1 (r=0.28), function at T2 (r=0.27) and pain at T1 (r=0.2). The significant predictors of depression at T2 on multiple regression were depression at T1 (R square change 24%) all other variables were not significant. Mediation analysis at T1, showed that the relationship between pain and depression was fully mediated by function (Sobel’s statistic = 5.32, P =0.01). The close association of pain to functional disability in OA found in this study is similar to other studies. Pain at baseline has both a direct and indirect path (through functional disability at baseline) that effects depression, which concurs with the ARM. However, the main predictor for depression at T2 is depression at baseline. Further studies are required to seek modifiable behavioural variables such as self-efficacy and coping strategies that mediate these relationships.

Keywords: depression, elderly, Osteoarthritis, pain, functional disability

Does the experience of work-life balance change across career stage?

HUMPHRYS, K. (Griffith University), BROUGH, P. (Griffith University)

Work-life balance (WLB) policies have become a major driver in recruiting and retaining skilled workers. As such, when considering the global trend of an aging workforce, it is imperative to understand how age structures affect WLB constructs. The present study will provide a detailed insight into how working individuals from difference career stages manage WLB and how exactly their needs change over time. Thus, this study aims to examine the role of career stage in Work-Family Conflict (WFC), Work-Family Facilitation (WFF) and WLB. 570 members of the Queensland Teachers’ Union responded to a survey on Teacher Demands and Work-Life Balance. Respondents were grouped into one of four career stages based on their professional tenure, occupational tenure and score on the Adult Career Concerns Inventory – Short form (Perrone, Gordon, Fitch & Cibiletto, 2003). Supervisor, colleague, family and friend Support, Job involvement, WFC, WFF and WLB were also measured (Carlson, Kacmar, Wayne, & Grzywacz, 2006; Carlson, Kacmar, & Williams, 2000; Kanungo, 1982; O’Driscoll, Brough, & Kalliath, 2004). Multiple Regressions were run for each group as a preliminary assessment of the associations between Job involvement, Support, WFC, WFF and WLB. Significant associations between involvement/support and work-to-family conflict were found for participants in the
Individual Oral Presentations

exploration, maintenance, and disengagement stages \( F(5) = 3.16, p < .05; F(5) = 2.71, p < .05; F(5) = 2.57, p < .05 \), respectively, while those in the establishment, maintenance and disengagement stages displayed significant associations between involvement/support and family-to-work conflict \( F(5) = 5.39, p < .001; F(5) = 8.5, p < .001; F(5) = 3.55, p < .01 \), respectively. Work-Family Conflict and Work-Family Facilitation were not significantly associated with WLB for any of the four career stages. Significant unique contributions also differed across career stage with supervisor support and colleague support yielding significant results for the exploration and establishment stages while job involvement and family support were predominant predictors for the maintenance and disengagement stages. Structural Equation Modelling (SEM) will be used to further evaluate model fit across career stage. In addition, Time 2 data is currently being collected and results will be analysed and reported over time. As career stage has not been investigated with relation to WLB, the data generated from this study is highly original and makes a valuable contribution to both international academic discussion and organizational/Government policies.

Keywords: work-life balance, age, career stage, work-family conflict, work-family facilitation

Driver behaviour theory: ninety years of psychological space in traffic

SUMMALA, H. (University of Helsinki)

With experience, car drivers learn to manage with risks on the road surprisingly well. But what are the critical measures that the drivers actually control while driving? Plenty of candidates have been presented by psychologists who often are eager to explain behaviour with one or few variables: attention, comfort, crash-risk itself, feeling of risk, effort, mental workload, task difficulty, and so on. This presentation follows one line of theorizing that dates back to the late 1910's - that of psychological space. Ninety years ago a Swedish engineer Chr. Sylwan looked down at busy street traffic from a skyscraper in New York and described the space required by vehicles and the psychological space in front of and on both sides of vehicles, as determined by speed and anticipated paths of traffic units. Twenty years later Gibson and Crooks in their now well-known work vividly described the field of safe travel, the field of possible paths which the car may take unimpeded. Another thirty-five years later we investigated safety margins in space and time as important roles in our motivational model of driver behaviour. The "zero-risk theory" essentially suggested that the driver tends to satisfy his (excitatory kind of) motives in traffic but so that he/she feels no risk. It postulated a risk monitor that alerts and triggers an avoidant reaction when a safety margin threshold is violated or violation is anticipated. Safety margins and elicited emotional reactions were suggested to serve as simple heuristics in dynamic driver behaviour just as optimising subjective utility models have been substituted by the satisficing principle and simple decision heuristics in more static decision making. This was in line with Antonio Damasio’s hypothesis, now achieving increasing interest among driver behaviour theorists. Road space allocation and safety margin control are now an essential goal in the intelligent vehicle and road concepts. However, we suspect that many years from now drivers will utilise the control loop which maintains safety margins, that is, keeping themselves within a safe "psychological space", or "safety zone", or "safety envelope" - through speed, steering, and attention control. This old concept will be put into the context of the present motivational and cognitive models of driving behaviour.

Keywords: driving behaviour, risks, motives

Education and training for practice with rehabilitation populations in the United Kingdom

STIERS, W. (Johns Hopkins University School of Medicine), KUEMMEL, A. (Tampa Veterans Administration Hospital), KENNEDY, P. (Oxford University), NICHOLSON PERRY, K. (University of Western Sydney)

The aim of the current study was to: (1) Identify the training opportunities to prepare psychologists for practice with rehabilitation populations in the U.K; (2) Apply evaluation research theories to study the structures, processes, and outcomes of these training
programs; and to (3) make recommendations for improving training program outcomes in this area. All the currently accredited professional psychology post-graduate courses in the United Kingdom were contacted (n=32) and asked to complete a questionnaire regarding their training program structures, processes, and outcomes. Data were collected regarding training program structures (faculty and trainee characteristics, patient populations, and goals and curricula), processes (training opportunities for each of the Rehabilitation Psychology core competencies identified by the American Board of Rehabilitation Psychology), and outcomes (the extent to which trainees went on to additional training, and/or took jobs in rehabilitation settings). It is estimated that 10% of the world’s population, approximately 650 million people, experience some form of disability, and this number is increasing. Rehabilitation Psychologists have developed methods to effectively assess and treat individuals with disabilities. However, Rehabilitation Psychology is currently not a recognized specialty of psychology in the United Kingdom. Opportunities to undertake practical training in some rehabilitation areas appear to be quite commonly available, but do not include many of the areas of physical rehabilitation. These findings suggest that currently available courses in the United Kingdom do not provide effective training to prepare a specialty workforce to best respond to important growing global health-care priorities to which Rehabilitation Psychology is relevant. Recommendations are given for a set of training pathways and guidelines for Rehabilitation Psychology.

Keywords: rehabilitation, training programs, United Kingdom, disability, practical training

Education and training in rehabilitation psychology practice in the United States and Canada

STIERS, W. (Johns Hopkins University School of Medicine), STUCKY, K. (Michigan State University)

The aim of the current study was to (1) identify the psychology internship and post-doctoral training programs in the United States and Canada which provide training in Rehabilitation Psychology practice; (2) Apply evaluation research theories to study the structures, processes, and outcomes of these training programs; and to (3) make recommendations for improving training program outcomes in this area. Public sources of information regarding psychology internship and post-doctoral practitioner training programs were examined to identify programs which involved rehabilitation patient populations. Each training program identified was asked whether they provided specific training in Rehabilitation Psychology. Programs which responded affirmatively (n=117) were sent a questionnaire regarding their training program structures, processes, and outcomes. Data were collected regarding training program structures (organization and funding, faculty and trainee characteristics, patient populations, goals and curricula), processes (hours per week of didactics and supervision, frequency and types of evaluation, consistency with the Patterson and Hanson 1995 guidelines for training in Rehabilitation Psychology, consistency with the American Board of Rehabilitation Psychology core competencies), and outcomes (the extent to which trainees went on to additional training, became licensed, and became employed in teaching, research, or practice jobs, including whether these jobs were in rehabilitation settings). It is estimated that 10% of the world’s population, approximately 650 million people, experience some form of disability, and this number is growing as a result of population growth, aging, a rise in chronic diseases, a rise in car crashes and violence, and medical advances that sustain life. Rehabilitation Psychologists have developed methods to improve adjustment, increase function, develop adaptive and compensatory techniques, employ assistive technology and personal assistance, modify the physical environment, reduce social stigma, increase social integration and participation, and advocate for disability rights and consumer participation. However, of the psychology training sites in the U.S. and Canada involving rehabilitation patient populations, few provided training in Rehabilitation Psychology. There is not enough specialty workforce pipeline capacity to best respond to important growing global health-care priorities to which Rehabilitation Psychology is relevant. Recommendations are
given for a clear set of training pathways and guidelines for Rehabilitation Psychology.

Keywords: psychology internship, training programs, rehabilitation, education, disability

Effect of death awareness on strength of believe, avoidance and depression of individual with obsessive – compulsive disorder

ALI AK BARI DEHKORDI, M. (Payame Noor University), DALIR, M. (Payame Noor University)

The purpose of the present research was to study the effect of exposure therapeutic method with death recalling (death awareness) on believe, avoidance, and depression variables of individuals suffering from obsessive compulsive disorder. 40 subjects suffering from obsessive compulsive disorder were recruited by means of a random simple sampling method and were placed in experimental and control groups. All the subjects filled out Yale Brown Obsessive – Compulsive Scale in two stages, pre-test and post-test. Data analysis with MANCOVA in significant rate of $P < 0.001$ has shown that Death Awareness has positive effect on reducing of strength of the individual with O.C.D believes, avoidances and depressions. By paying attention to the results of present research it can be suggested to all psychotherapists all over Islamic Iran to use Death Awareness method as the elective therapeutic method for obsessive compulsive disorder.

Keywords: death awareness, avoidance, depression, obsessive compulsive disorder

Effect of optimism – pessimism attitude on depression and coping strategies amongst Indians during different life stages

JOSHI, R. (D.A.V. (PG) College)

The present research was undertaken to study the effect of Optimism-Pessimism attitude on depression and coping strategies among adolescent, adult and old age subjects. The sample consisted of 600 subjects of either sex equally divided into three groups: adolescents, adults and old age. All the subjects were matched on socio economic status and belonged to urban background coming from Dehradun, Uttarakhand, India. Educational qualification of all the subjects was 12th and above. Quota random sampling technique was used to draw the sample. Data was collected individually by using Optimism-Pessimism Scale developed by Prasar, D.S. (1998), Depression Scale of Shamim Karim and Roma Tiwari (1986) and Coping Strategy Scale of Folkman and Lazarus (1985). Factorial design (3x2) was used to test the proposed hypotheses. The inferences were drawn by calculating Means, SDs, ANOVAs and ‘t’ tests. The findings revealed that Pessimists have significantly higher level of depression than the Optimists subjects. Optimists possessed significantly higher tendency of using Distancing, Seeking Social Support, Planful Problem Solving and Positive Reappraisal techniques of coping strategies as compared to the Pessimists. Adolescents were found to be more optimistic than adults and old age subjects. Adults were found to be significantly higher on the level of Depression as compared to adolescents and old age subjects. No significant difference was found on Sleep Disturbance dimension of Depression among all the three groups of the study. Old age subjects were found to have significantly higher tendency of using overall coping strategy than adults and adolescents. Seeking Social Support and Escape Avoidance tendency of Coping strategy was similar among all the three groups of the study. Males were found to possess significantly higher levels of Sleep Disturbance, Social Withdrawal and Self Centeredness as compared to females. Significantly higher tendency of using Planful Problem Solving and Positive Reappraisal technique in stressful situations was found in male as compared to female subjects. Optimism / Pessimism Attitude significantly affect the level of Depression and Coping strategies amongst different age groups in Indian population. The findings of the study will be discussed in reference to current Indian social context.

Effectiveness of online methods for proctoring high-stakes exams

FOSTER, D. (Kryterion, Inc.)

The purpose of this paper is to describe and demonstrate several new online methods of proctoring important exam administration. It will also present research on their effectiveness. The author conducted a meta analysis of security incident “tickets” or “logs” created by Kryterion online proctors as they detected and dealt with various types of security problems during several thousand certification and distance education exams. The paper will provide a listing and categorization of the types of security problems occurring for high-stakes testing where no proctor is physically present but other methods of proctoring are. The frequency of each type of security incident occurring under conditions imposed by online proctoring will be presented indicating that they are lower than might be expected for a circumstance where individuals are taking the high-stakes test usually in their own home without a proctor physically present. A comparison of these results with security incident results from traditionally proctored exams lends credibility to the idea that online proctoring methods may be a more effective alternative.

Keywords: exam administration, online proctoring methods, distance education exams, security problems, high-stakes testing

Effectiveness of structural family therapy on Oppositional Defiant Disorder

MOUSAVI, R. (Shahed University), ABBASI, Z. (Imam Hesein University)

The aim of the present study is to investigate the effect of structural family therapy on five to ten year-old children with Oppositional Defiant Disorder. This study is a pseudo experimental single subject study with pretest-posttest design. In order to do the study four families with at least one child with Oppositional Defiant Disorder were selected by lumpy sampling method. The whole families' members were exposed to therapy interventions with the same treatment design for eight sessions. The sessions were held weekly. Using Rutter’s behavioral problem scale, the cases were assessed in four phases; before, during, and after the completion of intervention and one month after the last session as the follow up. The data were presented in charts. The results indicated that the structural family therapy is a significant factor in decreasing the symptoms of Oppositional Defiant Disorder. The Structural Family Therapy was effective to decreasing the symptom of Oppositional Defiant Disorder. Regarding to present research results, it is recommended this method should be used for children with Oppositional Defiant Disorder.

Keywords: structural family therapy, Oppositional Defiant Disorder

Effects of a labour dispute on students: A longitudinal perspective

WICKENS, C. (Centre for Addiction and Mental Health), WICKENS, C. (Centre for Addiction and Mental Health), FIKSENBAUM, L. (York University), WIESENTHAL, D. (York University), GREENGLASS, E. (York University)

Despite the increasing frequency of university labour disputes, few studies have examined their impact on students, with even fewer focusing on the longitudinal perspective. The current report presents a longitudinal (4-phase) study of the affective, cognitive, and behavioural responses of students to a 12-week strike by teaching assistants and contract faculty at a large Canadian university. Students were asked to complete questionnaires approximately one week before the strike, one week and five weeks into the strike, and two weeks after the labour dispute had been settled. A total of 104 participants completed all four phases of the study. A comparison of students who completed all phases versus those who did not revealed minimal differences on pre-strike measures. Repeated-measures ANOVAs using Bonferroni-adjusted levels of significance indicated that the gratification that students felt as the strike began was soon replaced by apathy toward their own academic work. Students’ opposition to the strike and to both the position of the administration and the union generally increased over the strike’s duration. Further, students’ satisfaction with their academic
programs declined during the strike and after the dispute was settled. Although students’ perception of fair treatment increased after the strike, their willingness to recommend the university to a friend decreased. Students’ perception of social support from professors and teaching assistants, and the belief that they had at least one faculty member to turn to, declined throughout the labour dispute, reaching its lowest level in the fifth week of the strike. For the majority of students, perceived support from professors and teaching assistants returned to pre-strike levels after the dispute was settled. Support from fellow students followed an identical pattern. Support from non-university friends and relatives was greatest in the pre-strike period, with subsequent declines throughout the dispute. Students reported spending fewer hours on academic studies and in the library during the strike, but more hours on email/Facebook and on recreation. Students also reported sleeping later than usual on weekdays. Increased consumption of alcohol over the course of the strike approached significance. Recommendations for improving student response to an academic labour dispute will be discussed.

Effects of a social cognitive career theory based group intervention on career decision self-efficacy and vocational outcome expectations of undergraduate students

IK, E. (Selcuk University), IK, E. (Selcuk University), ÖZYÜREK, R. (Cukurova University), AKBAŞ, T. (Cukurova University)

Originated by Bandura’s general social cognitive theory, Lent, Brown and Hackett developed a modern career theory called Social Cognitive Career Theory (SCCT). Many studies have primarily focused on the relations between the key elements of SCCT (self-efficacy, outcome expectations, goals, barriers). However, more intervention studies are needed to understand the effectiveness of SCCT-based programs and there is a call from the theorist and field researchers as well (Lent, 2005). Thus, this study aimed at examining the effects of a social cognitive career theory based group intervention on career decision self-efficacy and vocational outcome expectations of undergraduate students. A pretest-posttest equivalent group design compared students who completed the 10 week intervention ($n = 16$) with a quasi-control group of students ($n = 16$). A repeated measures ANOVA was used to assess students’ pre-intervention and post-intervention self-efficacy career-decision and vocational outcome expectation scores. The results indicated that students who completed the career intervention program showed increased career decision-self efficacy and vocational outcome expectation when compared with quasi-control group. As hypothesized by Lent et al. and other researchers, doing activities in order to increase four sources of learning experiences (personal accomplishments, vicarious learning, emotional arousal, and verbal persuasion) also helped increasing self-efficacy and outcome expectations of undergraduate students. The importance of preparing theoretically based career interventions and the increased need for research in this area are discussed.

Keywords: Social Cognitive Career Theory, career decision self-efficacy, vocational outcome expectations, undergraduate students, self-efficacy

Effects of alcohol (0.5 ‰) and MDMA (100 mg) on simulated driving performance and traffic safety

VELDSTRA, J. (University of Groningen), BROOKHUIS, K. (University of Groningen), DE WAARD, R. (University of Groningen)

Research convincingly shows that drug use and especially multiple drug use and drug-alcohol combinations among drivers is an important risk factor for traffic accidents. Since drug- and medicine use is proportionally increasing over the years, special efforts have to be directed towards gaining better knowledge of the various aspects of this problem and developing appropriate solutions. The objective of the recently started European Commission (EU) project DRUID (Driving under the Influence of Drugs, Alcohol and Medicines) is to give scientific support to the EU transport policy
Individual Oral Presentations

Effects of anxiety on working memory

SCOTT, E. (Bond University), EDWARDS, M. (Bond University)

Despite considerable research demonstrating the differential effects of state and trait anxiety on working memory performance, little research has investigated the mechanisms which might underpin this relationship. Premised on the Processing Efficiency Theory (PET; Eysenck & Calvo, 1992), which predicts that elevated state anxiety might contribute to deficits in working memory (WM) performance, the present study examined the effect of state and trait anxiety on the functioning of the central executive (reading span task), visuo-spatial sketchpad (analogical mapping task) and phonological loop (forward and backward digit span tasks) components of WM (Baddeley & Hitch, 1974). A student sample was employed and participants were assigned to High Trait Anxious (HTA; n=30) or Low Trait Anxious (LTA; n=30) groups based on a median split of scores on the State-Trait Anxiety Inventory (STAI), with state anxiety manipulated through the threat of electric shock. Half the participants in each Trait Anxiety group were randomly assigned to the Shock Threat and Shock Safe Conditions based on their arrival at the laboratory. Contrary to PET’s claim, there were no significant state or trait anxiety group differences on phonological loop performance as indexed by a digit span task. In support of PET, however, participants in the Shock Threat Condition recalled fewer last words and cloze test words than participants in the Shock Safe Condition (Daneman & Carpenter, 1980) on a reading span task which was employed to tap the central executive. In partial support for PET, significant Trait Anxiety x Shock Condition interactions were found on mapping tasks (Tohill & Holyoak, 2000) utilized to tap visuo-spatial sketchpad performance. The pattern of these interactions suggests that elevated state anxiety might contribute to performance dissociations on visuo-spatial tasks, but that this effect is moderated by the individual’s trait anxiety status. Results are discussed in terms of PET and clinical implications are suggested.

Effects of diabetes knowledge, attitudes, and self-management on satisfaction and the impact of diabetes

KUEH, Y. (Victoria University), MORRIS, T. (Victoria University), TOPLISS, D. (The Alfred, Melbourne), NUGENT, P. (The Alfred, Melbourne)

The challenge that Type 2 Diabetes Mellitus presents to individuals, families, and health services is substantial. It is important to identify the most effective strategies to manage diabetes and reduce the occurrence of complications. Psychological measurement in diabetes has been widely studied and developed, but research examining the links between diabetes...
knowledge, attitudes, self-management, the impact of diabetes, and satisfaction is scarce. The main objective of this research is to identify the relationship between knowledge, attitudes, and self-management and their effect on satisfaction and the impact of diabetes. Through the Department of Endocrinology and Diabetes, Alfred Hospital, Melbourne, we mailed out 500 questionnaire packs, including measures of diabetes knowledge (DKN), attitudes (ATT39), self-management (SDSCA), and quality of life (DQoL) to people with Type 2 diabetes. DQoL of patients treated at the hospital was evaluated based on their satisfaction, impact of diabetes, and social and diabetes worry. We analyzed 100 usable sets. Approximately 45% of the participants were women and 55% were men, aged between 30 and 70 years. Due to missing values for the social worry subscale in the DQoL, only satisfaction and diabetes impact subscales were used for analysis. We applied Structural Equation Modeling (SEM) to explore the interrelationships of the variables, using AMOS 17.0. The mean age of participants was 58.3 (± 10.82 years). Participants’ mean time since diagnosis with diabetes was 12.5 years (± 9.15 years). Results of the study revealed that self-management (p < 0.05) and the impact of diabetes (p < 0.05) were significant predictors of satisfaction, whereas, attitude to having diabetes affected the impact of diabetes (p < 0.05). The indexes of fit for the tested model indicated a good fit: TLI=1.03, CFI=1.00, GFI=0.99, AGFI=0.96, RMSEA<0.01, and X2 (2) = 1.43, p=0.49. Greater understanding of the relationships between knowledge, attitudes, and self-management, and their impact on quality of life in people with diabetes is important for developing appropriate strategies for diabetes management that can be tested through interventions in future research. We discuss implications of these findings for self-management and its impact on QoL in people with type 2 diabetes.

Keywords: diabetes, knowledge, attitudes, self-management, satisfaction

Effects of reading various genres of books on empathy: A panel survey of elementary and junior high school students

SUZUKI, K. (University of Tsukuba)

The purpose of this study is to examine the longitudinal effects of reading books on empathy. A panel survey was conducted with a total 933 elementary school students and 450 junior high school students. They were asked to indicate their frequency of reading all genres, such as picture books, fantasy, science fiction, adventure and historical fiction, mystery, old tales, biography, instruction guides, illustrated books, dictionaries, text books, books about hobbies, comic books, magazines, and rule books for video games, and their empathy. A multiple regression model was constructed to examine the causal relationship between each genre's reading frequency and students' empathy. The results showed that elementary school students' frequent reading of fantasy, adventure, and historical fiction, illustrated books and dictionaries, and text books increased their score on measures of empathy or some subcategories of empathy. Junior high school students' reading of science fiction and mystery increased their score on measures of some subcategories of empathy, whereas their frequent reading of picture books decreased their score on measures of a subcategory of empathy. Depending on genres of reading books, the empathy in the students of elementary and junior high schools increased and decreased.

Keywords: empathy, reading, longitudinal effects, genres, school children

Effects of social relations to parents and teachers on the changes of students’ perceived instrumentality

SHIN, J. (Seoul National University), SEO, E. (Seoul National University), HWANG, H. (Seoul National University), CHOI, Y. (Dept. of Education, Seoul National University)

Perceived Instrumentality (PI) is an important motivation factor for students to regulate their school work. Research has shown that PI has positive effects on students’ study efforts and achievements (Creten, Lens & Simons, 2001; Simons, Dewitte, & Lens, 2004). Recently, there has been increased research interest in what
increases PI on school work for future goals students hope to accomplish in society after graduation. In this study, we examined the effects of social relations to parents and teachers on the changes of students’ PI over time by using a longitudinal data set. Parents and teachers are significant others who have huge impact on students’ learning and motivation; therefore, it is necessary to investigate their influences on students’ PI changes over time. A four-year longitudinal data was analyzed by using the Hierarchical Linear Modeling technique. Parents’ and teachers’ expectations on students’ school works and their career guides were used as predictors which were measured in the first year of data collection. The change measure of students’ PI over a 4-year period was a dependent variable in the analysis. A total of 6,908 students in grade 7 were followed for 4 years until they became 11th graders. They were selected from 150 junior-high schools. The PI had been increased over a 4-year period. The growth pattern turned out to be negatively quadratic over time. For the initial status of PI, parents’ expectations and career guides were significantly positive predictors; the variable of teachers’ expectations was a significant predictor, but the measure of their career guides was not. For the linear growth rate of PI, only parents’ and teachers’ expectations were significant and the other predictors were not. The two predictors were also significant predictors on the quadratic term of the PI change rates in a negative way. The results of the study show that parents’ and teachers’ expectations had significant influences on the increased changes of students’ PI over time. In contrast, their career guides did not have any effects on the changes. The results suggest that expectations of significant others on students’ school works would increase their perceptions on why they have to study hard in school over time. However, their career guides did not make any differences in the PI changes in the study. The reason might be that their career guides were not specific much or that the life goals students had then would be built up in earlier ages so that later career guides from parents and teachers did not have much impact on the PI changes. Regarding these interpretations, further empirical investigations are necessary.

Keywords: perceived instrumentality, students, social relationships, parents, teachers

Effects of the key steps and non-key steps in worked example learning about algebraic operations

Qi, Z. (Liaoning Normal University), HONGXIN, L. (Liaoning Normal University)

Paas (1992) found that the learning effects between incomplete and complete worked examples were not obviously different, but Stark (1999) discovered that the learning effects of incomplete worked examples were better than complete worked examples. We analyzed these previous studies and proposed that the learning effects of key steps in worked examples determined the worked example learning effects. This means that if learners understood the key steps, they would master the worked examples. Conversely, if they didn’t understand the key steps, they would not get through the worked examples. In the first experiment, 120 seventh grade students chosen with a pre-test were shown four kinds of incomplete worked examples about absolute value inequality operation and were requested to fill out the deleted steps. Then, another 90 seventh grade students were separately shown and learnt complete worked examples (CWE), incomplete worked examples with a deleted a key step (IWEK) or incomplete worked examples with a deleted a non-key step (IWEN), and took part in the post-tests. In the second experiment, firstly, 90 seventh grade students were shown three kinds of incomplete worked examples about powers with the same base operation individually and were requested to fill up the deleted steps. Then, another 60 seventh grade students were respectively shown CWE or incomplete worked examples which deleted the key step (IWEKF), and were given timely feedback (IWEKF), and participated in the post-tests. The third experiment was about the extraction operation worked example learning, and the experiment design and procedure were the same as the second experiment. The first experiment showed that the learning effects of CWE and IWEN were better than IWEK, and there was no significant difference between CWE and IWEN. The second experiment showed that the learning effects of IWEKF were
obviously higher than CWE, but in the third experiment, there was no significant difference between IWEKF and CWE. From the results, we concluded that the key steps significantly influenced effects of the incomplete worked example learning, and the non-key steps had no obvious effect on the incomplete worked example learning. The incomplete worked example learning with feedback could improve the learning effects of powers with the same base operation, but couldn’t improve the learning effects of extraction operation.

Keywords: key steps, worked example, learning

Effort-reward Imbalance and psychological health: The impact of offshore working in the oil and gas industry

COWAN, S. (University of Abertay Dundee), GUISE, J. (University of Abertay Dundee), STEVE, M. (University of Abertay Dundee)

The oil and gas industry plays a vital, global, economic role, in terms of the financial benefits deriving from the extraction of oil and gas reserves, and the substantial workforce employed by the operations that support the industry. However, the UK North Sea sector of this industry currently faces serious staff recruitment and retention problems. It has been suggested that this may be, in part, due to the psychological stress of offshore working. The impact on psychological health of offshore working is therefore an important area of investigation. However, to date little research has been done in this area. This paper reports part of a large-scale, mixed methodological study that sought to explore these issues. Our aim here is to examine the impact of offshore working on the health of UK sector oil and gas employees, using the Effort-Reward Imbalance model (Siegrist et al., 1997). A cross-sectional, questionnaire postal survey of 2,300 UK sector, offshore employees was conducted; 732 questionnaires were returned, giving a response rate of 32%. A battery of questionnaires included: the Effort-Reward Imbalance at Work Questionnaire (incorporating Over-commitment); the 12-item, General Health Questionnaire as a measure of psychological health; offshore quality of life and family contact measures derived from focus groups conducted in the qualitative stage of our study. Hierarchical regression analyses were conducted. Effort-reward imbalance was independently associated with psychological health at a highly significant level ($p < 0.001$). When over-commitment was added, these two variables accounted for 24% of the variance in psychological health ($p < 0.001$). Offshore quality of life contributed a further 6% ($p < 0.001$). Family contact did not, however, significantly add to the explanatory power of the model. Effort-reward imbalance, over-commitment and offshore quality of life are important contributory factors to the psychological health of offshore workers, and these are, to varying degrees, modifiable. It is anticipated that the findings of this study will be of use to employers who are concerned with the recruitment and retention of offshore staff.

Keywords: oil and gas industry, staff recruitment, staff retention, psychological stress, Effort-Reward Imbalance model

Elicitation of expert opinion concerning uncertain events: Using a 4-step question format, DELPHI workshops, and an online elicitation tool

SPEIRS-BRIDGE, A. (University of Melbourne)

The current study aimed to develop an elicitation protocol to help minimize cognitive biases in expert judgements of uncertain events. We used a 4-step question format to reduce overconfidence in interval judgements. This was embedded in a DELPHI facilitated workshop to minimise any halo effect in the expert panels. A purpose built online elicitation tool was used to capture and display the interval judgements, to facilitate discussion in the workshops. DELPHI workshops were run on diverse topics including the impact of new pharmaceuticals on recycled water quality and environmental factors influencing species extinction in frogs. Workshops included between 8 and 12 experts and 40 to 60 questions. Domain specific calibration questions, with known answers, were interspersed with elicitation questions regarding unknown or future events. For each question, expert’s first entered their private interval
judgements into the online elicitation tool using the 4-step question format. The intervals for all panel members were then displayed on a single chart, and the facilitator encouraged discussion regarding: the similarities and differences of opinion; and the background knowledge which informed judgements. Post discussion, panel members had an opportunity to privately update their estimates in the online tool. The post-discussion estimates were taken as the final judgements, and the calibration questions used to assess a panel’s accuracy. Final interval judgements may be aggregated for a group judgement using statistical techniques, or the visual overlap between intervals used as an indicator of panel consensus, or lack thereof. The 4-step question format has been shown to substantially reduce overconfidence in experts from multiple disciplines (N=135, 17% [95% CI 13, 21]). By combining the 4-step format with the DELPHI workshop protocol, final expert judgements were calibrated to be 63% [59, 67], that is to say the expert panel provided interval judgements which captured the true value (when known) 63% of the time. Using the 4-step question format to reduce overconfidence, and the DELPHI workshop to reduce halo effects, cognitive biases can be minimised improving the calibration of the expert panels. Furthermore by leveraging an online elicitation tool virtual expert panels become feasible and practical, both reducing the cost of elicitation and improving levels of participation.

Keywords: elicitation protocol, cognitive bias, expert judgements, uncertainty

Emotional and behavioral responses to terrorism threat

WEISS, D. (California State University, Los Angeles), JOHN, R. (University of Southern California), ROSOFF, H. (University of Southern California), BAUMERT, T. (Universidad Complutense de Madrid), SHAVIT, T. (The College of Management), ROSENBOIM, M. (Ben-Gurion University of the Negev), BUESA, M. (Universidad Complutense de Madrid), VALINO, A. (Universidad Complutense de Madrid)

We conducted two bi-national studies of emotional and behavioral responses to terrorism threat, examining both feelings and projected action. The studies employed scenarios in which terrorists were planning to shoot, or had already shot, MANPADS (shoulder-fired missiles) at commercial airliners as they were taking off from the airport. The scenarios included two factorially crossed variables, each with three levels: (1) government announcements regarding threat severity and (2) public response, expressed as variation in airline ticket sales. In Study 1, conducted in California and Spain, the threat was expressed as a plot that had been discovered in the planning stage. In Study 2, conducted in California and Israel, the threat was more severe, consisting of an escalating series of attacks on planes. There were 216 participants from each country in both studies. In California, the respondents had no personal experience with terrorist attacks; while in Spain and Israel there have been dramatic incidents with which the respondents were familiar. Most respondents were students, except that in Spain we were able to also recruit people from a national registry of terrorism victims. Each subject saw only one of the nine scenarios. After presenting the information in the scenario, we asked them to imagine they had planned a trip to a destination 1500 miles away. We regarded that as sufficient for other modes of transportation to be inconvenient. The importance of the trip was varied within subjects; the trips were to a close friend’s wedding, a job interview, or a family vacation. In Study 1, respondents expressed only moderate fear, and most indicated they would fly as planned. In Study 2, the fear was elevated as the attacks escalated, and more trips were cancelled. Government announcements and ticket sales had little impact on either fear or planned flying. People were more likely to fly to the wedding or job interview than for the vacation. Emotions show more responsiveness to threat than actions. An important feature of attacks on commercial flights is that, unlike biological attacks or bombs in public places, degree of exposure to the risk is under personal control; one can simply refuse to fly.

Emotional intelligence cross-cultural assessment: Adaptation and validation of an Argentinean version of the TEIQue (trait emotional intelligence questionnaire; Furnham & Petrides, 2003)

MIKULIC, I. (University of Buenos Aires), CASSULLO, G. (University of Buenos Aires), CRESPI, M. (University of Buenos Aires)

School desertion is the result of a combination of internal and external factors. The causes of school desertion are multiple but in all cases create the conditions of failure of social integration, as it reduces significant chances of personal realization. The present study shows the importance of evaluating quality of life of adolescents undergoing “ecological transition” (Bronfenbrenner, 1979) from primary to secondary in order to understand this phenomena. As in Argentinean public schools adolescents tend not to continue their studies it is crucial to invest in research on this issue. Following a descriptive design, 500 adolescents participated in answering five inventories specially designed for this research. Ages ranged from 13 to 15 years, consisting of 250 men and 250 women. 68 teachers of these adolescents also participated. Instruments selected were: PQofLI-Perceived Quality of Life Inventory (Mikulic, 2001); CPI-Coping Response Inventory (Moos,1993); LISRES-Life Stressors and Social Resources Inventory (Moos, 1994); SIASCA-Structured Interview to Assess Strength in Children and Adolescents (Mikulic, 2001) and SIATP- Structured Interview to Assess Teachers Practices (2007). The Perceived Quality of Life Profile shows specific configuration of factors regarding adolescents and environments. Also, importance and satisfaction with life shows differences according to gender. Data obtained suggests that adolescents’ resources and their teachers’ characteristics are resilient sources. Parents, siblings and friends are perceived as an important resource but when importance and satisfaction with life assessed turn out to be a conflict factor. There is only one convergent factor regarding perceived quality of life in adolescents and it is “teachers as resilient guides”. Importance and satisfaction with life correspondence indicates that students assign high importance to teachers’ role and school context. Family and school context and climate represent two significant factors in promoting adolescent resiliency. Specifically, teachers guide as a medium to develop resiliency and convey hope is an important factor to prevent school desertion.

Emotional-social Intelligence and dyadic adjustment of couples

DINCA, M. (University Titu Maiorescu), ILIESCU, D. (The SNSPA University at Bucharest), MIHALCEA, A. (Titu Maiorescu University at Bucharest)

Bar-On (2009) hypothesized that those individuals with higher than average emotional-social intelligence (EQ-i) are in general more successful in meeting environmental demands and pressures. He also notes that a deficiency in EQ-i can mean a lack of success and the existence of emotional problems. In 1976, Spanier created an instrument to measure the separate components of marital adjustment and called it the Dyadic Adjustment Scale (DAS). The separate dimensions of marital adjustment were reported to be the following: (a) consensus on matters of importance to marital functioning, (b) dyadic satisfaction, (c) dyadic cohesion, and (d) affectional expression. The purpose of this study is to explore whether the level of emotional-social intelligence of the partners influences the dyadic adjustment marital relationships. 90 couples (50% males and 50% females) aged 32 to 59 years completed the Dyadic Adjustment Scale (Spanier, 2009) and Emotion Quotient Inventory (Bar-On, 2009). This study examined relationships between emotional-social intelligence and different patterns of marital interaction. Correlations and hierarchical moderated regression analysis show that emotional intelligence differentiates dyadic satisfaction, consensus and cohesion of couples but not the affectional expression. The results provide different pattern of marital interaction and emotional intelligence for males and females. These findings are important for clinicians and researchers, for family counseling and psychotherapy revealing important information about the influence of emotional intelligence on couple relationships.
**Keywords:** emotional-social intelligence, marital adjustment, dyadic adjustment

**Enabling formalization, collective mood, and team performance: Testing a dynamic mediated longitudinal relationship**

GONZALEZ-ROMA, V. (University of Valencia), GAMERO, N. (University of Seville), FORTES, L. (Polytechnic Institute of Setubal), PEIRO, J. M. (University of Valencia)

The objective of this study is to test a dynamic mediated relationship that involves the following hypotheses: that change in work team climate of enabling formalization over time is positively related to change in perceived team performance over time, and secondly, the aforementioned relationship is partially mediated by change in collective mood (job tension) over time, so that change in enabling formalization is negatively related to change in collective job tension, which in turn is negatively related to change in perceived team performance. A sample of 174 work teams participated in the study. Data were gathered at three time points along a 2-year period. The study variables were operationalized at the team level. The data were analyzed by means of hierarchical linear modeling. The study hierarchical models were estimated by using the Multilevel module of Prelis/Lisrel 8.80. The results obtained supported the study hypotheses. Change in enabling formalization was positively related to change in perceived team performance (.15, \(p<.01\)), and negatively related to collective mood (job tension, -.15, \(p<.05\)). Moreover, after controlling for change in enabling formalization, collective tension was negatively related to perceived team performance (-.13, \(p<.01\)). The indirect effect of change in enabling formalization on change in perceived team performance via change in collective tension was statistically significant. Adler and Borys (1996) proposed to distinguish between two distinct types of formalization (coercive and enabling) to disentangle the inconsistent pattern of relationships shown by this variable. Our study confirms that enabling formalization is beneficial in the sample of work teams investigated, since it contributes to improving work team performance and reducing job tension. The analytical strategy used and the results obtained support the idea that the addressed relationships are dynamic and develop over time.

**Keywords:** work teams, formalization, team performance, collective mood, job tension

**Ensuring test security in online assessment for recruitment**

BARTRAM, D. (SHL Group Ltd)

Two main types of tests are used in recruitment settings. On the one hand there are tests of maximum performance where items have right and wrong answers. On the other hand are tests of typical performance or preference, where there are no ‘right’ answers. This presentation considers how each of these types of assessment instrument poses different problems for the recruiter. The solutions necessary to reduce the likelihood of faking good on preference measures are very different to those needed for reducing the risk of cheating on measures of ability. The solutions adopted by SHL to each of these challenges will be illustrated with the Verify suite of ability tests and the OPQ32r personality inventory. The former uses test generation techniques to create novel instruments for each test taker and it includes a provision for a follow up supervised assessment for short-listed applicants. In addition procedures are in place to add further layers of security to protect the items against compromise and to maintain the validity of assessment scores. These layers include web patrols and data forensics analyses. The former involves regular proactive searching of the Internet for the presence of test items and procedures for ensuring their removal. The latter relates to methods of analysis used to check the item response data for indicators of aberrant responding patterns. For preference measures, lack of supervision is not the issue as faking good is ‘invisible’ and can take place as easily under supervision as when there is no supervision. Instead, item format and scoring methods are used to reduce the ease with which someone can fake good. This is embedded in a large set of procedures for reducing both the means and the
opportunity applicants might have for distorting their data.

Keywords: online assessment, recruitment, maximum performance, typical performance, faking

Environmental attitude of New Zealand farmers: The importance of affect and direct contact with nature

DURPOIX, D. (Massey University)

The first aim was to assess the relevance of a tripartite attitude model to assess farmers’ attitude towards the natural environment, and of particular interest was the affective attitudinal component, so commonly absent from environmental attitude models. The second aim was to examine the extent to which direct experience with nature determined farmers’ attitude towards the environment, and notably, how it related with the affective attitudinal component. Models were assessed using the Structural Equation Modeling framework. Models were compared between New Zealand farmers who did not have native forest fragments on their property and farmers who had forest fragments; and within the group of farmers with fragments, farmers with forest fragments by choice were compared to farmers with fragments by chance. Farmers’ attitude model was constituted of two parts. The first part assessed farmers’ general attitude towards the natural environment, measured by Dunlap and colleagues’ (2000) New Ecological Paradigm (NEP) scale and Schultz’ (2001) Environmental Motives Scale (EMS). The second represented farmers’ specific attitude towards New Zealand native forest using a tripartite attitudinal model, defined by cognitive, affective and conative (behavioural intentions) dimensions. Direct experience with nature included frequency of direct contacts with New Zealand forest and frequencies of outdoor recreational activities. We found that farmers with and without forest fragments responded to different attitudinal models. The attitude construct of farmers without forest fragment suggested that they perceived native forest differently whether it was on farmland or outside, whereas farmers with fragments presented a more integrated attitude towards the forest. Also, the affective attitudinal response of farmers without fragments was more cognitively-driven than for farmers with fragments. Direct experience with nature had a strong and positive impact on farmers’ environmental attitude in general. However, the strongest effect of direct experience with nature occurred with farmers’ affective response. Thus, farmers with forest by choice and farmers with forest by chance with the same amount of direct experience with nature showed almost equal affective response, but still different levels of pro-environmental beliefs. These results showed that a tripartite attitudinal model including an affective dimension was relevant to the assessment of farmers’ attitude towards the natural environment. They also suggested the importance of direct contact with nature in explaining farmers’ pro-environmental attitude.

Keywords: environmental attitudes, New Zealand farmers, affect

Environmental risk perception: The case of global warming among lay people

DE CAUSANS, A. (LPA University of Reims Champagne Ardennes)

The aim of this study is to understand public perception of environmental risk, by exploring the social representation of Global Warming linked to environmental concern, personal involvement and conservation behavior. A Web questionnaire has been conducted among a sample divided in three groups based on environmental concern scores (Dunlap, Mertig, & Jones, 2000): pro-environment member of environmental association, pro-environment non-member, and “against environment”. The social representations are examined by the free association method and a prototypical analysis (Vergès, 1985) coupled with an SCB characterization (Guimmelli, Rouquette, 2003). The three independent level of personal involvement (Flament, Rouquette 2003): personal identification, valorization of the issue, and action perceived ability, are studied as mediator variable in the investigation between social representation and behavior. Global Pro-environmental behavior is measured as a
complex assemblage of specific behavior. Pro-environmental behaviors are conditioned by the social representation of environmental issues, as the social representation emerges from a range of behavior, and communication in a specific social group. The specific association produced by each group shows this double link. If the “pro-environmental” activist as lay people evokes spontaneously the scientific causes as the consequences of global warming, they differ with a strong presence of catastrophic expressions among lay people. Meanwhile the “against-environment” refers to political fallout and evokes skepticism. Furthermore we can observe that a strong personal involvement seems to be essential to allow people to adopt real pro environmental behavior. This study shows how risk communication could be counter-productive when even informed and concerned people are slowed in their conservation behavior by information stressing dramatic consequences without giving efficient coping strategy in order to increase action’s perceived ability. Therefore, we are proposing a strategy based on the manipulation of the personal involvement dimensions in order to promote global conservation behavior and by this way influence the emergence of a new social representation taking account of the green-action we have to promote to face Global Warming.

Envisioning engagement: Social representations of public engagement with renewable energy technologies

DEVINE-WRIGHT, H. (Placewise Ltd), DEVINE-WRIGHT, H. (Placewise Ltd), DEVINE-WRIGHT, P. (University of Exeter)

UK energy policy to reduce carbon emissions is rapidly evolving. A substantial increase in renewable energy technologies (RETs) such as wind turbines, biomass plants and solar panels has been proposed but little is known about how these policy changes are being communicated to the public. This study aimed to investigate changes over time in the way in which newspaper images anchor and objectify public engagement with renewable energy technologies. This paper draws upon the theory of social representations to explore how public engagement with renewable energy technologies is represented within newspaper images. Images of RETs were collected from stratified sample of UK national newspapers over a two-year period. These images were thematically analysed. Wind turbines were the most frequently depicted renewable energy technology. Representations of renewable energy technologies shifted from illustrative depictions of experts with actual RETs toward symbolic images of lay people with renewable energy especially within energy company advertisements. Objectifying wind as a symbol of renewable energy per se may mitigate against greater public awareness of alternative renewable energy sources. Whilst there are a variety of image formats that can be used to communicate about renewable energy policy e.g. cartoons, photographs, diagrams, each is anchored to a particular domain e.g. cartoons with political satire. This has implications for promoting public engagement with renewable energy policy and practise.

Essential role of consciousness in control of cognitive processing in cognitive system theory

BURTON, P. (Australian Catholic University)

Human consciousness, the relationship between the mind and the brain, and the nature of knowledge all await fundamental new insight before a scientific account of human cognition can be settled. To this end I have sought to sketch some significant new concepts that have emerged from fivefold axiomatic analysis of this very complex domain, particularly in relation to cognition itself, and to the nature of mind-brain interaction. In a tightly interlocking and nested theoretical framework, diverse evidence converges to a single unequivocal conclusion about the nature and role of consciousness in human cognition. Consciousness, in its richly varied forms, invariably is directly and intimately
engaged in cognitive processes, because such processes invariably require some means of control: consciousness provides the means of that control; consciousness is that control. This paper will outline the functional contribution of consciousness to cognitive processing, and provide an operational elucidation, together with supporting mechanisms linked to specific brain activity, to explain how cognitive processing develops through major transitional phases as each individual matures. In particular, basic human cognition, at first similar to the processing of other mammals, is shown to respond to an exogenous form of control vehicle whose remarkable efficacy leads to the introduction of new kinds of sequenced and punctuated cognition. The major survival benefit of this elaborated cognitive competence is to catalyse the introduction of deliberate navigational tasking associated with the self-model to complement a default and reactively instrumental form of challenge response. At each stage of advanced cognitive processing, it is the emerging flexibility of new kinds of conscious control over cognition that lead each transition. The ultimate transition to self-conscious control is formulated upon a previously un-described form of internal perspective-taking over many forms of knowledge, which serves in the case of the self-model to afford a particular two-dimensional field of control over navigational tasking which subsumes simpler forms of conscious control. A simple heuristic is identified whereby the operational self-model systematically invests in the behavioral repertoire subserving increasingly intelligent performance.

**Evaluating the effect of didactic versus experiential intercultural training on the intercultural competence of university students**

BEHRND, V. (Dresden University of Technology)

Universities sometimes provide language classes and area studies which are didactic instead of experiential intercultural training. We assumed that the effect of area studies in the combination with language classes equals the effect of didactic intercultural training and that didactic and experiential intercultural training foster intercultural competence. We measured intercultural competence before and after experiential intercultural training with university students that already had received didactic training, plus another experiential group that had not received didactic training, and a control group. In study one, intercultural competence was measured on the behavioral level of evaluation with an instrument consisting of critical incidents in the sub-domains individual, social, and strategic intercultural competence, and the use of problem solving. Study two measured cognitive, affective, and behavioural intercultural competence by a theory-based questionnaire on the learning level of evaluation. An impact of the didactic preparation was found for cognitive intercultural competence in the second study. The theory-based questionnaire on the learning level of evaluation seems to be able to detect the competencies that can be developed by didactic intercultural training. The experiential training had a significant influence on individual, social, and strategic intercultural competence, and on problem solving in both experiential training groups in study one and on affective and behaviour competence in study two. The pre-post differences and their tendency to become significant were higher in the group with didactic preparation. We conclude that experiential training does foster intercultural competence and that didactic intercultural training should be supplemented by experiential intercultural training.

**Evaluating the effectiveness of a counselling service utilising online technologies**

This prospective pilot-study explores the effectiveness of an Australian counselling service
for people with depression, utilising online technologies. The study seeks to: 1) evaluate the effectiveness of the counselling processes utilising online technologies, and 2) evaluate the technologies employed to facilitate counselling. Eligible clients and the counselling team are invited to participate, with a minimum of 20 pairs intended for inclusion. Participants will engage in eight counselling sessions incorporating synchronous and asynchronous dialogue. A mixed method collection of data at pre- and post-counselling will be employed, including psychometric assessments and client and counsellor evaluative feedback forms. The clinical efficacy of the counselling processes will be evaluated at pre- and post-counselling using the World Health Organization’s Major Depression Index and Wellbeing scales. The therapeutic efficacy will be evaluated with regard to the working relationships, goal achievement, coping-skills, and self-esteem. Counselling through the provision of online technologies is predicted to be both clinically and therapeutically efficacious. The potential of the technologies to facilitate the counselling will also be explored. It is predicted that the technologies employed will be effective means of facilitating counselling. Findings of the study will be used to inform best practice, improve services, and provide a foundation for future research on Internet-based counselling efficacy.

**Keywords:** perceptions, counselling, depression, online technologies

**Evaluation of the telephone cognitive behavioural therapy component of the Australian access to allied psychological services (ATAPS) projects**

BASSILIOS, B. (The University of Melbourne), KING, K. (University of Melbourne), FLETCHER, J. (University of Melbourne), KÖHN, F. (University of Melbourne), BLASHKI, G. (University of Melbourne), BURGESS, P. (University of Melbourne), PIRKIS, J. (University of Melbourne)

The Access to Allied Psychological Services (ATAPS) projects, implemented by Divisions of General Practice, enable general practitioners (GPs) to refer consumers with high prevalence disorders (e.g., depression and anxiety) to allied health professionals for up to 12 (or 18 in exceptional circumstances) sessions of mental health care. Interventions are evidence-based, focused psychological strategies and cognitive behavioural therapy. In July 2008, the Department of Health and Ageing provided new funding for a trial of telephone-cognitive behavioural therapy (CBT) to 22 rural and remote Divisions of General Practice under the existing ATAPS model. The trial was introduced as a means to assist consumers to overcome geographical and other access barriers. This presentation will describe the evaluation findings of the trial. Data sources include a web-based minimum data set which collects consumer- and session-based data on the projects. Quantitative and qualitative data from and purpose designed interviews with project officers and providers also inform the evaluation. Uptake of the telephone-CBT trial is underestimated by the minimum data set. Telephone sessions are being delivered more widely across the ATAPS projects and not just within the T-CBT pilot. The majority of consumers are females, aged around 40 years, and are on low incomes. The majority of consumers are diagnosed with depressive or anxiety disorders. The majority of sessions are an hour in duration, with an average number of four sessions delivered per consumer. Despite a general consensus among stakeholders that face-to-face treatment is preferred, it is acknowledged that the telephone-CBT modality is particularly valuable for consumers for whom no other option exists. Accordingly, Divisions are keen for the service to continue.

**Evaluation of treatments provided by clinical psychology interns using videoconferencing**

DUNSTAN, D. (University of New England), TOOTH, S. (University of New England)

The aim of the study was to evaluate the effectiveness of psychological treatment, delivered via videoconferencing by clinical interns, for the two of the most prevalent mental health conditions in Australia: anxiety...
and depression. A noncurrent, multiple baseline design across subjects and settings was used. Six patients suffering from anxiety and/or depression were referred to a university psychology clinic and received six sessions of treatment via videoconferencing or face-to-face therapy. A number of treatment outcome and treatment process measures were used. Continuous data measuring subjective well-being was analysed using a single case, time-series simulation modelling methodology. Individual outcome measure scores, covering the domains of symptomology (DASS-42) and life functioning (OQ-45), were evaluated for meaningful change using a two-step criterion method. 100% of videoconferencing participants achieved a significant improvement in subjective well-being from baseline to follow-up. In addition, 66% of participants showed a clinically significant and reliable reduction in self-report scores on symptoms of depression and/or anxiety, 66% of participants also showed a clinically significant and statistically reliable reduction in self-report scores on disturbance of life functioning. These outcomes were commensurate with those of participants receiving face-to-face treatment. Clinical psychology interns can deliver effective treatment via videoconferencing with equivalence to face-to-face therapy. The use of videoconferencing as a treatment modality and delivered via university clinics has potential training and public health benefits.

Keywords: psychological treatment, videoconferencing, anxiety, depression, subjective well-being

Evaluation of yoga as a mind body approach for certain ailments

NITHYANANDAM, L. (Department of Ageing, Disability & Home Care (DADHC))

Dissatisfied with modern medicine, many clients are turning to alternative and complementary therapies, especially mind body approaches, discovering that they receive a more successful and satisfying experience in these. In this endeavour, Yoga, an ancient mind body system that serves both as a preventative and a cure, came into the limelight. However, the scope of this system has not been really scientifically exploited. This study is an attempt to investigate the Therapeutic role of Yoga for various disorders. It specifically purports to answer the following research questions. (1) Is Yoga effective as a therapy for various ailments? (2) If so, for which specific ailments? (3) Is it effective as a supportive Complementary Therapy or as a stand-alone Alternative Therapy or Both? (4) Is its effectiveness independent or dependent on the number of associated minor symptoms? 88 patients with a clinical diagnosis did a subjective rating of their clinical symptoms for a period of 2 months to establish a baseline in this quasi experimental design so as to serve as control. After that, they were given Yoga training for a period of 3 months and evaluations done each month, were considered for the study. To answer the Research questions the patients were grouped under different categories and a Before and After Experimental Design with repeated measures was used. The results showed that Yoga has been effective in improving the health status by way of reported reduction in symptoms. Of the 13 clinical conditions considered, Yoga had been effective for 10 clinical conditions within a period of 3 months. The study also showed that it can function as a Complementary therapy as well as can also be an Alternate system based on the clinical condition. Finally its effectiveness is independent of the number of symptoms a person has. Yoga is a potent therapeutic tool for various ailments as the patients are proactive in their own healing.

Evidence of impaired event-based prospective memory in clinical obsessive compulsive checking

HARRIS, L. (University of Sydney), VACCARO, L. (University of Sydney), JONES, M. (University of Sydney), BOOTS, G. (University of Sydney)

Based on their work with subclinical OCD checking Cuttler and Graf (2009) suggested that checking may develop to compensate for prospective memory failures. This study examined prospective memory performance,
confidence in memory, and subjective complaints about prospective and retrospective memory in a sample with clinical OCD checking. A group with OCD checking \((n=26)\) was compared to a matched control group \((n=26)\) on a time-based and an event-based prospective memory test, memory confidence ratings, and scores on a measure of subjective memory complaints. The OCD group performed worse than controls on the event-based prospective memory task. There was no difference between the groups in subjective complaints about memory. The OCD group was more confident on both the event-based task and the time-based task. Cuttler and Graf (2009) argued that checking is a consequence of poor prospective memory coupled with awareness of prospective memory failures and concern about these failures. The present study found no evidence of more complaints about either prospective or retrospective memory in the past six months among OCD checkers compared to controls. In fact, checkers expressed greater confidence in their event-based prospective memory than controls and predicted that they would be more accurate on the time-based prospective memory task. This latter finding appeared to be due to the availability of an extrinsic checking strategy for ensuring success. It is possible that concern about prospective memory failures is important in the early development of checking compulsions, but that, over time, checking becomes a habitual (and successful) strategy for avoiding prospective memory failures. This explanation accounts for the present findings of (a) no deficit on the time-based prospective memory task where the OCD group were checking more often in the 10 minutes before the response was required and performance was no worse than that of controls; and (b) no difference between the groups in complaints about prospective memory in the last six months. Further research assessing both subjective memory performance and the strategies understood to support memory is needed to clarify the contribution of prospective memory to OCD checking.

Keywords: memory impairments, obsessive compulsive disorder

**Examining the psychometric properties of the restraint scale (RS-10) among Hong Kong Chinese adolescents**

LAI, C. (The Chinese University of Hong Kong)

The Revised Restraint Scale (RS-10; Herman, & Polivy, 1980) is a widely used measure for dieting tendency. Ample previous studies have examined the factor structure of the RS-10. However, there is still no agreement on its dimensionality and the factorial assignment of its items. This study aims to evaluate the factor structure and psychometric properties of the 10-item RS-10 for Hong Kong Chinese adolescents using exploratory (EFA) and confirmatory factor analysis (CFA). A total of 909 adolescents aged between 13 and 22 years (55.3% boys) completed an anthropometric (height and weight) datasheet, the RS-10, and the 26-item Eating Attitudes Test (EAT-26; Garner, Olmsted, Bohr, & Garfinkle, 1982). For cross-validity, the sample were randomly divided into two groups: one group for the EFA (S1: \(N=454\)) and the other group for the CFA (S2: \(N=455\)). Acceptable levels of internal consistency were observed for the total score of the RS-10 (\(\alpha=.71\)). Results of EFA revealed a three-factor solution, with interrelated concern for dieting, weight fluctuations, and food preoccupation factors in the S1. CFAs were then computed in the S2 comparing the three-factor model identified in S1 with other proposed models, which included the original Herman and Polivy’s (1975) ten-item two-factor model and van Strien et al.’s (2002) eight-item two-factor model. CFA model comparison supported that the exploratively obtained three-factor model from S1 provided the best fit to the data. Multigroup CFAs suggested the three-factor model is stable across genders, age groups, and weight statuses. The RS-10 also demonstrated good convergent validity, as suggested by its moderate correlations with the factors of fat concern and dieting (\(r=.48\)) and food preoccupation (\(r=.36\)) of the EAT-26 obtained previously in Chinese samples (Lee, & Lee, 1999). The factor structure of the RS-10 among Chinese adolescents is different from those obtained in previous studies with western samples. Nevertheless, findings evidence the RS-10 is a reliable and valid measurement of restraint eating for Chinese adolescents.
Keywords: revised restraint scale, adolescents, dieting tendency

Examining the role of personality factors and perceptions of the school as a learning organisation on workplace learning among teachers

TENGIKU ARIFFIN, T. (Universiti Utara Malaysia), AWANG HASHIM, R. (Universiti Utara Malaysia), YAHYA, K. (Universiti Utara Malaysia)

The study investigates the contribution of the Big Five personality factors (neuroticism, extraversion, openness, agreeableness and conscientiousness) and teachers' perceptions of the school as a learning organization towards the teachers' engagement in informal workplace learning activities. A structural model based on Kurt Lewin's Field Theory was proposed to explain how a person (in this case represented by personality factors) relates to his or her environment (or how one perceives the school as a learning organization), and thus, influence one's behavior in terms of engaging themselves in informal workplace learning activities. Sample involved a total of 400 schoolteachers who were selected through a multistage cluster analysis sampling procedure. The data analysis involved an adoption of the two-step procedure—the analysis of the overall measurement model through confirmatory factor analysis (CFA), followed by the analysis of the structural equation model (SEM). Results of the disattenuated correlations indicated that all five personality factors are significantly correlated with teachers' perceptions of the school as a learning organization. Besides that, three of five personality factors (extraversion, openness and conscientiousness), and teachers' perceptions of the school as a learning organization significantly influence teachers' engagement in workplace learning activities. Both the measurement model and the postulated structural model are acceptably fit models based a few fitness indexes (TLI & CFI values of more than .90; RMSEA & RMR values of less than .08). The findings support the reciprocal relationships between person (personality factors) and his or her environment (perceptions of the school as a learning organization), which influence his or her behaviour (engaging in workplace learning activities), as theoretically assumed in Lewin's Field Theory. The discussion focuses on the importance of highlighting personality factors and perceptions of the school as a learning organization as antecedents of workplace learning with regard to the use of personality as a selection tool and the adaptation of the learning organization concept in school as to enhance the practice of continuous professional development among teachers

Keywords: big five model of personality, teachers, school, learning activities

Examining the validity of driver prototypes using driving-specific measures of personality and coping

MACHIN, T. (University of Southern Queensland)

This research examines the validity of using driving-specific measures of personality and coping to develop driver prototypes. Previous research has used the Five-factor Model (FFM) of personality to classify drivers into three common configurations: resilient drivers, over-controlled drivers and under-controlled drivers. Self-report data from drivers were analysed using cluster analysis in order to determine whether a similar set of patterns emerged when driving-specific measures were used and whether these patterns were linked to driving behaviour and accidents. The 402 participants (323 females; 79 males) were mainly first to third year psychology students. The Driver Stress Inventory (DSI; Matthews, Desmond, Joyner, Carcary, & Gilliland, 1997) measured the following characteristics: Aggression, Hazard Monitoring, Thrill Seeking, Dislike of Driving, and Fatigue Proneness. The Driver Coping Questionnaire (DCQ; Matthews, et al., 1997) measured confrontive coping, task-focused coping, emotion-focused coping, reappraisal, and avoidance. All scales were found to be reliable with coefficient alphas of at least .70. Data were also obtained on the drivers' level of self-reported speeding (measured using six items with an alpha of .84), their number of near misses in the previous six months (one item), and their number of accidents in the last six months (one item). A two-step clustering procedure produced a result with three clusters in the solution. Cluster 1 ($N = 152$) was defined
by more maladaptive coping (higher confrontive, lower task-focused and lower reappraisal) and greater aggression and thrill-seeking. Cluster 2 (N = 150) was defined by more adaptive coping (lower confrontive, higher task-focused and higher reappraisal), lower aggression and greater hazard monitoring. The third cluster (N = 98) was defined by more moderate scores on the coping scales (apart from a much greater level of emotion-focused coping), higher dislike of driving, and higher fatigue proneness. Validation against the three outcome measures showed that cluster 2 reported significantly less self-reported speeding than cluster 3 which was significantly less than cluster 1. Cluster 2 also reported significantly smaller number of near misses than clusters 2 and 3. Cluster 2 reported significantly fewer accidents than cluster 3. The cluster analysis confirmed that three subtypes of drivers can be identified from driver-specific measures of personality and coping. These subtypes differ in their driving behaviour with one cluster being linked with better driving outcomes (cluster 2) while clusters 3 and 1 were most at risk of adverse outcomes. These clusters may also respond differently to road safety messages particularly as cluster 3 expressed a strong dislike of driving and greater emotional exhaustion from driving.

Keywords: personality, coping, driver prototypes, big five model of personality

Executive function development and stress effects on driving performance: Preliminary findings from a young adult sample

WHITE, M. (Queensland University of Technology / Centre for Accident Research and Road Safety - Queensland), YOUNG, R. (Queensland University of Technology), RAKOTONIRAINY, A. (Centre for Accident Research and Road Safety - Qld / QUT)

Driving is a complex task requiring the integration of several cognitive ‘executive’ functions which involve brain dopaminergic pathways and are still developing in young adults. Developmental impairments in executive function associated with adolescence could potentially contribute to the over-representation of young people in traffic accidents. Stress affects brain dopamine activity and moderates effects of dopaminergic genes on executive function. This study aimed to examine the interactive contributions of psychosocial stress, physiological stress response, and executive function development/impairment to young adults’ driving behaviour in a driving simulator. 40 healthy young adult drivers were randomly allocated to either an acute stress or relaxation induction condition and were tested individually. Participants completed four computerized performance-based measures of executive function and completed self-report measures of their chronic stress exposure (Chronic Stress Scale) and driving behaviour (Driver Behaviour Questionnaire) prior to undergoing the induction, followed by a 25 minute driving simulator session. Pre-induction, post-induction and post-simulator samples of saliva were collected for cortisol analysis as an index of physiological stress response. Several measures of driving performance (e.g., lane control, speed and speed variability, braking, steering control and hand motor activity) and participants’ physiological stress response (change pre to post-induction) will be analysed as a function of the acute stress manipulation (stress vs. relaxation), chronic stress exposure, and executive function performance (lower vs. higher scores based on a median split). Preliminary findings will be presented. Findings will help to elucidate the nature of the relationship between executive function deficits (in this study primarily due to continuing development in adolescence and young adulthood) and psychosocial stress with driving performance, and highlight the impact of individual differences in physiological stress reactivity. Increased understanding of the influence of these multiple factors may lead to the development of more customised education, prevention and treatment/intervention programs for reducing risk of driving-related accidents and injuries in young people.

Executive functions, attention and juvenile delinquency

FRIAS ARMENTA, M. (Universidad de Sonora), CORRAL, V. (Universidad de Sonora), VALDEZ, P. (Universidad Autonoma de Nuevo Leon)
The aim of this study is elucidated whether juvenile delinquents have poorer executive functioning in inhibition, flexibility, and attention, than control adolescents. Seventy-five Mexican teenagers participated in a study. The total sample was divided into three groups, one consisting of minors institutionalized by a juvenile court for serious offenses \((N = 24)\), another reported by antisocial behavior \((N = 24)\) and a control group from the general population \((N = 27)\) that was matched by sex, age and schooling to the juvenile court group. Demographic variables were considered and executive functions were assessed by means of the Wisconsin Card Sorting Test, and the Shifting Criteria Stroop Test- a modified version of the Stroop test- and the Continuous Performance test. An ANOVA (GLM procedure) was conducted to compare the three groups: the control group, the juveniles with serious offenses, and the juveniles with statutory offenses. Results showed means differences in some tasks of the Wisconsin test between the institutionalized adolescents and the control group. There were no significant differences in the STROOP test between the control group and the delinquent group. However, significant differences in inhibitory tasks were found between juveniles with serious and statutory offenses. Differences were also found in some indicators of selective and sustained attention, and tonic and phasic alertness, between the control group and the delinquent group. Results showed that women’s awareness of sexism is not necessarily related to their values, or what they interpret as the values of their organization, but can rather be related to what they expect of their lives as women. On the other hand, in our experience, men who become aware of sexism tend to do so in relation to changing their awareness of feminist issues and/or adapt some feminist values. It has been suggested that male doctors become more aware of gender issues once the amount of female doctors reaches or surpasses 50 percent, and it is possible that the 70/30 ratio of the Swedish dental programs have contributed to the feminist awareness of male dental students in a similar fashion.

Keywords: juvenile delinquents, executive function, teenagers, Wisconsin Card Sorting Test, neuropsychological impairment

Experienced sexism influences the extent to which male dental students share the values of their organization

SCHÉLE, I. (Umeå University), HEDMAN, L. (Umeå University)

The understanding of university students, especially in programs with clinical practice, isn’t covered by classical educational psychology and will benefit from a Work-environment approach.

In a previous study we found that the extents to which dental students share the values of their organization (SV) influence their perceived justice (PJ). In this study we investigate how (SV) is influenced by gender and experienced sexism (Sexism). We hypothesize that Sexism will negatively influence SV. A web-survey was distributed to all \((N = 850)\) Swedish dental students of which 50 percent answered the survey, a percentage in line with corresponding Swedish surveys. A SEM analysis was conducted on the data \((\text{Chi-square} 582,473; \text{df} = 176; p > .000; \text{Normed Chi-square} 3,310; \text{RMSEA} .085)\). Our analysis shows that Sexism influences SV negatively, \((- .27 \text{ for men}; -.14 \text{ for women})\) but hardly changes the extent to which SV influences PJ \((\text{model without Sexism} .56 \text{ for men}; .43 \text{ for women}, \text{model with Sexism} .53 \text{ for men}; .42 \text{ for women}, \text{gender difference significant})\). However, the influence from Sexism on SV is not significant for Women \((p = .103)\). Our results indicate that women’s awareness of sexism is not necessarily related to their values, or what they interpret as the values of their organization, but can rather be related to what they expect of their lives as women. On the other hand, in our experience, men who become aware of sexism tend to do so in relation to changing their awareness of feminist issues and/or adapt some feminist values. It has been suggested that male doctors become more aware of gender issues once the amount of female doctors reaches or surpasses 50 percent, and it is possible that the 70/30 ratio of the Swedish dental programs have contributed to the feminist awareness of male dental students in a similar fashion.

Experiences and needs of siblings of illicit drug users in Western Australia

MCALPINE, A. (Edith Cowan University)

Siblings can play key roles in an adult’s life. Sibling relationships may be a source of support, alliance, advice, learning, frustration, competition, and protection. The impact of having a family member who has an illegal drug use problem appears to have never been investigated solely from the point of view of a
sibling. This research aimed to explore the life experiences and needs of adults with siblings who have an illegal drug use problem. The exploratory nature of this research necessitated a qualitative approach. Therefore, this study used a phenomenological approach to investigate how adult siblings constructed their life world and shared meaning in relation to the experience of having a sibling with an illegal drug use problem. Therefore, themes related to the lived experiences and needs of this population were identified. Using thematic analysis, several themes related to stress and distress, coping, support systems, and positive impacts, such as resilience and growth, were identified. Participants were likely to feel distress both from direct experiences with their sibling and from the impact on parents and other family members. Common experiences included a cycle of engagement and support of the user followed by detachment and bounded relationships. Participants were also more likely to find support in partners and friends rather than seeking treatment and support from Alcohol and Other Drug Services. The findings of this research inform the understanding of the quality and nature of sibling bonds during times of distress. Results of this research indicated that siblings feel distress that is comparable to a parent or child of an illicit drug user. However, siblings appear to feel they have more freedom to detach from the relationship if needed. These findings also inform clinical practice in terms of the psychological needs of this population, such as issues with adjustment, grief and loss, stress, general coping, and the impact of often protracted disruptive life experiences as a result of having a sibling with an illegal drug use problem.

Keywords: siblings, illicit drug use, stress, coping, support systems

Experimental group session for cross-cultural social skills learning for international students in Japan from the social-clinical psychological perspective

TANAKA, T. (Okayama University)

The aim of the present study was to develop a cross-cultural social skills learning session for international students in Japan, a small group session was conducted based on cognitive and behavioral learning techniques, such as role plays. Ten international graduate students who studied at a Japanese university and were interested in learning about Japanese culture joined the two-day session. Five Japanese graduate students who were interested in cross-cultural education also joined the session as helpers of learning. The international students learned cognitive and behavioral social skills that focused on culture-specific behaviors. In the first session, self-assessment about cross-cultural social skills performance was done and target learning behaviors were selected. During the session, they learned about Japanese hesitation, Japanese drinking “communication”, visiting behavior at Japanese homes and indirect refusals. Each session included lectures about Japanese behavior patterns and cultural backgrounds. They learned about situations through target behaviors, situational role plays, feedback, a second role play and finally discussion. Participants reported more interest in Japanese cultural behaviors increased self-confidence and greater motivation to experience cross-cultural contacts. As a result of the evaluation to their role play in video tape, their improving of the performance had been shown. It is suggested that cognitive-behavioral culture learning in this session would enhance their social-cultural adjustment during their studying abroad.

Keywords: cross-cultural, social skills, cognitive learning techniques, behavioral learning techniques, Japan

Explaining patient involvement in chronic disease self-management: Five discourses of decision-making

HEPWORTH, J. (The University of Queensland), MARLEY, J. (The University of Queensland)

The national review of chronic disease management in Australia is in a crucial period of rethinking health care and patient involvement to address the increasing rates of chronic diseases, particularly obesity and type 2 diabetes. In this critical review of national interventions and cognitive approaches to
enhancing patient self-management evidence clearly demonstrates that interventions to date have had limited effectiveness. The aim of this research was to develop a new approach to the explanation of chronic disease self-management within the context of the practitioner-patient consultation to increase the capacity for health behaviour change. Three major methods of analyses were conducted: a critical review of the international literature, analysis of in-depth interview data, and clinical observations. A typical example of a patient with chronic disease was selected to illustrate in detail the capacity of a new theoretical framework applied to self-management. Based on three forms of evidence, being theory, research interviews and clinical observations, five major ways in which patients with chronic disease make decisions about self-management were identified. The case study of ‘Alan’, a patient with type 2 diabetes, is examined using discourse theory to illustrate the potential practical application of this new explanation. It is concluded that to advocate for patient involvement without a serious reconsideration of the underlying barriers is likely to result in more of the same; limited health behaviour change on the part of patients. The implications of a discourse approach to chronic disease self-management are discussed in terms of its application in primary health care as a generic decision-making tool. The development of understanding patient involvement in chronic disease self-management is proposed a move forward in that it addresses both the medical and psychosocial aspects of patients’ chronic diseases in primary health care.

Keywords: chronic disease, national interventions, patient self-management, effectiveness, behaviour change

Exploration of early maladaptive schema and attachment domains in sexual offenders

The present study explored early maladaptive schema (EMSs) and attachment domains among sexual offenders. This group was compared with normal individuals. The study examined the hypothesis that “sexual offenders in comparison with normal individuals have significantly higher score averages in EMSs and attachment domains.” 34 sexual offenders kept in the Central Prison of Mashhad city were randomly selected. 34 other subjects, normal individuals, matched with them on variables of age, marital status, occupation status and literacy level. Normal individuals were selected in accordance to GSI score in SCL-90-R. Subjects completed Young Schema Questionnaire–Short Form (YSQ–SF) and Close Relationships–Revised (ECR-R). Data was analyzed by dependent t test. The results revealed that when compared with the normal group, sexual offenders had a significantly higher score average in early maladaptive schema (P<0.05). In the clinical group, highest scores were for the vulnerability to harm and illness, subjugation, defectiveness/shame, dependence/incompetence, entitlement/grandiosity early maladaptive schemas and disconnection and rejection, impaired autonomy and performance schema domain. No significant results were observed in self-sacrifice maladaptive schema (P>0.05). Also, the results revealed that, when compared with the normal group, rapists had a significantly higher score average in the attachment anxiety domain. Between the two groups, there were no significant differences on attachment avoidant domain. In conclusion, high scores in early maladaptive schema and attachment anxiety domains, specifically in disconnection and rejection and impaired autonomy and performance schema domains, can lead to sexual crimes and to sexual offenses behaviors and rape.

Exploring organisational emotional intelligence and its relationship to employee attitudes
DA CAMARA, N. (Henley Business School, University of Reading), DULEWICZ, V. (Henley Business School, University of Reading)

Following on from research highlighting the importance of emotional intelligence and emotions for successful leadership and performance in organisations (Goleman, Boyatzis and Mckee, 2002; Fineman, 1993), this study examines the relationship between perceptions of organisational emotional intelligence (OEI) and attitudes such as trust, commitment and advocacy amongst employees. Although Goleman (1998) hinted at the importance of collective emotional intelligence in realising intellectual capital and determining performance over time, it was Higgs and Dulewicz (2002) who suggested that organisations can have an actual climate for emotional intelligence, as a result of the behaviours and practices that occur within them. Previous research in organisational behaviour generally confirms the significant relationship between individual perceptions of organisational climate, also known as psychological climate, and evaluative criteria such as employee attitudes (James & James, 1989; Parker et al., 2003). This study uses a new Organisational Emotional Intelligence Questionnaire (OEIQ) (author’s names excluded for purposes of blind review), based on previous work by Higgs and Dulewicz (2002), to measure employee perceptions of organisational emotional intelligence on seven dimensions, namely: Self Awareness, Emotional Resilience, Motivation, Interpersonal Sensitivity, Influence, Intuitiveness and Conscientiousness. In addition, the study uses measures of employee trust, commitment and advocacy from previous research in corporate reputation (MacMillan et al., 2004; Hillenbrand, 2007). The study reports data on a quantitative cross-sectional research design (n=100) carried out in two organisations: a UK-based multinational services company and an Australian NGO operating in the field of public health. The results show that organisational emotional intelligence has a strong positive correlation with trust, commitment and advocacy amongst employees, with trust acting as a partial mediator. The major drivers of employee attitudes were found to be Interpersonal Sensitivity, Influence and Motivation with Self Awareness, Emotional Resilience, Intuition and Conscientiousness playing a relatively minor role. The study shows that organisations which develop a more emotionally intelligent climate, particularly around allowing employees to be involved in strategy and decision-making and to communicate with management, will experience higher morale and increased behavioural support, namely commitment and advocacy, amongst their staff.

Extending to groups: The effects of attitude bases and affective-cognitive consistency on the attitude-behavior relation

ZHOU, J. (Chinese Academy of Sciences), ZHOU, J. (Chinese Academy of Sciences), WANG, E. (Chinese Academy of Academy Sciences)

Recently social psychologists began to focus on identifying properties of attitudes that moderated the attitude-behavior relationship. Of the investigated attitudinal properties, two extensively researched constructs are attitude bases and affective-cognitive consistency (ACC). The current set of three studies referred to the supervised groups’ attitudes and behaviors toward the supervising groups and provided initial tests of the effects of attitude bases, ACC, and their interaction on the attitude-behavior relationship in the context of both preexisting and new attitudes at the group level. Study One collected data at the group level measured the undergraduates’ preexisting attitudes and supportive behaviors in the lab. Study Two manipulated the participant groups as the supervised groups and focused on the supervised groups and supervising groups with the direct interests. The supervised groups’ attitudes and supportive behaviors toward the supervising groups were formed and measured in the lab. Study Three collected the data at the individual level and attained the public’s attitudes and opposed behaviors toward the central government and the local government in a questionnaire in order to test the generalization of the findings gotten in the lab. Study One suggested that attitude-behavior
consistency was higher when the attitudes had an affective focus. Study Two demonstrated that when the attitudes had a cognitive focus, a positive correlation existed between ACC and attitude-behavior consistency, while for the affective focus attitudes, ACC did not influence attitude-behavior consistency. Study Three showed that the results about public’s attitudes toward the central government were close to the findings from study 1 which involved no direct interests; whereas for the public’s attitudes toward the local government, the results were similar to those in Study Two which dealt with some direct interests. The present research proved that for the attitudes and behaviors with low personal relevance, only attitude bases had impacts on the attitude-behavior relation, suggesting that the affective focus attitudes predicted the following behaviors better than the cognitive focus attitudes. However, for the attitudes and behaviors with high personal relevance, the interaction between attitude bases and ACC influenced the attitude-behavior consistency so that the cognitive focus attitudes with high ACC predicted the behaviors better than those with low ACC, while the relations between affective focus attitudes and behaviors were not influenced by ACC.

**Facial emotion processing in individuals with autistic disorder and Asperger’s disorder**

SERCOMBE, A. (University of Newcastle)

Autistic Disorder and Asperger’s Disorder are characterised by difficulties with social interaction. Yet it is still unclear if such difficulties are related to deficits in emotion processing. This project examined facial emotion discrimination, facial feature discrimination, and the discrimination of complex visual stimuli in individuals with Autistic Disorder and Asperger’s Disorder. In addition, this study attempted to address several methodological issues raised in previous research into facial emotion processing in Autistic Disorder and Asperger’s Disorder. Boys aged 9-16 years were recruited for participation. Individuals with Autistic Disorder were matched with individuals with Intellectual Disability on age, gender, and VIQ. Similarly, individuals with Asperger’s Disorder were matched with typically developing individuals on age, gender and VIQ. Participants were presented with three discrimination tasks: Facial Emotion, Facial Identity and Complex Visual Discrimination (Butterfly). Stimuli were developed so that three discrimination tasks were equivalent in terms of difficulty and did not produce floor or ceiling effects. Participants were asked to decide whether presented pairs of pictures were ‘same’ or ‘different’. Task performance was measured in terms of discriminability, hit rate, false alarm rate, bias and mean response time. There was a trend for individuals with Autistic Disorder to respond faster than individuals with Intellectual Disability and have higher scores of discriminability on the Butterfly task, with performance comparable for the Identity and Emotion tasks. Furthermore, there was a trend for individuals with Asperger’s Disorder to yield lower scores of discriminability overall, have a lower hit rate for the Emotion task, and show a higher false alarm rate on the Butterfly and Emotion tasks when compared with typically developing individuals. There were no significant differences between individuals with Asperger’s Disorder and individuals with Autistic Disorder on any task measure. There appears to be some differences in the ability of individuals with Autistic Disorder and Asperger’s Disorder to process facial emotions when compared with control participants. However, these differences are only approaching significance. This research partially supports the hypothesis of an emotion specific deficit related to Autistic Disorder and Asperger’s Disorder that is not a function of overall intellectual functioning.

**Keywords:** facial emotion processing, Autism spectrum disorder, Asperger’s syndrome

**Facilitating conditions of learning: Stability and relationships of personal constructs and significant others in and out of school**

MCINERNEY, D. (The Hong Kong Institute of Education), YEUNG, A. (Nanyang Technological University), LIEM, G. (The University of Sydney)
The aim of the present study was to examine the stability and relationships of personal constructs and significant others in engaging in learning across two waves of data. In order to establish the validity of the scales over two points in time, confirmatory factor analysis was conducted with the longitudinal data of students responses to the Facilitating Conditions Questionnaire (FCQ) from 11 secondary school in Sydney (N=724 in Grades 7-9). In order to examine stability over time, a repeated-measures multivariate analysis of variance with the scale scores of Time 1 and Time 2 parallel variables as a within subject factor. Eight distinct factors were found for each of two time points (T1 and T2), representing 35 items at T1 and T2 respectively. The factors were (a) parent positive academic climate (Parent Positive), (b) parent negative academic climate (Parent Negative), (c) peer positive academic climate (Peer Positive), (d) peer negative academic climate (Peer Negative), (e) teacher positive academic climate (Teacher); (f) perceived value of schooling (Value), (g) affect toward schooling (Affect), and (h) educational aspiration (Education). It was found that the positive constructs were positively correlated with each other. The Parent and Peer negative constructs were correlated positively with each other but negatively with all the positive constructs. These patterns were consistent across T1 and T2, providing support for the convergent and discriminant validity of the FCQ scales and stability over time. A path model relating all eight constructs over time found no additional significant path other than those for the identical constructs, providing strong support for the stability of the FCQ scales. A path model relating the significant others (parent, peer, and teacher constructs) at T1 to the personal variables at T2 (Value, Affect, Education) found significantly positive paths from Parent Positive to Education, from Peer Positive to Value and Education, and from Teacher to Affect, but a significantly negative path from Parent Negative to Value. Interestingly, the path from Peer Negative to Value was positive, which calls for further investigation. Repeated-measures multivariate analysis of variance found no significant difference between parallel variables at T1 and T2 variables except for Value, which was lower at T2. Overall, the results suggest that facilitating conditions for learning tend to be quite stable over time, but significant others may have differential impacts on crucial personal factors.

Keywords: learning, relationships, stability, personal constructs, significant others

Facilitating the pathways to adolescent mental health services: Enhancing teacher recognition of and referral rates for internalizing problems

PAPANDREA, K. (The University of Adelaide)

Research has identified that teacher recognition of and referral rates for mental health problems are increase according to the greater severity of students’ externalizing problems, but decreases with the severity of internalizing problems, such as anxiety and depression. This is primarily explained by the fact that externalizing problems are disruptive and thus highly visible to teachers, whereas anxiety and depression are less obvious, and may not be noticed until they result in school absenteeism. Consequently, students’ problems with anxiety in most cases remain largely “hidden” in the classroom environment. The aim of this study was to investigate the factors contributing to the lower referral rates of internalizing problems and to apply the knowledge gained to facilitate the pathways to mental health services for adolescents experiencing internalizing problems. A community sample of one-hundred-and-four South Australian Year eight to Year 10 high school teachers (n=78 females) with a diverse range of teaching experience completed an online survey. The majority of teachers (84%) reported that to a moderate extent or greater, teachers do share a responsibility to identify students with mental health problems. However, 79% “Strongly Agreed” that with regards to internalizing problems, teachers do not possess the skills to adequately fulfill this responsibility. When asked if the pre-service training program they received sufficiently prepared them to recognize internalizing problems in their students, 82% “Strongly Disagreed”. It is evident that schools have a crucial role in and are opportunistic environments for supporting the mental health and wellbeing of many young people of school age. The findings from this research indicate that an important factor...
Factors associated with depression among aged care residents

DAVISON, T. (Deakin University), KNIGHT, T. (Deakin University), MCCABE, M. (Deakin University), MELLOR, D. (Deakin University)

Depression is particularly common among older people living in residential aged care settings. Yet our understanding of factors associated with depression among this population is limited. This study aimed to examine risk factors for depression previously reported in research with community samples, including physical illness, functional disability, and bereavement. The strength of association of depression with these risk factors was compared with individual psychological factors, including religiosity, self-acceptance, positive relations with others, autonomy, environmental mastery, purpose in life, and personal growth. One hundred aged care residents with normal cognitive function (mean age = 83 years; 80% female) took part in the study. Fifty of the participants had a diagnosis of Major Depressive Disorder (MDD), according to a SCID interview and fifty participants without depression were matched according to facility, gender and age. Assessment measures of risk factor and psychological variables were administered by a clinician in an interview format, with medical data validated by a file review. Risk factor and psychological variables which correlated significant with scores on the 15-item Geriatric Depression Scale were entered into a multiple regression analysis. The model explained 60% of the variance in depression scores, with the unique predictors being environmental mastery, purpose in life and autonomy. Previously established risk factors such as poor health and disability did not provide unique variance in predicting depression. In order to validate the psychological variables, a discriminant function analysis was conducted. Environmental mastery, purpose in life and autonomy significantly distinguished between individuals with and without a diagnosis of MDD, with 80% accuracy. While limited through the use of a cross-sectional design, this study provides preliminary evidence of the importance of psychological factors in understanding depression in aged care. This suggests a fruitful avenue to investigate in larger prospective follow-up studies, with a goal to reducing the high prevalence of depression among frail elderly people.

Keywords: depression, aged-care residents, risk factors

Factors contributing to students’ perceptions of fairness following an academic labour dispute

FIKSENBAUM, L. (York University), WICKENS, C. (Centre for Addiction and Mental Health), GREENGlass, E. (York University), WIESENTHAL, D. (York University)

University labor disputes can be especially difficult for students caught in a tug-of-war between the administration and the striking party. Students affected by an academic labor dispute have reported experiencing distress and adverse academic and financial consequences. A strike can impact the opinions that students hold concerning the groups involved in the work stoppage, the academic institution itself, and the quality of the education received. A recent longitudinal study surveyed the experiences of students of a large Canadian university when their classes were suspended during a 12-week labor dispute by contract faculty and teaching assistants. The present analysis focused on identifying factors contributing to students’ perception of fair treatment in the post-strike period, with an emphasis on factors that the contributing to lower referral rates for internalizing problems is the inability of teachers to identify the associated symptoms in their students. Hence, through incorporating a clinically and evidence-based ‘mental health toolkit’ package outlining student behaviors, speech and expressions that are indicative of internalizing disorders into the pre-service teacher curriculum, teachers-in-training may be more effectively prepared prior to interacting with students. This may ultimately increase referral rates and enhance the capacity of schools to support young people experiencing internalizing problems.

Keywords: adolescents, mental health services, teachers, referral rates, internalizing difficulties

Factors contributing to students’ perceptions of fairness following an academic labour dispute
University administration could influence. Hierarchical regression analysis examined the impact of satisfaction with remediation (i.e., changes made to course requirements following the strike) and the availability of faculty assistance in the post-strike period on students’ perception of fair treatment. Demographic variables, satisfaction with academic program before and during the strike, availability of faculty assistance before and during the strike, attitudes toward the strike, student financial concern resulting from the strike, and the degree to which students’ plans for graduation, future studies, travel, and employment had been affected were also included in the analysis. Results indicated that pre-strike satisfaction with academic program contributed to a perception of post-strike fairness. The more students’ plans had been affected by the strike, the greater the reduction in perceived fairness. Post-strike fairness increased significantly the more students were satisfied with remediation and the more they felt they had a faculty member to turn to following the labor dispute. Interestingly, neither students’ levels of financial concern, nor their attitudes toward the strike, predicted perceptions of fairness. Implications of these findings for addressing students’ concerns and frustrations in the wake of an academic labor dispute will be discussed.

Keywords: university labor disputes, strike, students, fairness

Faith and religious practice as they relate to the wellbeing of older people

WALDEGRAVE, C. (Family Centre Social Policy Research Unit)

The aim of this research program, entitled ‘Enhancing Wellbeing in an Ageing Society’ (EWAS), is to identify the drivers of wellbeing and quality of life among the older population. Amartya Sen’s capabilities approach has formed the conceptual basis of the theoretical framework of this research program (Sen, 1999). Subjective measures that complement Sen’s emphasis on the importance of human freedom were included to balance the otherwise objective, material emphasis of the capabilities approach. An extensive survey of a national random sample of 1680 older New Zealand citizens aged between 65 to 84 years was carried out using computer assisted technology interviewing (CATI). A theory driven approach to the survey questionnaire construction led to the selection of the domains of wellbeing, which included faith and religious practice, were chosen to highlight wellbeing capabilities, functionings, instrumental freedoms and needs. These variables were correlated with a range of subjective wellbeing measures, including the World Values Survey Life Satisfaction Question and satisfaction with their economic standard of living. For those aged 65 to 84 years, significant associations were found between the importance of faith, religious practice and wellbeing. It was found that a higher than expected number of older people considered faith to be either extremely or reasonably important to them. Strong gender and significant cultural differences were found. Other important associations included the importance of faith and: leadership in a church or religious organisation; participating in community or service organisations that help people; involvement in women’s organisations; and being members of choir, drama or music societies. This research program provides the first New Zealand results from a large national random sample of older people’s attitudes to faith, their frequency of practice and the association with subjective and objective measures of wellbeing. The results demonstrate the high level of involvement by older people in faith and religious activities and a significant association with wellbeing. These finding is particularly important given the general neglect of this area of satisfaction and wellbeing for many older people in ageing research and public policy.

Keywords: well-being, quality of life, ageing, religious practice, faith

Family and social factors as predictors of improvement in drug intake, health, and criminal behaviours in adolescents in a residential setting

DUA, J. (Ted Noffs Foundation)
The objective of this research paper is to report on the predictors of drug intake, drug dependence, health, and criminal behavior three months after treatment (Outcome Variables), in adolescents treated in a residential facility run by Ted Noffs Foundation in Sydney, Australia. Ted Noffs Foundation is a residential facility for the treatment of adolescents who have problems caused by alcohol and/or other-drugs, and related mental health problems. At admission, the clients complete questionnaires designed to assess their personal background, health, drug intake, family functioning and criminal behaviors. An Action Plan, a Treatment Plan and a Vocational Educational Assistance Plan are devised for each young person. Young people are assisted/treated by a clinical psychologist, counselors, and alcohol and other-drugs workers. Young people stay in the residential facility for up to three months. Approximately three months after their departure, we contact them again and collect the follow-up information about their drug intake, family functioning, health and criminal behaviours. We used multiple regression analyses to determine the comparative predictive value of length of stay, number of drugs of concern, achievement of set goals, family/social functioning at follow-up and demographic variables in predicting the Outcome Variables. Results showed that young persons, who reported living in a well-functioning family since their departure (Family/Social Functioning variable) showed the best outcomes in terms of substance use, health and criminal behaviours. We further explored the role of family and social variables by dividing the social and family assessment questions into the following categories: association with drug users, availability of social support, extent of social support, conflict with family and friends, family functioning. Multiple regression analyses, that used these five variables in predicting the outcome variables, showed that (a) association with drug users since treatment was the best predictor of drug intake, drug dependence and physical health at follow-up, and (b) conflict with family and friends and association with drug users since treatment were the two major predictors of mental/emotional health. The results of this study provide strong support for maintaining a well-functioning family. Results show that young people who continue association with drug users are likely to continue their drug intake and drug dependence.

Keywords: social support, drug dependence, criminal behavior, health, adolescents

Family size in northern Sudan: Its economic and cultural associations and its implications for child adjustment

AL-AWAD SHENNAN, A. (University of Gezira)

The present study attempted to explore the determinants of family size in the Sudan and how it contributes to patterns of problem behaviour displayed by Sudanese children. A stratified sample of 300 parents completed demographic and family factors questionnaire and Conners’ parent-48 rating scale about their children’s behavioural adjustment. The children’s classroom teachers have also completed Conners’ teacher-39 rating scale. Results indicated that cultural and religious factors were found to be related to the number of children in the Sudanese family. The present results also pointed out, in contrast with Western findings, that large family size did not necessarily lead to behaviour problems. Instead, big family size in our sample mitigated symptoms of psychosomatic problems and anxiety as rated by parents, and unsociability and poor attention as rated by teachers. It was suggested that whether big family size represent a risk or protective factor depends on the developmental processes embedded in the wider sociocultural context in which they exist.

Keywords: family, Sudan, problem behaviour

Feedback referent and feedback sign: An examination of their interactive effect on task performance throughout skill acquisition

YEO, G. (University of Western Australia)

Feedback interventions (FIs) are viewed as potential tools for facilitating learning and performance, however, there is confusion...
regarding what FIs to use and when to use them. Self-regulation and goal orientation theories were used to generate predictions regarding how the interactive effect of feedback referent and feedback sign unfolds within individuals over time. 139 students performed 60 one-minute trials of an ATC task. Points were awarded according to speed and accuracy. After each block of six trials, participants chose to receive self-referent or normative feedback (points on current block compared to a) own performance on previous block versus b) others’ performance on current block). Dummy variables were used to model feedback referent and sign. Task practice was modelled with growth parameters. Total points per trial were used to measure task performance. Data were analysed using multi-level modelling. Self-referent feedback was associated with higher performance on the subsequent trial if it was negative rather than positive; whereas normative feedback was associated with higher performance on the subsequent trial if it was positive rather than negative. This interaction was more pronounced at the end of practice. Early in practice, however, there was a negative effect of self-referent feedback, which was detrimental when compared to self-referent positive feedback and normative negative feedback. This research contributes to the FI literature by examining the combined role of two FI dimensions on task performance over time. This study demonstrates that FIs can have differential effects on task performance depending on the feedback referent, feedback sign and stage of skill acquisition. In general, results suggested that once some skill has been acquired; the most effective FIs are self-referent negative feedback or normative positive feedback. The interpretation and implications of these findings will be discussed within a self-regulatory theoretical framework.

Keywords: feedback, learning, performance, self-regulation, goal orientation

The current study was designed to examine the relation between actual competence and third-party reports of competence using the Financial Competence Assessment Inventory (FCAI). It was anticipated that there would be a significant positive relationship between scores on the FCAI-A (people with a cognitive impairment), and scores on the FCAI-B (third party respondents). The sample comprised 112 adults. This included 23 people with acquired brain injury (ABI), 11 with schizophrenia, 10 with dementia, and 12 people with intellectual disability (ID). These groups of people were of interest because they represent people with different types of cognitive impairment, and they are also people who, because of their disability, may have questions raised about their ability to manage their own financial affairs. Fifty six caregivers of those participants with a cognitive impairment also participated in this study. The FCAI was used to assess: (1) “everyday financial abilities,” “financial judgment,” “estate management,” “cognitive functioning related to financial tasks,” “debt management,” and “support resources”; and (2) four subscales designed to assess: “understanding,” “appreciation," “reasoning,” and “expressing a choice,” in relation to financial abilities. The results suggest moderate agreement between carers and dependents on four of the FCAI subscales, and Total FCAI score, but a lack of agreement between carers and dependents on the “support resources” subscale. Unexpectedly few carers were able to comment on dependent’s “debt management” practices. Significant positive relationships were found between the items that comprised “understanding,” “appreciation," “reasoning,” and “expressing a choice,” however, “appreciation” and “expressing a choice” were only moderately related. This finding suggests that there is some disagreement between carer’s judgment and the dependent’s actual ability to plan and state long term financial goals. In addition, carers rated dependents’ abilities lower than dependents scored on items that required dependents to self-report. The discrepancies in rating of financial abilities between third-party respondents and dependents is of some concern as the determination of competence usually involves evidence provided by caregiver or family members of the person whose competence is in

Financial competence: Actual performance and self-report vs third party reports

KERSHAW, M. (Deakin University), WEBBER, L.
question. It is possible that carers did not know their dependents as well as they thought they did. Alternatively, it is possible that carers may have under-estimated the persons’ abilities on the kinds of tasks that they themselves have assumed responsibility for on behalf of their dependent. In addition, carers may tend to report less ability in their dependent in those abilities that tend to fluctuate.

First clients: Initial professional encounters with psychotherapy clients of counselling psychology students and recent graduates

SIMMONDS, J. (Monash University)

The experience of students training or recently graduated in counselling psychology was researched. Participants were asked about their professional contact with clients and the aspects of training that they drew on. Their experience of supervision and use of other resources was also explored. The aim was to further understand students’ and graduates’ experiences of field practice, how they used their training, what additional resources they drew on, and their needs. The study had three components in an evolving research design. Participation of first year masters students and graduates supplemented the range of experience of students willing to be interviewed during their first field placement. A total of 32 students and recent graduates participated in interviews, emailed questionnaires (using the same questions as in the face-to-face interviews), and a focus group. Students and recent graduates vividly recalled their first experiences of seeing ‘real’ clients in a field setting, and their own anxieties and excitement. Systematic thematic analysis indicated that participants experienced supervision as variously immensely supportive and encouraging, to bullying and burdening. Personal self care emerged as an important issue, in that students felt they had been taught about it and knew it was important, but under pressure to ‘be professional’, found it difficult to allow themselves sufficient time for it. Postgraduate counselling psychology students and graduates who had ‘tried out’ some of their training contributed fresh and interesting reflections on their experiences with clients, including on topics such as balancing professionalism and self care, and appropriate levels of responsibility and self determination. They also specified what they found useful in their pre-practicum training and practicum experience and what they thought should be revisited.

For whom message framing is persuasive? Investigation of goals and temporal framing effects on health information seeking

MARTINEZ, F. (University of Lyon), FIEULAINE, N. (University of Lyon)

An important issue for research concerning health communications is to understand how they might influence intentions and behaviours. This study investigates the influence of message framing according to individual differences in the context of a behavioural intention to come in an information centre on drugs. 705 undergraduates (400 females, 305 males) participated in the experiment. An A4-sized folded paper booklet was handed to participants to complete and collected later at an agreed-upon time. Participants were randomly allocated to experimental condition by pre-packaging the booklets. A 2 (temporal frame) X 2 (regulatory focus: promotion vs. prevention) X 4 (frame: gain vs. loss vs. non gains vs. non losses) between-subjects design was used. All sixteen versions began by describing the information centre on drug. Although the same consequences were presented in each passage, the temporal frame in which the consequences were presented (benefits/costs X short/long term), regulatory focus was manipulated in the content of the message (promotion/prevention focused) and gain/loss frame was manipulated in the end of message. Immediately after reading the message, participants completed a thoughts listing task to assess their cognitive responses and then
responded to a series of items to assess constructs specified by the theory of planned behaviour. The final part of the questionnaire contained the 12-item Consideration of future consequences measure and the 18-item prevention/promotion scale. Persuasive impact of messages on behavioral intentions varied across conditions, and appeared as dependent on individual differences as such as framing. Coherence and fit between message and subjects dispositions are suggested as predictors of behavioral intentions to use information centre on drugs. Results demonstrated how multifactorial framing in health communications can enhance persuasiveness of messages. Applied in the context of information seeking, this study has implications for elaborate and evaluate communications in community or public health programs.

**Function of apologies for the victims and the third-parties: Empathy, responsibility attribution, and their antecedents**

HASHIMOTO, T. (The University of Tokyo), KARASAWA, K. (The University of Tokyo)

The principal aim of this study is to compare how the victim and the third-party react to an apology given by a transgressor in a social predicament. Specifically, we examine the cognitive and the emotional processes that take place within the victims and the third-parties by considering responsibility attribution and emotional empathy as potential mediators between apology and forgiveness. In addition, we aim to further scrutinize the psychological mechanism that governs such cognitive and emotional reactions by taking into account morality inference and perceptions of apology elements (e.g. remorse). 357 Japanese undergraduates were presented with a hypothetical transgression vignette manipulated on the perspective (victim or third-party) and the type of account given by the transgressor (no apology, low-sincerity apology, or high-sincerity apology). Then they responded to a set of questions measuring their responsibility attribution judgments, emotional reactions, moral trait inference, perceived elements of an apology, and forgiveness motivations towards the hypothetical transgressor. The results indicated that emotional empathy and the perceived stability of the transgressor responsibility played a key role in the participants’ forgiveness judgments for both the victims and the third-parties; whereas, the apology affected the perceived locus of responsibility only for the third-parties. Furthermore, the study revealed that the perceptions of morality and remorse regarding the transgressor are key factors that determine the empathy and stability judgments. Also the morality inference based on the sincerity of the given apology was shown to moderate the effect of apologies on the third-parties’ perceived locus of responsibility. We found out that the apology induces emotional reactions for both the victims and the third-parties, while affecting the responsibility judgments of mainly the third-parties. In addition, our study signified how the judgments on the moral character of the wrongdoer function as a fundamental basis of responsibility judgments, as well as empathic reactions.

**Keywords:** victim, apology, empathy, responsibility, forgiveness

**Germans think secondary tasks while driving aren’t dangerous at all**

HU EMER, A. (Technische Universität Braunschweig), VOLLRATH, M. (Technische Universität Braunschweig)

Accident studies find some kind of driver distraction in about 10 to 30% of all crashes (e.g. Stutts, Reinfurt, Staplin, & Rodgman, 2001). However, relatively little is known about how often and when drivers engage in secondary tasks while driving without an accident. Naturalistic driving studies from the USA indicate that drivers engage in secondary tasks in about 30% of their driving time (e.g. Klauer, Neale, Dingus, Ramsey & Sudweeks, 2005). In order to examine the prevalence of distraction in Germany, about 300 drivers were interviewed in a field study immediately after stopping their driving time.
vehicle. They were asked to report all secondary tasks during the last 30 minutes of their driving time. Five groups of drivers were examined: (1) Truck drivers at the Autobahn (N= 90), (2) car drivers at private trips at the Autobahn (N= 71), (3) car drivers at business trips at the Autobahn (N= 29), (4) car drivers at private trips in town (N= 85), (5) car drivers at business trips in town (N= 12). Between these groups the pattern and frequency of engagement in secondary tasks differs. Overall, about 80% of all drivers conducted one to three secondary tasks within the last 30 minutes of their driving. With regard to the duration of these tasks, interactions with passengers lasted longest. Handling clothes and body care was shortest. While subjects judged most tasks as being distracting in general, they were quite convinced that they were only a little distracting for themselves in the specific situation. Thus, drivers seem to believe that they engage in secondary tasks only when it is safe for them. Overall, the results indicate that secondary tasks may pose a serious problem for traffic safety in Germany, too. The face-to-face interview directly after a trip seems to be a cost-effective alternative to naturalistic driving studies.

Keywords: driver distraction, secondary task

Giving up on school: Investigating mediating mechanisms between parental support and provision for career counseling and persistence

GARCIA, P. (The Australian National University), RESTUBOG, S. (University of New South Wales), FLORENTINO, A. (University of New South Wales), TOLENTINO, L. (De La Salle University)

The declining persistence of students in academic programs is a current problem faced by tertiary institutions worldwide. For example, approximately 20 to 33% of students in the United States leave university without completing their degree (National Center for Education Statistics, 2005). This trend is even higher in non-western countries such as the Philippines, where 40% of students drop out of university (Commission on Higher Education, 2008). Given these staggering turnover rates, an empirical examination of how to reduce its occurrence is of critical importance. Drawing upon Social Career Cognitive Theory (Lent, Brown, & Hackett, 1994), we examined how types of contextual support (e.g., parental support and career counseling) influence student persistence in an academic program. In addition, we test the roles of career self-efficacy and career decidedness in mediating the relationship between these types of contextual support and persistence. One hundred and forty-six undergraduate students were surveyed over three measurement periods. To address the issue of common method variance, multiple sources of data were collected (Podsakoff et al., 2003). Aside from self-ratings of self-efficacy and career decidedness, parent ratings of parental support were also collected. Furthermore, archival data from the university’s records were obtained as a measure of provision for career counseling and academic program turnover (i.e., non-persistence). Results of structural equation modeling analyses provided support for our hypothesized mediated model. Specifically, Time 1 parent ratings of support and provision for career counseling led to greater Time 2 (6 months after Time 1) career self-efficacy and career decidedness. This, in turn, resulted in Time 3 (18 months after Time 2) persistence (i.e., lower program turnover). Our findings show that both parental support and career counseling uniquely influence persistence, albeit indirectly. Most importantly, we found that career self-efficacy and career decidedness acted as explanatory mediating mechanisms through which these types of contextual support influenced students’ persistence in their academic program. A collaborative approach between parents and schools in providing career support and a focus on improving self-efficacy in career counseling interventions are recommended.

Globalized work and intelligent working environments: Employees’ adaptation to the implementation of new working strategies

KALANTIDOU, E. (Aristotle University of Thessaloniki)
Aim of this paper is to identify the impact of globalized work and new working conditions on employees’ psychosocial qualities such as privacy, territoriality, place attachment, sense of belonging, socialization etc. Mobile working, hotelling, hot-desking and home working mirror contemporary aspects of organizational culture, where the permanent working place, private working and stable timetable no longer exist. Intelligent working environments that incorporate technological advances and provide the possibility of the implementation of globalized work and new working strategies create a distributed workplace to which employees have to adapt. A questionnaire survey method using structured questions was chosen to collect data from employees working in two intelligent office buildings in London. The set of questions covered three areas of interest: employees’ perception, evaluation and expression of wishes related to their working environment. The questionnaire was distributed to participants from both genders (30 male and 30 female employees) and from various ranks across departments. Descriptive statistics and content analysis were used to analyze gathered data. Results showed that the transformation of working environment and the implementation of new working practices are related to the inability of employees to experience privacy, concentration and place attachment. In addition, results revealed that employees demonstrate signs of deterritorialization towards their working environment, express desire to adopt home working and identify their lack of personal time and social interaction. These findings highlight the loss of workplace identity and point out distributed workplace’s insufficiency to cover the psychosocial needs of its users. The working space is becoming a “non space”, characterized by liquidity and neutralization, which prevents the growth of social connectivity. This paper invites a discussion about the future consequences of the present working circumstances and the hidden dangers related to the balance between individual and professional activities, personal and public life.

Goal-performance discrepancies and cognitive effort: A multilevel analysis

JOHNSTON-BILLINGS, A. (University of Western Australia), YEO, G. (University of Western Australia), BALLARD, T. (University of Queensland)

The central concern of this study was the relationship between goal-performance discrepancies (GPD) and effort within an avoidant goal context during the goal setting and goal striving phases of self-regulation. These phases were modelled at two within-person levels of analysis (between-trials or goal setting episodes; and within-trials or in the goal striving phase). Drawing on control theory and social cognitive theory, predictions regarding these relationships were examined in relation to two potential mediators, namely, self-set goal during the goal setting phase and tense arousal during the goal striving phase. 130 participants completed ten, ten-minute trials of an Air Traffic Control task. Participants were required to accept and prevent conflicts between aircraft. Penalty points were accrued for errors, thus their broad goal was avoidant in nature, namely to minimise their penalty points. Individuals set avoidant penalty goals at the beginning of each trial. Measures of tense arousal and effort were obtained via self-report five times within each trial. Results relating to the goal striving phase of self-regulation indicated that when an individual was performing well during a trial, he or she reported expending more effort than when he or she was performing poorly. This finding is inconsistent with control theory predictions that an individual will increase effort when performing poorly as a means to avoid goal failure. As expected, however, tense arousal was positively related to effort. As an individual increased their tense arousal from one time-point to the next within a trial, the more the individual reported expending more effort than when he or she was performing poorly. This finding is inconsistent with control theory predictions that an individual will increase effort when performing poorly as a means to avoid goal failure. As expected, however, tense arousal was positively related to effort. As an individual increased their tense arousal from one time-point to the next within a trial, the more the individual reported expending more effort. Thus, GPDs and tense arousal had opposing independent effects on effort. Results relating to the goal-setting phase of self-regulation indicated that the further an individual was away from their undesired penalty goal at the end of a trial (i.e., the better they performed), the more challenging goal they set for the next performance episode. However, GPDs had the opposite effect on effort – the higher the goal success, the lower the effort in the subsequent...
Abstracts of the 27th International Congress of Applied Psychology

Individual Oral Presentations

1. Performance Episode. Self-set goals were not associated with effort. Thus, although goal attainment prompted individuals to set a more challenging goal, they did not appear to match their effort level to their new goal. Follow-up analyses of time and skill acquisition effects did not explain this unexpected result. These findings provide mixed support for social cognitive theory, which predicts that goal attainment motivates individuals to set more challenging goals and increase effort expenditure. Results highlight the importance of examining subjective psychological states across different time points as the GPD to cognitive effort relationship was found to operate differently depending on whether it is examine during the goal setting or goal striving phase of self-regulation.

2. Going up or coming down? Differences in psycho-social determinants of ecstasy use and GHB use

PETERS, G. Y. (Maastricht University), ABRAHAM, C. S. (Sussex University), KOK, G. (Maastricht University)

Ecstasy has been a prevalent club drug for decades, while in the past decade, GHB has been gaining ground. Both substances have their dangers, and although for ecstasy use, recent reviews are starting to map the relevant determinants, for GHB, such research is lacking. Because both drugs are used in the same setting, psycho-social determinants may be similar, and if they are, intervention efforts addressing GHB use could be informed by the evidence base that has accumulated for ecstasy use. On the other hand, both drugs have opposite effects: while ecstasy is a stimulant, GHB is a sedative. The determinants may therefore also be different. The current study compares the determinant configurations of these drugs. An online survey was administered by a virtual interviewer at a virtual dance party. The survey consisted of three data waves. Ecstasy determinants were measured at wave 1, and GHB determinants at wave 2. Self-reported behavior was measured at wave 2 for ecstasy and wave 3 for GHB. Data was collected for 3169 participants from the club scene. Intention to use strongly predicted subsequent use for both ecstasy ($d=1.3, p<.001$) and GHB ($d=2.6, p<.001$). For ecstasy, this intention to use was strongly predicted by attitude and injunctive norm (both with $r>.5, p<.001$), and moderately by perceived behavioral control and descriptive norm (both with $r>.3, p<.0001$). The determinant structure of GHB was different: with the exception of injunctive norm, all determinants were significantly less strongly associated to intention, with medium effect sizes for the difference between the correlations ($Q); all $Qs>.3, all ps<.001$). Although intention to use GHB more strongly predicts actual use than is the case for ecstasy, the determinants of ecstasy use more strongly predict intention to use than is the case for GHB. The strong intention-behavior link implies that GHB use can be considered a planned behavior, which is promising from a health promotion perspective. However, at the same time it clearly demonstrates that more needs to be learned in terms of the determinants predicting this intention to use GHB.

Keywords: ecstasy, drug use, GHB use, intention-behavior link, planned behavior

3. Good governance of Thai small and medium sized enterprises

CHONGVISAL, R. (Kasetsart University)

The purpose of this study was to study good governance in Thai small and medium sized enterprises (SMEs) and to examine the structural relation among psychological factors; leadership, instinct motivation and attitude toward good governance, affecting good governance and success in business. The sample were 435 SMEs entrepreneurs in three types of enterprises comprising of manufacturing, wholesale and retail selling, and providing service enterprises. They were selected by simple random sampling. Instruments for data collection were one questionnaire for biosocial data and 5 measurement tools for leadership, instinct motivation and attitude toward good governance, good governance and success in business. Data were analyzed by Mean, Standard
Individual Oral Presentations

Deviation, Variance, Correlation and Structural Equation Model. The findings from the study were found that good governance in Thai SMEs had high level including their three factors; the performance on employees, consumers and social and environment, had high level as well. In addition, instinct motivation, attitude toward good governance and success in business also had high level. The structural relation model fitted the empirical data ($\chi^2= 510.93$, $df=175$, $p=0.00$, $CFI=0.93$, $GFI=0.90$, $RMSEA=0.07$). In terms of effect size, leadership of entrepreneurs had positive direct effect on attitude toward good governance and good governance at .05 statistic significant level. Their standardized coefficient were .35 and .48 respectively including had positive indirect effect on success in business through attitude toward good governance and good governance. Its standardized coefficient was .16. Besides, Instinct motivation had positive effect on attitude toward good governance, good governance and success in business. Their standardized coefficients were .29, 15 and .25 respectively. Attitude toward good governance had positive effect on good governance. Its standardized coefficient was .35. Moreover, good governance had positive effect on success in business. Its standardized coefficient was .65. According to research results, organizations should promote and develop leadership, instinct motivation and attitude toward good governance to SMEs entrepreneurs by activities such as workshop or case study. Furthermore, they should be supported, promoted and realized in ethics in business through training or activities, for example; to advise by experts or mentors in good governance development, to create the entrepreneur network for knowledge sharing and to publish information data declared that if organizations had high good governance, it could lead to be success in business and economic development in country and global level.

Good vibrations – the effect of playing the drums on violence prevention and social integration among secondary school students

DREXLER, A. (University of Innsbruck), UFFELMANN, P. (ComPetto - Gesundheitscoaching und Bildungsmanagement), WOELFL, A. (Institut of Music-Therapy Munic), FERDIG, G. (University of Innsbruck)

The aim of this project was to investigate the effect two short-term music-based interventions in secondary schools aimed at violence prevention, social integration, and fostering (creative) conflict resolution strategies. The study is based on research evidence indicating that music is accepted by children of all languages, cultures and religions. Music evokes emotional responses in children. Actively making music and improvising with the use of rhythmic instruments affects mood, communication and the ability to form relationships. Two modern secondary schools based in Southern Germany (Munich) participated in this study. Each school contributed one treatment and one control group (classes). The two treatment groups took part in two week-long interventions focused on making music using rhythmic instruments. The interventions were provided by two music therapists working in collaboration with students and teachers. At the end of the intervention the students performed in front of an audience. The effects of the interventions were measured using standardised questionnaires. Data was collected during one year at five different time points before and after the interventions plus a follow up. The tools used included a rating scale for teachers eliciting their views on the social behaviour and learning behaviour of students. Another questionnaire was used to gather student data on empathy, sociability, aggressive behaviour and aggressive tendencies. The study also included a projective tool, which was used prior to the first intervention and after the second intervention period. The tool consisted of students writing two short stories informed by two pictures. One picture portrayed violence and the other a neutral stimulus. The stories were analysed using a qualitative technique. Finally, interviews were conducted with participating teachers to explore changes in the participating classes. The data analysis is currently being finalised but the outcomes will be ready for presentation at the conference. So far, the analysis indicates a complex set of outcomes with few intended causal effects. Some of the outcomes are contrary to
expectations. For example, among the control groups a sense of community (social integration) was established faster than among the intervention groups. Yet, the sense of community was stronger in the control groups following the two intervention periods. Teachers and students considered making music as equally engaging and exciting. The study outcomes will inform the development of effective and cost-effective social skills training for the use in schools.

Keywords: music-based interventions, secondary schools, violence prevention, social integration, conflict resolution

Graduate training and commitment in construction SMEs

GILBERT, G. (RMIT University)

The present research investigated which graduate career development activities implemented by construction organizations are successful. Formal graduate development programs were compared to informal training activities for graduates across construction organizations varying in size and industry sector. The research adopted the philosophy of a traditional program evaluation format within a sequential mixed method structure. The first phase of the research ascertained what training activities are implemented and why, in which “success” was defined in terms of desirable outcomes of development programs. The second phase measured the type and frequency of training activity undertaken by each graduate and compared this with the definition of “success”. Both qualitative and quantitative data were collected and analyzed. Phase 1 identified that large construction organizations define “success” as increasing skills and graduate retention. For logistical reasons, Phase 2 focused on measuring potential retention as represented by organizational commitment. No significant correlation was found between the presence of a formal graduate development program and commitment, even though a slight positive trend was reported. Of the individual development activities, job rotation was found to be significantly associated with an increase in affective commitment; multiple interviews during recruitment were found to be significantly associated with a lower continuation commitment. Large construction companies with sufficient facilities may be encouraged to implement a formal graduate development program with the potential for positive outcomes. However, small construction organizations can achieve an increase in attractive commitment levels without the implementation of such a program. Carrying out multiple interviews and job rotation will achieve an increase in commitment and are not financially prohibitive. The research proposes that these results are not exclusive to the construction industry and that job rotation and multiple interviews should be implemented in other industries such as nursing and teaching.

Keywords: graduate, career development, success, recruitment, commitment

Guilt over consumption vs. the healthy wine message: What is accepted by everyday drinkers?

MORAN, C. (Charles Sturt University), SALIBA, A. J. (Charles Sturt University)

The media has been quick to promote the health affordance of wine (initiated by the so-called French Paradox), while public health messages tend to focus on the need to reduce alcohol consumption. People get mixed messages about drinking alcohol and its effect on their wellbeing. At least one study has shown an increase in guilt over drinking despite reduction in alcohol consumption in recent years (Messiah et al, 2008). Given the complexity of the relationship between alcohol and wellbeing, different messages and reactions are understandable. We were interested in whether drinkers’ motives and beliefs reflected ‘acceptance’ of the health affordance message for wine and whether there was a differential relationship with the guilt scores on the CAGE questionnaire. We expected wine drinkers to be those most affected by the health affordance message. We were also interested in ‘normal’ drinkers. The interview questionnaire collected information on motives, beliefs, type of beverage preferred (defined as consumed 90% of the time), and items on attitudes and behaviours related to alcohol
consumption. Over a thousand participants completed a national telephone survey. The acceptance of the health message was modest across the sample, with wine drinkers scoring slightly but significantly higher on ‘drinking because it’s healthy’ than beer or spirits drinkers. There were no differences on the guilt item across preferred beverage, but there were differences for the other CAGE questions with wine drinkers more likely to disagree with statements associated with potential problem drinking. Women were more likely to consume wine exclusively, but less likely to believe it is healthy for them. Drinking red wine, being male and older were variables most related to a high scores on health belief. Although there were no differences in guilt across subgroups, male beer drinkers reported a higher perceived need to cut down on drinking. Perceiving wine or other beverages as healthy does not interact with guilt over drinking, but motives and beliefs have a more complex relationship with consumption and perceived need to ‘cut down’ in a non-clinical sample.

Keywords: wine, alcohol use, well-being, attitudes, guilt

Hazardous drinking in young adults: Role of reward and punishment sensitivities, drinking motives, and alcohol outcome expectancies

GALLIGAN, R. (Swinburne University of Technology), ALLEN, S. (Swinburne University)

The aim was to examine how drinking motives and outcome expectancies mediated the link between more basic personality factors of reward and punishment sensitivity and hazardous drinking in young adults. The study also examined potential gender differences and whether differences in ‘hyper-masculine’ values held by males influenced the extent to which motives and outcome expectancies and personality factors influenced hazardous drinking. Participants (135 females and 63 males) aged from 18 to 30 years ($M = 22.5$ years) completed an internet-based self-report questionnaire that assessed alcohol use, drinking motives, outcome expectancies, punishment and reward sensitivity and hyper-masculine values. Results indicated that reward sensitivity predicted hazardous drinking with major mediators of this relationship being positive expectancies, especially assertion; and drinking motives, especially enhancement of positive emotions, but also including social, coping and motives related to intimacy and gaining personal experience; and negative expectancies that alcohol use leads to dependency. While no direct effect was found for punishment sensitivity and hazardous drinking, indirect relationships were found such that young adults who expected more immediate negative outcomes such as negative mood were less likely to drink at hazardous levels. No gender differences were found in the relative importance of variables predicting hazardous drinking, although more males (49%) engaged in hazardous drinking than females (41%). Hyper-masculinity in males was correlated to hazardous drinking levels in order to cope and to enhance cognition, whereas those low in hyper-masculinity were more inclined to drink for sexual enhancement. Implications of results for interventions are discussed. Since hazardous drinkers are aware of the long-term consequences of dependency it is unlikely that shock tactics that emphasize these outcomes will work to reduce drinking, although emphasis on more immediate negative outcomes may. Since young adults drink to enhance positive mood, be sociable, assertive, and to enhance personal experiences and intimacy, one set of interventions needs to foster a general cultural change so that these ends can be met without excessive alcohol use. Other interventions that teach more effective management and coping with life problems would seem necessary for those who use alcohol to cope with emotional distress.

Keywords: drinking motives, personality factors, young people, hazardous drinking, hyper-masculinity

Health care and psychosocial situation of patients with a rare disease: The example of 228 patients with Neurofibromatosis type 1 in Germany

LANGENBRUCH, A. (University Clinics of Hamburg, CVderm), MAUTNER, V. (University Clinics of Hamburg), GRANSTROM, S. (University Clinics of
The aim of the current study was to survey psychosocial burden, health care and treatment benefit from the patients’ point of view. Neurofibromatosis type 1 (NF-1) is a rare acute disease (incidence 1:3000). To date, there is a lack of studies about the patients’ health care and psychosocial situation. In a non-interventional study, a total of 228 adult patients with NF-1 filled in a questionnaire on social situation, clinical data, quality of life, body image, treatment benefit and diverse health care parameters. Different subgroups were compared (e.g. patients with vs. without affected relatives, or patients with vs. without specialist treatment). The participants had a mean age of 44 (+/- 13), 61.7% were female, 74.1% were members of a self-help organization. 37% of the patients stated to be diagnosed with a depressive disorder. 51.3% had long term relationships which is lower than the national average (Germany ~ 62.4%). 11% of the patients older than 27 still lived in their parents’ home (Germany ~2.2%). Most patients were treated by general practitioners (67.5%), NF-1 specialists (59.2%) and/or neurologists (43.2%). Patients who were treated by specialists were more satisfied with treatment. They had also higher treatment benefit in areas closely related to the disease, but they did not report more benefit with regard to daily life experiences and personal relationships. 48.3% of the patients had relatives affected by NF-1. These patients had more long-term relationships and more had children. These results indicate that medical care on a high standard can help moderate the disease’s symptoms. However, it does not seem beneficial to improve patients’ daily life experiences to the same extent. Relatives of those affected by the disease might help them to cope with certain daily life challenges which then lead to better psychosocial integration. In summary, to improve the situation of patients with rare psychosocially burdensome diseases more comprehensively, we suggest that psychologists and physicians work closer together.

Keywords: psychosocial burden, health care, treatment, rare disease

Healthy lifestyle patterns among rehabilitation patients: Physical activity as a gateway behavior?

FLEIG, L. (Freie Universität Berlin), LIPPKE, S. (Freie Universität Berlin), POMP, S. (Freie Universität Berlin), SCHWARZE, R. (Freie Universität Berlin)

Physical activity might be a gateway behaviour for an overall healthy lifestyle, including healthy nutrition and non-smoking. Being physically active is associated with psychological resources, such as planning-ability and self-efficacy, which might promote other behaviours as well. Moreover, the stronger a physical activity routine the more resources might be available to invest in other health behaviors. The goal of the study was to assess the prevalence and interrelations of three health behaviors and its social-cognitive determinants in a sample of rehabilitation patients. A sample of 256 patients filled out a computer-based questionnaire assessing three health behaviours (smoking, physical activity, nutrition), stages of change for physical activity, physical activity self-efficacy and habit strength. Multiple linear regression analysis was conducted. Overall, 20.3% of the study participants met recommendations for all three behaviors, 38.3% for at least two of the three health behaviors and 30.1% displayed one health behavior. 8.2% did not reach any health recommendation. Stages of change for physical activity, physical activity self-efficacy and habit strength significantly predicted whether individuals met recommendations in zero, one, two or three behaviors (p<.01, R²=.40). This study documents that different health behaviors tend to cluster among rehabilitation patients. Results indicate that being physically active, having a high level of physical activity self-efficacy and having developed a physical activity routine might promote other health behaviors. This might be explained by transfer effects. Such effects can be targeted in interventions for adopting and maintaining multiple health behaviors.

Keywords: physical activity, healthy lifestyle, rehabilitation, self-efficacy
Help-negation for suicidal ideation and other symptoms of psychological distress

WILSON, C. (University of Wollongong), DEANE, F. (Illawarra Institute for Mental Health / University of Wollongong)

Help-negation refers to the help avoidance or refusal that has been found in samples with clinical and subclinical levels of common mental disorders, for a variety of professional and non-professional help sources. This paper provides a critical review of existing help-negation research, highlights implications for prevention and intervention, and suggests directions for further research. Studies have repeatedly found that people with higher symptom levels are also those with higher intentions to seek help from no one and the lower intentions to seek help from health care professionals, family and friends. Although the determinants of help-negation are not yet known, studies so far have found that help-negation is not fully explained as a function of hopelessness or lack of prior help, the belief that previous help-seeking experiences were of poor quality, or co-occurring symptoms of common mental disorders. Beliefs about the need for mental health treatment and the need to solve one’s problems alone are associated with help-negation, but the role of these cognitions is still unclear. Findings of help-negation suggest that aspects of at least some types of psychological symptoms impede help-seeking. These findings also raise important implications for prevention initiatives and interventions that rely on proactively accessing and engaging in help. How successful can we expect to be if a consequence of experiencing psychological distress, even in its very early stages of development, is a tendency to withdraw from specific helping opportunities or avoid help altogether? Future consideration might be well placed on both identifying the determinants of help-negation and better understanding the role of neurological, social and cognitive variables in strengthening and maintaining the help-negation process. Improving what we know about help-negation might provide further clarification about why, globally, large proportions of people with common mental disorders do not access mental health services when such help is warranted.

Keywords: help-negation, suicidal ideation, psychological distress, mental disorders, help-seeking

How do value priorities of Muslims, Roman Catholics, Protestants, Eastern Orthodox, Jews and religiously unaffiliated differ?

SCHWARTZ, S. (The Hebrew University of Jerusalem)

Differences in basic values may underlie conflicts among religious groups that have flared on the international scene. This presentation aims to provide a snapshot of value priority differences among Muslims, Roman Catholics, Protestants, Eastern Orthodox, Jews and religiously unaffiliated in Europe. It then identifies the influence of religion per se on these value priorities. Data are from representative national samples in 28 European countries plus Turkey and Israel, gathered in the European Social Survey between 2002 and 2006 (N=102,000+). A 21-item scale measured the Schwartz (1992) basic values. Multi-group confirmatory factor analysis assessed meaning equivalence (metric invariance) of values across religious groups. MANOVA across countries examined differences in religious group value priorities. To reveal the influence of religion per se, MANCOVA controlled individuals’ background and within-country comparisons controlled country cultural differences. Six basic and unified values exhibited meaning equivalence: security, conformity/tradition, hedonism, power/achievement, self-direction/stimulation, and benevolence/universalism. Significant between group differences included Protestants attributing the most importance to benevolence/universalism and Muslims the least, Eastern Orthodox the most to importance to security and Protestants and unaffiliated the least, Muslims and Eastern Orthodox the most importance to conformity/tradition and unaffiliated and Jews the least, and many more for each value. Substantial differences prevail in the priority religious groups give to the basic values that serve as guiding principles in life. These differences are largely due to religion per se and may contribute to intergroup conflict.
**How does employment-status affect psychological well-being? An analysis of the meditational qualities of the latent benefits of work.**

SELENKO, E. (University of Linz), BATICNIC, B. (University of Linz), PAUL, K. (University of Erlangen-Nuremberg)

Unemployment has been related to serious psychological problems across several decades and cultures (Paul & Moser, 2009). According to latent deprivation theory (Jahoda, 1982) unemployed persons have less access to the latent and manifest benefits of work, which is why they report more distress. The presented study examines the individual impact of the latent benefits of work as possible mediators of the effect of employment on health. A longitudinal study among employed, unemployed and persons out of the labor force was conducted (nt1 = 1026). Access to latent benefits and psychological health were measured using the Latent and Manifest Benefits of Work scale (Muller, Creed, Waters & Machin, 2005) and the General Health Questionnaire (Goldberg & Hillier, 1979). The results show that the effect of unemployment on well-being was mediated by access to latent and manifest benefits at each time point. Multiple-mediation analyses indicated that while financial benefits mediated the effect of employment status on health at each time point, the latent benefits worked differently well as mediators. Longitudinal analyses confirm the causal direction underlying the mediation. The presented study provides support for the proposed mediatiion of the effect of employment status on health by the latent and manifest benefits of work. In line with previous studies, the findings stress the need to consider the latent benefits of work as separate dimensions rather than as one overall concept.

**Keywords:** unemployment, latent deprivation theory, distress, longitudinal study, psychological health

**How sharing influences emotions among friends**

HASHIM, I. (Universiti Sains Malaysia)

The aim of this study is to discover the kind of issues and the level of sharing that occurred among pairs of close friends. The other aim is to understand how sharing may change their feelings and why. Thirty pairs of self-identified close friends took part in the study. They were university students from Malaysia. Participants were presented with 30 situations (e.g. when I have financial problems, when I am happy) and were asked whether they shared about these situations/feelings with their partner in this study. They were also asked to report how their feelings changed after these sharing sessions and why. This study is part of a bigger study on friendships of young adults. Findings suggest there was high level of sharing among close friends in this sample. Sharing also had a positive correlation with emotions, whereby the more sharing they did, the higher likelihood their emotions changed for the better. Sharing is highest when participants were stressed, bored, happy and excited. Participants reported less sharing when they have financial problems and when they experiencing jealousy. There were very few people reported feeling worse after some forms of sharing. Reasons why sharing related to feeling worse were either related to the partner (e.g. partner not responsive, partner over-reacted) or related to the self (e.g. not comfortable in sharing about financial problems). Reasons as to why sharing related to feeling better were also related to the partner (e.g. partner can help) or self (e.g. feeling better after sharing). These findings highlight several important issues. One is the importance of sharing, and secondly, how sharing can change the dynamic of friendship. Findings also suggest situations when sharing may not be helpful and can change the sharing experience to a negative one.

**Keywords:** sharing, emotions, friendship
Human factor aspects of signing complex road interchanges: Practice is lanes away from theory

MORGAN, H. (Centre for Accident Research and Road Safety - Queensland), RAKOTONIRAINY, A. (Centre for Accident Research and Road Safety - Queensland), HAWORTH, N. (Centre for Accident Research and Road Safety - Qld / QUT)

Complex interchanges, abundant in the US, account for more crashes per kilometre driven than any other segment of freeways (Northrup & Retting, 2004). Despite their lower prevalence in Australia, they account for 597 crashes in 2004. One factor contributing to these crashes is poor signage. Currently, sign designers apply the principles contained within the Manual of Uniform Traffic Control Devices (MUTCD) to sign complex interchanges. This manual is not designed to be a complete guide, and does not provide specific guidance for signing complex interchanges and lacks any human factors supplement (Smith, 1977). This research aims to identify human factors theories, empirical research and practice relevant to the problem of signing complex interchanges. This systematic review will be conducted to assess sign design characteristics and the implications for safety and system efficiency. A comprehensive search of databases and reference lists of articles was conducted. The selection criteria included peer-reviewed articles which addressed human factors principles (trials, studies) relating to the following aspects of signage: sign properties, interaction with the environment, and driver information processing. A set of recommendations to enhance signage practices on complex interchanges were identified. Sign self-evident properties (colour, shape, distinctiveness, familiarity, simplicity) recommendations were suggested to enhance the salience of signs and reduce information processing time. Recommendations included sign placement and interaction with the visual environment which were aimed toward reducing visual clutter and enhance driver information processing speed. Other recommendations target other aspects of information processing (driver perception, mental workload and driver comprehension) in terms of signage information/content and design of the overall signage system. This systematic review will contribute significantly to the knowledge on complex signage design. It suggests that well designed signs may prevent road traffic crashes. However, further research using controlled experimental designs e.g. using simulators and computer studies, is needed to determine the effectiveness of each of the recommendations of improving system efficiency and road safety.

Keywords: driving accidents, signage, human factors

Human factors in non-destructive testing (NDT): First steps in approaching the challenge. Nuclear waste management in Sweden and Finland.

The nuclear power industry has the responsibility for management and disposal of all radioactive waste from its plants. Finland and Sweden are leading in the world in the disposal of spent nuclear fuel. Their method consists of encapsulating spent nuclear fuel in copper canisters and depositing them in the bedrock at a depth of about 500 meters for the next 100 000 years, leaving the radioactivity to decrease naturally through the decay of the radioisotopes in it. The copper canisters, consisting of a copper tube, a lid and a bottom which make the outer shell and an insert made of a cast iron, need to be inspected for their structural integrity. This is done using Non-Destructive Testing (NDT) methods, such as ultrasound or radiography, to ensure no critical defects are present in the materials and welds that could lead to a leakage of the waste into the environment. Evaluations of the data gathered by NDT are performed by skilled human operators and could therefore be subject to human error. A multidisciplinary team of engineers, physicists and psychologists is working on estimating and improving the complete reliability of these testing methods. The capability of the NDT system to detect critical defects (those that exceed the acceptance criteria) is evaluated by calculating the probability of detection (POD). Different cognitive and organizational factors as well
methods of optimizing the detection of critical defects are a part of the human factors approach. Customized Failure Modes and Effects Analysis (FMEA) was used to identify possible risks that might lead to potential human errors. Several experiments (e.g. use of decision aids in identifying critical defects, social responsibility within the 4-eye principle, complacency bias in interaction with automated systems, or using the eye tracking methodology to optimize the detection of defects) have been proposed and some of them will be experimentally tested in ongoing projects. The first results are expected in the first half of the year and are, in general, expected to lead to the optimization of the procedures followed by the NDT operators and finally to improving the overall reliability of the system.

Keywords: human factors, non-destructive testing, nuclear waste management, reliability, human errors

Human factors influencing the social acceptability of forest landscape management in Tasmania, Australia

FORD, R. (University of Melbourne), WILLIAMS, K. (University of Melbourne), SMITH, E. (University of Melbourne), BISHOP, I. (University of Melbourne)

Forest management is highly contentious, but the basis for public concerns is not well understood. Knowing the psychological factors that underlie public responses could help managers to better align forestry with the values and beliefs of the wider community. This research sought to explore the relative importance of psychological factors that underlie the social acceptability of forest landscape management. About 490 Australians filled in a questionnaire in which they recorded their: held values for the natural environment; deontological normative beliefs about how forests should be managed and trust in forest management agencies. They were also asked to respond to information about current forest management and they recorded scenic beauty, beliefs about impacts and social acceptability. Structural equation modeling was used to test whether the data collected were consistent with theorised relations between factors. The most important factor directly underlying social acceptability was people’s beliefs about whether management was good for the environment or not. Also important were people’s trust in management agencies and their scenic beauty ratings. If people had more trust, or rated the managed landscape more beautiful, they tended to think it was better for the environment, and therefore more socially acceptable. There is a particularly strong relationship between scenic beauty and beliefs about environmental impacts. Held values for the natural environment were fundamental, underlying all the other factors. People with stronger use values tended to have higher levels of trust in managers, viewed current management as having more positive impacts on both the environment and the timber industry and rated it more socially acceptable. The reverse was true of people with stronger intrinsic values for the environment. This research shows that impacts on the natural environment are an important concern for many members of the public. The findings suggest managers would achieve more socially acceptable results if they placed greater emphasis on improving the environmental outcomes of forestry. The close relationship between beliefs about environmental impacts and scenic beauty begs theoretical questions that cannot be fully answered by this research.

Humour at work (HAW): The development and validation of a scale useful for human resources

RAWLINGS, M. (Swinburne University of Technology), FINDLAY, B. (Swinburne University of Technology)

To describe the development of the Humour at Work (HAW) scale and its validation against humour, personality and work related scales using two independent Internet samples. An international sample (N=350) was asked to respond to 150 items developed from a wide variety of humour theories and approaches. Factor analysis reduced these to 62 items in eight factors. A second sample of 379 Australian workers responded to these items, plus
Abstracts of the 27th International Congress of Applied Psychology

measures of mood, personality, general humour styles, climate of fear, job satisfaction, and other workplace measures. Confirmatory factor analysis indicated that the factors were reliable, and correlated in expected ways with general humour styles, job satisfaction and workplace climate. Confirmatory factor analysis further reduced the 62 items to two scales, essentially Pleasant and Unpleasant Climates of humour in the workplace. These factors were predictive of occupational climate factors which have been predictive of productivity. The HAW (either the 8-factor version or the 2-factor version) may be a useful measure in the workplace, since it is predictive of workplace measures that relate to workplace performance, but is less threatening than asking directly about such performance measures.

Keywords: humour, humour, personality, climate, job satisfaction

If you want to be a happy newcomer, find a role model!: A longitudinal study of new employee proactive behaviours and their relationship with socialisation success

COOPER-THOMAS, H. (University of Auckland), ROBERTS-HITCH, R. (University of Auckland), OWEN, F. (University of Auckland)

Research on new employees during organisational socialisation typically assumes that proactive behaviour will improve socialisation success, yet there is a lack of longitudinal research to examine relationships more closely. Hence the aim of this research was to assess whether increases in new employees levels of proactive behaviour were associated with greater socialisation success, as measured by typical indicators of this process. Data were collected from 80 new employees and newly-promoted employees across a range of organisations. Participants responded to a survey at weeks 2 and 12 after entry into their new role. Survey items included proactive behaviours (e.g., role modelling), newcomer learning (e.g., role domain), and work-related attitudes (e.g., job satisfaction). It was found that increases in role modelling predicted increases in learning in the three domains of role, social, and organisation, as well as increases in job satisfaction and decreases in turnover intention. Increases in networking predicted increases in role and organisation learning, job satisfaction, and decreases in turnover intention. Increases in relationship building and positive framing predicted increases in role learning, job satisfaction, and decreases in turnover intention. Increases in general socialising were not associated with any of these criteria. These results provide the first longitudinal evidence that, in general, behaving more proactively is associated with better socialisation outcomes for new employees and newly-promoted employees. From a theoretical perspective, this research looking at the influence of individual proactive behaviours mirrors findings for organisational socialisation tactics. Specifically, in both cases, targeted actions with a social focus have a stronger positive influence on newcomer adjustment. From a practical perspective, given that careers are increasingly multi-role and multi-organisational, socialisation interventions should support newcomers in being more proactive, for example providing experienced employees to act as role models, and making their effective use the responsibility of all parties.

Keywords: socialisation, employees, role modelling, work-related attitudes

Impact of disasters on youth: disaster-related trauma, life events, and PTSD symptoms as predictors of children’s somatic symptoms

LA GRECA, A. (University of Miami)

Natural disasters contribute to symptoms of posttraumatic stress disorder (PTSD) in children many months after destructive disasters. However, little attention has focused on health consequences of disasters, even though psychological stress affects one’s health. Using a conceptual model of risk and resilience, this study examined the impact of hurricane-related traumatic stress and other life stressors on children’s somatic symptoms almost two years after a natural disaster. Hurricane Charley, a Category 4 storm, struck Florida in August 2004, devastating 90% of the surrounding area. 220 children (55% girls; 85% Caucasian; M age = 8.7
years) participated. At 9- (Time 1) and 21-months (Time 2) postdisaster, children completed measures of hurricane-related stressors (Hurricane Related Traumatic Events-Revised), PTSD symptoms (PTSD-Reaction Index for Children), and life events; somatic symptoms were assessed at Time 2 with the Youth Self Report. Children reported moderate levels of PTSD symptoms (Time 1 $M=19.81$; Time 2 $M=17.71$), one major life event (Time 1 $M=1.27$), and multiple somatic symptoms (Time 2 $M=7.26$). Regression analyses evaluated predictors of somatic symptoms 21 months post-hurricane, controlling for children's age, gender, and ethnicity. Hurricane-related traumatic experiences accounted for 9% of the variance in somatic symptoms ($p=.01$) and Life Events accounted for 6% additional variance ($p=.001$). Time 1 PTSD also predicted Time 2 somatic symptoms ($r=.40$, $p=.001$), but hurricane experiences were not significant when PTSD symptoms were entered. Further tests revealed that Time 1 PTSD symptoms mediated the relationship between hurricane experiences and Time 2 somatic symptoms. This study is one of the first to examine children's health reactions to disasters and the first to examine predictors of such responses. Findings indicate that children report moderate PTSD and somatic symptoms almost two years following a disaster; that somatic symptoms may result from hurricane-related traumatic experiences; and that PTSD symptoms explain this prospective association. Children experiencing significant PTSD symptoms post-disasters are likely to report health or somatic concerns. Attention to children's physical health and mental health are important goals for assessment and intervention following natural disasters. Further study of the health consequences of disasters in children is important and desirable.

Impact of parent – adolescent conflict on adolescent’s psychological development

PAJKIC, I. (Chadstone Family Mediation Centre), WILKS, R. (International Medical University), KIENHUIS, M. (RMIT University)

This paper will report the results of the first of three studies and describe two planned studies aimed at the development of a conflict resolution model for use by parents of adolescents. This paper will also discuss the current literature related to parent-adolescent conflict, identify gaps in the literature, and suggest a number of steps that can be taken to fill these gaps. Study 1 was a retrospective study investigating the impact of parent-adolescent conflict on adolescent psychological development, the nature of the conflicts and conflict resolution methods used by parents and adolescents. Interview responses from 19 young adults (11 females and 8 males) aged 18 - 30 years ($M=23$ years), were qualitatively analyzed through the application of Grounded Theory. Results indicated that the most severe conflicts resulted from parental enforcement of their own values, morals, and beliefs and that this pattern of conflict was particularly prevalent among fathers, irrespective of the gender of their adolescent child. The resulting conflicts were reported to have long-term effects on the psychological well-being of the participants. Given the findings obtained from Study 1, Study 2 is planned to investigate the same issues as Study 1 using a sample of parents and adolescents. Fifty parents and their adolescent child from intact, sole parent, and separated families will be recruited for this study. A questionnaire consisting of the Depression Anxiety Stress Scale (DASS21), the Satisfaction With Life Scale (SWLS) and opened ended questions focusing on the current levels of conflict and conflict resolution methods will be administered. Based on results from the above studies, Study 3 will see the development and evaluation of a conflict resolution model for use by parents and their adolescent child.

Keywords: conflict resolution, parents, psychological development, adolescents

Impaired semantic memory in the formation and maintenance of delusions post traumatic brain injury: A new cognitive model of delusions

ROSELL, S. (Monash University), BATTY, R. (RMIT), HUGHES, L. (Macquarie University)
This paper proposes a new cognitive model to explain the aetiology of delusions irrespective of diagnosis and/or phenomenology. The model hypothesises the influence of two processes in the formation and maintenance of delusions; (i) impaired perceptual abilities, particularly affect perception, which fosters the encoding of (ii) idiosyncratic semantic memories, especially those with an affective/self referential valence. Previous research has established that schizophrenia patients with delusions have impaired semantic memory function. In the current paper we sought to provide evidence for (ii) abnormal semantic processing in persons with delusions with an alternative aetiology. Performance of four cases with a significant delusion post a traumatic brain injury was examined on a broad range of semantic memory tests. Overall semantic processing was impaired in the four cases relative to a normative healthy control sample. Cases performed better on tasks which required categorical identification, relative to the novel production of semantic information, which was poor in all four of the cases. We have shown atypical semantic processing in deluded individuals who have sustained a traumatic brain injury. Importantly, the pattern of semantic performance recorded by our cases is consistent with schizophrenia patients with delusions, although in some cases they did not show such global semantic processing impairments. Taken together, we consider this as preliminary evidence for consistent abnormal semantic processing in persons with delusions, irrespective of diagnosis and phenomenology. This finding will need to be verified in larger sample groups of persons with delusional beliefs across a range of diagnoses.

Keywords: delusions, perceptual abilities, semantic memory, traumatic brain injury

Improved safety and reduced speeds resulting from a self-explaining roads process

The research investigated whether a Self-Explaining Roads (SER) approach could improve road safety by establishing a road hierarchy with visually distinct designs at each level. Traditional approaches to improving road safety have focussed on treating isolated “black spots” in response to crashes or public complaints. Treatments that are highly localised or idiosyncratic may have the disadvantage of adding to the multiplicity of road categories and result in the migration of the original problem to nearby locations, rather than building driver expectations around a few consistent road types. The study area was divided into two equivalent sections, one to receive SER treatments and the other a control section. Analysis of speed data, crash reports, and resident surveys were used to identify: functional exemplars (roads at each level in the hierarchy that functioned well) and functional outliers (roads with speed, safety, or volumetric problems). The analysis revealed few physical and visual differences between local and collector road categories and corresponding heterogeneity of speeds and traffic volumes across the two road categories. A design template was created to extend design features from functional exemplars to functional outliers and reinforce the desired functions at each level in the hierarchy. Approximately 11km of local and collector roads were treated to create visually distinctly road categories. Following treatment, vehicle speeds showed greater homogeneity of speeds within each road category and greater differentiation between categories. Speeds on local roads were reduced significantly (mean speeds fell from of 45km/h to 30km/h and 85th percentile speeds fell from 55 km/hr to 37km/hr). On collector roads, speeds were also reduced significantly, particularly the number of vehicles travelling at high speed (52% reduction of vehicles in the 70-80km/h range). Analysis of pedestrian and cyclist movements have shown increases in pedestrian activity and decreases in pedestrian and cyclist conflicts with motorised vehicles. The project was successful in demonstrating how an SER process can be applied to improve safety. The project has had a significant impact on how other road safety projects in New Zealand are undertaken with elements of the approach applied in two road safety projects in other cities.
Keywords: road safety, reduced speed, self-explaining roads (SER)

**Improving critical thinking skills: Business students’ gender, race, abilities, and motivation**

TANG, T. (Middle Tennessee State University), AUSTIN, J. (Middle Tennessee State University), HOWARD, L. (Middle Tennessee State University), TANG, T. (Tang Global Consulting)

This study attempts to identify factors that may help business students improve their critical thinking skills. We also adopt a case-based critical thinking module (a short intervention) using the Solomon Four-Group Design and examine the effects of pre-test and intervention on possible changes of business students’ critical thinking skills. We collected data from 659 business students in 14 courses at a regional state university in the US using multiple sources. Using the Solomon Four-Group design, we adopted a short cased-based critical thinking intervention, used the Watson-Glaser Critical Thinking Appraisal (CTA) to measure students’ CTA scores, contacted university’s record office to obtain students’ official age, sex, race, ACT test scores (English, Math, Reading, and Composite), and overall GPA (grades), and used an online survey to collect data regarding students’ learning styles, modality, cognitive styles, and motivational orientations in one semester. Results showed that the main effects (cased-based intervention and pre-test) and the interaction effect on CTA 2 (post-test) were not significant. From pre-test (CTA 1) to post-test (CTA 2), students in both Groups 1 (with intervention) and 2 (without intervention) improve their critical thinking skills. Overall, low pre-test scores (CTA 1) and high composite ACT scores contributed significantly to students’ improvement. Female and white students improved their performance, whereas male and non-white (minorities) did not. Moreover, 35.5% of the students improved their CTA scores from pre-test to post-test. In Group 2, students who performed better had high GPA, were older, and female. Students with a strong competitive goal of “outperforming the average student” performed better; whereas those expected to “perform worse than their own usual level of performance” and used reflective and kinesthetic learning styles performed worse. It is concluded that students’ demographic variables, abilities, and motivation contributed to the improvement of critical thinking skills. Faculty and students are encouraged to set positive goals and create a warm climate for improving critical thinking skills in order to meet the future challenges of the competitive global market.

Keywords: critical thinking, gender, race, abilities, motivation

**Improving elderly pedestrians’ safety with a simulator-based training: Short- and long-term effects and age-related differences**

DOMMES, A. (INRETS), CAVALLO, V. (INrets)

The present study aimed at improving the safety of elderly pedestrians through training. Past research has shown that elderly have trouble taking the approaching vehicles’ speed into account and that they make many unsafe decisions when vehicles are approaching at high speeds. Twenty seniors (65-83 years) were enrolled in a street-crossing training program (experimental group). The training promoted repeated simulator-based practice and addressed the strategies elderly adults bring into play. Twenty other seniors (61-82 years) were assigned to a control group (internet-use training course). Before the training, immediately after, and six months later, the street-crossing behaviors of the 40 older participants were assessed using a simulated street-crossing task. The virtual environment displayed an urban scene with traffic coming from one side. Time gap between cars varied between one and seven seconds, and vehicle’s speeds from 30 to 70km/h. The participants had to cross the experimental road when they judged that crossing was safe. Twenty younger participants (20-30 years) performed also the task to serve as a baseline. The training produced significant short- and long-term benefits by shifting the decision criteria towards more conservative judgments. Considerable improvements were also found in the control group, in such a way that no significant difference was found between the two older groups on the long-term follow-up. When
Abstracts of the 27th International Congress of Applied Psychology

compared with younger participants, older pedestrians globally improved their behavior so that no differences in the mean safety-related indicators were observed any longer. However, the older participants' ability to take the oncoming vehicle's speed into account did not improve. Six months after training, older participants still made more unsafe decisions than younger when vehicles were approaching at high speeds. The findings suggest that combining repeated simulator-based practice with enhanced awareness of street-crossing dangers improve the overall older pedestrians' safety. However, the training failed to improve the seniors' use of oncoming vehicle's speed in deciding whether to cross. This finding may reflect age-related perceptual and cognitive impairments that cannot be remedied by a simulator-based training. A better understanding of the perceptual and cognitive abilities involved in street-crossing decision-making is needed and would be useful in designing future training programs.

Keywords: elderly, pedestrians, safety, judgement

Improving service quality through reflection in action, competence mix and role clarity

NANSUBUGA, F. (Makerere University)

The paper highlights the need to translate tacit knowledge into job tailored explicit competences to allow the managers in organizations improve service quality. The study was conducted to build on the Reflection in Action theory by examining how reflection in action can influence competence mix, role clarity and improve service quality. Reflection in action is understood as means of translating tacit knowledge to explicit competences (Keating, Robinson, & Clemson, 1996) by examining one’s past behaviour and then determining new better actions that can address performance challenges especially as a result of changing work demands (Schön, 1987; Marsick & Watkins, 1990). A cross-sectional correlational study utilizing a questionnaire was used to collect data from 120 managers in six districts local governments in Uganda. The sample included head of departments and heads of units. Validity of the items was established using both factor analysis and group differentiation techniques for all variables in terms of; role title/position; education level and time spent on job. Data was analysed using Pearson moment correlation and linear regression analysis. Results confirmed that reflection in action helps to unpack tacit knowledge in order to create explicit competence mix by indicating a significant positive relationship when Pearson moment correlation was used. Further on competence mix was found to correlate positively with role clarity. Consequently this leads to improvement in the quality of the services being delivered. Linear regression analysis indicated that the study variables linearly predict each other. In order to improve service quality, managers need to continuously look back and reflect on the way they have been solving their role/task related challenges, and what actions have led to successes or failures. They need to think critically on the challenges they have faced in relation to the work demands and determine new efficient ways of dealing with these challenges. This process helps them to acquire new relevant competences and thus become clearer when addressing problems that may arise as a result of changes in the work situation.

Keywords: tacit knowledge, service quality, reflection, explicit competences

Improving workability: Investigating modifiable organisational factors to ameliorate the effects of the ageing workforce

DAY, D. (Deakin University), PALERMO, J. (Deakin University)

Australia in one of the world’s most rapidly ageing workforces due to its falling mortality and fertility rates. There is a strengthening case for retaining skilled employees at work for a longer period over their life-course. The Finnish Institute of Occupational Health has for some decades now used an indicator of workability (that is, one’s subjective or objective assessment of ability to work into the future) as a way of signaling health and functionality in the workforce over time. With the increase in

845 | Individual Oral Presentations
demands between work and family life for Australian employees, this may also require considering the effects of family and work on workability and occupational health. This study aimed to investigate the relationships between work life balance and workability. The study also aimed to investigate organisational factors that may mediate this relationship, such as stress and leadership culture. The cross sectional study involved surveying participants of a large government organization and private consulting organization (N = 128). Surveys were distributed through participants’ organisations and completed online. As predicted, the results of a hierarchical regression analyses suggested that work-life balance (WTFS: negative work to family spillover) and psychological rather than chronological age were significant predictors of workability. These relationships were partially mediated by leadership culture and entirely mediated by occupational stress. The results of the final model suggested that workability is likely to increase when psychological age, negative WTFS, and vocational strain decrease. These findings provide new pathways for planning strategic long term interventions to promote retention of mature aged workers by addressing issues of work-life balance, leadership culture and occupational stress.

Keywords: ageing workforce, workability, occupational stress, occupational health, work-life balance

Increasing rates of organ donation – the role of the “ick factor” and anticipated regret

O’CARROLL, R. (University of Stirling), FOSTER, C. (University of Stirling), MCGEECH, G. (University of Stirling), SANDFORD, K. (University of Stirling)

Over 90% of the general population state that they are in favour of organ donation, however far fewer are registered on the organ donor register. This research tested the role of emotional barriers to organ donation such as the “ick factor” (a basic disgust reaction to the idea of organ donation). In addition we tested the potential role of manipulating anticipated regret to increase intention to donate in people who are not yet registered as organ donors. In three experiments involving 635 members of the UK general public, participants were invited to complete questionnaire measures tapping the emotional factors such as “ick”, the desire to retain body integrity after death and medical mistrust. Registered organ donors were compared with non-donors. Non-donors were randomly allocated to an anticipated regret manipulation (2 additional questions) versus a control condition, and the impact on intention to donate was tested. In all three experiments non-donors scored significantly higher than donors on the “ick” factor and bodily integrity scales. Traditional rational/cognitive factors such as knowledge, attitude and subjective norm failed to distinguish donors from non-donors. For non-donors, the anticipated regret manipulation led to a significant increase in intention to register as an organ donor in future. Negative emotional factors are important barriers for people becoming organ donors. In particular, a basic disgust reaction when contemplating donation and the desire to retain bodily integrity after death are key areas to target to test if they are changeable. In addition, a simple anticipated regret manipulation has the potential to significantly increase organ donation rates.

Keywords: organ donation, “ick factor”, emotional barriers

Increasing specificity of autobiographical memory: An investigation of the contribution of pictorial cues

BELCHER, J. (Macquarie University), KANGAS, M. (Macquarie University), HOMEWOOD, J. (Macquarie University)

Over-general autobiographical memory has been implicated as vulnerability for the development of depressive and posttraumatic stress symptoms following stressful life events. Imagery has been found to increase memory specificity among clinical and non-clinical participants. Therefore the primary aim of the current study was to investigate whether emotion picture cues increase autobiographical memory specificity compared to emotion word cues in a non-clinical sample. A non-clinical student sample (N = 79) completed the Autobiographical Memory Test (AMT) with
emotion word cues and emotion picture cues. Both tasks were completed with and without prompting for a specific memory. Participants also completed a questionnaire package including measures of depression (BDI-II), past traumatic life events (LEC), and posttraumatic stress symptoms (PCL-C). A significant interaction between cue type and prompting was found (OR = 3.36, $p = .001$). When participants were prompted to retrieve specific memories in response to positive and negative cues, they retrieved significantly more specific memories in response to picture cues compared to word cues (OR = .40, $p = .001$). However, when no prompting was given, there was no difference in memory specificity between picture cues and word cues (OR = .98, $p = .88$). Among female participants, there was a trend ($t(65) = 1.85, p = .07$) for quicker retrieval of memories in response to picture cues compared to word cues on the prompted AMT. Findings indicate that images enhance memory specificity, even when they are of emotional content. However, this does not seem to be due to the initiation of direct memory retrieval as picture cues only increased memory specificity when participants were prompted. Moreover, these results have implications for imagery training in enhancing memory retrieval particularly for populations susceptible to developing mood and trauma-related disturbances.

Keywords: autobiographical memory, depression, post-traumatic stress, Imagery

Individual factors explaining resilience in extreme poverty

PALOMAR-LEVER, J. (Iberoamerican University)

Poverty exposes individuals to many risk factors that compromise their quality of life and their psychological functioning. Sameroff, Bartko, Baldwin, Baldwin, and Seifer (1998) state that the greater exposition to risk factors in infancy diminishes their social and emotional development and increases the probability of psychological disadjustment. At the same time, research on resilience seeks an answer to the question as to why some individuals at high risk or with a very adverse background seem to grow well adjusted, while others failed (Anthony & Cohler, 1987; Cicchetti & Garmezy, 1993; Garmezy, 1990; Masten, Best, & Garmezy, 1990; Ruter, 1987; Werner & Smith, 1982). The purpose of this study is to contribute with information about which individual factors (motivation to achievement, ability to cope with stress, religiousness, control locus, emotional intelligence) promote resilience in extremely poor beneficiaries of a social development program of the Mexican federal government. The sample was constituted by 914 individuals, all of them beneficiaries of the program “opportunities” during the period 1997-2008. Their age ranged between 22 and 93 years old, with a mean of 43.71 years and a standard deviation of 12.58. Besides, 595 (65.2%) were women and 318 (34.8%) were men (husbands of these women). The results from this research allowed to identify some characteristics associated with resilience, which contributed to determine which factors should be addressed in high risk individuals (extreme poor) in order to promote or increase opportunities to improve their condition.

Keywords: poverty, resilience, quality of life

Individualised teaching and learning by online assessment

Changing educational structures and increasing student diversity call for valid information for students, career advisors and teachers to individualise the learning. It requires custom-fit advice on subject choice, learning and study methods, management of time and choices for further learning and career options. This custom-fit advice requires a detailed and valid student’s profile. Together with governmental bodies in Ireland and the UK an online assessment system has been implemented that provides feedback on: learning style, learning capabilities, time and organisation management, interests and multiple and preferred intelligences. Results from a first evaluation study in Irish schools (N=9,423) indicate acceptance by the users and validity of the measures. The schools use the information to guide individual students but also
formulate holistic strategies and decisions for the entire school to change the way they teach.

Keywords: teaching, education, individualised learning, online assessment, learning strategies

Individualized age-related leadership

EBERHARDT, D. (University of Applied Sciences)

Demographic change makes it necessary to keep elderly employees integrated in the work process. The only highly-significant factor to improve the employability of elderly employees is age-related leadership (i.e. FinnAge Studies). The objective of the study was the measurement of perception, attitude and behavior as aspects of individualized age-related leadership of managers/leaders with respect to age-related factors of employability and integration of elderly employees. The framework of this study was the concept of individualized age-related leadership (Braedel-Kühner, 2005). N = 394 leaders from Switzerland and Germany completed a questionnaire with scales to their attitudes, leadership behavior, perception, performance ratings in respect of age-related aspects of the employees. One scale measured the self-perception of the own aging of the leaders. Different factors of attitudes and leadership behavior in individualized age-related leadership are identified. Descriptive analysis shows attitudes and leadership behaviors of European leaders with respect of aging employees. Differences between attitudes and behaviors where analyzed. Age-related leadership behavior and attitudes show a significant difference in the most items of the questionnaire. In general is the level of age-related leadership behavior below the appropriate attitude. The biggest difference between attitude and behavior shows the scale “work design”. “Employability” of the employees is most relevant for the leaders: training and development, managing of the work load and ergonomics will be more actively influenced by the leaders than i.e. health and health management. Most areas of age-related leadership show a positive age-related attitude compared to the appropriate leadership behavior. There is no sign of an age-related negative stereotype of elderly employees. Some areas of leadership behavior are less developed than others (i.e. health management). Information and training will be helpful for leaders. Discrepancies between attitude and leadership behavior might be a lack of empowerment or flexibility in leadership. Management decisions are necessary to improve the age-related leadership as it is not a matter of the attitudes of the leaders.

Keywords: elderly employees, individualized age-related leadership, employability

Influence of occupation and low income on study success of first year students

STRASSNIG, B. (University of Vienna), LEIDENFROST, B. (University of Vienna), SCHÜTZ, M. (University of Vienna), CARBON, C. (University of Bamberg), SCHABMANN, A. (University of Vienna)

The transition from school to university is a critical life event. Besides new academic tasks students are often confronted with economic aspects of life, like financing life and study. Prior research demonstrated a negative effect of working and/or financial problems on academic achievement, for example the need to work to make a living increases drop-out. In fact, approximately two thirds of all students at Austrian universities work during the studies. The aim of this study is to investigate the effects of occupation during study and low income on study success during the first semesters. In addition, factors that may counteract the negative effects are examined. 989 psychology undergraduate students answered questions about their occupation status, hours of work per week and monthly income in their first semester. Study success was measured after four semesters by number of taken courses and the received grades. Using cluster analysis, students were classified in four groups (depending on monthly income and status of occupation): very low income/no occupation, low income/no occupation, low income/occupation and high income/occupation of half of group. Results demonstrate that low income students, who are occupied, have the lowest grades of all four groups and take fewer courses than students, who are not occupied. The high income group,
where about the half of the students is occupied, takes fewer courses too, but has better grades than the occupied low income group. Interestingly, the number of working hours per week has no influence on received grades. When students hold contact with a higher number of colleagues, the occupied low income group shows improved grades, but the number of taken courses remains stable. Being occupied and having a low income is a risk factor for students and leads to less academic success. Social assistance from colleagues, on the other hand, can counteract the effect and improve the grades of this group. Possible effects of tuition fees are discussed.

Keywords: transition, financial problems, academic achievement, occupation, study

Influence of organizational capacity factors in perceived changes

DOMINGOS, S. (Universidade de Brasilia)

Change in the organizational environment is constant and necessary. The technological development, the market dynamics and the relationship with customers require quick and flexible strategies. Changes can occur only in some aspects of the organization with a view to implementing adjustments and improving efficiency. This is called Transactional Change. When the organization itself is reframed, resulting in a new mission and a shift in its underlying strategy and processes, change is referred to as Transformational. Change occurrences can be hindered or enhanced due to some organizational capacity factors, including the information flow, an organizational action strategy, coalition support for change, turbulence in the external environment, group autonomy, bureaucracy and reliance on managerial action. The present paper aims at appraising whether these factors influence or not the way individuals perceive the transformational and transactional changes in an organization. The data (N = 340) have been gathered in a number of questionnaires applied in a public institution that has been merged with other organs, undergone management changes and had some of its areas restructured. The Organizational Capacity Assessment Tools for Changes and the Change Perception Tool have also been used. The results point out that the organization’s action strategy, the coalition dynamics and the communication flow (R² = 0,35; p = 0,011) are predictive factors for Transformational Changes perception. As for Transactional Changes, group work (R² = 0,16; p = 0,001) is barely considered a predictive factor. As previous research work in public institutions have already demonstrated, the analyzed organ has failed to present organizational capacity for changes. The research results are analyzed taking into account the reviewed literature and the practical implications of this work.

Keywords: organisational change, organisational capacity, transformational change, transactional change

Influence of social support on workplace adaptation of Serbian migrants in Australia

AIMAN, (Deakin University), KILIBARDA, J. (Deakin University)

The aim of the current study was to ascertain whether social support as a coping strategy is useful in mitigating work related stressors amongst Serbian migrants and examining its influence in their adaptation to the Australian organizational climate. This is important to determine to understand the nature of Serbian migrants’ adjustment to the Australian workplace. Participants included 78 Serbian migrants including 43 males and 35 females who completed a Demographic Questionnaire, the Coping Resource Inventory and the Work Environment Scale - Form R. Standard multiple regression analyses were conducted to determine the effects if social support on adaptation to the work climate. The results show that social support partly predicted adaptation to organizational climate amongst Serbian migrants. Specifically, it was found that social support makes the most significant contribution to peer cohesion (20 %), followed by supervisor support (13 %), clarity (10 %), innovation (9 %), physical comfort (9 %), involvement (8 %), task orientation (7 %) and autonomy (6 %). However social support did not significantly predict work pressure and managerial control. The findings
suggest that social support is a tool that eases the impact of cross cultural adjustment to the organizational climate amongst Serbian migrants. Consequently these findings have the potential to assist both current and future migrants in successfully adapting to the work environments in their host country.

Keywords: Serbian migrants, work related stressors, social support, Australian workplace, organizational climate

Influencing desire and intention to perform health behaviours: a reverse effect of regulatory fit

KAPLAN, R. (Monash University), JORY, M. (Monash University)

This study’s aim was to investigate the interaction between an individual’s chronic regulatory focus and the framing of persuasive health messages (either loss-framed or gain-framed) in influencing desire and intention to perform the advocated health behaviour. From a theoretical perspective, a message’s effectiveness is thought to be greater when there is congruence between regulatory focus and message frame (“regulatory fit”) than when there is incongruence. This study sought empirical support for this idea for messages advocating smoking cessation and undergoing skin cancer examinations. An online questionnaire system randomly assigned participants to a behaviour type (either smoking cessation or skin examination) and message frame (either loss-frame or gain-frame) condition (thus there were four conditions). Participants were presented with questions about current/past health behaviour followed by a set of messages advocating smoking cessation and undergoing skin cancer examinations. An online questionnaire system randomly assigned participants to a behaviour type (either smoking cessation or skin examination) and message frame (either loss-frame or gain-frame) condition (thus there were four conditions). Participants were presented with questions about current/past health behaviour followed by a set of messages advocating the respective health behaviour framed either in terms of losses or in terms of gains. Participants then completed Likert scale items assessing intention and desire to engage in the behaviour (within 6 and 12 month timeframes). After controlling for past/current behaviour, moderated regression analyses revealed a significant message frame-by-chronic regulatory focus interaction effect for intention and desire to quit smoking (for both 6 and 12 month timeframes) but it was a reverse effect to that predicted (i.e. intention and desire to quit was greater in the absence of regulatory fit than in its presence). No significant interaction effect was found for skin examination conditions. Although regulatory fit typically enhances the positive evaluation of a message, it has been suggested that if the message is negatively evaluated to begin with, regulatory fit may enhance that negative evaluation. It is suggested that the anti-smoking messages may have provoked a negative response among participants (e.g. through psychological reactance) that was strengthened when regulatory fit was present. Thus, in developing health campaigns/messages/interventions, under certain circumstances regulatory fit is not always desirable for maximal effectiveness. The lack of effect for skin examination is thought to have resulted from insufficient framing strength, as indicated by a non-significant framing manipulation check for that behaviour.

Keywords: chronic regulatory focus, persuasive health messages, desire, intention

Influencing tactics at work: Managers and subordinates perspectives

GEERTSHUIS, S. (University of Auckland), COOPER-THOMAS, H. (University of Auckland), MORRISON, R. (Auckland University of Technology)

The aim of this research was to build understanding of subordinates’ influencing tactics. Work to date indicates that the relationship between a manager and their staff member may affect which influencing tactics subordinate may use, as well as the subordinate’s political skill. Other work suggests that higher performing staff use tactics differently to staff who perform less well. This study which seeks to identify the relative contribution of relationship and individual factors captures the perspectives of both managers and subordinates. Unmatched subordinates (N=182) and managers (N=110) completed an online survey which assessed the frequency of use of six influencing tactics. Subordinates and managers also assessed Political skill, Leader Member Exchange, Role Breadth Self-Efficacy, Control and Change Orientation and Performance. Poorer self-
reported performing subordinates used tactics more than did higher performing subordinates. High and low performing subordinates, as measured by self assessment, reported using tactics differently. Adaptivity and change orientation predicted influencing tactic use for high self reported performers only. Relationship with manager and political skill were found to be only weak predictors of influencing tactics. Current understanding of the determinants of subordinate tactic usage is incomplete and suggests that higher performing individuals would influence more, and favour rationality as their preferred tactic. This study suggests that this may be an oversimplification, although providing an insight into the complex role of individual differences in predicting the means by which subordinates seek to influence their managers.

Keywords: influence tactics, political skill

Information and reputation influences in portfolio decisions: Herd behavior

PARK, J. (Ajou University), ZHANG, C. (Ajou University), KIM, D. (Ajou University)

This investigation adopted the notion that risk decisions change as a function of perceived gain and loss situations (Tversky & Kahneman, 1981; Thaler & Johnson, 1990) and aimed to distinguish between two types of investment propensity that stock investors have. The tendency to sell winning stock and keep losing stock is called the disposition effect. The opposite tendency, to keep winning stock and sell losing stock is called the non-disposition effect. Two experimental studies were conducted examining whether sources of expert or non-expert information in stock investment would facilitate (or impede) the initial investment propensity (i.e., disposition or non-disposition effect) of the participants, resulting in forward (or backward) herd behavior. 75 participants were randomly assigned to Non-expert (N=25), Expert (N=25), and Control (N=25) groups in both study 1 and 2, respectively. In the Pre-test, each participant made stock portfolio decisions about how they would buy, sell, or keep each three of winners and losers, which were used to classify them as showing either disposition and non-disposition effects. In study 1, the Non-expert group was shown the decisions of ordinary people showing a non-disposition effect. The Expert group was given identical scenarios, but instead of ordinary people, the decisions appeared to be from experts. The control group was not exposed to any decisions. Study 2 was identical, but with one twist: The Non-expert and Expert groups were shown the decisions of both ordinary and expert people showing a disposition effect (selling winners and keeping losers). In the Post-test, participants completed the portfolio decisions as at Pre-test. In study 1, disposition effect participants in Non-expert and Expert groups showed a tendency toward a non-disposition effect than those in a control group, whereas no reliable difference was found for non-disposition effect participants. In study 2, non-disposition effect participants in Non-expert and Expert groups showed a tendency toward a disposition effect than those in a control group, whereas no reliable difference was found for disposition effect participants. Observing the decisions of both others and experts who have counter-investment propensities to their own may result in the reversal of the initial investment propensities of stock investors (i.e., backward herd behavior).

Keywords: risk decision-making, perceived gain, perceived loss, disposition effect, non-disposition effect

Integrating the educational themes of Vygotsky’s theory: Speech as a mediator between the zone of actual development and the zone of proximal development

DAMIANOVA, M. (Monash South Africa), LUCAS, M. (WITS University (University of the Witwatersrand)), SULLIVAN, G. (Monash University)

The conceptualization of speech as a core mediator and instrument of thought is a pinnacle of Vygotsky’s socio-cultural theory, whilst the notions of the Zone of Actual Development (ZAD) and the Zone of Proximal Development (ZPD) have become central to contemporary educational practices and interventions. The contextualization of the use of speech as a tool for cognitive operations...
within the continuum of the child’s ZAD–ZPD has remained insufficiently explored from both theoretical and empirical perspectives. The aim of the study was to explore the role of speech as a tool for problem solving in the context of the child’s ZAD and ZPD. In a prediction model, it was explored whether the use of various task-oriented speech subtypes would predict the outcome of individual global task performance (success or failure). The participants were 120 children, aged between 5 years, 6 months to 9 years, 5 months selected from pre-primary and primary schools in South Africa. Speech utterances produced during completion of the Raven’s Coloured Progressive Matrices were transcribed and then coded into distinct speech subtypes—inner, private (self-directed), social (addressed to another) speech, encompassing various semantic contents. The findings revealed that those children, who performed successfully, demonstrated a higher mean use of the overall task-oriented speech subtypes compared to the children who failed the task. The semantic contents of social and private speech with the most pronounced task-oriented salience (describing task activity and describing task material) together with inner speech showed high predictive values and predicted significantly the outcome of individual task performance. The results obtained suggest that both the diversity and the extensive use of task-oriented speech subtypes are implicated in the child’s attainment of a successful task performance. Speech in its various forms was conceptualized as a multifarious mediator, which provides the internal integrative links within the child’s ZAD–ZPD continuum and carries out the transition of his or her competencies from the ZPD to the ZAD. It is concluded that the potential of children’s use of various task-oriented speech subtypes for fostering academic performance should be acknowledged and implemented widely in contemporary educational practices and interventions.

Keywords: Vygotsky’s socio-cultural theory, speech, Zone of Actual Development (ZAD), Zone of Proximal Development (ZPD)

Integration courses students with learning disabilities: Their self-concept and sense of loneliness

STEPHANOU, G. (University of Western Macedonia), KALAMATA, F. (Open University)

This research investigated (a) high school students’ self-concept and sense of loneliness, who had Learning Disabilities (LD) and attended Integration Courses (IC) through the school year, (b) the formation of self-concept, sense of loneliness, and of the association between the two constructs through the school year (from the first to the third school term), and (c) the role of both gender and LD type (General Learning Disabilities -G.L.D.- / Specific Learning Disabilities -S.L.D- ) in the generation of self-concept and sense of loneliness. The participants were 200 high school students, both gender, 7th to 9th grades, who came from schools of various towns of Greece. The students completed the scales twice, in the first and third school terms. The main scales were the ‘Self-Perception Profile for Children’ (Harter, 1985) and the ‘Children’s Loneliness Questionnaire’ (CLQ, Asher, 1985). The results showed that the students’ self-concept was high, with the exception being in the overall academic competence and ability in mathematics that remained low during the school year. Furthermore, during the IC, the students’ self-concept increased, particularly in literary ability, and in ability in relationships with their peers, close friends and parents. Students’ sense of loneliness was low, and it decreased through the school year. Self-concept was moderately and negatively related to sense of loneliness. Gender had limited significant effects, since boys as compared with girls had a higher self-concept in physical appearance, in the third school term. Students with G.L.D. as compared with students with S.L.D. had lower self-concept in both overall academic competence and sport ability, in the first and third school terms, and in ability in their relationships with close friends, in the third school term. The findings are discussed for implications in education and future research.

Keywords: self-concept, sense of loneliness, students, Learning Disabilities, gender
Integrity and corruption: A cross-cultural analysis

FINE, S. (Midot)

Despite the extensive research on integrity testing in personnel selection over the past few decades, very little cross cultural evidence is currently available. Advancements in the area of cross cultural integrity testing are of particular importance to the numerous organizations and practitioners using these tests internationally today. In light of this importance, the present study aims to provide contributing evidence towards a better understanding of cross cultural integrity testing. This study compares mean integrity test scores across 27 countries, based on data collected from 60,952 job applicants, and examines the relationship between these scores and the Corruption Perceptions Index (Transparency International, 2009), a comparative index of country-level corruption, as a broad measure of cross-cultural validity. G. S. Hofstede's (2001) cultural dimension indices per country are then used to explain these findings. It was hypothesized that cultural attitudes towards employee crimes, as measured by aggregated levels of overt integrity, would vary in accordance with the degree of Hofstede's “power-distance” and “collectivism” dimensions, which are traditionally related to loyalty and a lack of criticism towards one’s in-group behaviors (even when these behaviors are corrupt), and that these cultural attitudes would in turn be associated with the corruption levels in those countries. Confirming this hypothesis, significant variance was found between cross-cultural integrity test scores overall \( F(26,60925)=164.38, p<.001 \), and this variance was significantly related to power distance \( r = -.72 \), collectivism \( r = -.46 \), and levels of corruption in the countries sampled \( r = .48 \), as expected. The results of this study are believed to make meaningful theoretical and practical contributions to the understanding of integrity tests as measures that are sensitive to differential cultural and attitudinal norms, and as robustly valid predictors of work related corruption across settings, organizations and countries.

Keywords: integrity, personnel selection, cross-cultural

Intention as a predictor and outcome of the career behavior of health professionals

ARNOLD, J. (Loughborough University Business School), LOAN-CLARKE, J. (Loughborough University), COOMBS, C. (Loughborough University), HARTLEY, R. (Loughborough University)

The Theory of Planned Behavior (TPB, Ajzen, 1991) has been used a great deal to predict behaviors in a variety of non-work settings. Recently there has been increased interest in applying and testing TPB in work settings (e.g. Van Hooft et al., 2006) but this remains a relatively under-researched context for the TPB. In particular, there is a need to establish the link between intention (a proximal predictor of behavior in TPB) and behavior. Many studies only investigate intention, and especially in an unpredictable world of work it is not clear that people’s intentions closely reflect their subsequent behavior. As part of a broader study, 1371 physiotherapists, radiographers, speech and language therapists and occupational therapists in the United Kingdom were surveyed in 2005 and again in late 2007. 756 (55%) responded on the latter occasion. Information about career histories and current status, and intention to be employed by the National Health Service (NHS) was obtained on both occasions. In 2007 respondents were also asked about their search for NHS and non-NHS jobs since they completed the previous questionnaire, and about what proportion of their current work was on behalf of the NHS. After controlling for employment status in 2005, intention in 2005 was a weak but statistically significant predictor of whether a respondent was employed by the NHS in 2007. Intention was a strong predictor of searching for jobs outside the NHS, and a moderate predictor of proportion of work time spent on NHS work. However, close inspection of subgroup means suggests that intention was at least as much an outcome of prior behavior as it was a predictor of subsequent behavior. Opportunities for these health workers in the NHS became very limited in the period studied, thus constraining movement. Nevertheless, intention in 2005 was still a predictor of employment status more than two years later, and of job search behavior. This adds confidence both in the TPB and in the use, for management
purposes, of attitude surveys that assess intention. However, there is also support for the role of past behavior as a shaper of intention.

Keywords: Theory of Planned Behavior, intention

Interactions between individual and organizational determinants of energy-related behaviors in office buildings

LO, S. (Maastricht University), PETERS, G. (Maastricht University), KOK, G. (Maastricht University)

Previous research on pro-environmental behavior in organizations has paid little attention to the interplay between individual-specific and organization-specific determinants. This paper aims to systematically examine these interactions for energy-related behaviors in the office building. We conducted a qualitative study (52 semi-structured interviews; 6 focus groups) and a cross-sectional survey study with office workers of two companies, a non-profit organization, and a university. Results were compared to identify inter-organizational similarities and differences with a focus on individual-organization interactions. In the qualitative study, salient themes found in all organizations were the prioritization of personal work interests, the relevance of self-efficacy and its interactions with the organizational context, and the relative absence of specific relevant social norms in the organization. Work interests such as personal work efficiency and quality were commonly perceived to be incompatible with energy-saving behaviors, whereas financial and other macro level organizational interests were more often argued to benefit from energy saving. Self-efficacy was very explicitly stated as a behavioral determinant. Furthermore, its relation to organizational facilities, policies, norms, division of labor, and managerial influences was frequently discussed. In contrast, social norms were usually not perceived to be an important determinant of current behavior, although interestingly, they were often proposed as an important element in improvement strategies. Preliminary quantitative results also indicate that, compared to the overall office population, the effect of social norms was strong and more consistently significant among respondents able to gauge social norms. The major inter-organizational difference was the relative importance of normative, gain, and hedonic motivations that could be related to the divergent organizational foci. Unlike the interpretation of gain as personal interest in goal frame theory, it was useful to interpret gain motivations as a cost-benefit analysis that could encompass personal, organizational, and societal or environmental interest (Lindenberg & Steg, 2007). The findings underscore the relevance of individual-organization interactions and can inform interventions aimed at harmonizing these interactions to improve pro-environmental behavior in organizations.

Keywords: individual-specific determinants, organization-specific determinants, pro-environmental behavior

Intercultural competence of early childhood teachers in creating a culturally inclusive and enriching learning environment

CHOY, G. (Yew Chung Education Foundation), CHOY, (Yew Chung Education Foundation)

Intercultural competence can be defined as the ability to communicate effectively and appropriately in intercultural situations based on one’s cultural knowledge, skills, and attitudes. In a multicultural or international education context, teachers and students coming from diverse cultural backgrounds engaged in frequent social interactions. Very often, two or more teachers from different cultural backgrounds may share responsibility for teaching the same class, which involves sharing responsibility for planning, implementation, evaluation of students, and creating a culturally inclusive and enriching learning environment. This pedagogical approach is a form of co-teaching and can be termed as “co-cultural teaching”. It has been suggested that Eastern and Western people have different cognitive styles. Without understanding the cognitive style differences and nurturing intercultural sensitivity, this co-cultural teaching partnership can present some difficulties for intercultural communication. On the other hand, it has been
suggested that teachers’ intercultural competence can facilitate developmentally and culturally appropriate practice. To date most studies on co-teaching have concentrated on special education in primary or secondary levels. Little information was available on co-cultural teaching in early childhood education, especially in an international school context. This study aimed to fill this gap by investigating the effects of co-teachers’ intercultural and social competence in determining their co-cultural teaching behaviour in an international early childhood context. Participants were early childhood teachers recruited from international schools in three locations: Hong Kong (China), Beijing (China), and Silicon Valley (USA). Co-teaching partners were formed by one Chinese-speaking and one English-speaking teacher in the same class. They completed a newly validated self-report questionnaire that assessed intercultural competence, social competence and four dimensions of co-cultural teaching (i.e., co-planning, co-implementation, co-assessment and creating a culturally inclusive and enriching environment). High level of reliability scores were yielded with an average Cronbach’s Alpha of above .80. Results indicated that Chinese and English teachers differed significantly in their perception of the importance of consensus in co-cultural teaching. Intercultural competence was predictive of creating a culturally inclusive and enriching environment. Social competence was predictive of co-planning, co-implementation and co-assessment. This result has strong implications for intercultural communications in international or multicultural early childhood settings.

Keywords: intercultural competence, co-cultural teaching, early childhood education, international

Interrelations between patients’ personal life events, psychosocial distress and substance use

NORDFJÆRN, T. (Drug and Alcohol treatment in central Norway), HOLE, R. (Drug and Alcohol treatment in central Norway), RUNDMO, T. (Norwegian University of Science and Technology)

This study investigated interrelations between life events, psychosocial distress, self-efficacy and substance use among patients with substance use disorders. Gender differences in these interrelations were also explored. Although research has established an association between negative events and substance use, it is important to consider both positive and negative events in this line of inquiry as positive events may buffer stress and reduce substance use. A convenience sample of 350 patients with substance addiction was recruited during 2008 and 2009 from 16 Norwegian treatment facilities for substance use disorders. The patients completed a questionnaire with validated measurement instruments. The SCL-90-R, Inventory of Interpersonal Problems – Circumplex, GSE, DAST-20 and AUDIT were used to measure psychological distress, interpersonal problems, self-efficacy and substance use respectively. Positive and negative life events were defined by the patients through open-ended text boxes. Interrelations between the variables were investigated by Structural equation modelling (SEM). The results suggested that negative life events facilitated substance use and psychological distress. Positive life events were associated with self-efficacy, but were weakly related to substance use. Important gender differences were detected in the role of negative life events for substance use. Such life events were solely a predictor of substance consumption among males. Positive life events related to self-efficacy among females, whereas it had a direct effect on substance use among males. The results supported the notion that males are more prone to adapt to negative life events by behavioural action (i.e. substance use). A clinical countermeasure could be to focus on adaptive coping strategies of negative life events during clinical consultations of male patients. Females could be more prone to construe positive events cognitively through improving their coping cognitions, whereas males could be more likely to utilise positive life experiences to alter maladaptive behaviour.

Keywords: personal life events, psychosocial distress, substance use, self-efficacy, gender

Interventions that simultaneously enhance resilience, cooperation, and intuition: The role of leadership and regulatory fit
MOSS, S. (Monash University), DUCK, N. (Monash University), SHARPLEY, E. (Monash University), FLEMING, A. (Monash University)

Recent advances in the fields of cognitive science, emotional processing, and neuropsychology have uncovered a system, called extension memory, primarily represented in the right hemisphere, which elicits positive emotions, promotes cooperation, and improves intuition. This system is activated when individuals are granted opportunities to pursue activities that align with their core inclinations. Three studies were conducted to assess this model. In the first study, 219 participants read either a threatening or supportive message. Threatening messages motivate individuals to redress problems, whereas supportive messages motivate individuals to expedite progress. Individuals next read an advertisement that either converges with, or diverges from, this motivation. If individuals read an advertisement that converges with this motivation, they subsequently exhibited more positive emotions, as gauged by the IPANAT—an implicit measure of core affect. In the second study, 90 participants were exposed to vignettes of either a collaborative leader (a style of leadership that enables employees to pursue their core inclinations), or an autocratic leader (a style of leadership that stifles these pursuits). Subsequently, participants completed a task that putatively assesses their ability to apply their intuition and reach accurate decisions. In particular, participants received 48 pieces of information, in a pseudorandom order, about four office locations, and needed to identify the best alternative. Participants exposed to vignettes about a collaborative, rather than autocratic, leader performed more effectively on this decision making task. In the third study, participants were instructed to imagine either an authoritarian or non-authoritarian leader. Next, they completed the IPANAT. Finally, to assess their implicit motives, participants completed the Multi-Motive Grid. If participants imagined a non-authoritarian, rather than authoritarian, leader (a leader who tends to grant employees enough autonomy to pursue their core values) they demonstrated less anxiety. Furthermore, they were more likely to exhibit a need to establish relationships rather than seek power. Accordingly, interventions that enable employees to align their behaviour with their core values seem to activate extension memory. When this system is activated, many of the qualities and attributes of employees that organizations covet are reinforced; resilience, altruism, and decision making are all likely to improve.

Keywords: extension memory, leadership style, core inclinations, decision making

Intolerance of uncertainty and meta-worry: Relative importance in discriminating GAD

KHAWAJA, N. (Queensland University of Technology), MCMAHON, J. (Queensland University of Technology)

The present study investigated the role of intolerance of uncertainty and meta-worry in Generalised Anxiety Disorder (GAD) by comparing individuals diagnosed with GAD to two non-clinical groups, those scoring high on measures of GAD and those with low scores on measures of GAD. The participants were 107 GAD clients and 91 university students. All participants completed a battery of scales. The students were divided into two groups, those scoring high on measures of generalised anxiety symptoms were labeled as high GAD symptom group and those scoring low on generalised anxiety symptoms were labeled as low GAD symptom group. The GAD clients were labeled as GAD group. A multivariate analysis of variance (MANOVA) indicated that intolerance of uncertainty distinguished between the low GAD symptom group and the high GAD symptom group, and between the low GAD symptom group and the GAD group. Intolerance of uncertainty did not distinguish the high GAD symptom group from the GAD group. Meta-worry distinguished all three groups. A discriminant function including intolerance of uncertainty and meta-worry was effective for classifying 94.4% of the GAD group and 95.7% of the low GAD symptom group. Only 9.1% of the high GAD symptom group were classified correctly, 84.1% of the high GAD symptom group were classified as GAD, possibly some of this group may have met the diagnostic criteria for GAD. The findings indicate that intolerance of
uncertainty and meta-worry may assist with the
diagnosis of GAD. Further, addressing both
intolerance of uncertainty and meta-worry in
treatment interventions may prove useful for
GAD clients.

Investigating the moderating role of prior exposure to aggressive home culture in the relationship between negative reciprocity beliefs and physical aggression

GARCIA, P. (The Australian National University),
RESTUBOG, S. (University of New South Wales),
DENSON, T. (University of New South Wales)

Attention to youth aggression has been rarely sustained, usually stimulated by the media, and then followed by blame. The same can be said regarding efforts to investigate its antecedents, mechanisms, and the following consequences (Marcus, 2007). Although youth violence and aggression has been studied in the past, current theories that take into account individual differences may shed additional light on the incessant question; ‘why do people aggress?’

Drawing upon the General Aggression Model (Anderson & Bushman, 2002) and Social Learning Theory (Bandura, 1973), this paper examines the role of negative reciprocity beliefs and prior exposure to aggressive home culture in predicting physical aggression. Specifically, we predicted that the relationship between negative reciprocity and physical aggression is moderated by prior exposure to aggressive home culture. A total of 170 student-parent dyads from the Philippines participated in the study. Self-ratings of negative reciprocity and physical aggression were obtained. To minimize common method variance, parents were asked to rate their son’s/daughter’s prior exposure to aggression within the home environment. Results suggest that self-reported negative reciprocity beliefs and parent ratings of students’ prior exposure to aggressive home culture were positively related to self-reported physical aggression. In addition, prior exposure to aggressive home culture moderated this relationship. Specifically, individuals with low and high negative reciprocity beliefs engaged in greater levels of physical aggression under conditions of high as opposed to low prior exposure to aggressive home culture. The study provided preliminary evidence about the pervasive effects of aggressive cultures in predicting physical aggression even among those low in negative reciprocity beliefs. Furthermore, it constructively builds upon Douglas and Martinko’s (2001) workplace aggression study by examining aggression in a non-western context and sample (i.e. university students from the Philippines), thus, demonstrating that the relationship between aggressive home culture and aggression goes beyond the workplace environment. Indeed, the family environment plays an important role in shaping an individual’s personality and behavior.

Keywords: general aggression model, social learning theory, environment, home culture, negative reciprocity beliefs

Investigating the relationship of Myers-Briggs personality dimensions with job attachment, job satisfaction, and organizational commitment

Personality is a fairly stable characteristic in people that is the subject of different research. There is a lot of disagreement among researchers about personality definition and related dimensions. Myers-Briggs type indicator (MBTI) is recognized as a tool for determination of personality types that has acceptable validity and reliability. There are four categorized scales in MBTI with two options for each scale: extraversion - introversion, sensory - intuitive, logical - affective, and judgment - process orientation. The current research investigates the relation of these scales with three organizational variables including: job attachment, job satisfaction, and organizational commitment, assuming that each personality dimension shows a different relationship with job attachment, organizational commitment,
and job satisfaction. 270 male and female employees of one industrial company were selected by random sampling method. Subjects respond to personality scale (MBTI) questionnaire (1940), Balfour and Wechsler’s organizational commitment questionnaire (1996), Kanungo’s job attachment questionnaire (1992), and job satisfaction questionnaire (Juge, 2000). Data were analyzed using through regression. According to stepwise regression analyses, sensory-intuitive dimensions of personality are the best predictors of organizational commitment. However, intuitive dimensions are negatively associated with organizational commitment. Sensory-intuitive and sensitive dimensions showed negative relations. In order to predicting job satisfaction through personality dimensions, purposed just one model, including intuitive dimensions, and relations negative. Results showed some personality dimensions have significant relationships with variable such as job attachment, job satisfaction, and organizational commitment, so managers can select appropriate personality types in selection, training and succession planning.

Keywords: personality, Myers-Briggs type indicator, organisational commitment, job attachment, job satisfaction

Is emotional intelligence really an advantage? Investigating the relationships between emotional intelligence, leadership, and performance

GOMES, J. (CIS-ISCTE/IUL), COELHO, J. (ISPA), MAUTHNER, E. (ISPA)

Emotional Intelligence (EI) is the aptitude of using reasoning in order to understand a person’s own and others’ emotions, and to manage them according to his or her will (Mayer & Salovey, 2004). Some have suggested a stronger link between EI and performance, than between any other form of intelligence and performance (Goleman, 1998). Some authors go further, and suggest that EI is the main aptitude for successful leaders (e.g. Cooper, 1997; Mayer, 2002). Notwithstanding this interest on the topic and alleged relationships with performance and leadership, there is a scarcity of empirical support to these contentions. The current study aims to investigate the relationships between transformational leadership, EI, and performance. Data from 725 salespersons was collected in a large organization in the state-agent sector. Performance evaluations were obtained from supervisors. All together, there were 640 dyads. EI was measured with the Emotional Shutte’s Inventory (Schutte, Mallouf, Hall, Haggerty, Cooper, Golden & Dornheim, 1998). Leadership was measured with the Transformational Leadership Behavior Inventory (Podsakoff, MacKenzie, Moorman & Fetter, 1990). Individual and organization-level performance measures were reported by supervisors and employees themselves, as well as from company’s official records. Confirmatory factor analysis revealed an acceptable set of results with regards to the measures used in the investigation. Results indicate that supervisors’ transformational leadership is positively related with EI of followers. Transformational leadership also showed a positive relationship both with extra role performance and role performance. Extra role performance is positively related with role performance. It was not possible to confirm a relationship between EI and role performance, but there is some evidence of the relationships between EI and extra role performance. There is a small significant and indirect effect of IE on extra role performance through leadership. These results confirm that leadership is still an important variable to take into account in explaining performance at its multiple dimensions. However, EI failed to reveal a strong influence on performance, which challenges some authors’ views on the importance of EI in organizations.

Keywords: emotional intelligence, performance, transformational leadership

Is searching for meaning in life associated with reduced subjective well-being? Confirmation and possible moderators

COHEN, K. (Macquarie University)

The aim of the present study was to explore the independence of the presence and search for
meaning in life (using the Meaning in Life Questionnaire, Steger, Frazier, Oishi & Kaler, 2006) and if searching for meaning in life reduces subjective well-being. Secondly, the study examined whether any of the three theoretical frameworks act as moderators of any possible negative impacts. Two quantitative studies were undertaken utilizing the internet. The first consisted of 106 subjects to test if searching for meaning in life does reduce subjective well-being and whether the two factors were independent. The second study, consisting of 500 subjects, examined the relationship between searching for meaning in life and subjective well-being (happiness) and further investigated the possible moderator effects of presence of meaning in life, demographic variables, self-actualization, self-efficacy and achievement motives on the relationship between searching for meaning and well-being. The first study confirmed the independence of presence and search for meaning in life and highlighted the significant relationship between happiness, presence and search for meaning in life. This study also confirmed the moderating effect that presence of meaning in life has on happiness scores when individuals are searching for meaning in life. The second study supported the initial findings and highlighted the further moderating effects of age and self-actualizing on searching for meaning in life and well-being. Overall the results suggest that individuals who are searching for meaning in life report lower subjective well-being when they hold little presence of meaning in life. As presence of meaning in life increases, the process of searching appears to be less distressing. Age, controlling for the moderation of searching by presence of meaning in life, was found to display moderating effects on happiness for individuals who were searching for meaning in life. Finally, controlling for presence of meaning in life and age, individuals’ level of self-actualizing moderated the impacts of the searching process on subjective well-being. These later findings are fully interpreted within the thesis.

Keywords: the meaning of life, subjective well-being

Is there a relationship between parent controllability attributions and problematic behavior in children with developmental disabilities?

WOOLFSON, L. (University of Strathclyde), TAYLOR, R. (University of Strathclyde), MOONEY, L. (University of Strathclyde)

The aim of the current study was to investigate the role of parental attributions of adult and child controllability as a moderator in the well-established relationship between child developmental disability and behavior problems. The influence of parental attributions of adult and child controllability on the relationship between problem behaviors and disability was explored in mothers of children with developmental disabilities (DD) (N=20), with a mean age of nine years and three months (SD=24.6 months); and in mothers of typically developing (TD) children (N=26) with a mean age of nine years and four months (SD=23.7 months). The DD group comprised 11 children with autistic spectrum disorders or communication impairments, three children with Down Syndrome, one with cerebral palsy, one with attentional problems, and four with specific or complex developmental problems. Child behavior was measured by four social interactional scales from the Child Behavior Checklist. Parental attributions were measured using a modified version of the Parent Attribution Test. Mothers were divided into higher and lower controllability groups on the basis of their responses on this test. Multivariate analysis of variance found significant group x adult controllability interaction effects for aggressive behavior, rule-breaking behavior, as well as borderline significant effects for other problems and social problems. Simple effects analysis suggested that when mothers had low attributions of adult controllability, there were indeed significantly more problem behaviors in the DD group, but when mothers had attributions of high adult controllability there was no longer any significant difference in problematic behavior between the two groups. Parent attributions of controllability may moderate the well-established effect of disability on problem behavior. Implications for parent intervention programs are discussed.
Keywords: parent-child relationships, attribution, controllability, developmental disorders, problematic behaviour

It’s so lonely being the king of all the wild things: All Max needed was a friend...

MORRISON, R. (AUT University), WRIGHT, S. (Canterbury University)

This paper is based on the notion that having even just one friend in a social environment significantly lowers an individual’s perception of loneliness; a phenomenon found to be true for children (Renshaw & Brown, 1993). The aim of the present study is to investigate whether this conclusion can be generalised to adult employees in a workplace setting. 188 employees from a government organisation volunteered to participate in the study. Data was collected via an online survey as part of a broader longitudinal study on employee retention. The UCLA-R loneliness scale (Hawkley, Browne & Cacioppo, 2005) was used to measure loneliness. The analysis shows that having at least one friend at work lowers the mean score of loneliness by 9.7 (31.1 for 0 friends, 21.4 for 1 or more friends, from a possible range of 12-48). Multivariate analyses also suggest that having no friends and little emotional support in the workplace, experiencing low levels of affective job commitment and feeling disengaged are antecedents of work-related loneliness, which is mediated by negative affect. It was found that having just one friend at work can be very powerful in overcoming feelings of loneliness. Lonely people tend to perceive situations and social environments through a negative lens (compared to non-lonely people), which has an effect on their ability to create and maintain meaningful relationships with those around them, perpetuating existing feelings of isolation and loneliness. Results are discussed within the contexts of (a) workplace relationship dyads and (b) the wider organisation. Suggestions and recommendations at both the individual and organisational level will be provided.

Job burnout in healthcare settings and productive organizations: Are call centres the most burnt-out?

PETITTA, L. (University of Rome "Sapienza"), MANNO, S. (University of Rome "Sapienza"), CONCETTA RINALDI, A. (University of Rome "Sapienza")

The study has investigated the comparison of job burnout and interpersonal strain levels among (a) health care operators, (b1) productive settings employees, and, within the latter, (b2) call centre agents. Literature suggests (Deery, Iverson, & Walsh, 2002; Isic, Dormann, & Zapf, 1999, Zapf & Holz, 2006) that social interactions with customers, clients (internal and external) or patients are a relevant part of the job in the service industry and sustained interpersonal interactions with people at work can lead to burnout. In particular, abusive and aggressive clients, standardized behavioural scripts in dealing with customers, emotional labour, and little discretion of call centre operators are associated with emotional exhaustion. Employees (N=1032) from healthcare settings (N=503; two hospitals, one school, one jail) and productive organizations (N=529; one bank, one research institute, one transportation company, one call centre), and, within the latter, from a call centre (N=159) returned an anonymous self-report questionnaire measuring: exhaustion, cynicism, professional efficacy (Maslach & Leiter, 1997), and interpersonal strain (Borgogni, Armandi, Amaducci, & Consiglio, 2007). Two ANOVAs investigated the differences related respectively to the type of organization: (a) healthcare and productive organization; (b) healthcare, call centres and “other productive organizations”. Surprisingly, employees from healthcare settings displayed lower levels of job burnout and interpersonal strain as compared to their colleagues from productive organizations. Nevertheless, call centres operators, when separated by the other productive organizations, displayed higher levels of job burnout, and particularly of exhaustion, and interpersonal strain as compared to employees from “other productive organizations”, and especially by those from the healthcare settings. Results yield support to the role of social interaction associated to different type of organizational settings, and related jobs, in explaining job
burnout. Levels of exhaustion of call centre operators, revealed as even higher when compared to healthcare colleagues, suggest the importance of further research on interpersonal factors and management of emotions. Implications for interventions are discussed.

**Job design, social support, and self-efficacy among technical workers in Malaysia: Their effects on job satisfaction and turnover intentions**

PANATIK, S. (University Technology Malaysia), O’DRISCOLL, M. (University of Waikato)

The purpose of this study is to examine the impact of job design variables (job demands and job control), social support, and self-efficacy on job satisfaction and turnover intentions among technical workers in Malaysia, a country characterized as collectivist with high power distance culture. This study also tested the moderating effects of job control, social support, and self-efficacy in the relationships between job demands with job satisfaction and turnover intentions. A non-experimental two-wave panel design with a six-month time interval was used in this study. Data were obtained from 429 technical workers at Time 1 and 245 at Time 2 in a large telecommunication company in Malaysia. Multivariate analyses were used to examine the direct and moderating effects hypotheses. The results showed that job design factors, social support, and self-efficacy were significantly related to job satisfaction and turnover intentions. The results also indicated that supervisor support and self-efficacy functioned as moderators. However, job control did not functioned as a moderator. These findings provided support for certain aspects of theoretical models and practical implications of job design in the collectivist Malaysian culture.

Keywords: job demands, job control, social support, self-efficacy, job satisfaction

**Knowledge and coping among Latina breast cancer survivors in the U.S. with Lymphedema**

BUKI, L. (University of Illinois), RIVERA-RAMOS, Z. (University of Illinois), KANAGUI, M. (University of Missouri), HEPPNER, P. (University of Missouri), OJEDA, L. (Texas A & M University)

More women in the U.S. are living with breast cancer than with any other cancer. One aspect of recovery that has been neglected in the literature is the recovery of Latina women who have developed Lymphedema. To address this gap, we developed a study that focuses specifically on this population. In this qualitative study, we conducted individual phone interviews with 10 Latina breast cancer survivors who have developed Lymphedema. Following a semi-structured interview guide, we obtained information about their daily lives, onset of Lymphedema, and how they cope with the stress that arises from their experiences with the condition. The interviewer, an advanced doctoral student in counseling psychology, was fully bilingual. Based on women’s preferences, she conducted four interviews in English and six in Spanish. Each interview lasted approximately 1.25 hours. Using a thematic analysis methodology (Ely et al., 1991), two advanced graduate students who were also fully bilingual coded the transcripts in their original language under the supervision of a senior faculty member. Transcripts were typed verbatim from the audiotaped interviews. Two themes that emerged from the data will be highlighted in this presentation: knowledge of Lymphedema and coping strategies. Women had very little knowledge of Lymphedema, experiencing the symptoms but not evaluating them as such. Their families and friends also neglected to recognize their symptoms as possible signs of Lymphedema. Social support was critical to women’s coping process. Types of support women accessed included emotional, informational, and instrumental. Other coping strategies included downward comparison (comparing themselves with other survivors who are worse off), and active, passive, and avoidant coping. Through this study, we brought to light information that can be used to develop effective psycho-educational programs for Latina breast cancer survivors with Lymphedema. For
example, we will present on key signs and symptoms that women, their families, and friends need to know to recognize they may be developing Lymphedema. Also, there are strategies women can learn to gain and harness various types of social support, and ways in which organizations can provide the support as well. In the presentation, we will include specific recommendations for types and sources of support women should have available to them. This information has great potential to improve the quality of life of Latina breast cancer survivors in the U.S., a population that has traditionally been neglected in the literature.

Keywords: breast cancer, Latina women, Lymphedema, coping strategies, knowledge

Leadership as sensemaking for capacity building

WARN, J. (University of New South Wales), COX, M. (University of Guelph)

This paper provides a framework for understanding leadership amongst institutional actors involved in restorative interventions in fragile states. The paper draws on the sensemaking literature to propose an integrative four point framework for an alternative understanding of how leadership can function in the complex environments of restorative interventions in fragile states. The method is qualitative and uses case analysis. An important foundation for effective leadership is an understanding of the professional and social identities of the key actors involved in the situation. These identities represent bodies of acquired knowledge and expertise that go to framing a conflict in certain ways. Recognition that different understandings are socially constructed underpins the capacity to generate insight into the drivers of the conflict in its local context. Sensemaking addresses the way in which cultural assumptions can be enmeshed with competition for power and resources. These insights are necessary to generate accounts of the complex and dynamic interconnectedness between sets of actions and consequences in these situations. These accounts eventually can be shaped into new narratives to identify and justify action. These emergent narratives create platforms around which to construct opportunities for shared leadership. Capacity building for sustainable peace is often initiated by peace keeping forces that have a military or paramilitary role and their early actions and the manner in which they can share leadership with other key actors can significantly influence the creation of subsequent opportunities for sustainable development. Key actors in the intervention process are drawn from a range of defence, diplomatic, aid and business institutions and their capacity for shared leadership is instrumental in sustainable capacity building. The complex nature of any intractable protracted conflict poses some severe challenges for traditional assumptions about how leadership might operate particularly where leadership is perceived as a phenomenon that resides within selected individuals with an organisational authority structure. This sensemaking approach offers distinct alternatives to the way leadership is defined by particular paradigms such as the charismatic and transformational approaches. The paper provides some implications for the preparation, composition and design of leadership teams involved in restorative interventions in fragile states.

Keywords: leadership, sensemaking, restorative interventions, fragile states

Learning and memory impairments in preclinical Huntington’s disease

ROBINS WAHLIN, T. (Karolinska Institutet), FRICK, A. (Karolinska Institutet), WAHLIN, A. (Stockholm University), BYRNE, G. (The University of Queensland)

Episodic memory difficulties are commonly reported in manifest Huntington’s disease (HD). There is evidence of deficits in the encoding, storage, and retrieval stages of learning and memory. However, it has not been shown whether episodic memory is impaired also in preclinical carriers of the HD gene mutation, and if so, which stages of memory are affected. The aim of this study is to investigate verbal episodic memory in preclinical HD. Seventy
presymptomatic participants were recruited from the predictive testing program for HD at Karolinska University Hospital, Stockholm, Sweden. A regression equation based on number of CAG repeats was used to estimate the mean years to disease onset of the carriers. This yielded three groups: carriers with less than 12 years to disease onset (HD+close, n=16), carriers with 12 years or more to disease onset (HD+distant, n=16), and noncarriers (HD-, n=38).

All participants completed a Fuld Object Memory Evaluation with selective reminding, which elaborates the processing of stimuli. Participants were asked to identify and name 16 covered objects by touch, thereafter they were shown each object and presented with its name. After this tactile and visual presentation and verbal naming, participants were asked to recall all objects. They were then reminded of all objects not recalled, and again asked to recall all objects. A total of five recall trials were administered. The HD+close group encoded significantly fewer objects, stored fewer objects in long-term storage, retrieved fewer objects from long-term storage, and found reminders less helpful than the HD- group. No significant differences were found between the HD+close group and the HD+distant group, and between the HD+distant group and the HD- group. The results suggest that verbal episodic memory is impaired in the preclinical phase of HD before motor symptoms become evident, and indicate that deficiencies in storage and retrieval contribute to the impairment. These impairments affect HD asymptomatic carriers and reflect dysfunction of striatum, frontal cortex, and fronto-striatal circuits more than a decade before manifest symptoms.

Keywords: episodic memory, Huntington’s disease, learning impairments, memory impairments

Lifestyle choices: Utility for alcohol and unhealthy food

WEISS, J. (California State University. Fullerton)

Many college students start to experience their first independent living and make lifestyle choices such as diet, physical activity, and alcohol use that can have life-long health implications. University students generally do not comply with the Dietary Guidelines for Americans, exercise too little, and drink too much. The persistence of unhealthy lifestyles among college students, who know better, constitutes a puzzle for researchers. In this study, we employed a descriptive version of the classical Multi-Attribute Utility (MAU) model to examine whether the perceived utilities of alcohol use and unhealthy food intake were associated with alcohol usage and eating behavior in this population. Participants (n = 427) completed questionnaires including measures of alcohol use, one-week food intake log, perceived consequences of alcohol usage and unhealthy eating behavior, stress, depression, and personality. Three MAU model parameters for each consequence (subjective value, likelihood of occurrence, and importance at the moment of decision) were elicited. Results for the two outcome measures (alcohol use and eating behavior) were consistent, in that mean MAU scores for alcohol use were significantly higher for those who reported past month alcohol use than for those who did not, and mean MAU scores for unhealthy food were significantly higher for those who reported eating more unhealthy food than for those who ate less unhealthy food. Similarly, the adjusted odds ratio for alcohol use was 1.81 (95% CI= 1.22-2.68) indicating MAU scores (more positive perceived consequences of alcohol use) was significantly associated with increased alcohol use. The adjusted odds ratio for food intake was 1.08 (95% CI= 1.01-1.16) indicating MAU scores (more positive perceived consequences of fast food) was significantly associated with increased unhealthy eating behavior. The descriptive MAU model now has empirical support for the domains of alcohol use and eating behavior. Poor choices are not the result of irrational thinking, but reflect how those choices are affected by multiple consequences. Better understanding of the decision making process of alcohol use and eating behavior may be beneficial in promoting healthier lifestyles for college students.

Keywords: alcohol use, eating behaviours, college students
Loneliness and impulsivity in delay discounting

IGARASHI, T. (Hokkai Gakuen University)

Previous studies have found that social exclusion from immediate surroundings impairs self-regulation, and thus promotes impulsive behavior, such as overeating (e.g., Baumeister et al., 2005). However, there is little evidence in the power of the subjective feeling of social exclusion, such as loneliness, on impulsivity. The present study investigated the impact of a chronic feeling of loneliness on how people prefer immediate but smaller rewards, or delayed but larger rewards in a delay discounting task. A total of 106 university students were enrolled in the experiment. After completing the revised UCLA loneliness scale (Russel, Peplau, & Cutrona, 1980), participants answered the Monetary Choice Questionnaire (MCQ; Kirby, Petry, & Bickel, 1999) that contains a fixed set of 27 choices between smaller, immediate rewards (e.g., 3000 yen today) and larger, delayed rewards (e.g., 5000 yen in 120 days). Discount rates (k) of each participant were estimated separately for the amount of rewards (small, medium, large, and the whole) based on patterns of choices in MCQ, and served as the index of impulsivity. A larger discount rate (k) indicates the preference for immediate, impulsive choices. Loneliness was negatively correlated with discount rates of medium, large, and the whole rewards (r = -.21, -.24, and -.21, p<.05). People with high loneliness tended to be reflective in relatively larger monetary choice situations. Contrary to the previous findings of social exclusion and self-regulation, loneliness did not increase impulsivity. Direct comparisons between temporal and chronic social exclusion in delay discounting should be conducted in future studies.

Keywords: self-regulation, impulsivity, social exclusion, loneliness, delay discounting task

Loneliness and impulsivity in delay discounting

A large body of health care literature points to the importance of considering the effects of socioeconomic inequalities on health (Marmot, 2004). The primary aim of the present study is to investigate the role of both objective and subjective indicators of socioeconomic status (SES) in explaining health disparities over time among older adults. Data were drawn from the New Zealand Longitudinal Study of Aging, with complete data available for 1765 participants (Mean age = 61.16 years; SD=4.47). SES and demographic data were taken from 2006 (Time 1) and health data from 2006 and 2008 (Time 2). SES Markers: objective SES was assessed by two proxies – income and education, and subjective SES was measured by economic living standards index. Health Markers: Physical and mental health from Short Form 36, self-rated health and health-risk behaviours were used to assess health status. Various demographic variables were also measured. In comparison to objective SES (assessed by income and education), subjective SES (assessed by perceived economic living standards) came out to be a significant predictor of an array of health outcomes. Hierarchical linear regressions suggested that low subjective SES at Time 1 significantly predicted decrements in health at Time 2, after controlling for sociodemographic characteristics and baseline scores of health outcomes. The concept of economic living standards (as indexed by subjective SES) takes into account the different daily living circumstances and social experience in which people may use income and assets, including different needs and subjective aspirations. Thus, subjective SES is a better longitudinal predictor in explaining the health disparities in older adults than objective SES.

Longitudinal study of Aussie optimism: Positive Thinking Program in preventing internalising disorders in 8-9 years old children

HASSAN, S. (Curtin University of Technology), ROONEY, R. (Curtin University of Technology),
The Aussie Optimism: Positive Thinking Program (AOP-PTS) is an innovative curriculum-based mental health promotion program based on cognitive and behavioural strategies. The program is aimed at preventing depressive and anxiety symptoms and disorders in middle primary school. The post-test, six month, 18 month, 42 month and 54 month outcomes of this new universal program on Year 4 children from Western Australia were investigated. Twenty state primary schools were randomly selected to receive the program implemented by teachers or to a control condition involving their regular Health Education curriculum. There were 435 children who participated in the intervention condition and 407 children who were in control condition. Initial results showed that there were significant differences in depression at post-test, and attributional style at post-test and six month follow-up. In addition, at immediate post-test, participants in the intervention group were less likely to receive a clinical diagnosis of a depressive disorder in comparison to those in the intervention condition. These results provide early evidence that AOP-PTS is associated with resilience in children from low SES backgrounds, and has the potential to prevent depressive disorders and decrease depressive symptomatology.

Lose to win: A national workplace weight management program

In Singapore the prevalence of obesity (BMI ≥ 30) among adults increased from 5.1% in 1992 to 6.9% in 2004 while the prevalence of overweight (BMI 25 – 29.9) increased from 21.1% in 1992 to 25.6 % in 2004. BMI stands for Body Mass Index which measures the amount of body fat, to assess the level of risks of developing obesity-related health problems. The higher the BMI, the higher was the amount of fat in the body. Studies have shown that a well-planned workplace health promotion (WHP) program contributes both directly and indirectly to a company’s bottom-line by boosting productivity, improving presenteeism, improving health-related behaviour and staff morale while reducing healthcare costs and absenteeism. In 2009, the annual National Healthy Lifestyle Campaign (NHLC) focused on obesity. As part of the campaign, a 12-week weight management challenge called Lose to Win was held. A reality TV program was also produced in conjunction with the challenge. Lose to Win was designed as a team-based challenge for workplaces. This setting encouraged the use of peer support to foster and sustain behaviour change. All interventions (fitness assessment, nutrition workshops & boot camp-style exercises) were evidence-based. Incentives such as cash prizes, trophies, recognition and time-off from work to attend the sessions were some of the levers used. Lose to Win challenge teams comprised 5 members each, with members coming from the same company. The workplace health facilitators screened staff for eligibility and readiness to participate. The participants were selected based on their Body Mass Index (BMI) being 25 kg/m² and above. A BMI of 25 kg/m² and above is classed as being in the medium to high risk category (based on the WHO-validated Asian BMI cut-offs) for developing diabetes and cardiovascular disease. With 60% of the population in the workforce, this setting was ideal for this challenge. Participants went through three Fitness Assessments, three Interactive Nutrition Workshops and 21 Boot Camp style exercises (11 Aug to 31 Oct 09). Follow-up activities and evaluation will be conducted at 6 and 12 months. Results of the 12-week program showed extremely positive outcomes. Participation rate was 86.3% of which 94% reported weight loss and 88% reported body fat loss. All participants reported increased fitness levels from the first to final assessment. Results on the pre and post challenge questionnaire as well as the follow-up evaluation will be available at the conference. The average ratings for the reality TV show ranged from 2.7%-8.1% and reached more than 1.6 million viewers. Compared to similar health-related
reality TV programs, *Lose to Win* achieved higher ratings with 1.4%-3.5% more viewers. In addition, healthy lifestyle activities featured and promoted in the TV show saw increased participation at local community centres. The success of this national workplace weight management program has engendered a lot of interest in the community as a result of the TV reality program. The plan is to bring together this initial group of participants at 12 months for a face-to-face meeting as part of the follow-up. A similar program for the community is being planned for 2010.

**Keywords:** obesity, workplace health promotion, productivity, absenteeism

### Managing organisational change and trust: The importance of ideological and casual social accounts

YEOW, P. (Kent Business School), TUCKER, D. (University of Kent)

This paper will look at two of Cobb and Wooten’s (1998) types of social accounts in particular causal and ideological accounts. Social accounts are concerned with the contents of communications, and aims to make sure the receiver understands the decision in its entirety. The use of social accounts as a means of providing an explanation to employees of the change decision has been found to increase trust and commitment in the organisation during the change implementation (Tucker et al, 2010). Put simply, causal accounts explain the problems which have led to the need to change whilst ideological accounts project the long term goals highlighted by the decision to implement change. This research consists of a case study, based in a German manufacturing organisation which has recently introduced a production change including new technologies as part of a five year change programme. From this case, qualitative data (interviews and focus groups), and quantitative data (field questionnaires) were collected and analysed. An experimental study compared causal and ideological accounts using a hypothetical merger scenario (as used by Giessner et al, 2006) creating a controlled and isolated setting to determine the role which each account played in the trust and commitment relationship, independently of the other accounts. This case study found that ideological accounts were best at maintaining trust and mediated the relationship between ideological accounts and organizational commitment. This paper will demonstrate that whilst the relationship between ideological accounts and organizational commitment were mediated by trust, the relationship between causal accounts and commitment was mediated by both procedural justice and trust independently. These findings have several implications for organizations embarking on a period of major change. This paper highlights the importance ‘cause and effect’ motives for a major organisational change. In particular, it is important to ensure the correct aspects of the social account reaches all levels of the organisational hierarchy such that the explanation for change can be easily identified by employees. Specifically, when organisations need both a causal and ideological account and when one is sufficient.

### Measurement of functional outcomes: Toward the development of an item bank in Australia

MAROSSZEKY, N. (Centre for Health Service Development), SHORES, A. (Macquarie University), OWEN, A. (University of Wollongong), EAGAR, K. (University of Wollongong)

This paper outlines a program of work into developing an item bank for the measurement of outcomes in the domains of functional abilities and social participation in Australia. Important treatment outcomes in the area of human functioning include basic and instrumental Activities of Daily Living (ADLs) and social participation outcomes. Central to this enterprise is the development of short and routinely usable measures which are uni-dimensional in structure and applicable across disease and client groups. A particular focus of this work will be on neurological and trauma patients. The Centre for Health Service Development (CHSD) has a fifteen year history in the development of functional instruments,
having built the Australasian Rehabilitation Outcomes Centre (AROC) Data Bureau for the Australasian Faculty of Rehabilitation Medicine (AFRM) and a nine-item functional screen for the national Home and Community Care (HACC) program (For further details see papers by Simmonds & Stevermuer, 2008; Eagar, Owen, Marosszeky & Poulos, 2006). In seeking to develop the operational parameters for the proposed item bank, this work will utilise existing large datasets developed by CHSD, including: SF-36v2 Physical Functioning data; Functional Independence Measure (FIM) data from the AROC database; and data on the use of the HACC functional screen. Following the development framework of Cella, et al. (2004) this work will review and identify common items and scales, and then analyse the items for dimensionality and fit. Suitable items will then be calibrated on a continuum of functioning with any construct difficulties being identified. The relationship between items based on self-report, clinical rating and proxy ratings will also be examined. This work will contribute to psychological assessment practice by developing short measures of basic and instrument (ADLs) and participatory function which can be combined with standard psychological tests (e.g. IQ and depression symptom measures). Test scores after injury or post psychological treatment can then be examined using a framework of common measures. This will be a contribution to understanding ‘real world’ outcomes for people with disabilities in terms of their level of functioning and limitations to their social participation.

Keywords: functional abilities, social participation, Activities of daily life (ADL)

Measuring alcohol craving: Development of the alcohol craving experience questionnaire

STATHAM, D. (University of the Sunshine Coast), CONNOR, J. (University of Queensland), KAVANAGH, D. (Queensland University of Technology)

The aims were to develop a robust measure of craving based on the Elaborated Intrusion Theory of Desire (EI) (Study 1) and to examine the construct, concurrent, discriminant and predictive validity of the instrument (Study 2). One hundred and fifty individuals (Study 1) and two hundred and ninety-nine individuals (Study 2) receiving treatment for alcohol use disorders, completed the Alcohol Craving Experience Questionnaire (ACE). The ACE consisted of questions focusing on the intensity and frequency of sensory aspects of craving (imagining the taste, smell, and somatic sensations of drinking), strength of craving and intrusive cognitive aspects of craving. Study 2 also included a sample of non-treatment seeking (N = 204) university students. Exploratory factor analysis demonstrated a clear three-factor structure representing Imagery, Strength and Intrusion. Confirmatory factor analysis supported the three factor structure. Concurrent validity with the Obsessive Compulsive Drinking Scale (OCDS) and with measures of alcohol consumption, alcohol dependence severity, depression, anxiety and stress (DASS), and alcohol expectancies (DEP) was demonstrated. The ACE discriminated between individuals in the clinical and non-treatment groups and between those who screened positive for alcohol dependence on the AUDIT and those who did not. The ACE was associated with an increase in days of abstinence at three month follow-up. Overall, the ACE performed well as a robust measure of craving. Further research could explore the application of this instrument with other alcohol using populations, for example, non-treatment seeking drinkers and heavy episodic alcohol consumers. Modifications of the ACE could be tested with other addictive substances.

Keywords: alcohol craving experience questionnaire, elaborated intrusion theory of desire, validity

Measuring driver fatigue on short regular trips

CAPONECCHIA, C. (University of NSW), WILLIAMS, A. (University of New South Wales)

Driver fatigue is recognised as a major cause of road crashes, and has recently received more attention as an occupational health and safety issue. However, driver fatigue remains quite difficult to measure, with many crashes listing
fatigue as a cause simply in the absence of other more obvious causes, like speed or alcohol. While long trips have been the focus of campaigns regarding driver fatigue, self-report investigations indicate that fatigue also occurs on short trips (e.g. commuting). This project aims to objectively measure fatigue on short trips, using a new device (“Optalert”) that records eye blinks as an index of drowsiness. Following a training session in a driving simulator (STISIM system), 30 participants, who work at UNSW, drove for 2 short trips, mimicking their regular morning and afternoon commute (approximately 30-45 minutes). The order of morning and afternoon trips was counterbalanced across participants. The Optalert system was used to record drowsiness. Self-report measures of fatigue were collected using a questionnaire, along with all driving performance measures available from the simulator (speed, lateral position). An actiwatch was worn by participants for 2 nights prior to test sessions, to measure the amount of sleep the participants had. Results will be discussed in terms of how drowsy participants were according to the Optalert algorithm, and relate this to driving performance. The potential for more objective measurement of driver fatigue could help refine road safety strategies about the importance and occurrence of fatigue on different types of trips.

Keywords: driver fatigue, Optalert system, drowsiness, driving performance

Measuring living standards and assessing the wellbeing of older people

WALDEGRAVE, C. (Family Centre Social Policy Research Unit), CAMERON, M. (University of Waikato)

The aim of this research program, entitled ‘Enhancing Wellbeing in an Ageing Society’ (EWAS), is to identify the drivers of wellbeing and quality of life among the older population. Amartya Sen’s capabilities approach has formed the conceptual basis of the theoretical framework of this research program (Sen, 1999). Subjective measures that complement Sen’s emphasis on the importance of human freedom were included to balance the otherwise objective, material emphasis of the capabilities approach. An extensive survey of a national random sample of 1680 older New Zealand citizens aged between 65 to 84 years was carried out using computer assisted technology interviewing (CATI). A theory-driven approach to the survey questionnaire construction led to the selection of the domains of wellbeing, which included living standards (income, housing, poverty measures), were chosen to highlight wellbeing capabilities, functionings, instrumental freedoms and needs. These variables were correlated with a range of subjective wellbeing measures, including the World Values Survey Life Satisfaction Question and satisfaction with their economic standard of living. The results are broadly congruent with most international studies. Personal income and wealth were both significantly associated with gender, age, marital status and education. Subjective assessments of living standards were generally in line with the results of the objective indicators. The poverty measures showed that a large percentage of older people on lower incomes clustered between the standard internationally accepted 50 and 60 percent of median, household income thresholds. Home ownership was very high. With regard to the living standards domain, subjective wellbeing was significantly associated with higher personal income and home ownership. The findings point to the importance of current income support and home-ownership for older people to meet their essential needs and services and to their assessment of their wellbeing and quality of life. For at least a third of the elderly population both income support and home ownership depend upon current policy settings and thus political will. These results raise important issues about the continued levels of wellbeing among older people as the ‘baby boomers’ begin to double the proportion of the population who are 65 years and over.

Measuring progress in student achievement

HÜLÜR, G. (Humboldt Universitaet Berlin), WILHELM, O. (Humboldt-University)
Educational assessment is usually restricted to measures collected at a single time point. When it comes to gaining estimates of learning and achievement changes this is clearly insufficient. For many applied purposes such estimates are warranted. However, gaining such estimates is laborious and challenging. Nevertheless, change in achievement is the parameter of pivotal applied interest. In the present study we investigate antecedents, covariates and consequences of changes in student achievement. Our research questions are focused on understanding change in student achievement in German (mother tongue) and Mathematics. About 150 ninth graders were recruited. Apart from two pre- and two post-test sessions they complete 40 test sessions of two hours – approximately every 2 weeks. In each testing session participants complete nationally calibrated measures of student achievement in German and Mathematics. Additionally, they complete two blocks of automatically generated parallel tests of three working memory tasks (N-back, Alpha-span, Memory updating). Finally, participants complete a variety of questionnaires on school-related behaviour and achievement related personality traits repeatedly. A control group only completed the pre- and post-test sessions. In preliminary analysis for the first 14 measurement points, we found growth in all domains. Change factors for mathematics and working memory from growth curve models were positively correlated. We will report results from 22 measurement points (the first year of the study) focusing on change in Mathematics achievement and its covariates. We will discuss the structure of Mathematics achievement and its covariates by focusing on the status quo and changes in terms of inter- and intra-individual variation. We will suggest new applications in the monitoring of student progress and discuss hints on early indicators of school problems.

Keywords: educational assessment, learning, student achievement, personality traits

Measuring subjective workload using the NASA-TLX: A proposed methodology for scale modification for use in the land vehicle domain

One of the most widely-used, self-report measures of operator workload is the NASA-Task Load Index (TLX) (Hart & Staveland, 1988). It consists of six subscales (Mental, Physical, and Temporal Demands, Frustration, Effort and Performance). In the last 20 years the NASA-TLX has been favoured in a variety of research contexts for its simplistic administration and ease of interpretation. Its adaptation to vastly different fields of investigation has resulted in modifications to the original subscale descriptions, and in some circumstances, the subscales themselves. However, the process of modification of the NASA-TLX to better suit specific domains has not been well documented within the literature. The aim of this presentation is to discuss a methodology for adapting the NASA-TLX to specific research domains, using vehicle evaluation as a case study. The aim is to adapt the NASA-TLX to increase its sensitivity to operator workload issues arising from differences between vehicles and associated vehicle systems. A total of 42 drivers completed the NASA-TLX on multiple occasions, over a range of driving courses and using multiple vehicles. In addition, drivers provided descriptions of what a rating of ‘Very Low’ or ‘Very High’ would mean to them within each of the six workload subscale categories. The quantitative workload data did not differentiate between vehicles. A qualitative analysis of the driver subscale interpretations showed considerable repetition of themes across the subscales, suggestive of intercorrelations between the subscales. This was supported by the data with significant intercorrelations between all subscales and strong positive correlations between the physical, mental and temporal subscales. While intercorrelations between subscales can be explained in terms of the original NASA-TLX design, the lack of observed sensitivity of the tool leads us to investigate the utility of more specific subscale descriptions. The qualitative data collected in this study will be used to modify the NASA-TLX subscale descriptions for use in a future vehicle evaluation activity. A comparison of original versus modified subscale descriptions will be performed in order to
identify any enhancement of vehicle evaluations in terms of workload assessment arising from these modifications.

**Measuring the effect of motorcycle rider training on psychosocial influences for risk taking**

ROWDEN, P. (Queensland University of Technology), WATSON, B. (CARRS-Q, Queensland University of Technology), HAWORTH, N. (CARRS-Q, Queensland University of Technology)

Whilst motorcycle rider training is commonly incorporated into licensing programs in many developed nations, little empirical support has been found in previous research to prescribe it as an effective road safety countermeasure. It has been posited that the lack of effect of motorcycle rider training on crash reduction may, in part, be due to the predominant focus on skills-based training with little attention devoted to addressing attitudes and motives that influence subsequent risky riding. However, little past research has actually endeavoured to measure attitudinal and motivational factors as a function of rider training. Accordingly, this study was undertaken to assess the effect of a commercial motorcycle rider training program on psychosocial factors that have been shown to influence risk taking by motorcyclists. 438 motorcycle riders attending a competency-based licence training course in Brisbane, Australia, voluntarily participated in the study. A self-report questionnaire adapted from the Rider Risk Assessment Measure (RRAM) was administered to participants at the commencement of training, then again at the conclusion of training. Participants were informed of the independent nature of the research and that their responses would in no way affect their chance of obtaining a licence. To minimise potential demand characteristics, participants were instructed to seal completed questionnaires in envelopes and place them in a sealed box accessible only by the research team (i.e. not able to be viewed by instructors). Significant reductions in the propensity for thrill seeking and intentions to engage in risky riding in the next 12 months were found at the end of training. In addition, a significant increase in attitudes to safety was found. These findings indicate that rider training may have a positive short-term influence on riders’ propensity for risk taking. However, such findings must be interpreted with caution in regard to the subsequent safety of riders as these factors may be subject to further influence once riders are licensed and actively engage with peers during on-road riding. This highlights a challenge for road safety education/training programs in regard to the adoption of safety practices and the need for behavioural follow-up over time to ascertain long-term effects.

**Keywords:** motorcycle, risk taking, psychosocial factors

**Mediated moderation or moderated mediation? Relationship between length of unemployment, coping styles, dispositional resilience, and social functioning of unemployed Venezuelans**

SOJO, V. (Universidad Central de Venezuela), GUARINO, L. (Universidad Simón Bolivar)

The aim of the present study was to evaluate a model of mediated moderation vs. moderated mediation that could explain the relationship among the length of unemployment (as a stressful factor), dispositional resilience, coping styles, and social functioning of unemployed Venezuelans. Self-report measures were administered to a sample of 328 unemployed residents of Caracas, Venezuela, that were looking for a job in public and private employment agencies. The questionnaires assessed: sex, age, the length of unemployment in months, coping styles: rational, emotional, detachment, and avoidance (Copying Style Questionnaire, Roger, Jarvis y Najarian, 1993), self-esteem (Rosenberg, 1965), optimism (Scheier y Carver, 1985), mastery (Pearlin et al., 1981), and the subscale of social functioning of the General Health Questionnaire-28 (Goldberg, 1972). A composite measure of dispositional resilience was created using the scales of self-esteem, optimism and mastery following Wamberg (1997). Using the analytic strategy proposed by Muller, Judd & Yzerbyt (2005) there were conducted regression equations to
evaluate at the same time the role of the measure of dispositional resilience as a moderator in the relationship between length of unemployment and social functioning, a process that should be mediated by coping (mediated moderation), an a second process in which the relationship between length of unemployment and social functioning is mediated by coping, with dispositional resilience acting as a moderator of the meditational role of coping (moderated mediation). These regressions show that people with greater dispositional resilience use more detach coping when unemployment is longer, while people with poorer dispositional resilience in the same situation use less avoidance coping (two simple moderations). More important, dispositional resilience acts as a protective moderating factor between longer periods of unemployment and social functioning, a process mediated by detachment coping (a mediated moderation). No evidence of moderated mediation was found. In conclusion, dispositional resilience seems to work as a protective factor for the social functioning of this sample of Venezuelan people experiencing unemployment. Finally, dispositional resilience works as a protective moderating factor and detachment coping as a mediator in the relation between the length of unemployment and social functioning of the sample, a process defined as mediated moderation.

Keywords: mediated moderation, moderated mediation, unemployment, coping styles, social functioning

Medication alliance: Development and implementation of a mental health staff training program for the enhancement of patient medication adherence

BYRNE, M. (University of Wollongong)

Patient non-adherence to prescribed medications remains a major hurdle in the effective delivery of health care services for people experiencing chronic illnesses. Non-adherence rates are particularly high among those with major mental health problems. The aim of this research was to investigate barriers to the implementation of adherence interventions, in particular, clinician skills, attitudes and knowledge, as well as describing a potential strategy to overcome these barriers. This research incorporated three phases. Firstly, mental health clinicians were surveyed using a series of cross-sectional studies to investigate the relationship between their beliefs and knowledge with respect to medications and adherence, and their self reported efforts to enhance patient adherence. Secondly, a clinician training program (Medication Alliance) was developed based on belief and knowledge deficits found in phase one and this was evaluated with a sample of mental health professionals. In the third phase, a sample of patients with mental health problems were assessed for changes in adherence behaviour and mental health status following the training of their mental health care provider in Medication Alliance. The first phase of research indicated that poorer knowledge and more negative attitudes were associated with the extent to which mental health clinicians sought to enhance patient adherence. The second phase of research provided significant evidence that Medication Alliance training improved clinician skills (CBT), knowledge and attitudes with respect to the enhancement of patient adherence. In the third phase, the data indicated that patients of clinicians who had received Medication Alliance training experienced an improvement in both their adherence and their mental health. A model was developed from the data which explained this improvement in terms of the therapeutic alliance and patient insight. Efforts to enhance patient adherence to treatment should include a focus on the ‘front-line’ clinicians delivering mental health services. Appropriate attention to clinician skills, attitudes and knowledge can enable the improvement of patient adherence to treatment. Larger studies across chronic health domains are needed to substantiate these findings.

Keywords: patient medication, mental health, training, attitudes

Membership stability and performance: A study of baseball clubs and laboratory groups

CHANG, K. (University of Cumbria)
This paper aims to analyse the effect that membership stability and group boundary have upon group performance. Using Chinese Professional Baseball League (CPBL) data (Seasons 2003-2007), Study One reveals that the membership stability of baseball clubs was correlated with their annual rank and win-probability, and that stable teams outperformed unstable teams. Membership stability also predicted win-probability in four of five seasons. Using undergraduate students, Study Two reveals that members from unstable groups (i.e. groups with higher membership-turnover) had higher intention of leaving their groups and more departures. Members from stable groups had better group performance, group cohesion, and group dynamics, which all resulted in members displaying more trust in their colleagues and an increased willingness to cooperate with them. Implications of the findings are that stable membership is a crucial factor in the promotion of group dynamics and overall performance, and that the nature of a group's boundary affects its membership turnover. Policies should also be devised to manage membership stability, as maintaining an appropriate turnover rate is essential to both individuals and groups, such as employees and their organizations.

Keywords: boundary, group membership, stability, performance

Men who abuse their partners: Aggression and empathy

ARMAS-VARGAS, E. (Universidad de La Laguna (Spain)), BETHENCOURT-PÉREZ, J. (Universidad de La Laguna), MARTIN-CABALLERO, R. (Universidad de La Laguna)

Aggressive behaviour and empathy are clinical and forensic criteria of importance in the evaluation of men who abuse their partners in the home. In this work we offer the results of a correlational study between the variables of the AQ (Aggression) questionnaire and the variables of the IRI (Empathy) questionnaire with the stated study population. The sample comprised 130 men who had abused their partners. Academic background included: primary education (15%), secondary education (34%), professional training/high school education (31%) and university education (20%). The instruments used were the: (1) Aggression Questionnaire (AQ, Buss and Perry, 1992) which measures four factors (physical aggression, verbal aggression, anger and hostility), and (2) Empathy Questionnaire (IRI, Interpersonal Reactivity Index; Davis, 1980, 1983) which measures four factors (Fantasy (F), Perspective taking (TP), Empathetic concern (PE) and Emotional Distress (ME)). We followed a multivariant form of analysis: factor and correlational analysis. We offer the results of the factor analysis for each factor, internal consistency (Cronbach Alpha) and the correlation between measures of the different factors of the IRI and AQ questionnaires. From the empathy questionnaire (IRI), we obtained two sub-questionnaires, each with two factors: (A) Questionnaire IRI-A, 2 factors: Empathetic Fantasy (25%; \( r = .76 \)) and Perspective Taking (20%; \( r = .69 \)); Explained variance = 45% and (B) Questionnaire IRI-B, 2 factors: Empathetic Involvement (23%; \( r = .71 \)) and Personal Distress for Empathy (21%; \( r = .60 \)); Explained variance = 44%. From the aggression questionnaire (AQ), we obtained two sub-questionnaires, each with two factors: (A) Physical Aggression (33%; \( r = .78 \)) and Anger (16%; \( r = .71 \)); Explained variance = 49% and (B) Hostility (30%; \( r = .81 \)) and Verbal Aggression (20%; \( r = .67 \)); Explained variance = 50%. From the correlational analysis of the measures of the different factors, we noted that the factor for physical aggression correlated positively with the factor for personal distress (\( r = .20; \ p \leq .01 \)) and negatively with perspective taking (\( r = -.29; \ p \leq .001 \)) and empathetic involvement (\( r = -.17; \ p = .025 \)). The factor for perspective taking correlated negatively with anger (\( r = -.14; \ p = .025 \)) and hostility (\( r = -.21; \ p \leq .01 \)). Conversely, the factor for personal distress for empathy correlated positively with anger (\( r = .34; \ p \leq .001 \)) and hostility (\( r = .41; \ p \leq .001 \)). The data which we found in this work significantly support the convergent validity for the combination of the variables of the aggression questionnaire (AQ) with the variables of the empathy questionnaire (IRI).

Keywords: aggressive behaviour, empathy, abuse
MENDS and relationship crisis: The hostile alienation syndrome

PERSHOUSE, O. (Pacific Behaviour Interventions)

Longitudinal research confirmed that compared to their ex-partners, men fare poorly in several measurable areas after a relationship breakdown and take longer to reconstitute healthy and productive lifestyles (Jordan, 1996). The reasons for this inform core component of the MENDS (Men Exploring New Directional Strategies) program and what has been identified as the Hostile Alienation Syndrome. Subsequent suicide research in Australia confirmed the need for a pro-social initiative to assist the high numbers of men who were suiciding in the midst of relationship crises (Cantor & Slater, 1995). This paper reports the outcomes of the first 10 years of operation of MENDS to assist men (N>1100) in significant relationship crisis. MENDS utilised an AB design for assessment of key high risk functioning (e.g. suicidality, depression, anxiety, social support etc). Comparisons of before and after PAI measures have statistically corroborated client and facilitator reports of notable participant improvements over the program period. The 12 x 2 hours/ week program focused on client self-auditing in order to address issues identified by John Gottman (Gottman & Silver, 1999) and responded to specific client needs such as physical and emotional health risks, personal and social skills, legal issues, as well as parenting and relationship training. Targeted assessment confirmed the value of the structured program approach, for up-skilling in areas of emotional processing; particularly self-management of anger and risks of acting out. Latest research (largest sample size to date) demonstrated positive treatment effects with a range of problematic functioning including, depression, anxiety, suicidality, self-medicating with alcohol/drugs and general stress levels.

Keywords: males, relationship crisis, men exploring new directional strategies (MENDS), structured program, problematic functioning

Mental representations (MR) of parenthood in infertile couples during their puerperal period after artificial reproduction techniques (ART) conception

VALORIANI, V. (University of Florence), VANNI, D.

Investigation of mental representations (MR) during puerperal period in couples who achieved conception after artificial reproductive techniques (ART) is not very common. We intended verify if infertility can cause an emotional distress influencing the mental representations of the future parenthood; to verify if exist evident gender differences considering the cause of infertility (masculine, feminine, both of them, idiopathic), the length of treatments and their different levels (Intra Uterine Insemination-IUI; In Vitro Fertilization-IVF or In Vitro Fertilization with Intracytoplasmatic Sperm Injection-ICSI) and the amount of failures. We recruited 21 Italian couples submitted to ART to the NHS University Centre of Florence Hospital who achieved pregnancy and we administered them a psychological protocol including an interview about mental representations (IRMAG for mothers and IRPAG for fathers) during third trimester of pregnancy. Interviews include 47 questions about pregnancy experience and parenthood expectations. Interviews transcripts were codified by two independent researchers to identify three different styles of parenthood representations: well-balanced MR, withdrawn MR and ambivalent MR. The styles of ART couples were compared with “natural” pregnancy couples. We applied Wilcoxon Test to find MR partners differences. We found a prevalence of withdrawn styles of MR in mothers (53%) while men (52%) reported more balanced style of MR. Women were incline to speak about their pregnancy with poor emotional words and they showed difficulties in recognize their psychological and physical changes. Men were more incline to describe their experience as an important chance to change their life and they appeared ready to welcome the baby. As reported in literature we found gender differences in psychological reactions to pregnancy obtained after ART and this result can be ascribe to different impact of infertility on women. Women’s partners can be witnesses of infertility experience while this is not possible for women who play an important physical and emotional role during treatments.
It’s probably this kind of involvement that paralyzed women’s emotions while men have to maintain a supportive role, during treatments, and this role can enable them to hold a cognitive position.

Keywords: mental representation, artificial reproductive techniques, infertility, emotional distress, parenthood

Mentoring styles, mentor’s self-assessment and mentee’s success in a peer mentoring program

LEIDENFROST, B. (University of Vienna), STRASSNIG, B. (University of Vienna), CARBON, C. (University of Bamberg), SCHABMANN, A. (University of Vienna)

Mentoring programs in the higher education context widely show positive outcomes for mentees as well as mentors. Most research is based on mentor support in general and does not include different types of mentoring styles. Mostly either the mentor’s perspective or the mentee’s perspective is taken into account. In this study, different mentoring styles using indicators of (online) mentoring behavior of peer mentors are presented. The aim is to examine if there is an effect of the received mentoring style on the mentee’s success of participation in the mentoring program. Further, to combine the perspectives of mentees and mentors, the relationship between the mentoring style and the mentor’s self-assessment of given mentoring is researched. Data were collected as part of an evaluation of a formal peer mentoring program in winter term 2007/08. Forty-eight peer mentors (senior students) lead mentoring groups of randomly assigned seven to eight mentees (first-year students). 298 mentees and 27 student mentors completed an online questionnaire concerning perceived mentoring and the self-assessment of given mentoring respectively. Using the assessment of perceived mentoring by mentees, online mentoring behavior and qualitative analysis of the mentors’ online messages eight indicators of (online) mentoring behavior are specified. Using cluster analysis three distinct mentoring styles are identified: “Motivating master” (N=14), “Informatory standard” (N=30), and “Negative minimalist” (N=4). The motivating master group had a positive effect on the mentees’ success in participation (more mentees than expected successfully completed the mentoring program) whereas the informatory standard and the negative minimalist groups did not show a significant effect. Self-assessment of given mentoring did not differentiate between the motivating master and the informatory standard group. Mentors in the motivating master group estimated their given mentoring alike to the assessment by their mentees, whereas mentors in the informatory standard group estimated their given mentoring higher than their mentees. Results indicate that mentors who are highly motivated in acting as mentors (motivating master) have a positive effect on the mentee’s success. Mentors who concentrate on giving information (informatory standard) fulfill their role as mentors too, but their given mentoring seems to be misconceived by their mentees.

Keywords: mentoring programs, higher education, mentoring behavior, mentoring behavior, peer mentoring

Mindfulness, stress and cognitive performance in a military setting

STEILER, D. (Grenoble Ecole de Management), TROUSSELARD, M. (ENOP Department - CRSSA/IRBA), CANINI, F. (ENOP Department - CRSSA/IRBA)

The aim of the current study was to test the applicability of the capacity to be mindful in a military simulated situation and its impact on the stress level and a cognitive performance. As mindfulness is considered as a predictor of adaptability to stressful events, it appeared pertinent to measure this same concept within a military context, given the short “termism” of operations as well as the long “termism” of global health in the interested participants. In the first stage, the relevance of using the Freiburg Mindfulness Inventory-short form (FMI-short form) in a military sample was tested. Results were nearly comparable to results on a civil sample: items grouped into a one-dimension solution, internal consistency of the scale based on this solution was ranged from .73 to .74, and the six month test-retest reliability was good. Positive correlates indicated that individuals scoring high on mindfulness are
conscientious, with positive emotions, with a seeking outlook of the world and with task-oriented coping abilities when faced with adversity. The lowest scores in mindfulness, observed for subjects reporting a stressful event in the past years, were associated with higher emotional disturbances. In a second stage, the intent was to test the applicability of the capacity to be mindful in a simulated situation. For that purpose, sympathovagal balance, salivary cortisol level, mood and sleep perception were assessed by questionnaires, and short-term and declarative memory were evaluated in thirteen submariners during a submarine simulation escape according to the level of mindfulness. Assessments were realized in three periods: before the escape (Baseline), immediately after the escape (Escape) and two hours after it (Recovery). In the results, submariners high in mindfulness score exhibited both lower stress reaction, higher vagal recovery ($p<0.05$), lower cortisol responses across the exercise time ($p<0.05$). They also exhibited a lower cognitive degradation in declarative memory ($p<0.05$). Results showed the importance of considering the mindfulness dimension for that population, both in terms of initial selection and training of further capacity. Furthermore, results trigger a reflection and drive an interest to develop this competence given the level of benefits which impact several domains of the participants outside of the mere operational venue. It sets the ground for the introspection of a balanced leverage for social cohesiveness both in teamwork as well as in the own individual spheres.

Mirror imagery, conflict styles, and willingness to seek forgiveness in post-crisis phase of intergroup conflict (a case study of Dayak-Madura communal violence in West Kalimantan, 1997)

NASROEN, R. (Gadjah Mada University), SUWARTONO, C. (Atmajaya University)

The aims of the present study was to describe level of mirror images generated by each group toward the other group in post-crisis phase of intergroup conflict; to understand the correlation of mirror imagery, conflict styles, and willingness to seek forgiveness in post-crisis phase of intergroup conflict; to explore interactions of psychological variables in intergroup conflicts which can be generalized to other intergroup conflicts; to predict the probability of recurring communal violence in intergroup conflicts; to recommend social psychological intervention to promote reconciliation processes during post-crisis phase of intergroup conflicts and to stimulate further cross-culturally sensitive research in peace psychology. Participants which consist of 50 members of Dayak group, and 50 members of Madura group affected by 2007 communal violence in West Kalimantan were selected by accidental sampling method. This research used ex post facto field studies research design. Three scales were administered to both groups, which are Semantic Differential Mirror Imagery Scales, Rahim Organizational Conflict Inventory-II, and Willingness to Seek Forgiveness Scale. All measures were translated into Indonesian by the author. Research is currently undergoing with no conclusive remarks yet. Results are anticipated to be available by the end of January 2010.

Keywords: intergroup conflict, post-crisis phase, mirror images, forgiveness

Mobile phone assessment of cognition: Development of a validation model

TIPLADY, B. (University of Edinburgh)

Tests of memory, attention and processing speed are widely used to assess cognitive changes due to illness, physiological state or treatment. Portable devices such as mobile phones are useful platforms in many situations as they allow assessment of such outcomes in an everyday context. Frequent assessments may be made, and correlations between cognition and factors such as sleep, eating, and fatigue examined. The limitations of these devices, in terms of processing power and user interfaces, make it important to assess the validity of such assessments. A three level approach to validation is proposed: (1) Device-level, evaluating the accuracy of internal timing and correct software implementation; (2) Intrinsic,
evaluating the ability of a test to discriminate between stimulus types of differing difficulty within a test; (3) Extrinsic, evaluating the ability of a test to discriminate between states affecting cognition within or between individuals. A mobile phone test battery has been developed using Java (Tiplady et al., 2009, Alcoholism: Clinical and Experimental Research 33: 2094-2102). Device-level validation confirmed correct operation in terms of presentation algorithms and error scoring. Internally-recorded timing was compared to externally measured response times, and showed high agreement ($r > 0.995$). Intrinsic validation used a memory scanning task in which responses to stimuli not in the memory set were expected to be longer than those in the set. This was confirmed in several studies, with differences of about 100 msec observed between the two conditions. Extrinsic validation has used the effects of alcohol. The impairments with alcohol assessed with mobile phone testing were similar to previous work with systems using conventional computers. Results were also similar when mobile phone systems were used in laboratory and everyday (unsupervised) settings. Taken together, these results support the validity of the use of mobile phones for assessment of cognition. Despite the limitations of the mobile phone as an assessment platform, a wide range of assessments can be set up evaluating relevant domains of cognition. These tests can be effectively used in an unsupervised environment, allowing the extension of ecological momentary assessment into the area of cognition.

**Keywords:** cognitive assessment, mobile phones

**Mobilizing support for and resistance to intergroup conflict resolution: The case of the ‘Annan Plan’ in Cyprus**

LYONS, E. (Queen’s University Belfast), ILLIA, N. (CResPP, Queen’s University Belfast), STOREY, L. (CResPP, Queen’s University Belfast)

In 2004, the ‘Annan Plan’, a UN proposal for a solution to the inter-group conflict in Cyprus, was placed before the Greek and Turkish Cypriot communities in a re-unification referendum. The proposal was accepted by the majority of the Turkish-Cypriots but was rejected by the majority of the Greek-Cypriot community. This paper examines how the main arguments of the ‘Yes’ and ‘No’ campaigns framed the public debate as reflected in the Greek Cypriot print media. It draws on theories of social movements, conflict resolution and identity to analyse the arguments of the campaigns ‘For’ and ‘Against’ the Annan Plan. A media analysis of newspapers’ coverage of the events leading to the referendum of the ‘Annan Plan’ in Cyprus was carried out. Using Thematic Content Analysis (Braun and Clarke, 2006), we analysed a sample of newspapers over the span of 45 days, covering the period before and after the national referendum. Our analyses illustrated the central role of in-group and out-group definitions in framing the Annan plan played in the both the ‘Yes’ and ‘No’ campaigns. However, they showed that the two campaigns employed different processes and frames in providing meanings of the content of the Annan plan. Within the ‘YES’ campaign, there was an ‘admitting share of blame’ in relation to the conflict; Greek-Cypriots needed to recognize and accept a share of blame and not just blame the ‘Others’. Within the NO campaign, the plan was framed as a case of victimization, injustice, and a human rights violation; thus not challenging the dominant social memories of the Cyprus conflict. Different identity constructions of the in-group and out-group were used in mobilizing people to either accept or reject the plan. Also particular constructions of past events were employed to support particular constructions of the Greek Cypriot identity.

**Keywords:** Annan Plan, intergroup conflict, conflict resolution, identity, resistance

**Moderating effects of team constructive climate and mediating effect of team conflict on the relationship between shared mental models and team performance**

BAI, X. (Chinese Academy of Sciences), LIU, W. (Hong Kong Polytechnic University), LIN, L. (Central University of Finance & Economics)

Adopting a cognitive approach, researchers have demonstrated that shared mental models (SMMs), defined as structured understanding or mental representation of team tasks and
interaction shared by team members, offer a common cognitive basic for team members to communicate and coordinate fluently and thereby enhance team effectiveness. However, high level of mental model similarity may not always have a positive effect on team performance. The current study aims to investigate the contingent relationship between SMMs and team performance, which remains an under-research topic in the literature. We speculated that team constructive climate would moderate, and team conflict would mediate, the effect of SMMs on team performance. 972 participants representing 154 teams (average team size is 6.3, SD = 4.1) from a large telecommunication corporation in China gave responses to the survey questionnaire. The responsibilities of these teams are in charge of the operation, monitoring, maintenance, emergent corresponding and other management of the core telecommunication network facilities. Individual mental models were elicited by asking members to rate the priority of 13 potential strategies when the team was required to resolve each of two critical incidents which were related to the malfunction of telecommunication network facilities. SMMs were indexed by calculating the average correlation between all members’ responses within each team. For the measures of team constructive climate and team conflict, ratings of individual team members were aggregated to create team-level data. Team performance was rated by team managers. Results of series of hierarchical regression analyses indicated that: a) the effect of SMMs on team performance was positive and marginally significant (β = .16, p < .10); b) the interaction between SMMs and team constructive climate was significant (β = -.19, p < .05), suggesting that the effect of SMMs on team performance was moderated by team constructive climate. Further analysis showed that when team constructive climate was weak, SMMs were positively related to team performance. While when team constructive climate was strong, the effect of SMMs on team performance was not significant; c) team conflict mediated the effect of SMMs on team performance; d) the mediating effect of team conflict was moderate by team constructive climate. Specifically, SMMs could enhance team performance by reducing team conflict only under the condition when team constructive climate was weak. Consistent with prior research, our findings suggested that SMMs were in general positively related to team performance. Furthermore, we also found that the positive effect was contingent on team constructive climate in that high level of mental model similarity added no value to team functioning when there was a strong constructive climate.

Moderator effects of cognitive control deficits on the relationships between emotional dissonance and burnout as well as absenteeism

DIESTEL, S. (Leibniz-Research Centre for Working Environment and Human Factors), SCHMIDT, K. (Leibniz-Research Centre of Working Environment and Human Factors)

Emotional dissonance refers to the perceived discrepancy between genuinely felt emotions and emotions required by the job role. A large body of evidence indicates that emotional dissonance exerts adverse effects on job strain, especially burnout. Results from experimental research suggest that cognitive control deficits as a vulnerability factor explain why emotional dissonance is more strongly related to burnout for some employees than for others. Cognitive control deficits involve difficulties of attention and memory, affective instability, and limited flexibility in dealing with novel and changing tasks. In the present study, we tested whether moderate cognitive control deficits strengthen the positive relationships between emotional dissonance and burnout and absence behaviour. The present field study draws on a sample of 327 employees of a German civil service organization. For all employees participating, absence data of the 12 months following the survey was available (sum of days absent and absence frequency). The measurement of emotional dissonance based on five items which stem from the Frankfurt Emotion Work Scales (Zapf et al., 1999). Cognitive control deficits were assessed using the Cognitive Failures Questionnaire (Broadbent et al., 1982). Emotional exhaustion and depersonalization
were introduced as burnout variables measured by the Maslach Burnout Inventory (Maslach & Jackson, 1986). In order to test the interactions, a non-linear structural equation model was analyzed. Parameter estimations revealed significant interactive effects of emotional dissonance and cognitive control deficits on all outcomes considered such that the positive relationships between emotional dissonance and burnout as well as absence behaviour were amplified as a function of cognitive control deficits. The results show that cognitive control deficits function as an individual vulnerability factor in performing emotion labour especially when emotions have to be displayed which may not be genuinely felt. Besides burnout, the interactions were also reflected by measures of absence behaviour that is strongly related to organizational costs.

Mothers for “technique” and mothers for “nature”: Early mother-infant interaction, maternal mood and transition to parenthood

VALORIANI, V. (University of Florence), VANNI, D.

Evidence about effects of assisted reproduction technique on parenthood and mother-infant interaction is poor and discrepant. The aim of this research is to increase understanding of the maternal mood status and the early mother–infant interaction according to two groups: one conceived by ART and one by natural conceived. In our study we observed 60 first-time mothers from pregnancy (3rd trimester) to 3 months after childbirth. The sample was selected from a larger sample of Italian population attending prenatal courses in Florence Hospital. Subjects included primiparous mothers (28 ART end, 32 naturally) with a stable partner relationship, with no reported previous psychiatric disorders, their pregnancy was without risks factors and their babies (32 ART and 32 natural) were born at the expiry date in good health. During pregnancy we assessed mothers’ mood state (Edinburgh Postnatal Depression Scale EPDS; Cox et al., 1987) and life-time psychiatric disorders. After childbirth we investigated again mood state and videotaped a 5-minutes mother-infant interaction according to the Global Ratings of Mother-Infant Interaction (GRS, Murray et al., 1996) which values maternal Sensitivity, Intrusiveness and Depression; infant Communication and Behaviour and Global Interaction. During the early interaction ART mothers are more intrusive with their infants. However they don’t show severe clinical behaviour aspects. Mothers undergoing ART display more intrusive behaviour patterns during interactions with their babies. They also show less depressive signs in the GRS evaluation. ART mothers display more depression signs in EPDS mean scores in contrast with naturally mothers after childbirth but not during pregnancy. High depression levels are shown only by ART mothers and no natural mother has severe depression symptoms. Analyses revealed that maternal mood is stable in each group. In fact mothers maintain the same level of depression showed during pregnancy and after childbirth. No natural mother had a high depression level, while some ART mothers show severe depressive symptoms. ART mothers with mild depression symptoms are more intrusive in the GRS. Babies of mild depressed ART mothers display a significant better communication during the interactions. A negative effect of assisted conception on the mothers intrusiveness during the interaction (GRS) and on mood state are identified.

Motivating prosocial behaviour among blood donors: The influence of affective commitment, role identity, and perceived obligation to donate

BEDNALL, T. (The Australian Red Cross Blood Service), BOVE, L. (The University of Melbourne)

The aim of the present study is to assess the influence of three motives for pro-social behaviour among experienced blood donors. Previous studies of donors have identified role identity as a blood donor and moral obligation to donate as motives for donation (e.g., Piliavin & Callero, 1991; Godin et al., 2007), but few
Abstracts of the 27th International Congress of Applied Psychology

This study investigated the relationships between approach and avoidance motivational traits and job performance, while considering the mediating role of self-efficacy. Approach motivation was divided into two traits: personal mastery (i.e., desire to achieve) and competitive excellence (i.e., desire to perform better than others). Avoidance motivation, which reflects one's sensitivity to negative stimuli and the desire to escape such stimuli, was conceptualized as motivation anxiety. Using structural equation modeling (SEM), the relationships were examined in a sample of 562 full-time employees. For the approach motivation traits, results showed that personal mastery and competitive excellence were positively related to job performance. For avoidance motivation, results showed that motivation anxiety was negatively related to job performance. Self-efficacy mediates these relationships very well. Our study shows that motivational traits were predictors of job performance and considers the mediating role of self-efficacy. We encourage future research on the links of these approach and avoidance motivational traits with other organizational outcomes.

Need fulfillment in the workplace and its effects on psychological well-being, job satisfaction and job engagement

FALLON, B. (Australian Catholic University), SANDRE, J. (Australian Catholic University)

The conceptual framework for this research was Self Determination Theory (SDT). The aim of the present study was to investigate the effects of total and balanced need fulfillment within the workplace. Need fulfillment consists of: autonomy, relatedness, and competency. It was hypothesized that as levels of need fulfillment (both total or balanced) increased, there would be proportionate increases in psychological wellbeing, job satisfaction, and job engagement.

Keywords: job performance, motivational traits, self-efficacy, Avoidance motivation, Approach motivation

Motivational traits and job performance: Mediating role of self-efficacy

ARSHADI, N. (Shahid Chmran University), ARSHADI, N.

This study investigated the relationships between approach and avoidance motivational traits and job performance, while considering the mediating role of self-efficacy. Approach motivation was divided into two traits: personal mastery (i.e., desire to achieve) and competitive excellence (i.e., desire to perform better than others). Avoidance motivation, which reflects one's sensitivity to negative stimuli and the desire to escape such stimuli, was conceptualized as motivation anxiety. Using structural equation modeling (SEM), the relationships were examined in a sample of 562 full-time employees. For the approach motivation traits, results showed that personal mastery and competitive excellence were positively related to job performance. For avoidance motivation, results showed that motivation anxiety was negatively related to job performance. Self-efficacy mediates these relationships very well. Our study shows that motivational traits were predictors of job performance and considers the mediating role of self-efficacy. We encourage future research on the links of these approach and avoidance motivational traits with other organizational outcomes.

Need fulfillment in the workplace and its effects on psychological well-being, job satisfaction and job engagement

FALLON, B. (Australian Catholic University), SANDRE, J. (Australian Catholic University)

The conceptual framework for this research was Self Determination Theory (SDT). The aim of the present study was to investigate the effects of total and balanced need fulfillment within the workplace. Need fulfillment consists of: autonomy, relatedness, and competency. It was hypothesized that as levels of need fulfillment (both total or balanced) increased, there would be proportionate increases in psychological wellbeing, job satisfaction, and job engagement.
140 participants met the inclusion criteria, consisting of 61 females and 79 males. Ages ranged from 18 to 65 ($M=30.02$ and $SD=12.67$) and all worked within Australia. Participants completed a questionnaire which assessed: Need Fulfillment; Psychological Wellbeing (environmental mastery, personal growth, purpose in life, and self-acceptance); Job Satisfaction (satisfaction with the work itself, co-workers, supervision, the work group/unit, and with the company) and Job Engagement. A seven point Likert rating scale was provided for each scale item. One-way ANOVAs with a priori polynomial contrasts found that greater total need fulfillment significantly increased psychological wellbeing, job satisfaction, and job engagement. Comparatively, greater balanced need fulfillment did not. The present study reveals the importance of total need fulfillment within the workplace, as it pertains to optimal individual functioning (i.e., psychological well-being) and greater organisational outcomes (i.e., job satisfaction and job engagement). It confirms that employees who have more positive experiences in relation to their three psychological needs at work, will experience greater feelings of psychological wellness, satisfaction and engagement (as emphasized by SDT). The relevance of balanced need fulfillment on such work-related outcomes needs further investigation as its effects did not contribute to any of the above mentioned outcomes. All in all, studying need fulfillment within the workplace may help us to develop a clearer conceptualization of the ways in which needs are fulfilled and of how these needs contribute to optimal human functioning and greater work outcomes.

Neural network-based systems for the predictive classification of academic performance: Assessments without testing

MUSSO, M. (Leiden University / CONICET), KYNDT, E. (Catholic University Leuven), CASCALLAR, E. (Catholic University Leuven / Leiden University)

This paper presents two highly successful examples of predictive systems approaches in the field of educational assessment. Because of the complexity of the variables involved in the field of education and educational assessment in particular, it is possible to use this approach to improve the quality of educational assessments. In particular, neural networks, with their superior potential for pattern recognition and classification are particularly well suited to use available data to give a broader expectation of academic performance, based on a wider set of predictors which lead to an increase validity of the constructs and the obtained results, while at the same time increasing the accuracy of the resulting classifications. Predictive systems approaches allow for the understanding of the students’ individual characteristics in addition to the prediction of expected performance levels. Several neural networks models were developed, to obtain predictive classifications in various performance tasks. Study 1, involving 1052 first-grade students, developed a predictive classification of students into three groups corresponding to three levels of readiness for reading instruction. The procedure used was a back propagation network, that is, a multilayer network composed of nonlinear units. Predictor variables included family, health, and general background. Study 2, involving 267 first-year university students, used a similar methodology to model predictive classifications of mathematics and general education performance. Predictor variables included motivational, general background, learning strategies and cognitive measures. All models were very successful. Study 1 results had a total accuracy of 94-98% for the classification of students into three levels of performance. Study 2 achieved total accuracy of 96-98% for the prediction of various levels of mathematics performance, and 94-99% accuracy for models of general academic performance at the end of year 1 in higher education studies. In summary, this predictive system methodology is proposed as a valuable alternative to develop more comprehensive and accurate assessment systems which can increase the validity and the accuracy of diagnostic, placement, and selection decisions in educational settings, thus achieving higher levels of fairness and efficiency, while also increasing the understanding of the
processes involved, with an opportunity for “continuous assessment”.

Non-technical skills, obstetrician expertise and the quality of clinical reasoning

DUNPHY, S. (University of Newcastle), CANTWELL, R. (University of Newcastle), DUNPHY, B. (University of Newcastle), BOURKE, S. (University of Newcastle)

There is widespread concern in the medical literature regarding patient safety and the potential impact of errors in clinical decision making (Healey, Catchpole & Yule, 2008; WHO, 2009; Dunphy et al., 2009; Yule et al., 2008). Recent evidence suggests that physician affect and metacognitive processes have a direct impact on the quality of clinical reasoning and ultimately the standard of patient care (Dunphy et al., 2009). The aim of our study was to explore the clinical reasoning processes of twelve consultant obstetricians through semi-structured interviews. We hypothesized that the interaction of obstetrician metacognition and affect is fundamental to the quality of their clinical reasoning. Researchers in the United Kingdom (Flin et al, 2007) have developed a taxonomy of surgeons’ non-technical skills (NOTSS) which has four categories: situation awareness, decision-making, communication and teamwork, and leadership. We analysed these interviews using the Non-technical skills (NOTSS) taxonomy (Flin et al, 2007), paying particular attention to the impact of metacognitive processes and affect on the application of non-technical skills. In performing our qualitative analysis we looked for evidence of an interaction between obstetrician affect and breadth of application of non-technical skills. We hypothesized that obstetricians who utilized a broad range of non-technical skills were more likely to be big picture thinkers, to be experts in their field and be associated with positive affect and superior patient outcomes. Conversely, obstetricians found to employ a narrower range of non-technical skills may have “tunnel vision” and their clinical reasoning may be compromised by negative affect. We have data on patient outcomes for the same group of obstetricians obtained from a high quality standardized perinatal database, and a matrix of data from standardized psychology questionnaires. When our qualitative analysis is complete we will triangulate our findings with psychology scales demonstrated to be predictive of patient outcomes in the same population of obstetricians and clinical information from the perinatal database.

Not yet, not here, and not us: Investigating the drivers of doubt and inaction in response to climate change

GARDNER, J. (CSIRO), VAN KASTEREN, Y. (CSIRO), QUEZADA, G. (CSIRO), RODRIGUEZ, M. (CSIRO)

For more than 30 years, extensive empirical evidence has been mounting about anthropogenic climate change. Despite the degree of scientific consensus, and the lack of credible alternative explanations, individuals, communities and governments have been slow to act. The degree of action taken in response to climate change has, so far, been inadequate to the scale of the threat. Further, there are extensive public expressions of doubt about the “reality” of climate change, and public opinion surveys have consistently shown that a large proportion of the community in many countries does not accept that a threat exists. How can this inaction and doubt be explained? In this paper, we critically review a number of potential explanations for climate change doubt and inaction, including both passive inaction and active resistance to climate change and/or the changes that have been suggested to address it. Relevant explanatory mechanisms include various psychological responses to threat, cognitive biases in decision-making, and an array of individual and societal responses to external pressure to change. We evaluate the existing empirical evidence in support of these mechanisms, focusing especially on the context of climate change and pro-environmental behavior. In turn, we attempt to identify the types of interventions that are most likely to be
able to overcome the relevant mechanisms. Results of our review provide support for a number of explanatory mechanisms. Although no single theoretical approach seems capable of fully explaining the current societal responses, biases in decision-making seem especially relevant. Evidence indicates that the lack of response may reflect a lack of perceived relevance and immediacy of climate change impacts, but rather a perception that the impacts will be felt by other people, in other places, in some unspecified future. The societal tendency to ever-increasing consumption is also recognized as an important underlying mechanism. On the basis of our review, we develop an integrated multi-level model of the drivers of doubt and inaction in response to climate change, and identify some important features of interventions that may be used to overcome these effects. We also develop an agenda for future empirical research in the area.

Keywords: climate change, threat, cognitive bias, decision making

Older adults' perceptions of the benefits of music making: community, coping and connectedness

SIMMONDS, J. (Monash University), SOUTHCOTT, J. (Monash University)

The ageing of Australia’s population is creating challenges for maintaining health and combating social isolation. Music has the potential to enhance quality of life in relation to health, activity, happiness, independence and the development of community. This research in progress investigates engagement with music by older Australians. We identify the perceived benefits which motivate individuals to begin and continue their involvement in individual and community music making. Participants were recruited through seniors’ newspapers, advertisements, and public online sites. They completed a purpose-designed questionnaire with fixed choice and open ended questions to investigate and quantify their engagement with music. Our research identifies a broad spectrum of ways in which older people engage with music individually and in the community and what benefits they perceive. Survey data regarding sense of community, environmental connectedness, feelings of wellbeing, meaning, spirituality, coping with losses, physical health, perceived mental health, and life transitions were analysed. Open-ended questions were analysed using the qualitative methodology of Interpretative Phenomenological Analysis. In this research in progress, we add to the scant research systematically investigating the benefits of music for older adults living in the community. To date this has not been undertaken anywhere in Australia. A single case study with a group of older amateur musicians in Victoria, Australia, recently identified that engagement with community music provided a sense of purpose and fulfillment, helped establish and maintain relationships and offered opportunities for personal growth. The current research maps engagement with music and motivations for continuing engagement. Implications for the development of further resources for healthy ageing are discussed.

Operationalising results based management in an African public service: some hard and soft competences

MUNENE, J. (Makerere University Business School), RWEMIGABO, T. (President’s Office, Uganda Public Service)

This study examines the antecedents of productive attitudes and behaviours, organisational citizenship behaviour (OCB), associated with the Results Based Management (RBM) initiative in an African context. Specifically we explored the relationship between organisational social capital (OSC), RBM work-based competences and OCB in a Public Service Ministry implementing RBM. We conducted two cross sectional surveys. In the first we interviewed ten key informants to articulate the competences required of a RBM facilitator. In the second we administered a structured questionnaire measuring RBM competences, organisational social Capital and Supervisor rated Organisational Citizenship Behaviour. Of these one hundred and eleven had been in the service for more than six years.
The majority of the respondents \((N = 114)\) were male, where 49 were above 41 years (mean age = 32 years). Using zero order correlation, we found high positive correlation (.41) between RBM competences and supervisory rated OCB providing support for the hypothesis stating a positive relationship between RBM competences and OCB. We also found a high and positive correlation (.61) between OCB and organisational social capital demonstrating support for the hypothesised relationship between OCB and OSC. These relationships were confirmed through a regression model using OCB as the dependent variable. Using the enter method, we found an Adjusted R Square of .45 indicating that the variables were able to account for 45% of supervisor rated OCBs among the sample of senior officers who took part in the study. On further examination we found that Organisational Social Capital could account for 56% of the variance in the OCBs while RBM competences independently accounted for 24%. Both antecedents were significant at .001 or better. The results from the study point to a number of issues that should be taken care of when implementing RBM in Africa. The first is organisational social capital. The second is organisational citizenship behaviour. The third is comprised of the actual behavioural or operant competences required to perform RBM related activities. We refer to the first two as the soft competences that must be attendant at all times during the RBM cycles but most especially during the throughput or activities/output phase. We refer to the third as the hard competence because it directly rather than indirectly impacts on the required outputs.

Keywords: organisational citizenship behaviour, results based management, productive attitudes, African public service

Optimism and readiness to citizenship activity in the future among young people from developmental perspective

ZALEWSKA, A. (Warsaw School of Social Science and Humanities), KRZYWOSZ-RYNKIEWICZ, B. (University of Warmia and Mazury)

The aim of the study is to examine the character of young people optimism and its relation towards citizenship activity. According to Czapiński (2005) and Stach (2006) we differentiate: (1) essential (passive) and (2) expansive (active) optimism. We assume that young peoples’ perception of the local future is related to the expansive optimism and global future to essential optimism. Then we expect that the higher optimism towards the local future, the higher readiness for social (participation in campaigns) and political (interested in politics, voting in election, belonging to political party, be elected) action. Research questions are (1) is there difference between young peoples’ optimism towards local and global future and does it depend on age, and (2) is readiness to political and social action related to optimism towards local and global future. 2473 young people in three age groups 11 (884), 14 (903), 18 (686) from 4 European countries (Poland, UK, Spain and Turkey) were examined by the questionnaire What do you think about future (by Holden). Questions about optimism towards five social issues (violence, poverty, unemployment, environment, tolerance) in local and global perspective were reported on five-point scale. Five questions about action were reported on a four-point scale. Results show that young people are more optimistic towards local then global future \((t=7, 88; p<0,001)\). Although optimism towards both local \((F(2/2472) =38,172; p<0,001)\) and global \((F(2/2460)=77,10; p<0,001)\) future depend on age - youngest children (10 years old) are most optimistic, the difference between them is stable. There was also a non-significant correlation between local and global optimism and declaration to political and social action. Young people from different countries perceive local future as more optimistic than global (which can go together with effect of unrealistic optimism of Weinstein, 1980). Although optimism towards social issues from local perspective could have a more active character, having the possibility of change, it is not related to declaration for social and political action. It seems that different ways of examining optimism and social and political action is needed to confirm the relationship between optimism and readiness to act (e.g. focus on optimism to positive social issue rather than negative).
Organizational climate and company performance: A multilevel test

VERBURG, R. (Delft University of Technology)

We aim to contribute to the Human Resource Management (HRM) literature by performing a multilevel test of the often theorized relationship between Organizational Climate (OC) and performance. Second, we aim to contribute to the theoretical knowledge of how actual and perceived Organizational Climate relate by testing the moderating role of leadership level. In a multi-source, multilevel study of 41,693 employees and managers in 47 branches of a large firm, we tested how Organizational Climate relates to organizational level outcomes, such as productivity, turnover and profit. We found direct relationships between Organizational Climate and both turnover and unit performance. Hierarchical linear modeling analyses showed that perceived Organizational Climate mediated the relationship between actual Organizational Climate and leadership level moderated the relationship between Organizational Climate and performance. These findings contribute to our understanding of how Organizational Climate affects company outcomes. The study has several strengths, including the relatively large sample and the multi-level nature of the study. An additional strength of our study is the use of different rater sources. Nevertheless, there are also limitations. For example, the choice to conduct this study in one large firm has both advantages and drawbacks. An advantage is that intended Organizational Climate as set out by head quarters was kept constant, thus we can be more confident than in a multi-organization study that variations are due to implementation by managers in the business units and perceptions. However, the generalizability to other firms or sectors may suffer from this limitation to a single firm that has its own specific policies and additional research in other contexts is needed.

Organizational support and its implications for Japanese professional athletes in career transition

OGAWA, O. (Kinki University), OKUMURA, K. (Rikkyo University (PDI Consultant))

The aims of this research are to explore the organizational career support offered to Japanese professional athletes transitioning to post retirement career, and to discuss its implications in regards to athletes’ transition in the volatile Japanese labor market. The services offered by the employment bureaus (Career Support Center) of the Japanese professional football league (J league) were reviewed, and qualitative semi-structured interviews were also conducted with eighteen ex-professional soccer players who were randomly selected for this research. The data were analyzed in order to examine the correlation between the services provided by the organization and the needs of athletes. This research clearly shows that the types offered by the employment bureau in J league, such as job training programs and exchanging the information, is found to be useful for transitioning athletes in the volatile Japanese society. However, there is a discrepancy between the employment bureaus’ capability and the ex-athletes’ essential needs during the ‘internal’ career transition (Schein, 1990). In addition, this research discovers that courageousness and approachability of the people in their social network are the important factors for the players’ internal career transition. Approachability consists of four components; career related information, acceptance, availability, and confidentiality. Our conclusions are the following: (1) the roles of formal career support are partly important for the athletes’ transition in Japan, (2) professional athletes who are seeking new career choices should have courageousness when networking during job-hunting and after retirement, and (3) people supporting job-seekers should improve their approachability skills.

Parallel play in acute mental health settings: Nurses and psychologists working within the time and space of acute wards

HAMILTON, B. (St Vincent’s Health Melbourne)

This paper explores the different ways psychiatric nurses and clinical psychologists interact with patients and colleagues, in the time and space of acute psychiatric wards. Ethnographic fieldwork over 18 months in a 44 bed acute unit was used to identify the shaping influence of time, hospital routines and various spaces on the practice of twelve psychiatric nurses. The temporality and located-ness of nurses was considered in contrast with that of clinical colleagues. Theoretical analysis was informed by the work of the post-structural social theorist, Foucault. Analysis highlighted how shift-working nurses’ relationships to ward time and space differed significantly from that of psychologists. Shift-working nurses were tied to the communal spaces of the ward and the ward office for the entire shift, where they moved through the ward space with a characteristic momentum and were subject to constant interruption. Psychologists spent time in staff-only meeting spaces or offices and entered the patient areas of the ward for planned events, such as groups or individual consultations. These differences were taken-for-granted among clinical team, and there was little intersection between work-worlds, despite staff working in close proximity. Their engagement with ward time and space produced parallel understanding of patients, their needs, and priorities for care and therapy. Neither nursing nor psychology perspectives were robustly discussed or embraced in multidisciplinary gatherings, such as ward rounds. Making such differences more visible can serve to strengthen complementary roles, teamwork and collegial support in hospital settings. It also highlights opportunities for re-configuring roles, spaces and routines, to enhance collegial understanding and teamwork.

Parental control and obsessive-compulsive symptoms: The role of metacognitions & self-identity

GUO, X. (National University of Singapore), SO-KUM TANG, A. (National University of Singapore)

Although the effect of parenting styles and the development of anxiety disorders has been proposed, its effect has yet to be studied in Obsessive-Compulsive Disorder (OCD). As yet, we know very little about how they might exert its influence on the development of OCD. Theories like the Metacognition (Wells, 2004) and the Discrepant self-identity theories (Purdon & Clark, 1999) have suggested some possible etiological mechanisms in OCD, yet they have not been thoroughly investigated as with the established cognitive theories of OCD. Therefore, this study aimed to examine the connections between parenting styles and OCD. In particular, we investigated whether OCD-like metacognitions and/or discrepant self-identities (i.e. the difference between one’s current self-attribution and desired self-attribution) would mediate the influence of negative parenting styles on OCD symptoms. A sample of 462 healthy adult community participants in Singapore was surveyed. Each participant filled out an anonymous questionnaire on: negative parental discipline styles, discrepancy between current and desired self-identity, metacognitive styles (e.g. thought fusion), and OCD symptom level and subtypes. Trait worry level was also taken, in order to control for its influence on OCD symptoms. Results of Bootstrap analyses showed that negative parenting style was significantly correlated with discrepant self-identity, worry, OCD meta-cognitions, and OCD symptoms. Bootstrap mediational analysis further illustrated that the association between discrepant self-identifies and OCD symptoms was fully mediated by worry. Furthermore, when worry was controlled for, the association between negative parental discipline styles and OCD symptoms was partially mediated by OCD metacognitive beliefs. The observed involvement of negative parenting style indicates a familial influence on OCD symptoms that warrants further exploration. In addition, the results lend support to the Metacognition Theory (Wells, 1997), which argues that the manner in which people process their thoughts
contributes to their OCD symptoms. Consonant with current literature, discrepant self-identity appears to influence OCD, albeit in a non-specific way. This finding is largely commensurate with Purdon and Clark’s theory (1999). This study has great implications on the understanding of OCD. It also contributed to the limited literature on parenting and mental disorders in the context of Singapore.

Keywords: parenting styles, obsessive compulsive disorder, meta-cognition, discrepant self-identities

**Parents’ work and family strains: A new mental health risk for children?**

STRAZDINS, L. (The Australian National University)

Combining work with caring for children can be stressful as well as rewarding. Our aim was to investigate if parents’ work-family strains (or gains) are important for children’s mental health and wellbeing. We use cross-sectional survey data from the Growing Up in Australia study of parents with 4-5 year old children (N = 2133 employed mothers; 2661 employed fathers). Child wellbeing was assessed using the Strengths and Difficulties Questionnaire (SDQ), a measure of children’s emotional and behavioural problems. Multiple regression modeling tested for associations between child SDQ scores and mothers’ and fathers’ reported work and family strains, and work and family gains. Parent’s work-family strains, gains and their own psychological distress were interrelated, suggesting that they affect each other. Parents’ strains, gains and distress were also associated with children’s difficulties, and these effects were observed after adjusting for their interrelationships. Elevated levels of work-family strain showed additional, independent associations with poorer child wellbeing. Further, parents’ experience of gains and rewards from combining work with family appear to be protective for children’s wellbeing. Children in socio-economically disadvantaged families benefitted the most from parents’ work-family gains, relative to children from more advantaged households. Our findings suggest that parents’ jobs can exert additional, independent effects on children’s mental health, after adjusting for parent mental health. This study indicate that reducing mothers’ and fathers’ work–family strains and increasing their gains and rewards from jobs may be another, essential foci for interventions to improve children’s mental health and life chances, especially in socio-economically disadvantaged families.

Keywords: parents, work, family, mental health, children

**Participants of online surveys on health care in dermatology have something in common: The critical view**

The aim of the current study was to compare data gathered online on health care between dermatological diseases and with data gathered paper-and-pencil based. In four different web surveys a total of 4428 patients (1946 with psoriasis, 542 with acne, 1348 with rosacea and 592 with atopic dermatitis) completed an online version of a questionnaire on clinical data, therapy and patient benefit. Subsequently, difference analyses were conducted between these diseases, which were partially investigated online for the first time. Additional difference analyses to paper-and-pencil based data of 5251 patients with psoriasis, atopic dermatitis and rosacea were carried out. Across all patients who participated online, more women took part. Most experienced with systemic therapeutics were patients with acne (64.6%), followed by atopic dermatitis (47.0%), rosacea (38.7%) and psoriasis (29.1%). Of the online participants, there were only minor differences regarding satisfaction with treatment (1 = very satisfied to 4 = very dissatisfied) between atopic dermatitis and rosacea (each 2.8 ± 0.9), psoriasis (2.9 ± 0.9) and acne (3.1 ± 0.9). Small differences between the diseases were also found regarding patient defined treatment benefit and perceived treatment success. The lowest patient benefit (range 0-4) was found in acne patients (1.1 ± 1.0), followed by atopic dermatitis (1.2 ± 1.0), rosacea (1.3 ± 1.1) and psoriasis (1.4 ± 1.2).
patient benefit across the diseases was only marginally above the cut-off-value of 1 (minimum relevant benefit). Both, patient benefit and treatment satisfaction are considerably lower in the web based surveys compared to the current paper-and-pencil surveys. The results indicate that patients with acne evaluate their health care situation worse than patients with other skin diseases. However, these differences are small indicating that the kind of disease is of minor importance. Striking results are the big differences between web based and paper-pencil-based data with regard to the patients’ evaluation of their health care situation. This implies that the evaluation of health care depends on the way of surveying. The satisfaction with health care may be overestimated because it’s mainly based on paper-and-pencil data collected in “traditional” settings.

Keywords: health care, dermatological diseases, online surveys

Patients’ beliefs about CBT and their relationship to outcome in panic disorder and agoraphobia

DROBNY, J. (Westmead Hospital), BLASZCZYNKSI, A. (University of Sydney)

This project aimed to investigate relationships between treatment knowledge, beliefs and outcome in Panic Disorder and/or Agoraphobia (Panic-Ag) following cognitive behaviour therapy (CBT). Research from the psychotherapy and medical literature indicates patients’ treatment knowledge and beliefs, specifically acceptance of the treatment rationale (ATR), expectancies of treatment outcome (ETO) and treatment self-efficacy (TSE), are associated with clinical outcomes for a range of disorders. However, many studies are methodologically flawed or have not been conducted in the field of Panic-Ag. It was hypothesised that treatment knowledge, ATR, ETO and TSE would be related to outcome, with associations mediated by belief in catastrophic cognitions. Measures of treatment knowledge, ATR, ETO and TSE were firstly developed using patient and clinician samples. The psychometric properties of these measures were satisfactory. Associations between CBT knowledge, beliefs and outcome were investigated among 41 Panic-Ag participants. There were four outcome measures: panic attack frequency, panic sensation severity, frequency of catastrophic cognitions and agoraphobic avoidance. Measures were administered at pretreatment and six-month posttreatment. Improved treatment knowledge was significantly associated with frequency of catastrophic cognitions and agoraphobic avoidance. Posttreatment TSE was significantly associated with panic attack sensation severity, frequency of catastrophic cognitions and agoraphobic avoidance. Contrary to the hypothesis, ATR was not related to outcome. Pretreatment beliefs were also unrelated to outcome. Mediational analyses revealed relationships between TSE and outcome were partially mediated by belief in catastrophic cognitions while relationships between treatment knowledge and outcome were not. These findings may have clinical value by assisting clinicians in identifying patients with insufficient knowledge and/or poor confidence in following treatment recommendations who may be at risk of poor clinical outcomes. Methodological limitations, clinical implications and future research directions are also discussed.

Keywords: panic disorder, agoraphobia, cognitive behavioural therapy

Pediatric medical traumatic stress: Prevalence, risk and prevention

KENARDY, J.

Serious non-intentional injury resulted in at least 2,500 hospital admissions per 100,000 children in Australia in 2003-2004 (AIHW, 2007), where a third of children who are admitted to hospital for traumatic injuries develop clinical levels of traumatic stress in the three months following admission. Many of these children go onto recover but about one in ten children tend to go on to have ongoing psychological problems. Furthermore the effects of hospital experiences have also been documented in child transplant recipients and cancer survivors, as well as children who have been admitted to Paediatric Intensive Care Units. The term Medical
Traumatic Stress has been used to describe the psychological and physiological responses of children and their families to pain, injury, medical procedures, and invasive or frightening treatment experiences. The presentation will describe a program of research aimed at delineating the extent of Medical Traumatic Stress in children, and responding to it. This includes a prevalence study examining new onset psychological disorder following admission; development of risk screening tools to children; preventative intervention evaluation; and early intervention within a stepped care model.

**Keywords:** paediatric medical traumatic stress, prevalence, risk screening, preventative intervention

**Perceived organisational support, positive employee attitudes, and the mediating influence of trust and fairness**

PIGNATA, S. (University of South Australia), BOYD, C. (University of South Australia), WINEFIELD, A. (University of South Australia), PROVIS, C. (University of South Australia)

Using a social-exchange theoretical framework, we examined the mediating influence of trust in senior management and perceived procedural fairness on relationships between Perceived Organisational Support (POS) and employee-level outcomes of psychological strain, job satisfaction and affective organisational commitment. POS was operationalized as employees’ awareness of stress-reduction strategies implemented in their workplace. We present longitudinal data from 861 academic and professional staff at 13 Australian universities who were surveyed in 2000 and 2003/4 as part of the Australian University Stress Study. Results of bootstrapping analyses found that employee perceptions of senior management trustworthiness, and perceived procedural fairness both mediated the positive relationship between POS and organisational commitment, and between POS and job satisfaction. Furthermore, perceptions of senior management trustworthiness and procedural fairness also mediated the negative relationship between POS and psychological strain. When trust in senior management and perceived procedural fairness were simultaneously entered in the mediation analysis, both were found to mediate the relation between POS and psychological strain, job satisfaction and organisational commitment. The results suggest that POS fostered perceptions of senior management trustworthiness or perceptions of procedural fairness, and in turn, employees responded with lower levels of psychological strain and/or pro-organisational attitudes such as job satisfaction and affective organisational commitment. Our findings add support for the mediational role of both trust in senior management and perceived procedural fairness. Further implications for organisational practice are discussed, and avenues for future research are suggested.

**Keywords:** management, job satisfaction, organisational commitment, procedural fairness, trust

**Perceived stress, stress appraisal, and coping strategies used in relation to exposure of terrorism on television**

KAUSAR, R. (University of the Punjab, Lahore, Pakistan), ANWER, T. (University of the Punjab)

The present study was conducted to investigate perceived stress, stress appraisal, and coping strategies used in relation to television exposure to terrorism. It was hypothesized that there is positive relationship between perceived stress, stress appraisal, coping strategies and television exposure of terrorism. A sample of 98 students (50 Males, 48 Females; age between 20-25 years) was selected from the Departments of “Faculty of Life Sciences” University of the Punjab, Lahore, Pakistan. A demographic questionnaire, Perceived stress scale (PSS) (Cohen, 1983), Stress appraisal measure (SAM) (Peacock & Wong, 1990), and Coping strategy questionnaire(CSQ) (Kausar, 2001) were used for assessment. Data was analyzed using correlation, t-test, and regression analysis. The results indicate that there is significant relationship between perceived stress, stress appraisal, coping strategies and television exposure of terrorism. There were significant gender differences in perceived stress, stress appraisal, and coping strategies. Depiction of
incidences of terrorism on television is causing immense stress to the viewers and the findings have important implications for digital media which is giving live coverage to terrorism activities for its viewers.

Keywords: perceived stress, stress appraisal, coping strategies, terrorism, media

Perceptions of acceleration at work: theoretical considerations and empirical results

KORUNKA, C. (University of Vienna)

In many modern work places employees are confronted with numerous changes. They also experience an intensification and acceleration of these changes. The sociologist Hartmut Rosa (2005) developed a sociological conceptualization on the process of acceleration in modern societies. We tried to transfer his sociological model into work and organizational psychology by integrating his assumptions into a general Job Demands-Resources (JD-R) model. The model contains three core assumptions: (1) In current work places, acceleration may be perceived by the employees, (2) there are acceleration specific job demands and job resources, (3) specific interactions between demands and resources influence the quality of working life (e.g. job satisfaction, burnout, engagement) in positive and/or negative ways. A questionnaire was developed measuring perceptions of acceleration and specific job demands and job resources related to acceleration. An item pool was generated based on a comprehensive literature search and on content analyses of focus groups. The following aspects were included in the scale development: (a) perceived changes/increases of working amount per time unit and perceived changes/increases of working outputs; (b) perceived changes in time resources, e.g., changes/decreases of pause times, changes/increase of working hours; (c) perceived changes in organizational conditions, e.g., deadlines and deadline pressure; (d) perceptions of acceleration based job resources, e.g., changes in degrees of freedom and changes in social resources; (e) personal resources helping to adapt to change, e.g., self efficacy and self regulation. The model was tested in three cross-sectional samples: 260 office workers (study 1); 1.810 human service workers (study 2) and university employees (study 3; data collection will be finished Jan. 2010). The three dimensions of acceleration (Rosa 2005): “technological acceleration”, “acceleration of organizational/social change” and “acceleration of pace of life” could be confirmed. Strong perceptions of acceleration were observed in the areas of “documentation”, “number of emails”, “information needs” and “work speed”. Only “acceleration of pace of life” was perceived as a stressor related to burnout. Perceptions of technological acceleration are related to work engagement. Perceptions of acceleration were confirmed as “new” work demands. Depending on the resources of employees these demands could be either positive or negative. In preventing negative effects of acceleration, resources need to be developed. A special prevention focus needs to be given on elder and/or low educated employees.

Keywords: acceleration at work, perceptions, job demands, job resources

Perceptions of legitimacy of political violence amongst Saudi Arabians

LYONS, E. (Queen’s University Belfast), ALBAZ, N. (CResPP, Queen’s University Belfast)

The paper examined factors influencing perceptions of legitimacy of political violence against either Western targets or targets within Saudi Arabian targets. In particular it examines motives ascribed to those who commit political violence against the two types of targets, the perceived causes for these phenomena, what beliefs and attitudes (e.g. beliefs in a just world, moral disengagement) and emotions are related to perceptions of legitimacy of political violence and what patterns of identification (religious, national) are related to such perceptions. The study involved conducting two surveys of Saudi Arabian students (N=287 and N=271). Data collected using self-completed questionnaires which included socio-demographic variables, measures of Religiosity, perceived threats, perceptions of history, attitudes toward the West, Intergroup contact, national identity, religious identity, shared grievances, emotions,
just world beliefs, moral disengagement and perceived legitimacy /illegitimacy of political violence against the West. Path analyses have showed that income, negative attitudes towards the political violence in the West, perceiving West as a threat and moral disengagement were predictors for the perceived legitimacy of the political violence against the West. In the case of perceived legitimacy of political violence in Saudi Arabia, age, marital status and exposure to violence, the type of, and number of victims, views of socio-political causes, emotions, moral disengagement and beliefs in just world were found to be statistically significant predictors for the perceived legitimacy of the political violence in Saudi Arabia. Our findings suggest that there are some similarities and differences in the factors which are associated with perceived legitimacy in political violence in the participants’ own country and that carried in the West. They also contribute to our understanding of lay theories of political violence amongst a Muslim population.

Keywords: perceptions, legitimacy, political violence, attitudes, identification

Personal and organizational factors facilitating job involvement among Nigerian workers

MOGAJI, A. (Benue State University)

The study was aimed at determining the personal and organizational factors that facilitate job involvement among Nigerian workers. Data were collected from 600 subjects randomly selected from the shoe, textile and food manufacturing industries in Lagos, Nigeria. The sample included 150 junior workers, 90 supervisors and 60 managers. There were 495 males and 105 females in the sample. Analysing the data, the t-statistics did not reveal any significant difference in job involvement between male and female workers at ($p > .05, df = 598, t = 1.12$). The One-way ANOVA showed significant differences in job involvement among the three categories of employees at ($p < .01, df = 2/597, F = 8.87$). There were also significant differences in job involvement among the three industries at ($p < .01, df = 2/597, F = 11.92$). Analysing the data further, the step-wise regression results showed that job involvement is positively influenced by organizational responsibility and negatively influenced by the workers’ age, work satisfaction, warm climate and the type of industry. The results indicated that job involvement is significantly influenced by interpersonal, intergroup and organizational climate factors at ($p < .01$) respectively.

Personality and demographic predictors of aggressive and distracted driving: implications for traffic safety

STANISLAW, H. (California State University, Stanislaus)

This study examined how the tendency to drive aggressively and the tendency to engage in distracting behaviors while driving relate to each other and to personality characteristics and demographic variables. The relationship of aggressive and distracted driving to self-rated driving ability and to the perceived likelihood of accident involvement was also studied. 137 male drivers and 137 female drivers (mean driving experience = 11.9 years, $SD = 12.5$ years) completed a survey designed to measure two forms of aggression (physical aggression and trait anger), perceived invulnerability, and driving history. They also rated their own driving ability, estimated their likelihood of accident involvement, and indicated how often they engaged in aggressive driving, such as tailgating, and how often they performed distracting tasks, such as texting while driving. Aggressive and distracted driving were highly correlated with each other. Both behaviors declined with increasing driving experience. There were no sex differences in distracted driving. However, aggressive driving was more common in males than in females, which appeared due to higher levels of physical aggression in males. Trait anger was positively correlated with both aggressive and distracted driving, while perceived invulnerability was correlated only with aggressive driving. There was no relationship between self-rated driving ability and aggressive or distracted driving, but the likelihood of accident involvement was positively correlated.
with both aggressive and distracted driving. Therefore, aggressive and distracted driving are distinct behavioral tendencies: they both decline as drivers mature, but they differ in their relationship to the driver’s sex and personality characteristics. Drivers do not regard aggressive or distracted driving as affecting their driving ability. However, they do recognize that these behaviors place them at greater risk of accident involvement, suggesting that interventions can be designed to capitalize on this knowledge and leverage it to reduce aggressive and distracted driving.

Keywords: driving behaviour, distracting behaviours, personality characteristics, Aggression

Personality as predictor of pro-environmental attitudes and behaviours

MILFONT, T. (Victoria University of Wellington), HARDLEY, J. (Victoria University of Wellington), MILFONT, T. (Victoria University of Wellington)

Several studies have examined the influence of individual differences variables on environmental engagement. Along with gender, age and education, variables such as values, time perspective, self-construals and connectedness with nature have been linked to environmental attitudes (EA) and behaviours. Specific personality traits have also been examined. Traits such as responsibility, conscientiousness and self-confidence have been found to relate to pro-EA, while selflessness and responsibility have been found to relate to ecological behaviours. However, to our knowledge there has been no systematic research exploring the effect of the Five-Factor Model (FFM) of personality on EA and ecological behaviours. We conducted two studies to address this gap in the literature. A total of 332 undergraduate students took part in Study 1 (70% female, mean age = 19, SD = 2.6), and a community sample of 150 participants took part in Study 2 (54% female, mean age = 33.8, SD = 15.9). Participants completed an online survey containing FFM measures (Study 1: Ten-Item Personality Inventory; Study 2: Big Five Aspect Scale), the New Environmental Paradigm (NEP) Scale, the Environmental Attitudes Inventory, and ecological behaviour measures. Hierarchical multiple regressions analyses were performed to examine the relationship between the Big Five dimensions and EA and ecological behaviours, controlling for age and gender. Only Openness to Experience consistently predicted people’s environmental engagement in both studies. The findings are consistent with another recent study showing that Openness to Experience predicts environmentalism, and also with studies showing the link between this personality dimension and universalism and self-transcendence values, which have been shown to relate to pro-EA and ecological behaviours. Thus, those people who are open-minded, hold a more altruistic viewpoint and are innovative in their outlook and behaviour tend to be more environmentally engaged. However, the effect sizes in our studies were small to medium, suggesting that the predictive power of personality on environmental engagement is low. This is a positive finding suggesting that intervention campaigns can influence people’s environmental engagement. Theoretical and practical implications of the findings will be discussed, and directions for future research outlined.

Keywords: environmental engagement, individual differences, big five model of personality

Personality correlates of colorectal cancer

KREITLER, S. (Tel Aviv University), KREITLER, M. (Bar-Ilan University)

The attempt to identify personality types that tend toward cancer is of long standing. Yet previous studies have led to inconclusive findings (e.g., Type C). The goal was to identify relevant personality characteristics of colorectal cancer patients by applying a new psychological methodology grounded in the cognitive orientation theory. The major tool was the cognitive orientation questionnaire of colorectal cancer that assesses four types of beliefs (about self, norms, others and reality, and goals) in regard to themes determined in pretest depth-interviews with colorectal cancer patients and healthy controls. The questionnaire was
administered to 230 colon cancer patients and two control groups: 165 matched healthy controls, and 90 patients with Crohn's disease, who also served as controls because they are known to be at risk for colorectal cancer. Discriminant analysis showed that the questionnaire provided a highly significant correct identification of cases of the three groups. The cancer group scored highest, the healthy controls lowest, and the Crohn’s patients in the middle. The thematic clusters that constitute the personality correlates of colorectal cancer were found to be tendencies for compulsiveness, control of oneself and especially of anger, self effacement, pleasing others, self assertion, distancing oneself from others, keeping regulations, and performing to perfection all ones obligations. These tendencies form three major foci which are: perfect duty performance, and two contradictory pairs: self effacement versus self assertion, and closeness to others versus distancing from others. The clusters and the contrasts constitute potentially sources of tension. It is suggested that the identified personality correlates could be considered as psychological risk factors for colorectal cancer and could serve as basis for psychological interventions.

Keywords: personality types, colorectal cancer, cognitive orientation theory

Personality traits and schemas characteristic of avoidant and narcissistic personality disorders

BUTRUS, N. (Australian Catholic University), WITENBERG, R. (Australian Catholic University), HAMMOND, S. (Australian Catholic University)

The aim of the current study was to identify personality traits and maladaptive cognitive schemas characteristic of avoidant and narcissistic personality disorders so as to better understand the underlying features of these disorders. A non-clinical sample of 293 individuals (M= 26.19 years, SD= 9.88, age range = 18-72 years) completed measures of personality traits, early maladaptive schemas, personality disorders and core beliefs hypothesised to be associated with the personality disorders. Hierarchical multiple regression analyses indicated that 76% and 74% of the variance in avoidant and narcissistic personality disorders, respectively, could be explained by traits and schemas. Specifically, results indicated that the most salient predictors of avoidant personality disorder were traits such as self-consciousness, avoidant beliefs, and the early maladaptive schemas of emotional inhibition, abandonment, social isolation and subjugation. In contrast, the most salient predictors of narcissistic personality disorder were traits such as low values, narcissistic beliefs and the early maladaptive schemas of entitlement/grandiosity, admiration-seeking and social isolation. Importantly, cognitive schemas and beliefs accounted for additional variance in these personality disorders over and above the variance explained by traits alone. The findings from this study highlight the important role of schemas in the maintenance of personality disorders and have direct implications for their assessment and treatment. Specifically, the findings suggest that more research is needed regarding the current call to re-conceptualise personality disorders solely through the use of dimensional trait models. The findings also suggest that the effectiveness of schema modification approaches to treating the personality disorders should be explored further.

Keywords: personality traits, cognitive schemas, avoidant personality disorder, narcissistic personality disorder

Person-job and person-organisation fit as predictors of intentions to quit: steps towards retaining Pacific healthcare workers in New Zealand

COOPER-THOMAS, H. (University of Auckland), POUTASI, C. (University of Auckland)

In New Zealand, Pacific peoples are high users of healthcare services, with higher rates of certain chronic diseases (e.g., diabetes) and lower life expectancy relative to the general population. The retention of healthcare workers, who reflect the local population of healthcare users, is likely to lead to the best health outcomes for that population. Hence, the retention of Pacific healthcare workers is critical issue. This research aimed to test the attrition aspect of
Schneider’s (1987) attraction-selection–attrition theory, that Pacific healthcare workers with poorer fit to their jobs and organisations would show a greater intention to quit. Survey data were collected from 104 Pacific healthcare workers from the three District Health Boards in the Auckland region. Surveys were distributed via managers and team leaders. Most participants were female (70%), 41-45 years, and in full-time employment (83%). The main ethnicities reported were Samoan (51%), Tongan (19%), and Cook Island Maori (13%). Both person-job and person-organisation fit predicted job satisfaction, organisational commitment, and intent to quit; person-organisation fit was the stronger predictor of these. Both job satisfaction and organisational commitment mediated the relationship of the fit measures with intent to quit, although this was only partial mediation for job satisfaction on the relationship of person-organisation fit with intent to quit. Our study is the first to concurrently look at the broader picture of different types of fit, as well as attitudes of job satisfaction, organizational commitment, and intent to quit. Our results show that person-organisation fit is a more important variable in considerations of intention to quit than person-job fit. Thus, referent-matching does not seem to influence results. Efforts to improve Pacific healthcare workers’ retention should focus on increasing perceptions of person-organisation fit, and also organisational commitment, since this was the key mediation path.

Keywords: health care services, attraction-selection–attrition theory

Phases of innovation – Do they exist?

ROSING, K. (Justus-Liebig-University Giessen), FRESE, M. (National University of Singapore)

Innovation processes have often been divided into several phases; most models of innovation identify at least two phases: creation and implementation. These phases imply activities that are quite different from each other, for example, exploration and exploitation. We argue that although the activities that accompany different phases might be distinguishable from each other, distinct linear phases do not occur in innovation projects. Instead, the activities implied by the four phases proposed by Farr, Sin, and Tesluk (2003) – problem identification, idea generation, idea evaluation, and implementation – are important throughout the whole innovation process. We used a longitudinal design with four to six measurement waves to study the activities of 80 student teams working on an innovation project for up to one semester. In every measurement wave, students indicated to what extent they conducted activities concerning the four innovation phases (2-3 items per phase). In addition, students assessed several cognitive and motivational variables (e.g. future-related cognitions, momentum) as well as stable individual differences (the latter were assessed only once). Multilevel confirmatory factor analyses confirmed that innovation activities could be distinguished both on measurement wave level and on team level. However, innovation phases were very highly interrelated (correlation coefficients of above .85), that is, innovation activities tended to co-occur. In addition, we could show that the different innovation activities proposed by Farr et al. (2003) are differentially related to diverse cognitive and motivational variables as well as stable individual differences. Our results confirm that innovation phases do not occur in a linear manner. Instead, innovation activities – such as generating ideas and implementing ideas – are important throughout a whole innovation project. In addition, different innovation activities require quite different motivational and cognitive conditions. Taking together these two results, we argue that innovation projects necessitate an ability to handle these cognitive, motivational, and behavioral demands simultaneously. Thus, our study underlines the importance of ambidexterity in innovation projects – the ability to handle the tension between different or even contradictory activities.

Phenomenological experiences of teenage mothers in Limpopo Province, South Africa

SODI, E. (Polokwane-Mankweng Hospital Complex)
This paper is based on the results of a phenomenological investigation that sought to understand the experiences of teenage motherhood by young women with a view to describing how this developmental experience has formed part of their lives. The study was prompted by the recognition of considerably higher levels of teenage pregnancy in Limpopo Province. Using snowball sampling method, five women aged between 26 and 35 were selected to participate in the study. Data was collected through qualitative interviewing. Five psychological themes associated with teenage motherhood were identified. These are: (a) lack of knowledge about sexual relationships contributes to teenage motherhood; (b) early childbearing has a negative impact on the teenage mother’s interpersonal relationships; (c) teenage mothers tend to experience emotional problems after delivery of their babies; (d) teenage motherhood has long term disruptive effect the teenage mother’s educational and occupational opportunities; and, (e) teenage motherhood leads to significant lifestyle changes for those who have been through the experience. In view of the above themes, sexual education both at school and at home is suggested as a more viable option to help minimize the risk of teenage motherhood in society. Together with other intervention, sexual education could also help in reducing sexually transmitted infections including HIV and AIDS.

Keywords: teenage motherhood, sexual education, interpersonal relationships, lifestyle, emotional problems

Pilot evaluation of a depression training program for eye health professionals working with patients with vision impairment

REEES, G. (University of Melbourne), MELLOR, D. (Deakin University), HEENAN, M. (Deakin University), KEEFE, J. (University of Melbourne), LAMOUREUX, E. (University of Melbourne)

Depression is common in people with vision impairment and has been shown to exacerbate disability and further reduce levels of functioning. Despite this, depression is rarely detected and often remains untreated in this group. The current study was designed to evaluate the effectiveness of a training program to assist eye care professionals to better recognize and respond to depression among people with vision impairment in hospital and community settings. 36 professionals completed the training program consisting of three 1.5 hour small group training sessions held over three consecutive weeks. The modules covered (1) Understanding depression, (2) Detecting depressive symptoms, (3) Developing and implementing referral pathways. Participants were provided with information, tools and resources and encouraged to develop local procedures and processes in their specific work contexts. A pre-post evaluation study was conducted to assess the impact of the training program. Five groups were conducted and included ophthalmic nurses and orthoptists from tertiary eye care services as well as optometrists and low vision rehabilitation staff working in community settings. The training program significantly improved knowledge of depression and confidence in responding to depression in people with vision impairment (p<0.05). Barriers to managing patients with vision impairment and depression were significantly reduced (p<0.05). The likelihood of providing information and education about depression, using a depression screening questionnaire, referring the patient to their GP for depression management also significantly increased (p all<0.05). The initial results of this pilot study suggest that a brief training program is able to increase practitioners’ knowledge, confidence and intentions to change practice. Further work is required to determine if these improved skills are sustained over time and actually improve the recognition and successful management of depression in people with vision impairment.

Keywords: depression, vision impairment, training programs

Positive and negative job affects as psychological indicators of job stress in Brazilian workers

FERREIRA, M. (Salgado de Oliveira University)

One of the main effects of the recent changes in work organization is job stress. This phenomenon has been considered as a stimulus,
as a process or as a response to the adverse conditions that individuals face in work and organizations. The continuous exposure to these conditions can cause physical, behavioral and psychological reactions. Job satisfaction has been for a long time one of the most used psychological indicators of job stress. However, the job affects, that is, the positive and negative emotional reactions toward work, can also be used as an indicator of psychological health and well-being in the workplace. The purpose of this research is to investigate the effects of some stressors on positive and negative job affects.

The sample was comprised of 630 Brazilian workers of both sexes, from industry, retail and service sectors. Stressors were measured using a Brazilian scale of 35 items distributed in seven factors: role conflict and ambiguity, workload, social support, work-family conflict, job instability, autonomy and responsibility. Whereas, job affects were evaluated using a Brazilian scale of 28 items divided into two factors, that is, positive and negative affects. The results from the hierarchical multiple regression analyses showed that the role conflict and ambiguity and workload are the only negative predictors of positive job affects, while on the other hand, responsibility is a positive predictor of the same criteria variable. In addition to this, the workload was the only positive predictor of the negative job affects. It has been concluded that job affects can be used as psychological meaningful indicators of job stress in future research.

Keywords: job stress, job satisfaction, job affects, well-being, work-family conflict

Positive politics – turning politics to organizational advantage

LANDELLS, E. (Monash University), ALBRECHT, S. (Monash University)

This paper assesses the viability of a positive conceptualization of organizational politics. The question of whether organizational politics can be reframed as both an organizational resource and a demand is considered. A model incorporating both the positive and negative dimensions of organizational politics is proposed. Research regarding perceptions of organizational politics is reviewed to determine whether conceptualizations of organizational politics are generally negative, neutral or positive. Particular attention is given to measures of organizational politics. Other constructs are integrated throughout the review including political skill, organizational engagement and organizational climate. Organizational politics is generally conceptualised in terms of undesirable and self-interested behaviors such as back-stabbing, self-promotion and ingratiating and existing measures are negatively balanced. The literature also suggests that organizational politics should be eradicated. In contrast, political skill is conceptualised positively. Other research presents a functional and more balanced view of politics where politics plays an important role in decision-making and during times of change. Researchers have therefore called for more balanced perspectives on and measures of organizational politics. A functional definition of organizational politics is proposed where organizational politics involves using inside knowledge of an organization and collegial networks to turn formal or informal processes to personal and team advantage. This enables accomplishment of objectives and reputation enhancement of individuals and teams. A proposed model of organizational politics suggests that organizational politics can be viewed as a job resource or a job demand and this perspective can lead to negative or positive political climates. Work is needed to develop a measure of positive political climate and to assess the viability of the proposed model.

Keywords: organizational politics, organizational climate

Positive with pets: The positive impact of pet ownership when living with HIV

HUTTON, V. (Monash University)

In developed nations, a diagnosis of HIV no longer entails the development of AIDS, and its medical management is that of a chronic rather than fatal disease. While in the 1980s, companion animals were seen as a potential source of infection and their removal from the home encouraged, today around half of all
Australians living with HIV also live with a pet. Significantly, around 60% of Australians living with HIV and pets report receiving a lot of support from their pet, second only to their partners. The aim of this study was to investigate the role of pets in the lives of people living with HIV in developed nations, specifically, the impact of pet ownership on emotional wellbeing. Participants were 160 people from developed nations living with HIV, ranging in age from 18 to 66 years. The sample predominately comprised homosexual men, reflecting the overrepresentation of this group in the HIV positive populations of developed nations. All participants completed a composite questionnaire comprising measures of social support, unsupportive social interactions, HIV-related emotional wellbeing, general health and demographic variables. Pet owning participants also completed an instrument measuring their attachment to their pet. Participants chose to complete the questionnaire either online or in pen and paper form. Eighty per cent of participants owned pets compared to 63% of all Australian households. All participants reported experiencing unsupportive social interactions related to their diagnosis, and worried about the effect of stress on their health. However, pet owning participants reported higher levels of emotional wellbeing than non-pet owning participants. Pet owners also reported valuing their pet’s non-judgmental support, companionship and ability to make them feel happy. Importantly, almost all pet owners (98%) agreed that loving their pet helped them stay healthy. This study provides evidence of a positive relationship between pet ownership and emotional wellbeing amongst people living with HIV. It is argued that if such health promoting relationships are found to reduce the disease burden of HIV, they should be not only encouraged but supported by the health systems of developed nations.

Keywords: HIV, AIDS, pets, support, emotional well-being

Precarious abodes: Hues of red, black and grey - a psychological exploration into the lives of Indian women in prostitution

The aim of the present study was to explore the psychological themes that surface on interviewing women in prostitution about their sexuality and the self. This was a qualitative study in which five unstructured interviews were conducted, of about two hours duration each, over the span of two months. Eight women in prostitution were interviewed within their naturalistic settings. The questions were based on the themes of sexuality and the self. Data were analyzed and interpreted using broad understandings from the psychodynamic approach and the gender discourse. The study found recurring themes such as the presence of troubled childhoods, which formed the template for traumas of a possibly inter-generational nature, the trauma being experienced throughout their lives. In addition, an inter-linkage and conflict was found between internalized moral voice and the continuation of prostitution which resulted in the use of defence mechanisms and a limited range of affects that centered around rage, grief, loneliness, alienation, fear, guilt and shame, self-hate, emptiness and pain. In naming this paper, ‘Precarious Abodes: Hues of Red, Black and Grey’ – the uncertainties of containment show up in the reds, being conflicts in these women’s lives, the blacks of separation and the greys of agency, choice and human volition. It can be concluded that a psychological exploration into the inner worlds of women in prostitution is difficult but possible and that any health-care program designed for them, or questions regarding the legality and morality of prostitution, need to relate to the experiences of these women. This is only possible after a long-term engagement with them and an attempt to understand the factors that affect their decisions and the circumstances of their living conditions.

Keywords: women, prostitution, sexuality, self, trauma

Predicting employees’ wellbeing using job strain and work-family conflict

KARIMI, L. (La Trobe University / Isfahan University of Medical Sciences), KARIMI, H. (Azad University / Isfahan University of Medical Sciences)
This study aimed to examine the effects of job-strain and work-family conflict models on the perceived wellbeing of Iranian employees. A hierarchical multiple regression analysis on data from 387 Iranian employees was used to predict the relationship between job strain, work-family conflict and wellbeing variables. The results of the hierarchical multiple regression analysis revealed that strain-based working-family conflict along with job characteristic variables (i.e. supervisory support, job demands, and job control) make a significant contribution to the predictions of an employee’s affective wellbeing, particularly their job satisfaction. Implications are drawn and recommendations made regarding future research and interventions in the workplace.

Keywords: job-strain, work-family conflict, wellbeing

Predicting neuropsychological performance among HIV-positive adults

VANCE, D. (University of Alabama at Birmingham), FAZELI, P., MCKIE, P.

With 25% of those with HIV being 50 and over, there is concern that cognitive deficits may become exacerbated as people age with this disease. The objective of this study was to identify predictors of neuropsychological performance among adults with HIV. The sample included 98 HIV-positive adults with a mean age of 45.2 years. Participants completed psychosocial measures (Lubben Social Network Scale, Profile of Mood States, drug use) as well as neuropsychological measures of speed of processing (Useful Field of View, Complex Reaction Time Test, Digit Symbol Substitution), executive function (CLOX, Trails B), psychomotor ability (Trails A, Finger Tapping Test, Digit Symbol Copy), and memory (Digit Span, Spatial Span). Regression analyses were used to investigate predictors of neuropsychological performance. Step 1 of the analysis examined the effect of age and education quality (WRAT-3 Reading), and step 2 examined the effect of health factors on neuropsychological performance. Results indicated that older age, poorer educational quality, mood problems, and higher drug use predicted poor performance on several of the neuropsychological measures. The individual regression models for each of these measures explained 8-34% of the variability. Overall, this study posits that among adults with HIV, the best predictors of neuropsychological deficits were older age and poorer quality of education. Additional predictors of cognitive deficits included mood problems and drug use. Health factors such as years diagnosed with HIV, and the size of one’s social network were not found to be predictors in any of the models. These results suggest that those aging with HIV are subject to decreases in cognitive functioning. Implications for clinical and research settings are provided.

Keywords: HIV, neuropsychological performance, cognitive deficits

Predicting positive and negative change in Australian expeditioners following Antarctic employment

NORRIS, K. (University of Tasmania)

The aim of the present study was to identify factors that influence positive and negative change in Australian expeditioners following Antarctic employment. 423 expeditioners completed a series of self-report measures assessing individual, organizational, and relationship dimensions across the employment experience in predicting self-reported positive and negative change following Antarctic employment. Data was analyzed using backward stepwise regression equations to determine the relative contribution of individual, organizational, and relationship dimensions across the employment experience in predicting self-reported positive and negative change following Antarctic employment. At both two and twelve months post-return positive change was predicted by a combination of individual, organizational, and relationship dimensions reported at pre-departure, absence, reunion and reintegration. At both two and twelve months post-return positive change was predicted by a combination of individual, organizational, and relationship dimensions reported at pre-departure, absence, and reunion. At reunion negative change was predicted by a combination of individual, organizational, and relationship dimensions reported at pre-departure, absence, and reunion. At reunion negative change was predicted by a combination of individual, organizational, and relationship dimensions reported at pre-
departure, absence, reunion and reintegration. Positive and Negative change reported by Australian expeditioners at both reunion and reintegration is predicted by experiences at these and preceding phases of the Antarctic employment experience. As such, proactive prevention and intervention strategies aimed at enhancing the Antarctic employment experience for Australian expeditioners should address each phase of employment from pre-departure through reunion and reintegration. In turn, such intervention may enhance employee well-being, performance, and retention.

Predicting the risk of financial trust violation: Assessing the interaction of work environment and offender characteristics

CURNOW, D. (Monash University), OGLOFF, J. (Monash University)

Financial trust violation is extremely costly but researchers from criminology, psychology and management/security are yet to agree on a standard model to explain this offence. The aims of this thesis were to: (i) develop a model to enhance our understanding of the core processes of financial trust violation, (ii) develop an assessment tool that evaluates the core processes of financial trust violation in individuals, (iii) review the personality traits within financial trust violators and how these impact on the core processes and (iv) to understand the role that the perceived security precautions of the organization and the organization’s actions and culture designed to support an ethical environment has on the core processes of financial trust violation. The Business Security Questionnaire (BSQ) was designed using Cressey’s (1953) model and supplemented with recent employee theft research to assess the core processes of: demographic factors, motivations, opportunity, values, evidence to support violation and rationalisations. The personality factors investigated were the neurotic personality type and ‘white collar’ psychopathy which were assessed by Young Schema Questionnaire (YSQ; Young & Brown, 1999) and the B-Scan (Babiak & Hare, 2004) respectively. Thirty incarcerated individuals (18 men and 12 women) from Victoria, New South Wales and South Australia convicted of financial trust violation from their own company or employer were assessed. The core processes were largely supported, especially through highly endorsed specific items but environmental factors did not have an impact on these processes. The YSQ showed that the schemas of self sacrifice and unrelenting standards and the B-Scan scales of blaming and shallow were elevated in this population. Significant gender differences and a range of specific relationships between elevated schemas and B-Scan scales were found between core processes of financial trust violation. A comprehensive model of financial trust violation is feasible and key foundation items were developed in this research for a precise measure of the risk of a staff member of committing a financial trust violation.

Keywords: financial trust violation, personality traits, assessment tools, schemas

Predicting work engagement, turnover intentions and family satisfaction over time: Organizational support, hindrance and work-life balance.

TIMMS, C. (Griffith University), BROUGH, P. (Griffith University)

This research assessed the impact of organizational cultures that either supported or hindered employees’ use of organizational work-life balance policies. It was expected that supportive organizational cultures would be consistent with work engagement, family satisfaction and reduced turnover intentions over time. Australian workers (n=540) were surveyed on two occasions with a one year time lag. Measures of organizational culture, use of work-life organizational policies, work engagement, family satisfaction and turnover intentions were included in the study. Structural equation modeling analyses assessed the ability of (Time 1) organizational culture and work-family policies to predict work engagement, family satisfaction and turnover intentions over time (at Time 2). As expected, we found that a
workers’ use of Work-Family Organizational Policies (WFOPs) was positively associated with supportive organizational cultures. Hindering organizational cultures demonstrated negative relationships with perceptions of organizational support. Organizational support predicted work engagement at time two, but demonstrated no direct associations with either time two family satisfaction or turnover intentions. Instead work engagement was positively associated with family satisfaction and negatively associated with turnover intentions. This research demonstrates that a supportive organizational culture in terms of the provision of appropriate WFOPs, is important to the facilitation of the interface between employees’ work and private lives. Importantly, a supportive organizational culture is pivotal to the engagement of workers. Work engagement in turn, has implications for both organizations and employees; directly influencing employees’ work commitment and family relationships. This research clearly demonstrates that organizational management cannot afford to ignore the impact of supportive workplace cultures on the psychological well being of their employees.

Predictors of mental health and quality of life in adults with craniofacial conditions

ROBERTS, R. (University of Adelaide), MATHIAS, J. (University of Adelaide), DAY, A. (University of Adelaide)

Adults with craniofacial conditions reportedly experience higher levels of psychosocial problems than the general population. However, our understanding of the factors that contribute to the mental health and quality of life in these adults is poor due to the limited availability of research. This study examined some of the predictors of positive outcomes in adults who have grown up with a variety of craniofacial conditions. Adults (n= 95, mean age 29 years) with congenital craniofacial conditions, who were treated as children in the Australian Craniofacial Unit, completed measures of: mental health (Hospital Anxiety and Depression Scale), quality of life (SF-36), social support (Multidimensional Scale of Perceived Social Support), self esteem (Rosenberg Self-Esteem Scale), satisfaction with appearance, fear of negative evaluation (Brief Fear of Negative Evaluation Scale) and appearance concerns (Derriford Appearance Scale). Multiple regression analyses revealed that the strongest predictors of anxiety were self esteem, appearance concerns and fear of negative evaluation, while depression was predicted by self esteem and social support. Age, gender and satisfaction with facial appearance did not contribute to either anxiety or depression. The Physical Health Component of the quality of life measure was predicted by satisfaction with facial appearance and appearance concerns, while the Mental Health Component was predicted by social support, self esteem and appearance concerns. Again, gender and age did not contribute to either outcome. These results highlight the importance of self esteem, social support and concerns about appearance to a range of mental health outcomes in these adults, with fear of negative evaluation specifically predictive of anxiety. Of note, satisfaction with facial appearance was unrelated to mental health outcomes, and gender and age were unrelated to all outcomes. These findings underline the importance of thoroughly assessing adults with craniofacial conditions and not simply focusing on satisfaction with appearance. They also provide some possible targets for childhood interventions designed to build resilience in this population.

Keywords: predictors, craniofacial conditions, psychosocial problems

Preliminary findings from a randomised controlled trial of mindfulness-based cognitive therapy for recurrent depression

SHAWYER, F. (Monash University), MEADOWS, G. (Monash University), JUDD, F. (The Royal Women’s Hospital), MARTIN, P. (Monash University), SEGAL, Z. (University of Toronto), PITERMAN, L. (Monash University)

Major depressive disorder (MDD) is most commonly experienced as a relapsing condition.
Mindfulness-Based Cognitive Therapy (MBCT) is a manualised group based intervention designed to reduce rates of relapse of MDD. It integrates aspects of cognitive therapy with components of a mindfulness-based stress reduction program. The aim of this multi-site randomized control trial is to examine the effectiveness of MBCT in preventing depressive relapse in people who have had at least three prior episodes of depression. We recruited 204 participants with a history of three or more episodes of depression but who were currently well. As an alternative to a treatment-as-usual (TAU) control condition, we developed a control called “Depressive Relapse – Active Monitoring” (DRAM) in an effort to balance treatment expectancy and prevent resentful demoralisation. DRAM comprised a manualised and supported self-monitoring protocol. Participants were randomised to either MBCT plus DRAM, or DRAM alone, and are being followed up for two years. Participants continue their usual treatment during the course of their participation in the trial. Outcome measures include the Patient Health Questionnaire-9, the Composite International Diagnostic Instrument 2.1, and number of days depressed in the past year. The Expectance/Credibility Questionnaire is being used to assess treatment expectancy. We will report findings related to rates of retention, rates of treatment completion and adherence, and treatment expectancy. Although preliminary at this stage of the trial, the available outcome data from the first 12 months of the study will also be presented. The early findings from this trial will provide a tentative indication of whether MBCT is an effective intervention for people with a history of three or more depressive episodes in a setting outside that of the initial developing group, and across multiple sites.

Keywords: mindfulness-based cognitive therapy, relapse, major depressive disorder

Pre-school education for the Turkish speaking Aazaree minority in Paarsee speaking Iran: an attempt at bridging the linguistic gap?

HAMEEDY, M. (Alzahra University), RASOOLEEE, S. (Alzahra University)

From a constructivist perspective cultural and linguistic experiences of early years play a significant role in a child’s later learning and development. Furthermore, the main objective of pre-school programs is to familiarize children with the school culture and language. Such an objective takes a whole new meaning when we consider students, like Turkish speaking Aazarees in Iran, who are challenged with the bilinguality of home and school since the official language of instruction is Paarsee, the language of the majority ethnic group. The aim of the research conducted was to see if attempts at bridging the linguistic gap through different complementary pre-school programs have been serious enough to be successful. To answer the research questions posed, three groups of Aazaree students and teachers were measured in three different times and ways, all within the school setting. A group of first graders just entering school, another group of students entering second grade, and a group of first and second grade teachers all in one school/district were selected randomly from among all such students and teachers in Maraagheh, a city in East Aazarbaijaan Province. The student groups are inclusive of different subgroups in terms of preschool education. Nevertheless, all were tested on their linguistic preparedness/achievement while the views of teachers were explored on the same subject, and the classroom interactions of some of them with the students were observed. The interval data on students’ preparedness/achievement and teachers’ views are to be analyzed statistically while the verbal data on classroom interactions will be processed accordingly. The preliminary perusal of the data reveals that in accordance with the expected status of the students, based on similar findings previously obtained, those who have no preschool experience have the lowest preparedness and achievement, while those who have both the regular preschool experience and the special one month program for linguistically different students score the highest. The other two groups are expected to rank in between. The views of teachers are also expected to be negative on the efficiency of the present programs, and positive on the impact of preschool acculturation on achievement. The observational data is expected to show the use of students' home language in the classroom
both by teachers and students. Iran, a mosaic of different cultural and linguistic groupings, while recognizing the right of the ethnic groups to the use of their native languages, imposes the national language, Paarsee, as the official academic language. Over the years witnessing the deficiencies of the non-Paarsee speaking students, attempts have been made to remedy the situation. However, as the projected results show, these attempts have not been that successful and more drastic approaches to the problem are required. Some forms of second language learning or bilingual education could be the path to take.

Keywords: preschool, bilingual, minority groups, supportive services

Primary inter subjectivity, early interaction and breastfeeding experience: Maternal satisfaction and depressive onset as risk factors in infant development

VALORIANI, V. (University of Florence)

In this study we observed 33 first-time mothers from pregnancy (3rd trimester) to three months after childbirth. We selected the sample from a larger sample of an Italian population attending prenatal courses in Florence area. Women were primiparous, with a stable partner relationship, with no reported previous psychiatric disorders, their pregnancy was without risks factors and the babies were born at the expected date in good health. During pregnancy we assessed the mothers’ mood state, couple relationship satisfaction, life time psychiatric disorders and a questionnaire about their social support network. After childbirth we investigated mood state and administered a brief interview on the context of the maternity experience, including breastfeeding practice, and we video recorded a five-minute interaction with the infant according to Murray’s method (GRS). Analyses revealed that mothers without signs of depression in pregnancy also maintained low levels of depression postpartum and they showed good “sensitivity” towards the baby. These mothers were also more satisfied with their couple relationship, they reported more satisfaction with breastfeeding their babies and they continued to breastfeed. On the other hand, mothers who showed mild postpartum depression were less sensitive towards their baby and they reported problems with breastfeeding. Babies of mothers who experienced less satisfaction with breastfeeding were less lively during the video interaction in comparison with babies of mothers who experienced satisfaction, confirming the emotional benefits of breastfeeding and more baby centered attitudes in breastfeeding mothers, when they were supported by their partner and social network. Our data revealed the importance of breastfeeding relationship as first occasion of mother-baby interaction. Breastfeeding can be considered a protective factor also for onset of postnatal depression such as a supportive partner relationship.

Keywords: first-time mothers, pregnancy, social support, mood, depression

Proactive personality interacts with job characteristics to enhance role breadth self-efficacy, which promotes work innovation

SEARLE, B. (Macquarie University)

Job characteristics and individual differences are thought to be important predictors of role breadth self-efficacy (RBSE; Parker, 1998) and intrinsic motivation (IM), two cognitive-motivational states which are in turn thought to drive workplace innovation (e.g., Amabile, 1988; Parker, Williams & Turner, 2006). IM provides an internal need improve work practices, while RBSE provides a feeling of capability to achieve any improvement steps; both of these are critical in generating and sustaining innovation and other proactive behaviors (Parker, Bindl & Strauss, under review). In cross-sectional studies, Ohly and Fritz (2007) found RBSE predicted innovation better than IM, while Parker and Sprigg (1999) found job characteristics were more predictive of RBSE among employees with more proactive personalities. The present study sought to identify the roles of job characteristics (method control and problem-solving demands) and proactive personality in predicting RBSE and IM, and ultimately on the suggestion and
implementation of work innovations. A survey was administered to 260 full-time employees in Australian organizations, and re-administered to the same individuals three weeks later. Data from both waves were analyzed using structural equation modeling, which can simultaneously assess independent effects on correlated dependent variables while correcting for measure unreliability. Alternative direct and mediation models were used to compare model fit and variance explained when testing study hypotheses. Despite past findings, RBSE was predicted by problem-solving demands only, while IM was predicted only by method control. Innovative suggestions and their implementation were predicted only by RBSE. Proactive personality was associated with neither cognitive-motivational states nor innovation behavior, perhaps because its effects were moderated by job characteristics. For example, RBSE was most likely to be high among those proactive employees who had previously experienced high method control. The data support a model in which direct and interactive effects of job control, demands and proactive personality influence RBSE, which mediates their effect on innovation. The findings highlight the importance of fit between person and situation. Proactive employees may be most likely to innovate in autonomous work situations, where they feel more capable of achieving desired improvements.

Keywords: job characteristics, individual differences, role breadth self-efficacy, intrinsic motivation, proactive personalities

Professional psychology training in Australia: How does it prepare psychologists for practice with rehabilitation populations?

NICHOLSON PERRY, K. (University of Western Sydney), KERIN, F. (The University of Sydney)

The aim of the present study was to (1) Identify the training opportunities to prepare psychologists for practice with rehabilitation populations in Australia and (2) to explore the conceptualization of training for psychological practice with rehabilitation populations in Australia. A list of all the currently accredited professional psychology post-graduate courses in Australia was obtained, including the names and contact details of course directors. An email containing information about the study and invitation to participate was sent to the course directors, with a web-link to the online survey. Recipients of the survey invitation email were given one month to respond after this time, and a reminder was sent out one week prior to the closing date. Twenty-one surveys were filled out, with complete data available for 16. The majority of responses related to clinical psychology courses (56%), and other responses were provided for organizational, health, forensic and sport/exercise psychology courses. Of the topics identified as essential for training in this field, the most commonly addressed was ‘substance abuse’. ‘Recreational functioning’ and ‘sexual functioning’ in relation to illness and injury were the areas that were most frequently not covered. The majority of the courses reported that placements in the areas of developmental intellectual disorders, substance dependence and abuse and psychiatric impairment were commonly available. The majority of courses reported no placements offered in burns, amputation, blindness and/or deafness or congenital conditions such as cerebral palsy. Rehabilitation psychology is currently not a recognized specialty of psychology in Australia, and as may be expected therefore, none of the courses surveyed covered all the required content expected in specialty training in the area in the United States. Opportunities to undertake practical training in some rehabilitation areas appear to be quite commonly available, but this did not include any of the areas of physical rehabilitation. These findings suggest that currently available courses in Australia are inadequate to prepare an appropriately trained workforce, and that none can be conceptualized as providing an effective training program for this area of practice.

Keywords: psychological training, rehabilitation

Promoting multilingual competence and academic achievement through mother tongue literacy and activation of cultural knowledge

PANDA, M. (Jawaharlal Nehru University), MOHANTY, A. (Jawaharlal Nehru University)
Mother tongue (MT) based multilingual education (MLE) is now a well-established framework for quality schooling of minority children (Cummins, 2009). The paper reports findings of a three-year longitudinal evaluation of intervention program, MLE Plus, (Mohanty & Panda, 2007; Panda & Mohanty, 2009) among primary grade (Grades I to III) Kui and Saora MT tribal children in Orissa, India. The intervention involved development of literacy and cognitive academic language proficiency in children’s MT, used as the language of teaching in the early school years (Grades I to V), and systematic development of multilingual competence from Grade II onwards. Ethnographic documentation of indigenous cultural knowledge and practices helped us plan activities for linking children’s everyday cultural practices and knowledge to classroom learning, and facilitate community oracy and literacy engagements. The MLE+ intervention was carried out over a period of three school years beginning with Grade I in eight Government MLE schools for children from Saora and Kond tribes. The intervention was longitudinally evaluated in all the MLE+ schools and compared annually with matched MLE and non-MLE schools (where the tribal children were taught in a dominant language which was not their MT). The findings show that MLE+ interventions resulted in better academic achievement and multilingual development compared to the MLE programs, which, in turn, were found to be better than the non-MLE ones. The MLE+ intervention resulted in greater classroom participation, favorable teacher and community perception of and involvement in MT based school learning. Pedagogic processes in MLE+ program creating multiple points of contact between everyday and school concepts are analyzed. Implications of MLE+ intervention for MLE pedagogy involving minority children are discussed.

Keywords: multilingual education, academic achievement, mother tongue literacy, cultural knowledge

Prospective remembering and working memory in a virtual world

TRAWLEY, S. (University of Edinburgh), TRAWLEY, S. (University of Edinburgh), LAW, A. (Liverpool John Moores University), LOGIE, R. (University of Edinburgh)

Current laboratory-based prospective memory (PM) paradigms pose problems that are very different from those encountered in the real world. Several PM studies have reported conflicting results when comparing laboratory with naturalistic based studies (e.g., Henry et al, 2004). With artificial stimuli divorced from any situational or social context, the prospective event in an experiment is unlikely to have been encountered outside the laboratory. We used gaming software to provide a cost-effective virtual reality (VR) tool to develop a more ecologically valid setting to study PM whilst maintaining the rigor of the traditional laboratory approach. We explored the relative importance of independent measures of verbal and spatial working memory capacity, retrospective and prospective memory, and planning ability to predict PM failures in healthy young adults. PM performance was extracted from the Virtual Errands Task (EVET) dataset. A total of 157 participants (95 females and 62 males - mean age 19.6 years) attempted eight location based errands in a four storey virtual building (e.g., collect computer from room G4). All participants learned the errand list to criterion and made a plan before starting the test. Individual difference measures assessed retrospective and working memory capacity, planning ability and PM. A PM failure was identified as a situation where a participant entered and exited the "cue" area outside an errand related room without performing the required errand whilst still successfully remembering that errand post test. Multiple regression analysis showed that independent measures of verbal working memory span, planning ability and PM were significant predictors of PM failure ($R^2 = .15$). Inclusion of an efficiency measure of pre-planning for the EVET task was a significant predictor and improved model fit ($R^2 = .22$). Overall, the data demonstrate the potential for VR to provide a realistic, but well controlled PM study. The relationship between the independent measure of PM and the PM failures in the EVET provides construct validity. Results are supportive of accounts that argue for domain-specific working memory processes and highlight a role for verbal working memory in PM. The study also offers a
methodology to address the relatively unexplored role of planning in PM.

Keywords: prospective memory, virtual reality, working memory, Virtual Errands Task

Psychological and demographic characteristics of individuals who engage in online sexual activity: An investigation based on sexual orientation

SQUIRRELL, M. (Swinburne University of Technology)

The number of individuals engaging in online sexual activity (OSA) is a growing trend, and a number of researchers and scholars have argued that the behaviour is pathological (Durkin & Bryant, 1995; Young, 1997). However other researchers (e.g., Griffiths, 2001; Cooper, 1998) have concluded that online sexuality is adaptive, and have emphasised sexual exploration, or highlighted educational benefits and advantages for socially disenfranchised individuals such as gay, lesbian and bisexual (GLB) individuals. Researchers have also suggested that GLB individuals tend to use the Internet more often than their heterosexual counterparts for experimentation and the expression of sexual behaviour (Cooper, Delmonico, & Burg, 2000). The overall aim of this paper is to report the findings of an online study that investigated the relationship between participant’s sexual orientation and their OSA. Participant’s offline meeting behaviour and personality characteristics are also discussed. The psychological variables investigated included measures of participants’ depression, anxiety, stress, impulsivity, social and emotional loneliness, adult attachment style and psychosexual adjustment (e.g., sexual-anxiety, sexual-satisfaction). International data for the current study were collected via an online questionnaire posted into a variety of sexually oriented news groups. Data was collected from 1325 participants aged 18 to 80 years, ($M$ = 41 years, $SD$ = 13), with males composing 91% of the sample. 39% of the sample identified as heterosexual, 35% indentified as gay/lesbian and 25% identified as bisexual. Participants spent an average of 12.25 hours per week engaged in OSA. Overall, bisexual males were significantly more likely than heterosexual and gay males to be assessed as being at high-risk of their OSA interfering and jeopardising important areas of their life (i.e., social, occupational and educational). Lesbian and bisexual women were significantly more likely to be classified within the high-risk group than heterosexual women. Males with a secure attachment style were approximately twice as likely to be heterosexual or gay than bisexual. Attachment style was however not related to female participant’s sexual orientation. Gay and bisexual males were significantly more likely than heterosexual males to meet someone offline that they first met online, however sexual orientation was not related to offline meeting behaviour for female participants. Increases in depression, anxiety, stress, emotional and social loneliness and impulsivity were associated with increased engagement in OSA for all participants, regardless of sexual orientation. Theoretical, research and clinical implications of the findings will be discussed.

Keywords: online sexual activity, sexual orientation, sexual behaviour, attachment style, psychosexual adjustment

Psychological and social influences on inequalities in health in European countries

The first reference to inequalities in health appeared in the “Report on the Sanitary Condition of the Labouring Population of Great Britain” written by Sir E. Chadwick in 1842. The earliest mention in the last century comes from A. Antonovsky (1967), and from F. Drever and M. Whitehead (1977). Despite this long world history, to date, the history of interest in the topic is rather short in the Czech Republic. The problem of health inequalities was not investigated from 1948 to 1989 in former Czechoslovakia due to political, economic and socio-historical circumstances. The basic data concerning social influences on equity in health in Czech districts (2002, 2005, 2007) are in our study which were compared with results from 18
European countries, and the EU data. A representative sample of Czech citizens were obtained by random quota sampling. Participants took part in a structured interview and responded to questions regarding self-reported health, income, and level of education. Data was also collected from Czech national statistical data on sick leave, unemployment, and income in respective districts of the Czech Republic. The presented data demonstrate the relationships between all mentioned variables. Income, unemployment and sick leave varied in different districts of the Czech Republic: the poorer districts reported a higher morbidity and higher unemployment rate irrespective of the influence of the process of European integration (incl. the EU enlargement). The similarities and differences in social influences were related to health inequalities within the European countries and were demonstrated using the comparison of national and European statistical data, and the correlation analysis of the above mentioned variables. The process of European integration is associated with many problems. One of the most important is the problem of social influences on equity in health, and its psychological reflection at both individual and social levels. Using the European and other best practices, both research and policy strategies in these countries should be focused on the closing this gap.

Keywords: Czech Republic, health inequalities, unemployment, social influences

Psychological issues facing international students in Australia

PRATT, C. (Australian College of Applied Psychology)

The aims of this research were to evaluate the psychological issues facing international students in Australia and to investigate the extent to which their psychological needs can be met. The research involved a series of focus groups with international students attending institutions in Melbourne and Sydney in conjunction with illustrative detailed case studies. A content analysis of the main themes arising from the focus groups was conducted. The results indicated that many international students face significant psychological issues including depression and high levels of stress and anxiety. Many students find it extremely difficult to adapt to the Australian culture generally and more specifically to the Australian post-secondary education system. They express feelings of immense isolation from both family and friends but especially from their family. Many also experience high levels of stress resulting from financial problems and from struggling to pass components of their courses. Students report feeling there is a lack of adequate support systems within their educational institutions and a demonstrated a lack of awareness about how to seek help. There are a substantial number of international students in Australia who are in need of support for a range of psychological issues they experience. Current support systems are inadequate often failing to take into account different cultural backgrounds and failing to provide adequate interventions for these students. It is important that the government address the issue of providing more effective psychological services for these students.

Psychological support to Tsunami victims in Sri Lanka: A 5 year intervention model

MONTEIRO, S. (CeFIPsi)

Helping people in grief to overcome their mourning process and be happy again is a demanding journey but also a challenging one in a therapeutic perspective. Victims of natural or human disasters benefit from psychological support during, at least, the first five years after the event (Demaria & Barrett, 2006). Since February 2005, CeFIPsi’s professionals have been psychological (and materially) supporting Tsunami victims in Sri Lanka, Batticaloa district. We have been working in five schools (with near 500 students, total), three nurseries and one orphanage. The main goal of this presentation is to illustrate how psychological support can be effective among natural disaster victims in an east country where the language, culture and death rituals are so different from the western
ones. We have been using Worden (2002) model regarding the four tasks of mourning: (I) accept the reality of the loss; (II) deal with emotions and pain of grief; (III) adjust to the new environment; (IV) emotionally relocate the deceased and moving on with life. To accomplish every goal of each task we used play therapy and educational materials constructed by us before each mission, mainly for that purpose. After five years of psychological support to Tsunami victims we have gathered data from the children and their teachers about the behavioral and emotional changes recognized: recognizing and accepting their negative emotions and thoughts about death and Tsunami; being able to openly talk about it, and returning to the beach. The oldest students have been “co-counselors” for the youngest ones and they also have been contributing to effects generalization. Some considerations regarding social and cultural differences will be made in order to facilitate the job of other Psychologists who have the chance (and aspiration) of working in humanitarian experiences with the purpose of enlarging life quality and well being of others.

Keywords: grief, mourning process, psychological support

Psychological trauma in a sample of police officers: A 10 year follow-up study

DE TERTE, I. (Massey University), STEPHENS, C. (Massey University), HUDDLESTON, L. (Massey University)

Limited longitudinal data exists regarding clinically significant traumatic distress in a sample of police officers. This study followed up a sample of New Zealand Police Officers 10 years after they were last surveyed. A comparison of the levels of traumatic stress was evaluated longitudinally in a sample of New Zealand Police Officers. The police officers were assessed at Time 1 (September 1997 to September 1998), Time 2 (September 1998 to September 1999), and Time 3 (2009). Time 1 was at the commencement of their police training. Time 2 was one year after they had been initially surveyed and this included six months of initial police training. Time 3 was approximately 10 years after the participants had been previously sampled. Time 1 and 2 involved the utilization of the Impact of Events Scale. Time 3 involved the utilization of the revised version of the Impact of Event Scale. At Time 1, 512 police recruits participated in the research. At Time 2, 326 police officers participated in the research. At Time 2 only serving police officers were invited to continue in the research. At Time 3, 131 individuals continued in the study. At Time 1, 16.73 percent of participants indicated clinical significance. At Time 2, 20.97 percent of participants indicated clinical significance. At Time 3, 11.71 percent of current police officers indicated clinical significance and 25 percent of former police officers indicated clinical significance. The results suggest that clinically significant levels of posttraumatic distress decreases with time as a police officer. Perhaps serving police officers become desensitized to traumatic exposure the longer they are members of the organization.

Keywords: traumatic distress, police

Psychology and cross-disciplinary education for mental health practitioners

DAVIDSON, G. (University of the Sunshine Coast), GRIFFITH UNIVERSITY, MORRISSEY, MCONNELL, H. (Griffith University), MCALLISTER, M. (University of the Sunshine Coast), MCAULIFF, D. (Griffith University), REDDY, P. (Deakin University)

There is growing interest in collaborative cross-disciplinary educational models for preparing mental health professionals who work in integrated or multidisciplinary mental health services. However, traditionally Nurses, Social Workers, Occupational Therapists, Psychologists and Psychiatrists are educated in ‘disciplinary silos’ at university prior to going out to placements and practice in multi disciplinary mental health settings. This paper presents both a summary of an Australian Learning and Teaching funded project: Developing Cross-Disciplinary Leadership Capacity for Enhancing the Professional Education of Multidisciplinary Mental Health Practitioners, and data from a series of workshops involving a range of mental health educators, mental health practitioners and industry stakeholders. A series of three workshops (learning circles) were conducted
between the main stakeholders from two Universities including members of the Mental Health Workforce, Mental Health Planners, field placement officer, field supervisors, and Deans, Heads of School and Program Convenors. More than 50 stakeholders attended the series of workshops. It was clear that there is a gap in knowledge about the current National Mental Health Standards while there was general acknowledgement of unmet needs for students beginning a multi-disciplinary mental health placement. Furthermore, while there is a current lack of cross-disciplinary educational preparation, enthusiasm for, and interest in, cross-disciplinary education was expressed. There is acknowledgement and support for cross-disciplinary pre-professional education. Efforts however, are limited at universities for models of cross-disciplinary education. There is a need for strong leadership at the discipline and faculty levels to create both a climate for cross disciplinary education and to offer practical and tangible support for such initiatives.

Keywords: education, multidisciplinary mental health services, cross-disciplinary education

Psychology students are learning coaching psychology by doing coaching psychology

SPATEN, O.M. (Aalborg University)

The research was intended to investigate our main hypothesis that our students coaching competences grew significantly during training. Furthermore, we had the idea that the students’ self-esteem and more general clinical/counselling skills would benefit from the intense coaching psychology training. Two rating scales were administered: Students’ coaching competences and social and emotional skills were measured pre-, midterm and end course. In the University program the students concurrently followed cognitive-behavioural therapy courses and cognitive coaching modules. Spanning 1.5 academic years (16 full days) the coaching modules include 104 hours of lectures and action-reflection-workshops. The students coaching competence skills grew from pre-program (Sept 07) to end-program (Nov 08) assessment. A Friedman test found a significant difference (chi square (2) = 6.0, $p < .05$). The social and emotional skills test showed that students’ social and emotional skills also grew significantly from pre- (Sept 07) to end course (Nov 08). A significant difference was found (chi square (2) = 8.19, $p < .05$). We interpret the results as performance enhancement within a non-clinical population. Consequently we propose that coaching should be included in future psychology student’s graduate training. In September 2009 the coaching psychology program was launched for the third time. We assume that the coaching program has been an overall rewarding introduction to cognitive behavioural approaches. The program allowed a combination of traditional lectures with “action-reflection-learning” workshops, during which students train cognitive behavioural techniques in their own pace. The findings from this psychology graduate program with an integrated module of coaching psychology show potential and usefulness of cognitive behavioural techniques applied in the cognitive coaching modules. But future measurement tools should include tailor-made scales and techniques for monitoring the learning process. Furthermore, future research with more participants and a control group is needed.

Psychometric test use in Botswana schools: Developing a consumer-oriented framework

NTINDA, K. (University of Botswana), MPOFU, E. (University of Sydney), MAREE, J. (University of Pretoria), OAKLAND, T. (University of Florida)

The study constructed the structure and content of a psychometric framework for use of tests in Botswana primary and secondary schools. Psychometric test services are an integral part of student education and development in school settings. The ways such services are delivered within specific school systems must be responsive to the needs of the host education system and its stakeholders. In the absence of an existing framework for delivering such services, a framework for their delivery must be developed. Two-thousand and ninety-nine
educationists, parents (n=162) and children (n=382) participated. Educationists completed a series of focus group discussions, which generated data for concept mapping analysis. They also completed a survey on perceived importance of psychometric test practices within Botswana schools. The students and parents or guardians completed a survey on developmentally appropriate considerations for the use of tests in schools, including preferences for accessing the tests, domains for assessment and use to which test results could be put. Data were analyzed using descriptive statistics, Multidimensional Scaling and Hierarchical Cluster Analysis. Participants’ data suggested a psychometric framework spanning the following clusters: guidance and counseling, learning readiness, personal development, societal influence and socialization. Students across developmental stages preferred to access psychometric services through their class teachers and counselors. Parents perceived a role for the school administration in supporting student access to psychometric tests. A consensus psychometric framework is possible from appropriate consultation with educationists, students and parents. Building into the design of the framework student and parent preferences enhances the targeting of the framework, making it likely that it will be used by students and parents.

Psychopathic-like traits and aggression in high school loner and non non delinquent/non delinquents

HOUGHTON, S. (The University of Western Australia), CARROLL, A. (The University of Queensland)

According to Hare (2006) psychopathy has been described as the single most important clinical construct in the criminal justice system and as what may be the most important forensic concept of the early 21st century. Is this a viable construct in children and adolescents in non forensic contexts, however? The aims of this paper are to (i) briefly examine the issues surrounding this question; (ii) describe the development of instrumentation for use in non forensic settings (e.g., schools, behaviour units); and (iii) determine levels of psychopathic-like traits and forms of aggression of loners and non-loner delinquent/non delinquents. 149 adolescents (73 with official school records of antisocial behaviour and/or behavioural problems and 76 with no official school records for antisocial behaviour) from four high schools and one behaviour unit in the metropolitan area of Perth participated. Three instruments - the Adolescent Loner Scale (ALS), the Adolescent Scale of Aggression (ASA), and the Constellation of Affective and Interpersonal Behaviours Screening Instrument (CAIBSI) - were administered. Based on LS data participants were designated as Loner delinquents (LD), Non-loner delinquents (ND) and Non-loner Non-delinquents (NN). Two separate one way between-groups multivariate analyses of variance (MANOVAs) were conducted. The first explored the effect of Loner-Delinquent Group (LD, ND, ND) on Physical-Proactive, Verbal-Proactive, Verbal-Reactive, and Physical-Reactive aggression. The second examined the effect of Loner-Delinquent Group on the psychopathic like traits (Narcissistic-Manipulative, Callous-Unemotional, Narcissistic-Egotistical, Thrill-Seeking, Impulsivity). Multivariate main effects were evident and these were explored using Univariate F values with Bonferroni-adjusted α levels to control for inflated Type 1 errors. Reliable instruments developed in Australia show loner status has important implications pertaining to psychopathic like traits and aggression. This research further enhances our understanding about loners and has important implications for interventions used in non forensic settings such as schools and behaviour units.

Psychosocial and economic influences on health risk behavior: A cross national comparison of older men and women in Australia and South Korea

FRENCH, D. (Australian National University), ANSTHEY, K. (Australian National University)
Men drink more alcohol than women in all countries, but the male to female (M:F) ratio for drinking varies markedly across countries. Cross-national gender differences in drinking behavior are related to role expectations for women; M:F ratios for drinking and heavy drinking are higher in countries where gender roles are more traditional. Economic development and gender equality are however typically confounded in these studies and most use samples aged <65 years. We aim 1) to examine gender differences in alcohol consumption among middle aged and older adults and 2) to distinguish between economic and psychosocial drivers of women’s risk behavior by comparing alcohol consumption in Australia with South Korea, which has similar per capita GDP but where traditional gender roles prevail. We used data from large nationally representative samples of adults aged 45-105 years (mean age = 61 years) in Australia (n = 5381) and South Korea (n = 9870) to examine drinking patterns for men and women. Multinomial logistic regression examined key socio-demographic associates of risky drinking (>14 standard drinks/week) in these groups. M:F ratios for current drinking were 1.15:1 in Australia, and 3.84:1 in Korea. Rates of risky drinking were similar for males (26.7% in Australia vs. 29.1% in Korea) but not for females (8.5% vs. 1.5%). Average weekly consumption was higher for males in Korea (9.8 drinks/week vs. 12.9 in Korea) but higher for females in Australia (4.0 drinks/week vs. 1.0 in Korea). Marital status was associated with drinking only in Korean women; risky drinkers were more likely to be without a partner. Non-drinking was the norm among Korean women (83% abstainers) but non-drinkers were more likely to be married. The M:F ratios for current drinking and risky drinking were much higher in Korea than in Australia; this is consistent with international data on gender empowerment in these countries but not with economic indicators. Being without a marital partner may free older Korean women from some of the social expectations that otherwise constrain their drinking behavior. We conclude that gender-related social pressures may be more important than economic factors in influencing older women’s risk behavior.

**Public perceptions of energy choices: The influence of beliefs about climate change and the environment**

POORTINGA, W. (Cardiff University), SPENCE, A. (Cardiff University), PIDGEON, N. (Cardiff University), LORENZON, I. (University of East Anglia)

Past research has documented high levels of public concern for risks relating to nuclear power, with environmental concern being associated with higher levels of opposition to nuclear energy. However recent UK energy policy, and other debates worldwide, has led to a repositioning of nuclear power as a ‘low carbon’ electricity source with potential benefits for mitigating climate change. Whilst many previous studies have examined perceptions of climate change and nuclear energy separately, this study explores the relationships between the two as well as with perceptions of other energy sources. More specifically, the study aims to examine (1) the associations between perceptions of climate change and evaluations of different energy sources, in particular nuclear power; (2) whether general environmental concern underlies these associations; and (3) participants’ agreement with the idea that nuclear power may help to mitigate climate change and how this relates to general environmental concern and concern about climate change. A nationally representative quota sample of 1,491 individuals aged 15 years and over was used. Respondents were interviewed in their own homes in 257 sampling points across England, Wales, and Scotland.

Respondents evaluated renewable energy sources most positively, followed by fossil fuels, and evaluated nuclear power most negatively. Whilst people tended to agree on evaluations of renewables and fossil fuels, there was much more variation in evaluations of nuclear power, reflecting the controversial nature of the technology. General environmental concern and concern about climate change were negatively associated with nuclear power perceptions and positively to renewable perceptions. Only a minority of people considered nuclear power to be a method for mitigating climate change, whilst people who thought that nuclear power can help to prevent climate change were those who were least concerned about the environment and climate change. Those who are
most concerned about climate change also reflect the philosophy of traditional environmentalist movements in supporting renewables and opposing nuclear power, showing that any public discussion which simply presents nuclear power as a solution to climate change, without an examination of wider alternative solutions, may be unduly restrictive for many. Framing nuclear power solely within the context of climate change may also result in misconceptions and possibly further skepticism and mistrust regarding the motives for the further development of nuclear power.

Keywords: public perceptions, energy choices, climate change, environment, nuclear power

Public uncertainty and scepticism about climate change

WHITMARSH, W. (Cardiff University), WHITMARSH, L. (Cardiff University), O’NEILL, S. (Melbourne University)

While there has emerged a scientific consensus about the reality of human-caused climate change, the media often emphasises disagreement and debate surrounding the issue due, for example, to journalistic norms to present a ‘balanced view’. As an issue, climate change also poses many challenges to communicators due to its complexity, intangibility, and the implicit threat it poses to modern, energy-intensive lifestyles. These unique characteristics may - at least in part - explain why we see low levels of public engagement - that is personal involvement at cognitive, emotional and behavioural levels - in the issue. We present results here of an investigation into the roles of uncertainty and scepticism as a barrier to engagement. This talk will present the latest findings from mixed-method research on public perceptions of climate change in the UK. Findings from semi-structured interviews (\( N = 24 \)) and from two major UK surveys conducted in 2003 (\( N = 589 \)) and 2008 (\( N = 551 \)) will be presented. We will describe how and why scepticism is more prevalent amongst different groups (e.g., age groups, political and environmental values), and why – despite the growing scientific consensus about anthropogenic climate change – scepticism actually appears to be increasing amongst UK and US publics. We expose the prevalence and dimensions of uncertainty and scepticism about climate change, identify what influences these attitudes, and highlight the links between uncertainty/scepticism and behaviour. The presentation will also discuss what research in this field can tell us about how better to communicate climate change and engage the public with this complex and uncertain issue.

Keywords: climate change, scepticism

Putting the pieces together – exploring the way forward in risk assessment of arson offenders

DOLEY, R. (Bond University)

Deliberate firesetting remains a significant concern to our community with devastating effects recorded from fires annually. In the wake of the Victorian bushfires experienced in 2009 efforts to better manage this national concern have been mobilised at policy, practitioner and operational levels. This paper will present the results of a preliminary review into current best practice for risk assessment and management of arson offenders. Issues pertaining to treatment goals will also be canvassed. Findings from empirically based research in Australia comparing serial, one-time and non-arson offenders across a range of offence features and personal characteristics will be referred to. In Australia, currently there is no consistent approach to the assessment and intervention of either juvenile or adult arsonists. Reference to advances in the international arena will be made and the applicability of the lessons learnt overseas to the domestic context will be examined. A proposed model for best practice risk assessment and management for this population will be presented based on the evidence available currently.

Keywords: arson offenders, risk assessment, treatment
Quality of life psychological assessment: Teachers as resilient guides for adolescents in Buenos Aires public high schools

MIKULIC, I. (University of Buenos Aires), LABANDAL, L. (University of Buenos Aires)

School desertion is the result of a combination of internal and external factors. The causes of school desertion are multiple but in all cases create the conditions of failure of social integration, as it reduces significant chances of personal realization. The present study shows the importance of evaluating quality of life of adolescents undergoing “ecological transition” (Bronfenbrenner, 1979) from primary to secondary in order to understand this phenomena. As in Argentinean public schools adolescents tend not to continue their studies it is crucial to invest in research on this issue. Following a descriptive design, 500 adolescents participated in answering five inventories specially designed for this research. Ages ranged from 13 to 15 years, consisting of 250 men and 250 women. 68 teachers of these adolescents also participated. Instruments selected were: PQoLI-Perceived Quality of Life Inventory (Mikulic, 2001); CPI-Coping Response Inventory (Moos,1993); LISRES-Life Stressors and Social Resources Inventory (Moos, 1994); SIASCA-Structured Interview to Assess Strength in Children and Adolescents (Mikulic, 2001) and SIATP- Structured Interview to Assess Teachers Practices (2007). The Perceived Quality of Life Profile shows specific configuration of factors regarding adolescents and environments. Also, importance and satisfaction with life shows differences according to gender. Data obtained suggests that adolescents’ resources and their teachers’ characteristics are resilient sources. Parents, siblings and friends are perceived as an important resource but when importance and satisfaction with life assessed turn out to be a conflict factor. There is only one convergent factor regarding perceived quality of life in adolescents and it is “teachers as resilient guides”. Importance and satisfaction with life correspondence indicates that students assign high importance to teachers’ role and school context. Family and school context and climate represent two significant factors in promoting adolescent resiliency. Specifically, teachers guide as a medium to develop resiliency and convey hope is an important factor to prevent school desertion.

Reckless behaviour in emerging adulthood: A test of a psychosocial model

TEESE, R. (Griffith University), BRADLEY, G. (Griffith University), ZIMMER-GEMBECK, M. (Griffith University)

Reckless health behaviours such as dangerous driving, unsafe sexual practices, and drug and alcohol use are associated with much of the illness, injury and mortality of young people aged 18-30 years. This study presents a model of emerging adult reckless behaviour incorporating aspects of personality, social influence, emotional influence and cognition. The study investigates multiple predictors of recklessness across a range of health risk behaviours simultaneously, across multiple points in time. The findings presented are from the first of three waves of data collection, consisting of approximately 300 participants sampled from university students, technical college students and the general population. Participants were required to complete an anonymous and confidential questionnaire assessing sensation seeking, impulsivity, peer and parental influence, perceived risks and benefits, emotional influence, as well as their involvement in various forms of reckless behaviour. The questionnaire was available either in a pen and paper format or online. Results demonstrated that each of the predictors of recklessness was significantly correlated with overall reckless behaviour. Hierarchical regression analyses were conducted separately for each of reckless sexual, driving, drug, and alcohol behaviours. The model explained significant variance across each form of reckless health behaviour. Furthermore, these analyses indicated that the significance levels for each of the predictors varied with the type of reckless behaviour under investigation. The findings of this study combined previous predictors of reckless health behaviour into a psychosocial model. By investigating multiple forms of reckless behaviour and multiple
Abstracts of the 27th International Congress of Applied Psychology

Individual Oral Presentations

predictors of recklessness simultaneously, the study demonstrated that different factors predict different forms of reckless health behaviour in emerging adulthood. This finding runs counter to claims of “coherent syndromes” of recklessness, and provides greater insight for intervention and prevention strategies targeting the different forms of reckless health behaviour.

Keywords: reckless health behaviours, predictors, adolescents

Recovery from serious mental illness: Contributions of traditional clinical factors and psychosocial factors

HOLLOWAY, E. (Swinburne University of Technology)

The aim of the current study is to examine traditional clinical and psychosocial factors (using an attachment framework) potentially involved in the consumer driven notion of recovery from serious mental illness (SMI). SMI is defined as an enduring psychiatric, emotional, or dual diagnosis that has a serious impact on quality of life, functioning ability and health, and includes schizophrenia and other psychoses. The study was a cross-sectional design using a quantitative measure of recovery (The Recovery Assessment Scale). 154 Participants were sourced from Mind Australia (a psychiatric rehabilitation service). Participants completed the questionnaire packs at the program sites. The questionnaire pack contained the scales measuring recovery (using the Recovery Assessment Scale), as well as affect, schemas, coping style, functioning, attachment experiences, severity of illness, number of hospitalisations in the past 12-months, medication adherence, alcohol use, and drug abuse. Relevant information was also collected from their case files and support staff. A hierarchical regression found that an active coping style, low negative sense of self, and low negative affect were the strongest unique predictors of recovery. Structural Equation Modeling shows a series of complex interactions between psychosocial variables and recovery involving affect, attachment anxiety and avoidance, self schemas, active coping and functioning. Of the clinical variables, number of hospitalisations, medication adherence, and severity of illness had the strongest relationship, but to a lesser extent than the psychosocial variables. Whilst traditional clinical variables appear to play a role, psychosocial variables appear to be vital in the prediction of self-rated recovery from SMI, in particular the presence of an active coping style, low negative affect and negative self schemas. These psychosocial concepts can be understood from an attachment perspective. Implications for the treatment of SMI are also explored.

Keywords: serious mental illness (SMI), recovery, quality of life, functioning, health

Reducing adolescent violence: Operationalising the theory of planned behaviour and cognitive behavioural strategies

BUCKLEY, L. (Centre for Accident Research and Road Safety - Queensland), CHAPMAN, R. (Centre for Accident Research and Road Safety - Qld / QUT), SHEEHAN, M. (Centre for Accident Research and Road Safety - Qld / QUT)

Adolescent injury is a significant health concern and can be a result of the adolescents’ engagement in violent behaviours. Early adolescents report injuries resulting from getting into fights involving the use of weapons. Psychological theory has been used to explain adolescent violent behaviour however there is limited research about how psychological theory is actually operationalised in the design of adolescent risk-taking harm minimisation programs. The aim of this presentation is to outline how Cognitive Behavioural strategies and the Theory of Planned Behaviour (TPB) were operationalised in the design of a school-based program to reduce adolescent risk-taking behaviour including violence. Secondly, it aims to provide detail about the effectiveness of the program in reducing adolescent violence and violent-related injuries six months following completion of the program. The program, Skills for Preventing Injury in Youth (SPIY) was evaluated with 198 participating students and 137 control students (13-14 year olds). SPIY is a curriculum-integrated program delivered by teachers designed to reduce adolescent injury. Students reported on their engagement in fights,
use of weapons in fights, threats to hurt someone and deliberately hurting someone as well as their experience of injury from violence. The theories were operationalised into the SPIY program and the program implemented. Results showed a significant difference between the intervention and control group from baseline to six month follow-up in some violent behaviours and violence-related injuries. The program thus demonstrated potential in reduce early adolescents’ violence risk behaviours and associated harm. The use of psychological theories to design the program and evaluation provides a step beyond understanding violent behaviour to an important area, that of behaviour change.

Reducing musculoskeletal discomfort in computer users: Evaluation of an inexpensive intervention

LOBB, B. (The University of Auckland), O’ROURKE, T. (The University of Auckland), RENNIE, A. (The University of Auckland), BRERETON, J. (The University of Auckland)

Musculoskeletal discomfort and injury is a costly problem for many organisations today. Prolonged computer use has long been associated with increased risk of musculoskeletal discomfort/injury attributed to various biomechanical and psychological factors and work characteristics. Many interventions have been tried: task redesign (rest breaks, micro-breaks, job rotation), workspace redesign (tools, furniture, layout), warning/reminder signs or devices, training in safer techniques, safety policies and management strategies aimed at compliance. However, scientific evaluations of effectiveness are scarce and many are poorly done, e.g. with several interventions introduced concurrently and/or many potential confounds unidentified or unmeasured, which reduces the ability to draw conclusions. This controlled field experiment aimed to evaluate the Microdesk™, an adjustable, clear, sloping writing surface designed to improve the comfort, safety and productivity of people working simultaneously with a computer and papers by reducing the need for risky postures. A within-subjects ABAB (double reversal) design was used to control for individual factors and for unmeasured constant external factors. Thirty-two administrative officers whose daily work included > four hours of work using a computer and documents simultaneously participated over four months. Participants used a Microdesk™ during months 2 and 4, but not during months 1 and 3 and completed a questionnaire at each month’s end. Pain/discomfort, productivity, fatigue, stress and usability were measured as well as workload and non-work injuries. Microdesk™ use reduced pain/discomfort and fatigue compared to non-use. Productivity increased similarly for half the participants while the remainder indicated no change. Pain, stress and fatigue decreased slightly but systematically across the four conditions suggesting study participation alone increased awareness of posture. These changes could not be attributed to changes in hours worked. All participants found the Microdesk™ easy to use. The Microdesk™ is an effective, easy-to-use intervention to reduce musculoskeletal pain/discomfort, stress and fatigue and increase productivity during prolonged simultaneous use of computers and documents.

Keywords: musculoskeletal discomfort, injury, prolonged computer use, interventions, microdesk

Regional diversity of teenagers media culture in Ukraine

NAYDONOVA, L. (Institute of social and political psychology)

Mass media is an important part of the modern culture, especially during societies’ transition to digital era. Media has the potential to create virtual worlds in recipients’ mind. As post-virtual reality they become the part of our daily life, which plays a role non-different from natural and social reality. Research of the virtuality is the way to understand the diversity of media culture. Research of social-psychological dimensions of the virtuality is the way to understand the diversity of teenagers and adults media culture in regional aspects for improving media literacy school programs. We suggest five social-psychological dimensions of the virtuality
in media culture: contextual weaving, realistic simulation, interactivity (including parasocial relations), reflexivity, resource ability. 5DV-inquirer was used for all-Ukrainian representative survey \((n=2250\) in 2008, and \(n=2000\) in 2009) which covers four traditionally differentiated Ukrainian regions: West, East, South and Center. Data show differences of media culture of the different age cohorts (teenagers and adults). The West region youth spent more time with TV, their media culture had higher levels of contextual weaving, realistic simulation and media interactivity than other regions (especially south). East region youth were more interactive (spent significantly more time with friends: offline and via Internet), had higher level of media resource ability, then in other regions. Adults’ media culture was more homogenous through all regions. We proposed experimental school media education course for teenagers with regional specify in three motivational modes: security, interactivity and creativity. Discussion about diversity of motivational impact on media education by social-psychological dimensions of the virtuality is required.

Keywords: mass media, virtuality, media culture, regional diversity

Regulatory model for the assessment of individual stress-resistance of professionals in demanding job conditions

LEONOVA, A. (Moscow State University)

The elaboration of adequate psychological instruments for reliable assessment of individual ability to cope with stress and to prevent its negative consequences needs the development of new approaches. In addition to traditional theories of stress-resistance (making the accent on neurodynamics’ and genetic predictors), Lazarus’ concept of psychological stress and state-trait paradigm can be useful for these purposes (Leonova & Velitchkovsky, 2008). The proposed regulatory model of stress-resistance was constructed on this basis. It includes estimations of anxiety, aggression, depression and exhaustion as stable dispositional traits which provoke different modes of subjective appraisals of the situation and enhance dissimilar emotional states. The battery of the relevant state-trait measures was used for validation of the model (Spielberger’s anxiety, aggression, depression paired scales and tests for chronic/acute fatigue). The data were collected on representative samples of professionals working in extreme and/or demanding job conditions (military personnel, policemen, medical staff, bank officers, etc., in total 1450 ss.). Experts’ evaluations and objective indices of work efficiency were used as independent criteria of high/low stress-resistance for each individual case. The results of the logistic regression analysis confirm high diagnostic properties of the model. It allows prediction of breakdowns in work performance as well as deteriorations in physical and mental health (by indices of sickness rate, psychosomatic disorders, lowered workability, burnout symptoms). An integrative score of stress-resistance, calculated upon the data of confirmatory factor analysis, reduces the number of multimodal initial indicators to a single standardized measure with 4 ordered categories (from “extremely low” to “high”) that makes a basis for a proper diagnostic solution. Empirical verification of the regulatory model shows its high potential for the assessment of the individual stress-resistance level in field studies. Besides the use in professional selection practice it can be also helpful for compiling stress management programs appropriate to the needs of particular persons.

Keywords: psychological instruments, psychological stress, stress-resistance, emotional states, mental health

Relation between work values and organizational commitment

Literature review indicates that values in general and work values especially are an important
variable for organizational commitment. The aim of the current research was to investigate relation among work value and organizational commitment components. The statistical population consisted of 4600 personnel of one large industrial company. The sample comprised 272 persons selected via simple random method. Participants respond to Furnham work values and organizational commitment. At the onset the questionnaire was factor-analyzed, then relations among these eight factors, with three dimensions and total commitment, were investigated through stepwise regression. Findings of factor analysis indicate that work values consist of eight components. The regression analysis found that among these factors only job prestige was predictor of identification and organizational commitment. Considering affiliation commitment, two factors of salary (and benefits) and job priestesses are the strongest predictors respectively. Exchange commitment doesn't show any significant relation (p<0.05) with none of eight factors. Considering relation between work values and organizational commitment to increment personnel commitment, efforts to recognize and institutionalize work value can increase organizational commitment. Therefore, one way to increment organizational commitment is to have managers focus on perceptions of employees.

Keywords: organizational commitment, work values, job prestige, salary, affiliation commitment

Relationship between psychological predictors and accident involvement of Malaysian drivers

ISMAIL, R. (Universiti Kebangsaan Malaysia), ANNADIAH, H. (University Kebangsaan Malaysia (UKM))

A broad amount of research has attempted to explain individual and psychological differences in peoples’ risky driving behaviors. This study is aimed to develop psychological profiles of Malaysian drivers and also to examine the relationship between psychological profiles and accident involvement. The study used self-reported questionnaire consisting of psychological variables such as personality, impulsivity, cognitive failure, sensation seeking, driving anger, driving behavior questionnaire and driving attitude and behavior questionnaire. The survey was carried out among 652 Malaysian drivers whom committed accident at least once since passing driving test. The results have revealed the relationship between drivers’ psychological variables and risky driving behavior. The results of the logistic regression analysis showed that there are five significant predictors (namely the cognitive failure, impulsivity, driving anger, age and gender of the drivers) found to be contributed towards the high risk behavior and road accident involvement. This study also proposed a model of road accident predictor for Malaysian drivers.

Keywords: risk taking, driving behaviour, individual differences, psychological profiles, Malaysia

Relationship of core behavioural features of passive-aggressive personality disorder with the big five personality factors

BUTRUS, N. (Australian Catholic University)

Passive-aggressive or negativistic personality disorder is listed in the appendix of the DSM-IV-TR for further study prior to its inclusion with the ‘official’ Axis II personality disorders. Therefore, the aims of this study were twofold: firstly, to examine the core behavioural features of this disorder using the passive-aggressive personality disorder subscale of the Wisconsin Personality Disorders Inventory-IV (WISPI-IV); and secondly, to examine the relationship between passive-aggressive personality disorder and the Big Five personality factors. As part of a larger study on personality disorders, a non-clinical sample of 289 participants (M= 26.20 years, SD= 9.94, age range= 18-72 years) completed the WISPI-IV passive-aggressive personality disorder subscale and the NEO Personality Inventory-Revised. Correlational analyses revealed that passive-aggressive personality disorder had a significant positive relationship with Neuroticism and significant negative relationships with Extraversion, Agreeableness and Conscientiousness. Furthermore, a principal
components analysis with Varimax rotation revealed four factors with eigenvalues over one, which together explained 53% of the variance in the WISPI-IV passive-aggressive personality disorder subscale. These factors were labelled Passive Defiance, Passive Resistance of Tasks, Perceived Unreasonable Demands/Criticism and Contempt for Authority. These four factors also displayed significant meaningful relationships with the Big Five personality factors. For instance, Passive Defiance and Contempt for Authority were negatively correlated with Agreeableness and positively correlated with Neuroticism; whereas Passive Resistance of Tasks was negatively correlated with Conscientiousness and positively correlated with Neuroticism. These results demonstrate that passive-aggressive personality disorder is comprised of several distinct behavioural features that can be understood within the Five Factor Model of personality. This has implications regarding the conceptualisation of personality disorders using dimensional trait approaches.

Keywords: passive-aggressive personality disorder, big five model of personality

Relationship of spirituality, resilience and post traumatic symptoms of bomb blast affectees

NAJAM, N. (Karakoram International University), ARIF, S. (Punjab University)

The aim of the present study was to evaluate the relationship between spirituality and resilience, health status and posttraumatic symptoms among survivors of bomb blast (direct), and compare their responses to those who were exposed to the bomb blasts through TV coverage (indirect). Adults (50 direct; 50 indirect bomb blast experience) matched on Age and Gender were selected using purposive sampling from the city of Lahore, Pakistan. Participants were administered Impact of Event Scale (IES), Religious Orientation Scale (ROS) and Strait Trait Resilience Scale for assessment of post traumatic distress and severity, physical and mental health, and resilience. Results showed a significant relationship between spirituality and resilience, but no relationship between spirituality and level of trauma reported. Findings suggest significant gender and age differences in experiencing trauma and resilience (and coping strategies), with females reporting more trauma and use of coping as compared to males. Further, older adults report higher religiosity, resilience and use of more coping strategies. In conclusion, spirituality and religiosity are significantly related and used as coping strategies especially in dealing with trauma of bomb blasts in urban Pakistani city. This finding has implications for helping those who have gone through recurrent experiences within the major cities of Pakistan.

Keywords: spirituality, resilience, post traumatic symptoms, bomb blast affectees

Research about the PTSD of teachers and students after earthquake: A report from DuJiangyan, Sichuan, China

LI, Z. (Shanghai Normal University), LIN, G. (Shanghai Normal University)

The aims of the present study were to (1) research and analyze the levels of post traumatic stress disorder (PTSD) of teachers and students after the Wenchuan earthquake, (2) to analyze and compare the levels of PTSD of different kinds of people (including students, teachers, and school administrative personnel), and (3) to analyze and compare the differences of PTSD of school staff among different schools. PTSD-SS (Liu, 1998): the PTSD-SS consisted of 24 items. The reliability coefficients were 0.9207 for internal consistence (Cronbach α), 0.9539 for split-half, and 0.8677 for test-retest. The correlations between PTSD-SS and SAS, and YSR were 0.2064, 0.3536. Participants were 334 teachers and students from DuJiangyan, a section affected by the Wenchuan earthquake (among which teachers were 95, school administrative personnel 94, middle school students 145). It was found that 1.54.19% teachers and students had PTSD symptoms of different degrees, and 33% participants were intermediate or serious. The level of PTSD of middle school students was significantly higher than the teachers and school administrative personnel (p<0.01) and the level of PTSD of teachers was significantly higher than the school
administrative personnel ($p<0.01$). The level of PTSD of teachers from the most serious school was significantly higher than other schools. The dimensions of PTSD were: re-experiencing, 2.90; avoidance symptom, 2.6; and arousal, 3.05. Therefore, the earthquake of 8.0 scales significantly affected teachers and students, where different kinds of people showed obviously different reactions to the earthquake and the level of PTSD of the victims was influenced by the seriousness of the earthquake.

Researching service effectiveness: The case of services for survivors of torture and trauma

MCFARLANE, C. (Victorian Foundation for Survivors of Torture)

This paper aims to outline methodological issues associated with researching the effectiveness of services for survivors of torture and trauma. Only a handful of studies have examined the effectiveness of established services for survivors of torture and trauma and the findings have been equivocal. In reviewing the torture and trauma literature, common issues relating to both the evidence based practice movement and researching rehabilitation services are raised. In order to examine these issues further, a description of direct services delivered is outlined and research being conducted to determine their effectiveness presented. The paper draws on current research in which outcome indicators for clients using the service have been developed. Qualitative research with key stakeholders has been conducted in order to identify and gain agreement about outcome indicators for children, youth, families and adults seen by the service. Results from qualitative interviews reveal the complexity of presenting needs and outcomes for clients associated with the service. Key outcome indicators are presented and their relationship to the delivery of direct services articulated. The development of these outcome indicators informs the development of a tailor-made assessment tool that aims to assist in the evaluation the effectiveness of the service. This paper highlights some of the issues that arise when researching complex interventions with vulnerable populations. It raises questions and highlights issues about how to best evaluate the effectiveness of established services for survivors of torture and trauma.

Resilience and organizational socialization: A cross-cultural study

CARVALHO, V. (UNIFAL), BORGES, L. (UFMG), VIKAN, A. (NTNU), HJEMDAL, O. (NTNU)

The aim of the present study was to analyze the relationship between resilience and organizational socialization among newcomers in two different job cultures, namely Brazil and Norway. The sample ($N=135$) was composed of Brazilian ($N=72$) and Norwegian ($N=63$) professors and technical-administrative employees at public universities. The data collection instruments used were the Organizational Socialization Inventory (OSI), the Resilience Scale for Adults (RSA) and a sociodemographic form. Hierarchical regression analyses were carried out, the first ones involving all participants ($N=135$), to observe the predictive power of resilience factors in relation to organizational socialization factors, beyond the effects of nationality and occupation. The other hierarchical regression analyses were conducted separately for the Brazilian ($N=72$) and Norwegian newcomers ($N=63$), to compare the predictive power of resilience in relation to organizational socialization between newcomers from the two cultures. Results showed that overall, after controlling for nationality and occupation, resilience factors added a significant incremental prediction to all socialization factors. The predictive contribution from five resilience factors (Perception of Self, Planned Future, Structured Style, Familiar Cohesion and Social Resources) was also noteworthy. Higher perception of self was associated with higher access to information. The planned future predicted various relevant proximal outcomes of organizational socialization. Individuals with a structured style tended to know more about organizational language and tradition, while
those with higher familiar cohesion reported both less access to information and less knowledge about organizational language and tradition. Contrary to familiar cohesion, social resources impacted positively on socialization outcomes, predicting higher access to information, integration to people, professional qualification, and knowledge about organizational objectives, values, language and tradition. Nationality and occupation also played a meaningful role in predicting the socialization scores. Comparing the predictive power of resilience in relation to organizational socialization between newcomers in both cultures it was noted that it is higher among Brazilians than Norwegians. The present study extends current understanding about newcomer adaptation by illustrating the relevance of resilience factors to the proximal outcomes of organizational socialization in Brazil and Norway. More empirical observations are needed to determine the extent to which the present findings may be generalized to different cultures.

Keywords: resilience, organizational socialization, job cultures

Resilience: Its nature, assessment and manifestations

KREITLER, S. (Tel Aviv University)

To predict the severity of chemotherapy side effects and extent of personal growth in a sample of cancer patients diagnosed with breast cancer or colorectal cancer. A further goal was to provide additional validation for the theoretical approach of cognitive orientation which enables identifying the cognitive-motivational processes underlying manifest behaviors. The participants were 150 cancer patients (breast cancer or colorectal cancer) undergoing chemotherapy for at least three months. They were administered the Kreitler cognitive orientation questionnaire of resilience (assessing 31 themes in the form of statements referring to four belief types), a questionnaire about personal growth (based on the Jones and Crandall Short Index of Self-Actualization) and the Memorial Symptom Assessment Scale. Regression analyses revealed that the cognitive orientation scores of beliefs predicted significantly the degree of side effect severity in terms of the physical and the psychological symptoms, as well as the extent of personal growth. The beliefs with the largest contribution to the prediction were goal beliefs, referring to themes expressing the relations between the self and reality (e.g., low self pity, low occupation with justice, strong belief in potential possibilities). The results are similar to those obtained in other studies with the cognitive orientation of resilience in Crohn’s patients, in individuals after car accidents, and in teenagers living under difficult family conditions. Resilience is a personality disposition that is manifested in weaker adverse symptoms and in stronger positive behaviors. It has deep motivational roots and may be predicted in the framework of a theoretical approach which allows also for promotion by means of targeted and systematic intervention.

Risky health and driving behaviours: Factors influencing perceptions of risk

TITCHENER, K. (Queensland University of Technology), WATSON, B. (Queensland University of Technology), WONG, I. (Queensland University of Technology)

Injury is responsible for almost 8,000 deaths and over 400,000 hospitalisations in Australia every year. It has been estimated that approximately $1.3 trillion of potential health gains can be made through reducing injuries resulting from intentional and unintentional behaviours. Risky behaviours such as speeding, drink driving, heavy drinking and water related activities have been identified as major contributors to injuries recorded in both Australia and globally. While research has established factors that show associations with injury prevalence such as gender and age it is less clear how risky health-related behaviours are perceived by the general public. The purpose of the current work is to better understand risk perceptions for 15 risky health and driving behaviours by studying the interactions between cognitive, emotional, and personality variables and how these influence perceptions of risk. A minimum of 300
Individual Oral Presentations

Participants will complete an online survey that focuses on risk perceptions for both risky health and driving behaviours. The survey is guided by previous work that successfully modelled the interaction between cognition and emotion and the influence this has on risk perceptions associated with radiation sources (Peters et al. 2004). The current work aims to broaden the model and apply it to risky behaviours. Structural equation modelling will be used to test the hypotheses concerning the likely interplay between the cognitive, emotional and personality variables. A new model of risk perception for health related behaviours that incorporates these elements will be proposed to provide a framework to guide future risk perception research. A clearer understanding of the public’s perceptions of risk associated with risky health and driving behaviors will help identify possible barriers to the uptake of injury prevention strategies. Tailoring educational campaigns to focus on issues, known to be used by the receiver in the formation of risk perceptions, will likely enhance the effectiveness of such campaigns. Identifying variables of importance to the public and providing a model of their relative influence is the first step towards this end.

Sarah: A systematic case study of change in a young depressed woman receiving process-experiential emotion-focused therapy (PEEFT)

HARTE, M. (La Trobe University)

Process-Experiential Emotion-Focused Therapy (PEEFT), an integrative, evidenced-based, manualised, experiential therapy developed by Les Greenberg, Robert Elliott and Laura Rice in the 1980’s, emphasises the quality of the client-therapist relationship and offers techniques to assist clients to deal with emotional experience in the present moment. Research into the effectiveness of experiential treatments has identified them to be effective with depression, anxiety and trauma in adults. Also known as Emotion Focused Therapy (EFT), the American Psychological Association has acknowledged and listed EFT as an empirically supported treatment for depression. This presentation highlights the case of Sarah who was part of a larger study that investigated in-therapy experiences and treatment effects of four severely depressed young women (20 to 26) counselled with PEEFT. The importance of the working alliance and the therapeutic interventions associated with change were investigated via self-report, interview and appropriate psychometric measures. Sarah, 21, an undergraduate student, resided with her mother and fraternal twin-sister. At the time of her screening-interview Sarah reported she had been depressed and anxious over the past two or three years and had at times been suicidal. Sarah also presented with body image issues, bulimic symptoms, severe facial flushing and Vestibulitis (painful intercourse). Within a participatory inquiry design, the expanded single case design allowed an interpretive approach, to examining client change and its causes. A simple thematic analysis offered a method to provide themes of change from the client’s perspective and clinical significance was also determined. By session four Sarah’s flushing was no longer evident and after session six her assessed depression had reduced from severe to mild and her bulimic symptoms markedly reduced. At session nine Sarah said “everywhere I go... everyone’s been telling me how stunning and beautiful I am.” A few weeks after therapy concluded Sarah reported she had experienced painless sex. At her twelve-month follow-up Sarah’s measured level of depression was minimal. The working relationship and PEEFT interventions were identified as catalysts for change. The expanded single-case design provided a detailed exploration of the intricate and complex shifts of feeling and content that occurred for Sarah in her PEEFT therapy sessions.

School-based group treatment of depression and anxiety for children at risk

FJERMESTAD, K. (University of Bergen), HOEYE, A. (Fjell Municipality Community Psychologist),

919 | Individual Oral Presentations
BJAASTAD, J. (The Assessment and Treatment of Anxiety in Children and Adults Study (ATACA))

The aim of the study is to document the effects of a manual-based CBT group treatment (“Friends for life”, Barrett et al., 2001) when applied in a school-setting for children identified as at risk for anxiety and depression in Western Norway. In addition, we will examine predictors of treatment effects. The sample is comprised of 24 children who were identified by School Nurses and a Community Psychologist as being at risk for anxiety and/or depression. The children were invited to attend 10-week group treatment using the evidence-based “Friends for life” manual. Anxiety and depressive symptoms were assessed pre-, mid- and post-treatment. Therapeutic alliance was measured after every even-numbered session (2, 4, 6, 8, 10). The strengths and difficulties questionnaire (SDQ) was administered after every odd-numbered session (1, 3, 5, 7, 9) to examine how therapeutic alliance and treatment effects developed during the course of treatment. We plan to use hierarchical multiple regression models to explore study hypotheses that therapeutic alliance and early improvement will predict treatment outcome at post-treatment. Therapeutic alliance and effect at mid-treatment will be included as co-variates when analyzing effects. The development of the therapeutic alliance and self-reported strength and difficulties over the course of treatment will be examined using paired sample t-test analyses. This study will provide critical information about the effectiveness of the “Friends for life” program in a school setting when applied to children identified as at risk for anxiety and depression. In addition, it will provide information about therapeutic alliance and onset of change as possible predictors of treatment outcome.

Keywords: school-based treatment, depression, anxiety, at risk children

Screening mental health risk among school children

ANIFTOS, M. (Inclusive Education Services (R))

Despite the prevalence of mental health problems among Australian school children (8-22%), few access clinical services. Depending on location and nature of symptoms, access to mental health services is reported to range between only 5-35% of children identified with mental health difficulties. In addition to testing the psychometric properties of the Strengths and Difficulties Questionnaire, the current study expands the epidemiological profile of mental health risk among Australian children and

Keywords: personality assessment, selection and development assessment, validity, screening, dysfunctional personality tendencies

DE FRUYT, F. (Ghent University), WILLIE, B. (Ghent University)

A comprehensive assessment of personality in selection and development assessment should encompass both the bright and the dark side of behavior at work. De Fruyt and colleagues (2009) recently examined the usefulness and validity in selection and development assessment of a screening technique to identify individuals at risk for exhibiting dysfunctional personality tendencies. Ten dysfunctional personality tendencies are defined and individuals are considered at risk when they scored beyond 1.5 SD above the mean on ten different compound traits. These compound traits are aggregates of (reversed) scores on specific facets of the NEO-PI-R (Costa & McCrae, 1992) assumed to identify dysfunctional personality tendencies. All data reported in this first research line were collected concurrently, i.e. personality assessments and the work criteria of interest were collected at the same time (De Fruyt et al., 2009). The current contribution provides new evidence on the validity of the ten compound scales examining prospective studies where personality assessments were done at baseline and the criteria were collected a considerable time thereafter. Besides validity evidence, a proposal is generated to compute compound traits indicative for dysfunctional tendencies from the general framework of the Big Five, rather than relying on a specific measure such as the NEO PI-R.

Keywords: personality assessment, selection and development assessment, validity, screening, dysfunctional personality tendencies

Screening for dysfunctional personality tendencies in selection assessment
examines the relationship between teacher ratings of children's psychosocial difficulties and patterns of referral of children to mental health services. Such data is particularly relevant at this time when state education policy is being developed which exhorts school staff to recognise and provide support for all students with mental health problems. The sampling frame consisted of all children enrolled in a state government primary school in south-east regional Queensland, Australia. A participation rate of 75% was achieved from the school population of approximately 540 children aged 5-13 (N=402). Data were collected from teachers rating the behaviours of approximately 25 students in their class. Statistical analyses confirmed the reliability and validity of the SDQ and extend available Australian norms to include children 6-12 years of age. In line with the 1998 population survey, the current data indicates that approximately 14% of children demonstrate a high risk of mental health problems as indicated by SDQ ratings by teachers. The study of 400 students indicates that of the High Risk-High Impact cases at school, teacher referrals (30%) are almost twice as likely as parent referrals (17%), emphasising the important role of schools in primary mental health care. This presentation emphasises the need for teachers to understand, recognise and respond to mental health needs of students; and for psychologists to value teachers as co-contributors for mental health referral, assessment, and intervention.

Self efficacy of adolescents and emerging adults from divorced families and married families, with regard to career decision-making, relationship intimacy and leisure time

ISRAELASHVILI, M. (Tel Aviv University), MORADI, E. (Tel Aviv University)

Parents’ divorce has a considerable effect on the self-efficacy of the children in acquiring life skills and undertaking responsibilities. As self-efficacy relies on positive feedback, social encouragement, and the observation of one's surroundings, the lack of sufficient parental support in divorced families might have a significant impact on the self-efficacy of children from divorced families. Interestingly, their level of self-efficacy has been investigated mainly in the context of relationships, but scarcely in the context of other aspects of self-efficacy. The current study explored three aspects of self-efficacy: Career Decision-Making (Betz, Klein & Taylor, 1996), Relationship Intimacy (Mourua & Lopez, 2005) and Leisure Time (Witt & Ellis, 1985). Participants (n=251) were adolescents (39%) and emerging adults (61%), 38% male and 62% female, from divorced (38%) or married families (62%). The general hypothesis was that divorce would have a main effect on the three aspects of self-efficacy. Research findings indicate that a main effect was found for divorce on self-efficacy in intimate relationships, but not on the other two aspects of self-efficacy that were measured. In addition, several gender and age main effects were also significant. Performing a discriminant analysis (gender X divorce) yielded one discriminant function, composed of the "caring for others" sub-scale in relationship self-efficacy and the "engagement with others" sub-scale in leisure time self-efficacy. However, significant product-moment correlations were found between all aspects, and sub-scales, that were explored. The current study findings suggest the possibility that the significant impact of divorce upon children's level of self-efficacy in relationships is only just the edge of a - more prominent and diverse – "self-efficacy glacier". These findings have several implications for counseling adolescents and emerging adults of divorced families in their career decision making as well as in managing their future relationships. The presentation will be ended by discussing the study limitations and future studies that are needed.

Keywords: divorce, self-efficacy, adolescents, career decision-making, leisure time

Self efficacy of adolescents and emerging adults from divorced families and married families, with regard to career decision-making, relationship intimacy and leisure time

PARR, J. (University of Queensland), KAVANAGH, D. (Institute of Health & Biomedical Innovation, Queensland University of Technology), YOUNG, R.
The aim of the present study was to establish whether there was a role for cognitive behaviour therapy (CBT) in assisting individuals to cease long-term benzodiazepine cessation and to trial two self-managed CBT approaches. Firstly, a meta-analysis of current treatment approaches for benzodiazepine cessation was undertaken to establish the effectiveness of CBT. Secondly, participants were recruited to a randomised control trial with the self-managed CBT program delivered to participants via correspondence while maintaining contact with their General Practitioner (GP). Thirdly, the self managed CBT program was made available to participants via the internet in conjunction with regular email support. The meta-analysis identified that providing CBT in addition to General Practitioner-managed gradual withdrawal increased cessation rates when compared with GP alone. Attempts to encourage GPs across Australia to participate in an RCT were unsuccessful, resulting in a decision to deliver the intervention via the internet. Despite extensive marketing, only 32 people registered for the program via the internet and 14 (44%) completed a 6-month follow-up. Of these, 8 (57%) reduced weekly intake by at least half, including 5 (36%) that ceased use. Self managed CBT may have the potential to assist a greater number of individuals to cease benzodiazepine use, although larger scale trials are required utilising the full potential of the internet to assess its potential impact. Marketing remote delivery treatments remains a significant challenge in both postal and internet formats.

Self-injury: Help-seeking attitudes and behaviours of Australia adolescents

BERGER, E. (Monash University), HASKING, P. (Monash University)

The aim of this study was to identify what adolescents believe parents, teachers and peers can do to help people who self-injure and to investigate differences in attitudes according to gender, help-seeking behaviour and previous experiences of self-injury. Students aged 12-16 years completed a self-report questionnaire including the question “what do you think parents and teachers could do to help people

Self efficacy: A new target in the treatment of adolescent depression

The aim of the current investigation was to test the feasibility of Self-Efficacy Focused Cognitive Behavioural Therapy (SEFCBT) for adolescents with depressive disorders and to demonstrate that SEFCBT improves depressive symptoms as well as self-efficacy. Young people (12-18 years old) who met criteria for depressive disorder were treated for 13 sessions using SEFCBT. A dual clinician model was used to provide treatment to both the adolescent and parents. Multi-method, multi-informant assessments were conducted prior to treatment, immediately post and at a six month follow-up to evaluate the efficacy of the treatment model. Standard cognitive behavioural therapy (CBT) was augmented in accordance with social learning theory. Specific areas of focus in the treatment regime for the young person were realistic self appraisals, mastery exercises, social self-efficacy, and management of rumination. Mechanisms utilized in the development of self-efficacy were direct experience, modeling and social persuasion. The parent sessions focused on communication and creating an awareness of how to foster adolescent self efficacy. Clinical outcomes of this pilot study will be discussed. A need exists to develop treatments that improve outcome for adolescent depression. Self efficacy offers a valid framework to enhance a standardized CBT treatment program of known efficacy. A randomized control trial is required to confirm the findings.

Self efficacy: A new target in the treatment of adolescent depression

who self-injure?” and “what do you think people your age could do to help people who self-injure?” Thematic analysis methods were used to identify themes and categorise responses, which were then analysed by gender, help-seeking and history of exposure to self-injury. General help-seeking and actual help-seeking scales (Rickwood et al., 2002) assess both formal and informal help-seeking for emotional problems. These scales have repeatedly been utilised with Australian youth. Eight broad categories of responses were identified covering possible ways of preventing and helping those who self-injure, including; talking and listening to the person, informing a parent or relative, seeking help from a professional or mental health organisation, inclusion of young people in activities, the importance of friendship, the need to reduce stress caused by school work and bullying, education to identify symptoms of mental illness and emotional distress, the need to reduce stigma of mental illness, and difficulties of preventing self-injury. The adolescents in this study considered family, friends and formal help organisations as paramount to helping those who self-injure. School-based programmes and policies should support healthy family and peer relationships and reduce unhealthy relationships (i.e. bullying). Many students were unsure about what could be done, while others reported the nothing or little could be done to help and the behaviour or person should be ignored. Enhancement of school-based mental health programmes should be provided to all secondary school students, addressing skills that better individual emotional health, promote tolerance and improve help-seeking views of adolescents.

Keywords: adolescents, self-injury, help-seeking

Self-reported use of emotional display rules

DADKHAH, A. (University of social welfare and rehabilitation), NOVIN, S. (Leiden University)

Sociocultural differences in children’s use and understanding of emotional display rules have been under-researched. In the present study, 56 Dutch and 56 Iranian children aged 10–11 years took part in a structured interview about their experiences of using emotional display rules. In comparison with the Dutch children, the Iranian sample was more likely to report having actually used emotional display rules themselves, more likely to identify family audiences for display rules, and less likely to identify peer audiences. In addition, they were more likely than the Dutch children to identify both pro-social and self-protective motives for concealing emotion from family audiences, and less likely to identify self-protective motives for concealing emotion from peers. Results are interpreted in the light of socialization processes involved in the development of emotion regulation.

Keywords: culture, socialisation, emotions, children, display rules

Shared values and perceived justice influences how students’ experience their work-environment

SCHÉLE, I. (Umeå University), HEDMAN, L. (Umeå University)

The understanding of university students, especially in programs with clinical practice, isn’t covered by classical educational psychology and will benefit from a work-environment approach. In this study we investigate how shared values (SV - the extent to which students share the values of their organization) and perceived justice (PJ - how just students perceive themselves assessed and treated) influence how students’ experience their psychosocial work-environment (ExpWE). We hypothesize that SV and PJ will positively influence ExpWE. A web-survey was distributed to all (850) Swedish dental students of which 50 percent answered. A path analysis was conducted on the data (Chi-square 62.138; df = 20; p > .000; Normed Chi-square 3.107; RMSEA .082). SV influences PJ (.56 for men; .43 for women), PJ influences ExpWE (.78 for men; .68 for women). ExpWE in turn influences Student Satisfaction (Sat) (.78 for men; .74 for women) and Perceived Stress (PSS) (.39 for men; -.52 for women). Tolerance for ambiguity in regard to problem-solving (ToAP) influences PSS slightly for women (.15) and significantly more for men (.35). Students who share the values of their organization seem more inclined to interpret actions and decisions
from staff as just. ExpWE seems to be more favorably assessed by students who perceive their organization as just. Not surprisingly, ExpWE influences Sat and PSS. That ExpWE, which influences PSS, is influence by SV and PJ, seems to be in analogy with recent results which suggest that SV and PJ influence the risk for burn-out. That ToAP influences PSS significantly more for men is in analogy with findings from our initial interview-study, where results indicated that male students were more concerned with ambiguous rules and guidelines than were their female fellow students. The influence of SV and PJ on ExpWE should be included in future studies of ExpWE and PSS, as should ToAP.

Signatures of creativity: The interaction of personality and work situation

BLEDOW, R. (University of Giessen), ROSING, K. (University of Giessen), FRESE, M. (National University of Singapore)

We apply Mischel and Shoda’s (1995) concept of “behavioral signatures” to creativity at work and argue that creativity emerges from the interaction of personality and work situation. As a consequence, individuals are characterized by distinct patterns of creativity across different work situations. These patterns are termed signatures of creativity. In departing from an idiosyncratic approach as proposed by Mischel and Shoda (1995), we argue that broad individual differences in personality functioning called action versus state orientation (Diefendorff, Hall, Lord, & Strean, 2000) lead to systematic individual differences in signatures of creativity. We used an experience sampling study with 102 employees holding professional jobs to test hypotheses on behavioral signatures. Participants filled out short surveys each morning and each evening during a one week period about characteristics of work situations and their level of daily creativity. Hypotheses were tested with cross-level moderation analyses in hierarchical linear modeling. The study provided support for the hypothesis that signatures of creativity departed depended on individual differences in action versus state orientation. More specifically, we found that action-oriented individuals were creative if self-efficacy was high and the work situation was characterized by high demands and low structure. In contrast, state-oriented individuals were creative if demands were low, if the work situation was well structured, and if they received social support. The study holds implications for employees and supervisors on how to select and shape work situations to facilitate creativity. Results warn against simplistic one-best-way approaches to stimulate creativity as individual differences in personality functioning need to be taken into account.

Keywords: creativity, personality, work situation, behavioral signatures, self-efficacy

Situation awareness, information use, and uncertainty. It’s not what you have, it’s what you do with it...

The aim of the present study was to map the relationship between situation awareness (SA - the building up of an awareness of the situation you are in and using that awareness to drive action) and any bias toward accepting or rejecting available information. This model of SA is based on the notion that we may hold both true and false information about our situation and we must select which information to use to build SA. Examining how “bias” shifts under uncertain conditions when SA is lost may give insights into human information processing in real-world situations that may underpin costly, and potentially fatal, mistakes such as Friendly Fire in military situations and human error more generally. A simple abstract category-learning task was used to assess the effect of uncertain feedback (some conditions contained a level of false feedback) on SA of a category present in the display. Participants had to learn a target
category by stating (T/F) whether they believed a category was present on a particular trial, and then using the feedback provided to learn the category. Signal detection theory was used to derive two measures: A’ A measure of sensitivity to true vs. false information = SA, and B” A measure of bias to accepting or rejecting information under uncertainty. The category was changed half-way through (all feedback then correct) to force a loss of SA. A second experiment used the same basic paradigm but was based around a real-world category-learning task. There was a relationship between SA and bias. In the control condition (true feedback) there was a negative correlation between SA and bias. As SA improved participants became more ‘lax’ in their use of information – they were increasingly likely to believe that a category was present. As the level of uncertainty in the information increased (more false feedback) the negative correlation was maintained but the bias became far more ‘strict’ with participants inclined to say that there was no target category present in the display. The pattern of results was similar in both abstract and real-world tasks. There appears to be a strong relationship between SA and bias. The nature of this relationship depends on the level of uncertainty in the task. As SA improves participants appear more likely to accept information as true. As uncertainty increases, participants are less likely to accept information. These data have implication for decision making in real-world situations. Work is ongoing to link changes in bias to underlying brain activity using EEG recording.

Social influence in stock markets

ANDERSSON, M. (University of Gothenburg), 
HEDESSTRÖM, M. (University of Gothenburg), 
GÄRLING, T. (University of Gothenburg)

Theories of herding suggest that individuals are sensitive to the actions of other people which, in the financial world, can lead to stock market bubbles and bank-runs. However, theories of herding neglect important psychological factors involved in this socially-derived influence. The aim of the present research is to better understand herding by applying theories of social influence, focusing on systematic and heuristic information processing. In a series of experiments a multi-trial approach in which participants made predictions of stock prices was used. On each trial they received information about the current stock price and the predictions of the future stock price made by fictitious participants, forming a herd. In the first experiment the size of the herd (majority vs. minority) and the accuracy in its predictions (accurate vs. random) varied. In the second and third experiment participants in addition received a focus manipulation, requesting them to focus on either the accuracy in the herds’ predictions or the consistency within the herd. In a fourth experiment, the accuracy of the herds’ predictions was held constant, but the validity in the current stock price (valid vs. invalid) and the inoculation (present vs. not present) varied across conditions. It was found that a majority herd was influential irrespective of the level of accuracy in its predictions. A minority herd was influential only when its predictions were accurate and when the participants were requested to focus their attention on the accuracy of the herds’ predictions. Augmenting the validity of the price information had the same effect. In prediction tasks based on uncertain information, people use heuristic processing more extensively than has been assumed in previous social influence research. A majority herd seems to be influential due to the use of a consensus heuristic. However, no support for Moscovici’s (1976) notion that minority influence is associated with systematic processing was found. Instead, the results suggest the use of a “minority heuristic”, implying a tendency to follow the price instead of a minority.

Social networking as a new organizational tool: determinants of time spent on the facebook

YURTKORU, S. (Marmara University), ULUSU, Y. (Bahcesehir University), KÇ, B. (Bahcesehir University)
Today, massive changes in the information technology enabled Social network sites (SNS’s) to integrate in our daily life more actively. SNS’s such as Facebook, MySpace, Bebo and LinkedIn have become enormously popular and widely used for interpersonal communication. In the business arena, as a result of competitive structure of the markets, social networking sites have emerged as a new marketing channel for the firms. To be able to gain competitive advantage and find cost effective solutions to reach customers, marketers have become more interested in learning about, organizing and facilitating online communities. The purpose of the study was to examine the factors that influence time spent on the SNS environment namely Facebook in this case and bring light to Facebook usage types and their frequencies. Data for the study were collected from 1682 Facebook users via electronic questionnaire. A multi item questionnaire was used to measure the dimensions of ‘time spend’, ‘usage types’, ‘trust’, ‘privacy concern’, ‘self-disclosure’ and ‘personality’. The sample comprised of 894 females and 788 males. The model was tested with path analysis which had a good fit (GFI=0.93; AGFI=0.90; NFI=0.95; TLI=0.94; CFI=0.95, RMSEA=0.07). The results revealed if a person has privacy concern, his willingness to disguise himself increases in virtual society. However the reputation of the virtual society increases the amount of trust one has on the SNS and also decreases his need to disguise, which in turn increases the amount of time spent. However even though the time spend increases people are still using the Facebook with the concern to get socialized instead of doing business. They use Facebook to ‘get connected to friends’, ‘look at profile/pictures’, ‘send messages’, and ‘get information about friends’, more frequently (M=3.83, M=3.54, M=3.52, M=3.05 respectively). Respondents used Facebook for ‘selling’, ‘marketing’, ‘buying’, ‘commercial purposes’ and ‘advertising’ less frequently (M=1.41, M=1.41, M=1.42, M=1.42, M=1.45 respectively). As people are getting more addicted to Facebook they spend considerable amount of time on this virtual network of communication. However from the organizations point of view people are not active in doing business as expected.

Social relations factors in job search self-efficacy among culturally and linguistically diverse immigrant jobseekers

MAK, A. (University of Canberra)

The present study aimed to trial a measure of job search self-efficacy and investigate its prediction by several sociocultural factors (host language fluency, cross-ethnic social contact, cross-ethnic social self-efficacy, and social interaction skills), and number of co-ethnic and other ethnic friends, among culturally and linguistically diverse (CALD) immigrants. Participants were 151 non-English-speaking background immigrants (64 men and 86 women) recruited from a job training program in Brisbane. The jobseekers were born in 42 countries, and had a median period of residence in Australia of 1.67 years, with 94.7% holding tertiary or technical qualifications. The participants completed an anonymous questionnaire that included a measure of job search self-efficacy, various sociocultural and friendship variables, and items seeking demographic information. The results showed that a 4-item measure of job search self-efficacy had high internal consistency reliability. Its distribution of scores suggests a general tendency towards being confident about job search, and a good spread across the range of possible scores. As expected, significant bivariate correlations among all the sociocultural factors and job search self-efficacy were found. However, hierarchical regression analysis showed that the effect of English fluency on job search self-efficacy disappeared when the cross-ethnic interpersonal relations were taken into account. In the final regression model, 41% of the variation in job search self-efficacy was explained; the significant predictors were cross-ethnic social self-efficacy (medium effect size), social interaction skills (medium effect), and having a greater number of co-ethnic friends (small effect). Sociocultural factors, particularly cross-ethnic social self-efficacy and social interaction skills, were found to influence job search self-efficacy among highly qualified, unemployed CALD immigrant jobseekers. Future
research could compare job search self-efficacy and additional psychosocial precursors among local and overseas-born jobseekers. Present findings further suggest that labour market programs for immigrant clients in multi-ethnic societies could focus on enhancing their confidence and skills in social interactions.

Social representations of terrorism: new empirical findings on the role of personal involvement in the shift to radical forms of lay thinking

ERNST-VINTILA, A. (Université de la Méditerranée Aix-Marseille II), ROLAND-LEVY, C. (Université de Reims Champagne-Ardenne)

This empirical study showed how personal involvement, a major explicative variable of lay thinking, contributes, in the absence of training/practice, to the shift from social representations to more radical forms of lay thinking: nexuses. Its originality consists of providing an analysis of lay thinking about terrorism at the positional level of explanation, a complement to the ideological level used in sociology and political science, and to the intra- and inter-individual levels adopted in psychology. Previous studies have shown that practices are a determinant factor in shaping social representations, and suggest personal involvement as a major explanatory variable. Personal involvement (Flament and Rouquette, 2003) corresponds to an individual’s relationship to a social object, such as threat, and is a combination of three dimensions: threat valuation, personal exposure to threat, and perceived capacity to act towards it. This study was completed within the structural approach to the Theory of Social Representations, which enables formal comparisons among representations with the aid of its specific methodologies (Abric, 1994, 2003; Vergès, 1996, 2000). The study compared the lay thinking about terrorism among participants (N=158) who had different levels of antiterrorism practice (French safety officers vs. French passengers) and of personal involvement (US vs. French passengers). It was run in the airports of Marseilles-Provence (France) and Boston-Logan (United States). The social representation of safety officers had a more practical orientation. In contrast, the lay thinking about terrorism of both US and French passengers was normative in nature and displayed a salient affective component. Moreover, for the US passengers, who reported higher scores of personal involvement, "Muslims" was a central element for defining terrorism. In fact, “Muslims” was as essential as “death”, “fear” and “attack” to define what terrorism meant for the US passengers. These empirical findings support the hypothesis that in conflict/threat situations heavy personal involvement, acting in the absence of training/specific practices, can shift lay thinking to a more radical, collective and mobilising form: the nexus (rather than social representations). Nexuses (Rouquette, 1994) command profound mobilisation and clear-cut opinions in conflict and threat situations, whether real, implicit or assumed. Their powerful symbolic value is deeply federative because it is anchored in the collective memory of the given groups. Recently, September 11/Islamic terrorism became one of those symbols. Unlike social representations, which enable reasoning about their objects (Moscovici, 1961), nexuses are activated upstream from rationality, and are not the result of a carefully considered and rational analysis. By confirming the major role of personal involvement in the sliding of lay thinking toward radical forms, and the crucial role of training/practice in inhibiting this process, these findings emphasize the necessity of training for the shaping of lay thinking about sensitive objects (terrorism), and for the change in the societal repertoire. Trained individuals are more likely to activate forms of lay thinking (social representations) that are more moderate than the radical ones (nexuses) likely to be collectively activated in the absence of training/practices.

Social support for Coup d’Etat in Africa: In search of an explanation

GARCIA-RIVERO, C. (Burgos University), ORTEGO, J. (Burgos University)
Political participation and alternation in office through elections is a major characteristic of contemporary democratic politics. However, in Subsaharan Africa, military coup has been, and still is, a common feature of daily politics. Hence, it is not uncommon to witness social support to military intervention in politics. Several theories have attempted to explain this, including economic, cultural, and political factors which account for coup support. This paper examines the underlying causes that propel this support for military intervention in politics. The research involves quantitative analysis and makes extensive use of survey data gathered from several countries in Africa at the individual level. Conclusions reached indicate that although peculiarities of every country show its own impact, social and personal support for military intervention in politics is mainly explained for a rational evaluation of economic expectations and perceptions and cultural differences existing within societies.

Socialization or selection? The gender-role self-concept of men in female-dominated occupations

KOREK, S. (University Leipzig), SOBIRAJ, S. (University Leipzig), MOHR, G. (University Leipzig)

Men in female occupations often have to face the stereotype of being less masculine and more feminine, which may be a hindrance to enter non-typical areas of work for young men. Until now little is known if this stereotype holds true. The present study therefore investigates the gender-role self-concept of men in different female-dominated occupations. We evaluate three different hypotheses: Selection processes could take place by which men with a more feminine and less masculine gender-role self-concept are attracted by female-dominated occupations. This would predict that these men have a more feminine gender-role self concepts than men in other occupations. Next we propose a socialization process. This process can point into two different directions: Theoretical considerations point to the assumptions, that the execution of female work will strengthen the feminine component of the gender-role self-concept. Likewise it could be that men in female occupations re-define their task as masculine and thus reinforce and protect the masculine component. 213 men in female-dominated occupations filled in questionnaires measuring their gender-role self-concept, and redefinition strategies via gender-typical work demands. 279 female colleagues also indicated the task redefinition. To control the selection hypothesis a comparison of the gender-role self-concept of our sample with a representative German sample revealed that the men of our sample scored significantly higher in femininity. The test of the socialization hypothesis revealed that in general, the gender-role self-concept did not correlate with tenure in a female-dominated occupation. However, when redefinition processes were included, we found a positive link between masculinity and tenure for men who defined their work as masculine. No such results were found, when task redefinition of the female colleagues was analyzed. Our data support the selection hypothesis as well as the socialization hypothesis: while the feminine component may underlie a selection process, the masculine component was strengthened by a socialization process via redefinition of work. In general, men’s’ masculinity can be protected by applying these redefinition processes. This might be important, because masculinity is positively related to psychosocial health.

Socializing for business in Taiwan: Ganxi development

BEDFORD, O. (Nanyang Technological University)

Most studies of business Guanxi (the personal ties between individuals as well as an individual’s whole network of personal relationships) have focused on outcomes and little attention has been paid to the process of Guanxi development. The aim of this study is to examine a natural context commonly used to foster business Guanxi to identify important components of developing and maintaining relations. We propose an indigenous Chinese psychological framework of Guanxi development
and maintenance as a framework for analysis. We expected to find that socializing is affected not just to obtain the specific business outcomes described in so many studies such as closing a contract or getting a job, but also to enhance real affective bonds, with implications for trust and ethical commitments. We used quota sampling to conduct qualitative interviews with 43 Taiwanese men (aged 20 to 75; $M = 38.5$) with a range of occupations and socioeconomic backgrounds. Interviews were recorded, transcribed, and analyzed using Spradley’s (1979) Developmental Research Sequence method. Results supported the framework and indicated the main purpose of socializing was to bond with and test the character of other men by demonstrating a facility with the social etiquette and exchanging mianzi (face) and renqing (favors). The majority expressed that the practice was helpful to their jobs or part of their job description, although nearly half felt compelled to participate. The issue of corruption emerged as an important consideration. Although relationships may be established on behalf of or because of organizations, Guanxi is by nature the relation between individuals; the rules governing Guanxi are the complex norms of interpersonal interaction that come into play every time people interact. However, socializing practices can have an impact that reaches far beyond the affective bonds of individuals. Guanxi networks can become a part of a corporate culture or a whole industry. They may impact the way those organizations conduct business, including corrupt practices. Policy implications are discussed.

Keywords: Guanxi, development, personal ties, relationships, network

Spatial and temporal biases in assessments of environmental conditions

MILFONT, T. (Victoria University of Wellington), MCCARTHY, N. (Victoria University of Wellington)

Individuals tend to hold spatial and temporal biases when assessing environmental conditions. Spatial biases refer to comparative optimism in terms of geographic distance, in which proximal environmental conditions are viewed more favourably than distal conditions (“things are better here than there”). Temporal biases refer to discounting, where present environmental conditions are viewed more favourably than future conditions (“things will get worse”). Gifford et al. (2009) developed the Environmental Futures Scales (EFS) to assess these biases, and found support for spatial optimism and temporal pessimism biases in community samples from 18 countries. The present study investigates these biases in a country not included in the original study. Participants were expected to assess environmental conditions less favourably as spatial distance increases (‘My area’, ‘New Zealand’, ‘globally’), and assess the future state of the environment less favourably compared to the current state. Going beyond the original study, optimism and future orientation measures were used to assess whether individual differences variables would affect the biases. A total of 108 community respondents (65.7% female; mean age = 27 years, $SD = 10$) completed an online version of the EFS, the Life Orientation Test, the Consideration of Future Consequences Scale, plus socio-demographic questions. A one-way repeated-measures ANOVA examining spatial optimism, with age, gender, optimism and future orientation entered as covariate, showed that assessment of current environmental conditions was significantly affected by the spatial level, $F(1.55, 147.24)=9.18$, Huynh-Feldt adjusted, $p < .01$. Pairwise comparisons indicated that participants rated current national conditions less favourably than local and global environmental conditions ($p < .001$), and local more favourably than global ($p < .05$). One sample t-tests examining temporal bias showed that participants were pessimistic about the future, rating that local, national and global environmental conditions will get worse, $t (107) = -5.72, -16.15$ and $-10.18$, respectively, $p < .001$. Respondents assessed New Zealand environmental conditions less favourably than local and global conditions. Overall, however, spatial optimism and temporal pessimism biases were confirmed in our sample. Construal level theory will be used to discuss the findings and implications for promoting conservation behaviours.

Keywords: spatial biases, temporal biases, environmental conditions
Spatial problem solving in real and virtual environments

DENIS, M. (LIMSI-CNRS), ABBASI, S. (LIMSI-CNRS, Université de Paris-Sud, Orsay), BURKHARDT, J. (LATI, Université Paris Descartes)

The aim of this study was to assess the strategies implemented by people who are trying to solve three-dimensional puzzles in real and virtual environments, with a special interest for the strategies based on people’s visuo-spatial capacities. We invited graduate students to solve a spatial task which consisted of assembling blocks of various shapes, sizes, and colors, to form a cube – a variant of the Soma Cube. Performance on this task was shown to be significantly better in those people who scored higher on two tests considered to reflect individual capacities of visuo-spatial imagery (the Minnesota Paper Form Board and the Mental Rotations Test). The analysis of participants’ verbal reports as they attempted to solve the puzzle was analyzed and reflected their efforts to visualize the target state and implement adequate strategies. Performance was also shown to depend on the classification of individual blocks according to their perceived complexity. Based on the behavioral data collected in this experiment, we developed a further study in which the same task was executed in a virtual environment. We compared interfaces involving commands based on distinct modalities (keyboard, voice commands, or gestures) or combined modalities (voice + gesture). An assessment of the respective values of these modalities in developing successful strategies is intended to help us build a computerized system of assistance to spatial problem solvers.

Keywords: spatial problem solving, virtual environment

Spirituality, job stress, organizational commitment, and job satisfaction among nurses in Tehran

GHOLAMALI LAVASANI, M. (university), PISHYAR, R. (Tehran University)

The study aimed to explore the amount and relationships between nurses’ spirituality, job stress, organizational commitment and job satisfaction in Tehran hospitals. A descriptive (regression analysis) design was selected and 379 nurses (307 female and 75 male) working in hospitals in Tehran completed four valid questionnaires. Results indicated that nurses felt low job satisfaction, moderate to extreme organizational commitment, high spirituality (spiritual care) and job stress. The analysis of regression showed that job stress negatively correlates with the other three variables. Moreover spirituality, organizational commitment and job stress play a significant predictors role on nurses' job satisfaction.

Keywords: nurses, job satisfaction, spirituality, job stress, organisational commitment

Stochastic change in driver’s reaction time with arousal state

YOSHIOKA, T. (Kyushu University), MORI, S. (Kyushu University), MATSUKI, Y. (Fukuoka Institute of Technology), UEKUSA, O. (Nissan Diesel Motor Co., Ltd.)

The purpose of this study is to examine how a driver’s reaction times (RT) change, in a stochastic manner, with his/her arousal state. In this study, we express reaction time distributions by ex-Gaussian function, which has been known to fit well with RT data. As an index of arousal state, we use eye-opening ratio (EOR), a relative distance between the upper and the lower eyelids at a given moment to that obtained under high arousal state. An experiment was conducted using a driving simulator. Seven students participated. The front view of the simulator showed a running car in front. The participant’s task was to keep distance from the front car and stop by hitting the brake pedal as soon as the front car’s brake lights turned on. RTs of hitting the brake were measured 300 times for each participant. During the experiment, the participant’s left eye was monitored by a digital video camera to compute EOR. For the data analysis, we classified individual RT data into 2 sets according to corresponding EOR values, Low (lower than 85%) and High (higher than 85%). Ex-Gaussian functions fitted quite well with RT distributions.
for the Low and the High EOR for all 7 participants. The change in the distributions with EOR values varied individually. For 3 of 7 participants, the mean of the distribution was larger for the Low than for the High EOR, which is reasonable. However, two participants showed little change in the distribution and the other two participants showed higher means for the High EOR. Our use of ex-Gaussian function to fit RT distributions was shown to be quite successful, suggesting that the ex-Gaussian function captures the stochastic nature of RT during driving. The results of using EOR to see the change in RT distributions with EOR are mixed. One possible reason for such an inconsistency is that RT data for the Low EOR were relatively small in size and may not be appropriate samples of parent populations for low arousal states. We are now investigating ways to obtain good samples for low arousal states.

Strategic behavioural advantage: A process theory of creating competitive advantage through strategic human resource management.

CHAMP, M. (Department of Transport and Main Roads)

A review of the Strategic Human Resource Management (SHRM) literature reveals a number of deficiencies in our current level of understanding of the theory and practice of SHRM in organisations, including; a lack of process for developing human resource strategy, lack of theory to explain how and why human resource practice contributes to long term organisational sustainability, a tendency to be overly concerned with Human Resource (HR) practice rather than how or why they work, research designs too narrow in scope, tend not to acknowledge organisational context, and are not behaviourally based. The research paper proposes a theoretical framework to address the deficiencies in the SHRM literature and tests it in a field based setting. Within a public sector organisation of about 5000 employees the research utilises a multi-method, repeated measures approach in a field based setting, using both qualitative and quantitative data. The research process proposes a theoretical framework, then uses the framework to systematically diagnose organisational performance issues, identify appropriate human resource strategies to address them, and evaluates performance outcomes of the strategies implemented over a three year period. Results suggest the framework effectively provides a foundation upon which a systematic approach to SHRM can contribute to overall organisational performance. However the research also identified a number of internal and external factors that can have profound implications upon the impact of human resource strategy extraneous to current approaches, such as; political considerations, individual personalities, senior managerial decision making processes, organisational culture, and external stakeholder influences that are outside the scope of current theory and practice. Current theory needs to expand to take into consideration such issues, the context of how practices are implemented, and to take into account influences outside of the “logic” of the immediate diagnosis-intervention-outcome process flow. Clearly current SHRM approaches largely fail to take account of organisational reality and until they do, theoretical approaches that look good on paper, will not translate to sustainable organisational performance.

Street children and delinquents: A holistic psychological intervention in Brazil

MONTEIRO, S. (CeFIPsi)

During August 2009 we accomplished a humanitarian mission in Timon among 848 children from the school “Mãos Dadas” (Hands hold together). We worked with 26 classes of students, from 3 to 18 years old, with 120 parents, 43 teachers and the civil and military police force of Timon. We intended to provoke some behavioral and emotional changes among all participants: motivating children for school
and for a personal and academic/professional life project; getting them out of streets, drugs and delinquent behaviors; improving parents-child relationships and elucidating parents about behavioral modeling for their children; improving first health care and alimentation habits among students’ mothers and; changing/improving the relationship between the Police Force and the community. During this presentation we will reveal each step of our psychological intervention with the different groups and discuss the results obtained. A seven session personal and social skills program was administered to each class, plus one session with classes of the same school year together. Two educational parenting skills training session were administered to parents, both at school and during visits to their houses. A two sessions motivational and burnout prevention training course for the 42 teachers of the school. A training course for the Police Forces of Timon regarding their relationship and involvement with the community, their image perceived by the community and the Portuguese model of Proximity Integrated Policing they can adjust and implement. Before and after the intervention program we did psychological assessment trough questionnaires of behavioral adjustment as well violence beliefs. After the program we gathered significant behavioral and emotional changes among students allowing us to consider our personal and social skills program as a successful one. Teachers keep on using the educational and motivational techniques we presented. Holistic intervention in these scenarios is needed to fulfill emotional and psychological needs. A follow-up mission is planned for August 2010.

Keywords: delinquents, Brazil, training, interventions

Students’ hope, performance expectations, attributions and emotions for school performance

STEPHANOU, G. (University of Western Macedonia)

This study, basing on Weiner’s theory of attributions and emotions for achievement behaviour, and Snyder’s hope theory, examined (a) children’s (N=322, both gender, 5th and 6th grades) attributions and emotions for their perceived successful and unsuccessful school performance in mathematics and language; (b) the role of children’s hope (total, pathways thinking, agency thinking) in the perception of their performance as successful or unsuccessful in the above school subjects, in attributions and emotions for the same performances, and in the impact of attributions on emotions; and (c) the effects of hope in the formation of school performance expectations, and in the impact of attributions and emotions on performance expectations. Teachers rated students’ academic performance, while the students completed the rest of the scales (e.g., ‘Children’s Hope Scale’ (for ages 8 to 16), Snyder et al., 1997). The results from MANOVA analyses, and subsequent Anovas and Discriminant Function analyses showed that the children attributed the perceived successful performance mainly to stable and internal factors, and the perceived unsuccessful performance predominately to unstable and personal uncontrollable factors, in both school subjects. Also, students experienced intense positive emotions for successful performance, and moderate negative emotions for unsuccessful performance. Hope influenced the perception of performance as successful or unsuccessful in language and, mainly, in mathematics. Furthermore, higher levels of hope (predominately, pathways thoughts) were related to less perceived unsuccessful performance in language, and more perceived successful performance in language, and, particularly, mathematics. Also, the results from a series of hierarchical regression analysis revealed that hope (mostly, agency thinking) positively influenced the formation of attributions (particularly, stability), emotions, and the impact of attributions on emotions (mainly in the perceived unsuccessful performance groups). Yet, in the perceived successful performance groups in both school subjects, high-pathway thinking children expected higher school performance. In contrast, in the perceived unsuccessful performance group in language, low-agency children had low expectations of future performance. Finally, hierarchical regression analyses indicated that hope moderately influenced the impact of attributions (mainly,
locus of causality) and emotions on performance expectations. The findings from the present study suggest that children have certain hope level that influences their causal attributions and emotions for their school performance. We should help children to maximize hopeful thinking.

Keywords: attribution, achievement behaviour, hope theory, emotions, school performance

Study of latency childhood depression: Clinical features revealed in the process of psychoanalytic psychotherapy

LIN, Y. (Fu-Jen Catholic University), LIN, L., LEE, J.

Psychotherapy research on childhood depression has proved that psychoanalytic child psychotherapy is an efficacious treatment. However, the clinical features revealed in the process of psychodynamic psychotherapy have rarely been studied. Hence this research intends to explore themes/features of childhood depression revealed in the process of psychoanalytic psychotherapy and of parent consultation. Four children (aged 9-11) diagnosed as having depression were referred from psychiatric hospitals. The Chinese version of the CDI-Parent Rating and Depression Rating Scale for Children (Chang, 2006) was conducted to ensure that the subjects matched the criteria. The four pairs of parents received 10 sessions each of parent consultation from one clinician whilst their four children received 10 sessions each of psychodynamic psychotherapy from the other clinician. All 80 therapy sessions were recorded, transcribed and coded, and then the quantitative data analysis software Atlas.ti 5.0 was used to code and analyze the psychotherapy session notes. Expert reliability was obtained with the contributions of two other senior child psychotherapists. The analysis of the parent consultation revealed the following themes/issues: the parents’ unresolved problems; parents’ lack of function; parents’ severe and punitive super-egos; blurred emotional boundaries within the family structure; and a perverted parent-child relationship. The analysis of the child psychotherapy revealed the following themes/issues: severe and punitive superegos; excessive guilt and inhibitions; inner deprivation; feelings of helplessness and hopelessness; the need to control; idealization and inferiority; internal aggression and anxiety; confusional internal states; negative object relations representation; and oedipal problems. It is hoped that this study will add to the knowledge of childhood depression and provide the child clinician with a useful reference for further research and the implementation of treatment plans. Three main categories and five features were found in the parent consultation; three categories and fourteen features were found in the child psychotherapy process. The result of this research is consistent with some of the research findings on childhood depression, especially the features of anxiety, guilt, helplessness and hopelessness in the children. It is hoped that this study will add to the knowledge of childhood depression and provide the child clinician with a useful reference for further research and the implementation of treatment plans.

Study of relationship between supporting services and quality of life of people with Multiple Sclerosis who live in Tehran

RAHEB, G. (Welfare and Rehabilitation University), EGHLIMA, M. (Welfare and Rehabilitation University), ZOHMAN, M. (Welfare and Rehabilitation University)

The aim of this research is to assess the relationship between supporting services and the quality of MS patient’s life. The study utilizes a correlational research design and randomized sampling. The research data were collected through interviews with the patients, a standard S4-instruments questionnaire (MSQOL-S4) on MS patients’ quality of life and the supporting services questionnaire. Spearman correlation statistical testing procedure was used to verify the relationship between the variables. The results have shown that there is a meaningful relationship between the supporting services and the mental and physical aspects of the patient’s quality of life, whereby increasing the level of supporting services improves the social and cognitive functioning of the patients. There
is a meaningful relationship between supporting services and reducing role limitation due to physical and emotional problems, whereby increasing the supporting services decreases the pain and fatigue of the patient. Meaningful relationships were also found between supporting services and increasing emotional well-being and decreasing health distress. Since the present study shows a meaningful relationship between supporting services and the patients’ quality of life, it would be beneficial to enhance the level of supporting services in order to improve MS patients’ quality of life.

Keywords: supportive services, multiple sclerosis, quality of life

Studying reasoning and judgment by tracking information accessing and processing behaviour in complex, dynamic environments

WASTELL, C. (Macquarie University), WEEKS, N. (Macquarie University), WEARING, A. (University of Melbourne), DUNCAN, P. (Macquarie University)

This research investigated the impact of cognitive traits and biases on human information processing and judgment in complex, dynamic and ambiguous environments. Using the Analysis Simulation Project (ASP) methodology for investigating reasoning and judgment behavior, two studies were carried out. The ASP methodology is a computer administered simulation of complex information environments which records and tracks information access, transfer and utilization as well as other variables of interest. Study 1 (n=40) examined the influence of the cognitive trait of “need for closure” on a threat estimate for a visit by a government official to a foreign country. This task is common in the Security and Military Intelligence analysis environments. Study 2 (n=50) examined confirmation bias. The experimental scenario was set within the context of investigating a murder as would occur in the work of Policing agencies. The results for study 1 showed that need for closure predicted the level of assessed threat even controlling for the amount of information accessed by participants. Study 2 results were consistent with the general findings on confirmation bias in that those higher in behaviour consistent with a confirmation bias approach were substantially less likely to choose the most likely suspect as the murderer. The studies taken together illustrate the capability of the ASP methodology to represent complex, dynamic and ambiguous information environments. These studies are the forerunners of a more extensive analysis of complex information environments with a view to better applying the findings of reasoning and judgment research to realistic environments.

Keywords: information processing, processing behaviour, judgement

Subjective wellbeing and psychological contract content: The relationship between employee wellbeing and dynamic performance expectations

WINDLE, K. (Deakin University), VON TREUER, K. (Deakin University)

Subjective wellbeing is known to influence the quality of an individual’s interpersonal relationship. A recent study found subjective wellbeing to also influence the nature of an individual’s employment relationship. Specifically, subjective well-being was found to predict a balanced psychological contract type, accounting for almost 40% of variance within a single organisation. This paper presents the findings of this first study, and aims to then examine the generalisability of the finding in a larger sample, across multiple organisations. A sample of 448 participants sourced from 17 organisations representing six industries was employed. Data was collected by means of an online survey measuring the psychological contract and subjective wellbeing. The previous study’s findings were confirmed with subjective wellbeing predicting a balanced psychological contract. Results found that subjective wellbeing was uniquely related to a balanced psychological contract type (β = .208, p = .001, sr2 = .02) and more specifically to dynamic performance expectations (β = .240, p = .002, sr2 = .02). These findings were consistent across organisations and industries, supporting the generalisability of findings. Results were explained within the framework of subjective wellbeing and coping theories, proposing that psychological contract
expectations surrounding the likelihood of change related stressors coupled with dynamic performance enhance employee coping abilities which in turn related to employee wellbeing. These findings hold practical implications for organisations wishing to implement programs that encourage flexible and adaptive behaviour in their employees. Such employee behaviour is desirable for organisations particular during times of change and/or economic downturn.

Keywords: subjective well-being, interpersonal relationships, psychological contract

Suicide prevention professional development training for mental health services in rural and remote areas (MHSRRA) Program: A pilot project

LOVELOCK, H. (Australian Psychological Society)

Suicide is not only a devastating tragedy for the individual and their friends and family, but it is also a major public health issue for the community as a whole. Several studies indicate that suicide rates are higher in rural and remote Australia compared with metropolitan settings, especially amongst particular populations. Clinicians providing mental health services in rural and remote Australia are likely to encounter people who demonstrate suicidal ideation or behavior, and are likely to have less access to the resources of their metropolitan counterparts. Under the Australian Government’s Mental Health Services in Rural and Remote Areas (MHSRRA) Program, designated allied health professionals are being offered Suicide Prevention Professional Development Training. This training has been developed using evidence-based practices, to inform participants of the assessment and management of people at risk of suicide or serious self harm, and to specifically highlight the issues and concerns relevant to working in rural and remote Australia. Sections of the training are expressly dedicated to engaging three Australian populations that are of higher risk: people of Aboriginal and Torres Strait Islander descent, men, and young people. In recognition of some of the barriers to accessing training for rural and remote clinicians, this training can be completed via long-distance with a comprehensive workbook that includes pre-reading, and assessment tools; two DVDs that present lectures, roleplays, and vignettes; and an online assessment. The program has been endorsed by the Australian Psychological Society and Australian Association of Social Workers for continuing professional development points for their members, and applications are pending with OT Australia and Australian College of Mental Health Nurses.

Supervisees’ views of supervisor effectiveness as a result of supervision training

O’DONOVAN, A. (Griffith University), DOOLEY, R. (Private Practice), KAVANAGH, D. (Queensland University of Technology), MELVILLE, L. (Private Practice)

Training for supervisors of probationary psychologists has become mandatory in several states of Australia. However, little is known about the effectiveness of existing training protocols for influencing supervisors’ task performance. In order to address this gap, the current study examined supervisees’ perceptions of supervisors who had participated in the Queensland-based Supervisor Training and Accreditation Program (STAP). The key objectives of the study were to determine whether supervisees perceived that their supervisor’s performance was enhanced by STAP-training, and to uncover trends in the supervisee experience that could further inform the process of supervisor training. An overview of the 6-year STAP program will be provided. As part of the STAP accreditation process, supervisees of supervisors-in-training were required to submit a pre- and post-STAP Supervisor Satisfaction Questionnaire. Of 508 supervisees entered into a database as having completed this questionnaire, 33 were randomly selected to discuss their supervision experiences in more detail via a structured, confidential telephone interview. A trend for supervisees to perceive their supervisor’s performance as improving was evident on 50 of the 53 tasks surveyed. The tasks on which supervisees were
most likely to report supervisor improvements were directly relevant to the supervisor’s performance under the Supervised Practice program, such as ensuring comprehensive contract, seeking feedback. Sixty percent of supervisees indicated that STAP training was the process that had had the most impact on their supervisor’s effective practice. Comparisons between Pathway 1 (Honours plus 2 years supervised practice) and Pathway 2 (post-graduate course) supervisees will also be discussed. STAP appears to have a positive impact on supervisors’ task performance in supervision, particularly in relation to SPP-relevant tasks. It may be pertinent to train supervisors to especially attend to different issues, depending on the pathway taken by their supervisee (e.g. responsibilities in supervision for Pathway 1 trainees and the power differential for Pathway 2 trainees). Asking supervisees to share their evaluation of their supervision with their supervisor has a negative impact on the validity and utility of data gathered. The collection of confidential supervisee ratings of their supervisor’s effectiveness pre- and post-supervision training is recommended.

Keywords: training, probationary psychologists, supervisors

Teacher resilience: A review of current literature

BELTMAN, S. (Curtin University of Technology), MANSFIELD, C. (Murdoch University), MCCONNEY, A. (Murdoch University), PRICE, A. (Murdoch University), PELLICCIONE, L. (Curtin University of Technology)

This paper presents a systematic review of literature related to teacher resilience. The review underpins a larger research project that aims to enhance the resilience of early career teachers by embedding evidence-based practice within the pre-service teacher education programs of two Australian universities. One aim of the paper is to identify constructs and consequent research methods to inform the development of a questionnaire for use with pre-service and early career teachers, and guide the nature of strategies implemented in the universities involved. There is concern internationally with the high attrition rates of early career teachers. Numerous studies have examined factors such as workloads and behavior management difficulties that contribute to teacher stress and burnout. More recently researchers have looked towards teacher resilience as a more positive way of addressing this problem. Definitions of resilience include the ability to “bounce back” after experiencing difficult events. It is the capacity to deal constructively with challenges and the ability to maintain social and emotional well-being in the face of difficult events. A shift in thinking from attrition to resilience offers the potential for more effective interventions to occur. A search of databases such as ERIC and ProQuest revealed over 250 journal articles and conference papers linked to key words such as ‘resilience’, ‘teachers’ and ‘burn out’ published between 2000 and 2009. Papers selected for systematic review are those most relevant to teacher resilience and are summarized according to key criteria such as conceptualizations of resilience, research methods used, key empirical findings, and issues raised. For example, one important issue arising from the literature is the relationship between teacher retention and teacher resilience. The assumption is that if new teachers develop greater resilience, they will be less likely to leave the profession. At the same time, however, there is evidence that some teacher education students consciously plan to teach only for a short time before moving on to achieve other life goals. The paper will provide an overview of strengths and limitations of current research suggest directions for future research and derive implications and recommendations for pre-service teacher education programs.

Keywords: teacher resilience, university, stress, burnout

Teachers’ competence in parent counseling: Evaluation of a training program in in-service and pre-service secondary-school teachers

HERTEL, S. (German Institute for International Educational Research), NAUMANN, J. (German Institute for International Educational Research)
Teachers’ professional responsibilities are constantly changing in a world where education is an increasingly important resource. Parents demand teachers’ advice in how to support their children at home (e.g. Cooper, Lindsay & Nye, 2000; Trautwein & Lüdtke, 2009). Positive effects of a frequent parent-teacher-communication and teachers’ counseling activities are well documented (e.g. Lengua & McMahon, 2000; Manz, Fantuzzo & Power, 2004). In line with this, recent conceptions of teacher professionalism include counseling knowledge in what is seen as a core set of teachers’ professional competencies (e.g. Baumert & Kunter, 2006), but an explicit training of counseling skills is rarely included in teacher education. We investigated the effects of a training-program designed to enhance teachers’ counseling competence in two samples: (1) a sample of in-service secondary school teachers (N=59), and (2) a sample of pre-service secondary school teachers (N=23). In each sample, a quasi-experimental pretest-posttest-design was used. Based on previous research, teachers’ counseling competence was operationalized as a five dimensional construct with the following sub dimensions: personal resources, social co-operation, counseling skills and pedagogical knowledge, solution and process orientation, and coping. The training consisted of a total of four training sessions that lasted for 210 minutes each. The sessions were held weekly. The main topics addressed were communication theory, and self-regulated learning. In both samples, counseling competence was measured by self-ratings and a knowledge test in pre- and posttest. For the self-ratings, participants were asked to rate their counseling competence (e.g. self-reflection, communication-skills) on six-point rating scales. These measures were combined into an over-all measure of perceived counseling competence. Cronbach’s α for this measure was .86 in sample 1 and .77 in sample 2. Participants’ counseling knowledge was assessed with a four-item declarative knowledge test covering topics addressed in the training. For in-service teachers, positive training effects were found for both outcome measures (perceived counseling competence and declarative knowledge). For pre-service teachers, training effect emerged for knowledge, but not for self-ratings of counseling competence. The results underscore the importance of training teachers’ counseling competence, and indicate that even a relatively short training can substantially improve teachers’ counseling competence.

Teachers’ understanding of school connectedness: Implications for the development and implementation of school based injury prevention strategies

CHAPMAN, R. (Queensland University of Technology), BUCKLEY, L. (Centre for Accident Research & Road Safety - Qld, QUT), SHEEHAN, M. (Centre for Accident Research and Road Safety - Qld / QUT)

Worldwide, injury is the leading cause of death and disability for young people. Injuries among young people are commonly associated with risk taking behaviour, including violence and transport risks, which often occur in the context of alcohol use. The school environment has been identified as having a significant role in shaping adolescent behaviour. In particular, school connectedness, the degree to which adolescents feel that they belong and are accepted at school, has been shown to be an important protective factor. Strategies for increasing school connectedness may therefore be effective in reducing risk taking and associated injury. Prior to developing connectedness strategies, it is important to understand the perspectives of those in the school regarding the construct and how it is realised in the school context. The aim of this research was to understand teachers’ perspectives of school connectedness, the strategies they employ to connect with students, and their perceptions of school connectedness as a strategy for risk taking and injury prevention. In depth interviews of approximately 45 minutes duration were conducted with 13 Health and PE teachers and support staff from two high schools in Southeast Queensland, Australia. Additionally, six focus group workshop discussions were held with 35 Education department employees (5-6 per group), including teachers from 15 Southeast Queensland high schools. Participants were
found to place strong importance on the development of connectedness among students, including those at risk for problem behaviour. Strategies used to promote connectedness included building trust, taking an interest in each student and being available to talk to, and finding something positive for students to succeed at. Teachers identified strategies as being related to decreased risk taking behavior. Teacher training on school connectedness was perceived as an important and useful inclusion in a school based injury prevention program. The established link between increased school connectedness and decreased problem behaviour has implications for school based strategies designed to decrease adolescent risk taking behaviour and associated injury. Targeting school connectedness as a point of intervention, in conjunction with individual attitude and behaviour change programs, may be an effective injury prevention strategy.

Team learning in command teams

VAN DER HAAR, S. (PLATO, Leiden University)

In case of large incidents and emergencies, multidisciplinary command teams have the mission to coordinate the multidisciplinary cooperation and actions of different services needed, like the fire brigade, the police and disaster medicine. Therefore, they need to develop a shared cognition as the basis for decision-making. The teams are composed ad hoc, and therefore lack a history and have a short life span. According to Van den Bossche, Gijzelaars, Segers and Kirschner (2006) team learning behavior, defined as processes of construction, co-construction and constructive conflict, gives rise to mutually shared cognition, leading to higher team effectiveness. Past research has not been specific about if and how team learning behavior is used in multidisciplinary command teams. With this study we explore the importance of team learning behavior for the team performance of multidisciplinary command teams. In a first pilot we explored the utility of the questionnaires we developed, and whether team learning behavior is used by the multidisciplinary command team existing of representatives of the police, the fire brigade and disaster medicine. For this pilot we collected data during a realistic exercise these teams do to be prepared for the real work. There was one team, existing of eight team members and there were nine observers. This team had two team meetings. During and after each team meeting, and after finishing the exercise, both the team members and the observers filled out a questionnaire with open ended and closed questions. So there were three measurement moments for each respondent. In addition, we have scheduled a data collection with 24 team exercises, planned on January 19, January 26, February 2, February 9, March 2 and March 9 2010. The aim is to collect data on how team learning behavior is related with the team result, being shared situation awareness and decisions, and with the results of the emergency management as a whole (i.e. number of victims). Again we collect data during realistic exercises of real teams, using multiple methods, and with repeated measures. The pilot showed the team members experienced team learning behavior and they were merely positive about their team decisions. Constructive conflict was the team learning behavior least used. The team members seem to make more use of team learning behavior in the second meeting than in the first. The observers also indicated team learning behavior. They were less optimistic about the team decisions. These findings underline the relevance of this study. The questionnaires had a good utility. Some changes were needed. We improved the instruction of the team members so that they could work faster, and we decided to observe the team results and the results of the emergency management by two different teams of observers. Data collection is ongoing. During the presentation we will present the results of the pilot and the results and implications of the 24 other teams studied.

Temporal changes in the factors influencing psychological contract formation and development in new recruits

WINDLE, K. (Deakin University), VON TREUER, K. (Deakin University)

The psychological contract is a popular framework for understanding contemporary employee-employer relationships. However, its utility as a management tool is potentially limited, largely due to an inadequate understanding of psychological contract formation and development. This paper presents findings from a national longitudinal study aimed at investigating psychological contract content formation in new recruits and the factors that impact development of contract content across the first year of employment. Over 600 Australian employees from seven industry sectors completed an online survey within their first month of employment at an organisation. Follow-up surveys were conducted after 6 and 12 months employment. Instruments used included the Psychological Contract Inventory, EASE Socialisation scale, and organisational outcome measures. Results from the first-wave data collection revealed that the type of psychological contract held by employees was significantly predicted by employer fulfillment of obligations, organisation socialisation, role socialisation, and work environment information. Results from the second-wave data collection demonstrated that the primary factors informing psychological contract content and subsequent type had changed. These predictive factors were employer fulfillment of obligations, employee fulfillment of obligations, social accounts, and careerism attitudes. Results from the third and final wave of data collection are pending early 2010 and will also be presented.

Keywords: employee-employer relationships, longitudinal study, temporal changes, recruits

Test construction by means of confirmatory factor models in considering the position effect

SCHWEIZER, K. (Goethe University Frankfurt)

Since confirmatory factor analysis is a method, which emphasize the homogeneity of the items of a measure, the presence of a position effect may cause a failure in test construction by means of this method. The position effect is a method effect that has been observed in various sets of items. It describes the systematic change in responding to items as a consequence of having already responded to other items of the same measure. Usually an increase in the consistency of responding is observed. In order to avoid model misfit, the model of measurement that is basic to confirmatory factor analysis needs to be upgraded appropriately. Such an upgrade can be achieved for the congeneric and essentially tau-equivalent models of measurement as basis of confirmatory factor analysis. An additional latent variable for representing the position effect can be included in each one of these models of measurement. The loadings on this latent variable needs to be fixed according to the expected position effect. Confirmatory factor models including upgraded models of measurement were applied to two data sets together with conventional models. The items of two reasoning measures were used for collecting the data. The results of investigating the data revealed that the model fit can be considerably improved by integrating a representation of the position effect into the model of measurement. According to the results of the study the position effect can be an actual source of model misfit in test construction. Since the position effect is a disturbance but not a danger to the validity of a measure, the consideration of the position effect can avoid the rejection of a possible valid measure in test construction.
Testing the mediating effects of self-efficacy on the relationships between work-life balance, its antecedents and consequences

WHITE, M. (Australian National University), KALLIATH, T. (Australian National University), MARMEN, J. (Australian National University)

The aim of this research is to develop a model of work-life balance (WLB), its antecedents and its outcomes. In addition, the mediating effects of self-efficacy (SE) between WLB and its antecedents are examined. The impact of WLB on key individual and organizational outcomes is also considered. The study used survey-based data collected from 1134 respondents in Canberra. Structural equation modeling was utilized in data analysis. Antecedents to WLB (mediated by SE) that are considered within the study are family and work control, work and family demands, work-to-family and family-to-work conflict, work-to-family and family-to-work enrichment, and colleague and supervisor support. Outcomes of WLB considered are turnover intentions, job satisfaction, anxiety/depression, social dysfunction, ill-health and job performance. Results show that in the base (non-mediated) model, only time-based and strain-based work-to-family conflict, work-to-family enrichment (affect), and family control are significant antecedents of WLB. Time based work to family conflict was the strongest predictor (β=-.44**) followed by affect-based work-to-family enrichment (β=.12**). The results also indicate that for this model, SE fulfilled the criteria of a mediating variable. The analysis of a mediated model did not show any suppression effect from the proposed mediator (SE). The direct effects of significant antecedents were not affected significantly by the presence of SE as the mediator. This indicates that SE is not a fully mediating variable. The impact of WLB on outcomes was consistent with findings in current research. Evidence was found for the effects of WLB on turnover intentions (-0.32**); psychological strain (both anxiety/depression (-0.55**)) and social dysfunction (0.42**)), ill health (-0.20*), job satisfaction (0.40) and job performance (0.15**). On average, 67% of variance in WLB is explained by the total variances of other variables. The main fit indices (X2=9017.026, df=3460, RMSEA <.05, NNFI .98, CFI=.98, IFI=.98, RFI=.96) indicate that the final model fulfilled fit criteria. The present study breaks new ground by providing evidence for the role of SE in mediating the relationship between WLB and its antecedents. The impact of WLB on key organizational outcome variables is consistent with current research. These findings have both theoretical and practical implications for organizations and working individuals.

Keywords: self-efficacy, work-life balance, job performance, job satisfaction

Thank you for not smoking! How smokers could be tempted towards quitting

GLOCK, S. (University of Luxembourg)

An associative network model of the smoking self-concept was developed which could explain why people smoke, how they feel about smoking, and could provide options to tempt smokers towards quitting. Smokers should feel cognitive dissonance about the harmful consequences of smoking. Nevertheless, they smoke. The model assumes differentiation of the smoking concept into positive and negative subconcepts as a dissonance reduction strategy. Positive aspects of smoking are coping-aspects including coping with stress and controlling performance level. Social aspects of smoking are also positively associated with the behavior including being cool and socially accepted. Positive subconcepts of smoking are linked to the positive valence node, and negative subconcepts to the negative valence node of the self. Because of these cognitive links smokers overemphasize positive smoking aspects to strengthen the positive valence node of the self. Nevertheless, smoking is negatively and positively linked, thus indicating ambivalent attitudes towards smoking. This ambivalent assumption was investigated in an affective priming task (N=30). In this task, smoking and non-smoking related pictures were used as primes followed by a positive or a negative word. Results argue for the ambivalent...
assumption and further indicate that smokers implicitly prefer non-smoking situations. They evaluate smoking situations more negative than non-smoking situations indicating negative feelings about positive aspects. This crucial finding led to the assumption that the associative network could be forced to form more cognitive links, links that connect the positive aspects of smoking with the negative valence node which should result in cognitive dissonance when the negative attitudes towards smoking were strengthened because they show the inadequacy of this dissonance reduction strategy. Using the associative model as well as empirical findings of the affective priming task, new warning labels without health-threatening information were developed and tested in an experiment (N=30). These warning labels contribute to positive smoking aspects and strengthen their negative sides. They were personally and generally formulated. Results showed that general warning labels changed perception of smoking aspects resulting in reduced smoking behavior. The new warning labels pick positive smoking aspects, turn them into negative and take away dissonance reducing strategies. Thus dissonance influences the behavior.

Keywords: smoking, self-concept, cognition, cognitive dissonance

The ability of offenders’ moral reasoning and the forms they prefer: The causal influence between offending behaviour and moral reasoning type

CHEN, C. (Chung Yuan Christian University)

This study aimed to address the question that whether offenders apply forms of moral reasoning they preferred. Four hundred and thirty two incarcerated offenders, consisting of an adult (n=290, M=34yrs, SD=9.0) and juvenile (n=142, M=16.6yrs, SD=1.4) groups, completed this research. Gibbs et al.’s (1992) Moral Reasoning instrument SRM-SF, along with a set of four moral reasoning principle statements formed according to Gibbs’s four-stage model of morality was presented to the respondents. Participants were asked to select the principle provided that reflects their own reasoning, the principle most people in the community adopt, the principle that would help them survive in the community, the principle that is the best for the community, and which is most frequently employed by their friends. The lowest moral level as 1 and the highest level as 4. The highest score was found in the context of “the best” in all offenders, whereas the “self” and “most people” contexts received the lowest score assigned by the juveniles and adults, respectively. Albeit a significant correlation emerged between socio-moral reasoning maturity score (SRMS) (M=288(adult), M=249(juvenile)) and the score for “the best” context in the older group, but was not the case for the “self” in both groups. Besides, offenders’ SRMS were significantly less mature than the moral principle given to “the best” context. These results show that participants distinguished between their own preferred moral reasoning and the moral reasoning they regard as optimal for a community. Also, contrary to the assumptions of developmental models of moral reasoning which define own moral reasoning level as also the limits of one’s comprehension, offenders understand forms of reasoning that would be defined as a developmental level higher than their own. Thereby, one may understand different forms of moral reasoning equally well but from which one selects according to personal preference. Findings support an alternative interpretation of any relation between moral reasoning and criminal activity – namely that a particular form of moral reasoning causes crime but that people with criminal habits may select from their repertoires of forms most consistent with their habits.

Keywords: offenders, moral reasoning, community

The analysis simulation project [ASP]: A new method for simulating complex, dynamic and ambiguous information environments

WEEKS, N. (Macquarie University), WASTELL, C. (Macquarie University), WEARING, A. (University of Melbourne), DUNCAN, P. (Macquarie University)
The aim of the present study was to develop a methodology to investigate reasoning judgment and decision-making in realistic complex, dynamic and ambiguous information environments (e.g. Security and Military Intelligence Agencies). The Analysis Simulation Project (ASP) methodology consists of a computer administered matrix of 64 information cells (50-130 words). The information accessing activity of participants is recorded including information cells selected, sequence of cells selected and the amount of time specific cells are accessed. Functionality testing has shown excellent usability and variability in behaviour. Information processing behaviour can be monitored, tracked, timed and analysed with great precision. ASP Methodology enables researchers to gather data on complex information processing environments that can be used to test a wide array of problems in the literature (e.g. Confirmation bias). Trainers and instructors can provide feedback to analysts as well as generate training and development programs with greater specificity than previously attainable.

Keywords: judgement, decision making, analysis simulation project, information processing, training

The application of the brain potential to a visual search task

YAGI, A. (Kwansei Gakuin University), NAGAE, S. (Kwansei Gakuin University)

Basic studies on the visual event related brain potentials (V-ERP) have brought many fruits on perception and cognition studies. However, it is difficult to apply the V-ERP to practical fields, because of limitation of an eye movement. A specific event related brain potential is obtained with averaging EEGs at terminations of saccadic eye movements. The potential called the eye fixation related potential (EFRP) which shows several characteristics similar to V-ERP. EFRP changes with attention, sensation and cognition. The purpose of the present study was to compare between EFRPs to standard stimuli and those to target stimuli in a visual searching task. 10 participants were asked to search visual stimuli consisting of geometrical patterns on a display. The task was to detect a specific colored pattern. Each pattern was lozenge or rectangular and colored green or blue. Set sizes were 20, 30 and 40. A target was defined by a pattern and a color at each trial. The participant was asked to detect a target. Each participant was assigned 48 trials. EEGs (Oz, Pz and Cz) were measured with amplifiers. An eye movement was measured with an EyeLink1000. EEG epochs associated with terminations of saccades were averaged to get EFRP. EEGs without noise and artifact triggered at offset of saccades were averaged separately to obtain EFRP to the target and other stimuli respectively. The reaction times increased significantly with set sizes. In EFRP, a positive component with latency of around 80 ms after terminations of saccades appeared clearly in all conditions at Oz, Pz and Cz. When the participants detected a target, positive component with latency of about 300 ms appeared significantly at all sites compared with non-targets. The positive component with latency of 300 ms would be the so-called P3 or P300 in ERP. The participant permitted to move eyes freely. In the present experiment, stimuli were presented on a display. Recently, we developed a new system to measure EFRP to objects at natural situations. Thus, EFRP has a possibility to apply to attention studies at industrial settings and at clinical fields.

Keywords: brain potentials, visual searching task

The application of the theory of planned behavior to teaching HIV/AIDS-related issues effectively among junior high school teachers in Indonesia

HINHUAN, Z. (Padjadjaran University), HOSPERS, H. (Department of Health Education and Health Promotion, Faculty of Health, Medicine and Life Sciences, Maastricht University)

It is estimated that there are more than one million injecting drug users in Indonesia (UNDP, 2008). On average, they started to inject when they were 14-15 years old; mostly at school canteens or toilets (Iskandar, 2008). As a result, teachers of local junior high schools have emerged as key players for HIV/AIDS prevention programs. A study was undertaken to explore the application of the Theory of Planned Behavior in explaining the intention among
teachers to teach sensitive issues related to HIV/AIDS effectively. In this cross-sectional study, three hundred and sixteen teachers from 25 different schools completed questionnaires regarding their intentions and behavioral, social and control beliefs in teaching drug education as well as reproductive health. Both environmental and individual barriers were also examined. The statistical analyses reveal that there are significant positive correlations of all theoretical constructs on the one hand and behavioral intentions in teaching HIV/AIDS related issues on the other hand. Almost 40% of the variance in teaching both two subjects is explained by the model variables. In general, their intentions are relatively high although there are several personal and environmental barriers that need to be addressed before the implementation of the programs. Therefore, before implementing the school-based intervention programs in Indonesia, a teacher training program is recommended as the key factor in affecting teachers’ intentions. It is not only to increase their knowledge and skills but also to change their attitude. Active involvement of the parents and other related stakeholders is also encouraged.

The application of vicious cycle anxiety model to women with urinary symptoms: A preliminary examination

MCCOWAN, E. (Sunshine Hospital / Swinburne University), KYRIOS, M. (Swinburne University of Technology)

The current study aimed to delineate the nature of the associations between urinary incontinence (UI) symptom-severity, anxiety and continence safety-behaviour on the quality of life in women with over active bladder (OAB) symptoms. In particular, this study instigated initial testing of the suggestion that the Clark and Wells (1995)’s vicious cycle anxiety model could be applied to individuals with urinary symptoms (Hunt 1996; Perry et al., 2006). This was done in two parts, using multiple regression analyses and tested for mediation effects. Eighty-four women with urinary symptoms, recruited from two continence services in Melbourne, filled in a self-report questionnaire package. This preliminary examination into the application Clark and Wells vicious cycle model to women with urinary symptoms is promising; support was found for both mediation hypotheses, which tested the model. The first part found anxiety partially mediated a relationship between UI symptom-severity and continence safety-behaviour, together anxiety and UI symptom-severity explained half of the variance in continence safety-behaviour. The second hypothesis of the vicious cycle model was also supported. As expected, continence safety-behaviour mediated the relationship between anxiety and the quality of life measure. Together these findings lend weight to the proposition that high scores in anxiety, would lead to continence safety-behaviour, in which over-vigilance, fluid restriction, and toilet availability are prominent issues, and lead to a decrease in quality of life.

Keywords: urinary incontinence, anxiety, quality of life, women, over active bladder (OAB) symptoms

The art of integrating forensic psychiatry/psychology with civil and criminal cases

AKAPUDO, H. (Meharry Medical College), BAILEY, T. (Meharry Medical College)

Forensic psychiatry encompasses the interface between law and psychiatry. A Forensic psychiatrist is first and foremost, a physician. Secondly, they are experts in evaluating individuals clinically, and applying those findings in a legal context. Forensic psychology on the other hand involves applying psychology to the field of criminal investigation and the law. Psychology professionals practice psychology as a science within the criminal justice system and civil courts. Billing in forensics is detailed and challenging, for both psychologists and psychiatrists. After a preliminary consultation, billing is recorded on an activity log. This log records all expenses, including evaluation of client, travel, and others such as testimony and deposition. Contractual rates are fixed, and services are billed based on time, regardless of
content or results. Psychological or neuropsychological assessment is billed separately. Psychological testing or psychometrics assesses the cognitive and emotional functioning of an individual. It involves the integration of information from multiple sources, such as personality testing, tests of ability or intelligence, tests of interests or attitudes, malingering tests, as well as information from personal interviews and collateral information. These standardized assessments help support a clinical diagnosis; and help courts decide issues such as disability, child custody, competency to stand trial, or to help assess job applicants or employees. Psychological assessment, diagnosis and subsequent treatment planning should be inextricably linked to each other. A forensic assessment is only useful if the results can be used to provide a clearer picture of the individual (e.g., needs, motivations, thought integration, relational style, etc.) and some indication(s) of what should be the best way to intervene. In other words, assessment results do more than inform diagnosis. They strongly influence treatment planning. Testifying for anyone is not desirable; however, forensic psychiatrists/psychologists provide this service out of necessity. As a forensic professional it is important to incorporate three fundamental themes of good practice: concrete credibility, an appropriate decorum, and being an advocate for one’s opinion and position. This symposium will address documented civil and criminal cases outlining the processes of evaluations, assessments, billing, treatment modalities, court room testimonies and outcomes.

Keywords: forensic psychiatry, Forensic psychology, criminal justice system, assessment, billing

The bully/victim continuum: Stability of peer victimisation in school and patterns of internalizing and externalizing psychopathology in early adulthood

LODGE, J. (Australian Institute of Family Studies)

This paper uses both prospective and retrospective data to explore patterns of peer victimisation and school difficulties in early adolescence (at ages 12-13 years and 13-14 years); and to examine the longer-term outcomes (at ages 23-24 years) along the bully/victim continuum with respect to internalizing (depression, anxiety, and stress) and externalizing (anti-social behaviour) psychopathology. Initial data on some 1000 young people was drawn from the Australian Temperament Project (an ongoing longitudinal community study). The data presented here are from two time points in adolescence (at ages 12-13 years and 13-14 years) and at follow-up, aged 23-24 years. Participants were classified as belonging to one of four bullying subtypes: bully, victim, bully-victim, or uninvolved. The results show that the experience of peer victimisation in school is relatively stable across time. Furthermore, peer victimisation was also related to persistent levels of difficulties in school, namely social isolation. Results also indicated differences at follow-up (age 23-24 years) between bullies, victims, bully-victims, and those not involved in one of these capacities (uninvolved), in terms of both internalizing and externalizing psychopathology. Specifically, symptoms of anxiety and depression were highest among victims and bully-victims. Victims also reported higher levels of stress: while bully-victims and bullies reported higher levels of anti-social behaviour. These findings underscore the relevance of chronic peer victimisation in relation to adolescent wellbeing. In the longer term, they also point to concerning patterns of internalizing and externalizing psychopathology along the bully/victim continuum – particularly for those who are both victims of and perpetrators of this behaviour. Implications for prevention and intervention programs are discussed.

The competency model of salespersons in the household appliances industry in China

WANG, L. (Beijing Normal University), CHE, H. (Beijing Normal University), LIU, X. (Beijing Normal University), ZHANG, W. (Beijing Normal University)
Abstracts of the 27th International Congress of Applied Psychology

945

Individual Oral Presentations

The purpose of this study was to explore the competency model of Salespersons in the household appliances industry in China. With the stronger and wider competition between companies in the household appliances industry, salespersons become one of the most important factors which decide the success of the household appliances companies in China. Firstly, this paper established a preliminary competency model for salespersons in the household appliances industry by applying the technique of BEI (Behavioral Event Interview) to 20 salespersons and the comparison of the competency characteristic of salespersons with different performances by t-test with SPSS 17.0. Secondly, the competency model built above was checked by natural observation. The observation was carried out between 20 groups of customers and the salespersons who served them. The competency model constructed by both BEI and natural observation has the same two discriminate competent characteristics: Impact and Influence, and Trustworthiness. There were three unique competent characteristics found by BEI method: Achievement Orientation, Learning and Developing, and Emotion Stability. In addition, there were three unique competent characteristics found by natural observation method: Initiative, Insight, Serving Consciousness, and Knowledge of Product. By integrating the discriminate competent characteristics found by BEI and natural observation, we developed the competency model of Salespersons, with nine discriminate competent characteristics included. The competency model of Salespersons in the household appliances industry in China consists of nine discriminate competent characteristics as follows: Achievement Orientation, Initiative, Learning and Developing, Impact and Influence, Insight, Serving Consciousness, Trustworthiness, Emotion Stability, and Knowledge of Product. Natural observation was found to be one of the best methods that can be used to check the competency model developed by BEI.

The concept of human resource systems strength: Empirical testing and contributions for a theory of content versus process in HRM

GOMES, J. (CIS-ISCTE/IUL), COELHO, J. (ISPA), CORREIA, A. (IPS/ESCE)

Bowen and Ostroff’s (2004) concept of human resource systems (HRS) strength is at the core of the current investigation. In strong HRS, employees share a view of desired behaviors, and therefore they exhibit the required patterns of efficient actions. In strong HRS, organizations are likely to show high level of results. Despite this link between the human resources function and performance, there has not been empirical evidence in support of such link. The goal of the current research was to test the link between HRS strength and performance, mediated by situation strength (Mischel, 1973; Schneider, Salvaggio & Subirats, 2002). The model further included leadership as an independent variable, since it has been proposed that it has a impact on how individuals shape their perceptions of the environment (Yukl, 1998). A total of 511 questionnaires were collected in a large hotel chain in Portugal, from both supervisors and employees. Data were collected at multiple level of analysis, from the individual to the department and the hotel levels. The questionnaire had gone through extensive development and testing, prior to the main research. Following Bowen and Ostroff’s (2004), the questionnaire covered a number of key topics: HRS strength, situation strength, organizational performance, and leadership. Biographical data was also collected. Overall, the measures used in the study showed a good set of reliability and validity results. To test the model, confirmatory factor analysis was used. The models which revealed the best pattern of indicators (including normed chi-square, CFI, GFI and RMSEA) were selected. The results showed that there is a positive, direct, and strong relationship between HR strength and situation strength. A weaker but significant relationship was found between HR strength and performance. Positive and strong relationships were also found between leadership and situation strength, and between leadership and HR strength. Situation strength showed a direct and strong relationship with a subjective measure of organizational performance. No significant relationship was found between
leadership and performance. All together, these results provide strong support for Bowen and Ostroff’s (2004) model, although a number of specific results suggest that the theory needs refinement, especially in terms of the subconstructs put forward by the authors. Moreover, the investigation also allows reflecting upon a new measure to assess the nine meta-attributes of HRM strength.

Keywords: human resources, situation strength, leadership, performance

The cultural intelligence scale: What does it measure?

GABRENYA, W. (Florida Tech), TRAME, E. (Florida Institute of Technology), VAN DRIEL, M. (Defense Equal Opportunity Management Institute), PATHAK, J. (Florida Institute of Technology), PETERSON, S. (Florida Institute of Technology), TURNER, S. (Florida Institute of Technology)

Cultural Intelligence (CQ) is a newly popular topic in the cross-cultural psychological literature. CQ studies often assess the construct using the 20-item Cultural Intelligence Scale (CQS). The four components of the CQS (cognition, metacognition, motivation, behavior) show poor face validity, inviting empirical scrutiny of its construct validity. We examined the construct validity of the CQS by looking at the relationships of each of its four components to existing measures and to performance criteria. Native and international students at an American university and international students at a German university (N = 335) were administered the CQS and 11 established measures of self-concept, multicultural attitudes, personality, personal adjustment, and intercultural judgment as well as measures of culture knowledge and cultural experience that were developed for the study. Mixed results were found for each component. For example, CQS-Cognition was weakly related to performance on a culture knowledge test, but was not related to culture judgment. CQS-Metacognition was related to cultural exposure, but only weakly to culture judgment. CQS-Motivation was related in the predicted directions to two measures of multicultural attitudes, but not to sociocultural adaptation. Hierarchical regression analyses were performed to assess the incremental value of the CQS over other measures in predicting sociocultural adaptation and cultural judgment. The CQS was found to have no incremental value. For international students, the CQS had no predictive value for sociocultural adjustment. The Cultural Intelligence Test demonstrates predictive value in certain circumstances despite its lack of face validity, but in others it appears to fall short. Its construct validity is not well established and it appears to be directly or indirectly tapping constructs that are assessed by other established instruments.

Keywords: cultural intelligence, construct validity

The development and validation of a multilingual forced-choice emotional intelligence (EQ) questionnaire for employment

PRIBYL, C. (Otsuma Women’s University), SAKAMOTO, M. (Bunkyo Gakuin University), KEATEN, J. (University of Northern Colorado), SONG, K. (Chungnam National University)

The aim of this research was to develop and validate a multilingual forced-choice EQ questionnaire for employment. This was accomplished by testing the efficacy of an instrument for sorting current high and low performers, and then using the instrument to screen applicants at selected companies in Japan and Korea. A team of Japanese, American and Korean researchers developed a pilot version of a forced-choice EQ questionnaire, called the EQ-NP (Neo-Predictor) based on themes put forth by the EQ Consortium. The test also included questions designed to measure Organization Fit, defined as the EQ of an organization or division within a company. The pilot questionnaire was validated on college and working populations in Japan and Korea, and a final version of 54 question pairs were selected using inter-item correlations, factor analysis, and multiple regression analysis. The questionnaire was then distributed and taken online by approximately 1000 customer-facing current employees in Japan and Korea in the pilot test, and by more than 2000 job applicants. A reliability analysis was run on all items of the EQ-NP; the resulting α was .90, suggesting a high level of internal consistency. Results suggested that
combinations of questions on the EQ-NP are able to effectively sort current employees based on company-determined Key Performance Indicators (KPIs), for example, sales, customer contacts, length of employment, etc. The explained variance (R2) analysis for both Japan and Korea ranges from .60 to .80 depending on the job and the country. Further, among a group of more than 2000 applicants for the jobs where the EQ-NP was used as a screening tool, the ability to predict higher than average performance ranged from 64% to 96%. Initial results of the development of a forced choice suggest that the EQ-NP is of use as a screening test in both Japan and Korea. With high levels of predictive ability, the test provides an objective prediction of an applicants’ ability to effectively perform the work for which they are applying. However, more testing needs to be conducted to determine the long-term results of those hired with the EQ-NP, as well as determine its validity for other positions.

The development and validation of the Quality of Performance Appraisal Systems Questionnaire

STEYN, R. (University of South Africa)

The perceived quality of a performance appraisal system (PAS) utilized by an employer, may influence the employee’s levels of work engagement and job satisfaction. Although measures of work engagement and job satisfaction are readily available, no measures could be located to measure the quality of a PAS in a comprehensive manner, and as such it was not possible to test the hypothesis stated in the first sentence of this abstract. The aims of the study are to develop and evaluate the Quality of a Performance Appraisal System Questionnaire (QPASQ) and to provide practitioners with information regarding the elements of a PAS that influence behavioral outcomes most significantly. The items of the QPASQ were compiled after a thorough study of literature pertaining to the dimensions of an effective PAS developed. Aspects of quality addressed in the questionnaire included procedural and substantive indicators. 300 students at a large South African business school, most of them employed in the role of middle managers, completed the QPASQ and standardized measures of work engagement and job satisfaction. The statistical techniques utilized to evaluate the questionnaire and assess the relationships between the constructs are reflected in the discussion of the results. The development of the questionnaire is discussed together with some psychometric characteristics of the scale. These include the factorial structure of the questionnaire and the relationship between QPASQ scores and work engagement, job satisfaction and the related intention to quit. Central statistics, as well as results pertaining to gender and race bias are also reported. Recommendations on the use of the QPASQ as well as suggestions for further research are presented. Of particular interest is how specific element of a PAS relates to behavioral outcomes. This will allow practitioners to design PAS and communicate information about systems that will enhance positive work outcomes.

Keywords: performance appraisal, work engagement, job satisfaction, Quality of a Performance Appraisal System Questionnaire, behavioral outcomes

The development of an instrument to assess the unmet needs of young people who have a sibling with cancer

PATTERSON, P. (CanTeen), MILLAR, B. (CanTeen), BUTOW, P. (University of Sydney), WHITE, K. (University of Sydney), PEARCE, A.

This presentation will report on the development of a needs measure for young people (aged 12-24 years) who have a brother or sister with cancer - the Sibling Cancer Needs Instrument (SCNI). It is the first known wide-ranging needs-based measure for this population – aiming to systematically assess and monitor the needs of this comparatively under-researched and largely under-serviced population. Phase 1 of the project involved a qualitative exploration of needs with this population (focus group, telephone interviews), and a survey of staff who worked with them
resulting in the first version of the SCNI. Following this, the SCNI was piloted on 71 young people. Phase 2 consists of psychometrically testing the latest version of the SCNI (73 items across 7 conceptual need domains) on a wider and larger sample, as well as measuring psychological distress and identifying risk and resilience factors such as family functioning, sibling relationship, and parent/child relationship. Results regarding unmet needs in the following domains will be reported: information about my sibling’s cancer; time-out and recreation; practical assistance; support from friends and other young people; dealing with feelings; understanding from family, and relationship with sibling. As well, the relationship between these unmet needs and other indices, such as family functioning and psychological distress will be discussed, along with preliminary reports on the psychometric properties of the SCNI. The development of the SCNI measure is an important step in assisting to systematically assess, monitor and better meet the various needs of this under-serviced population of young people at risk of ongoing psychosocial challenges, both within the family and in the community at large.

The differential effects of work-group resources on well-being and engagement for male and female police officers

BIGGS, A. (Griffith University), BROUGHR, P. (Griffith University), BARBOUR, J. (Griffith University)

Research investigating gender differences in well-being within high-stress, traditionally masculine occupations, has often produced conflicting results. Although some research has demonstrated that significant differences exist between males and females for a range of physical health and psychological well-being indicators, other research has failed to establish such differences. A limitation of much of this previous research is the tendency for gender differences to be studied in isolation, which fails to account for contextual factors that may assist in explaining the presence or absence of significant effects. To address this limitation, the present research adopted a contextual approach to the investigation of gender differences. Utilising the motivation hypothesis of the job demands-resources model as a theoretical framework, the primary purpose of this research was to investigate the moderating effect of gender in a structural equation model (SEM) containing several resource variables and well-being indicators. This research extends current occupational stress research by incorporating multiple forms of resources available to employees, such as individual job-related resources (control over the timing and method of work), individual-organisational interface resources (e.g., alignment with strategic priorities), work-group level resources (supervisor support, colleague support, and workgroup cohesion), and non-work resources (social support from friends and family). Furthermore, this research also adopted a positive-strengths focus in which the ability of resources to predict three positive health outcomes was included. The sample consisted of 1956 male and 626 female police officers, who completed an online questionnaire. Results indicated that supervisor and colleague support, greater alignment with the strategic priorities of the organisation, job control, and work-group cohesion were associated with positive well-being, higher engagement, and greater intrinsic job satisfaction. After establishing factorial invariance of the measurement model, a number of structural pathways from resources to well-being were moderated by gender. Although this research was limited due to the cross-sectional methodology employed, the relationships discussed above will be examined further utilising longitudinal data (in early 2010).

The discounting effect of counterfactual thinking in economic decision-making

LIAO, J. (Tsinghua University), PENG, K. (University of California - Berkeley), WANG, L. (Peking University)

Counterfactuals are thoughts of what might have been. Previous research has indicated that counterfactual thinking has a preparatory function. This function plays a role in behavior
Abstracts of the 27th International Congress of Applied Psychology

949

Individual Oral Presentations

regulation and performance improvement. The purpose of this study was to explore the impact of counterfactual thinking on economic decision-making, in order to clarify the contribution of the prepared function of counterfactual thinking for economic Decision-making. We investigated 289 stock investors in real situations in the first study, and 106 students in simulated situations in study two and three. The results indicated that the findings were inconsistent with prospect theory on risk decision. In study one, the stock investors tend to be conservative to make decisions and set the invest goals (stop loss and stop gain) when facing high risk conditions after priming counterfactual thinking, which inhibits risk-seeking. On the other hand, subjects tend to be adventures when facing low risk conditions after priming counterfactual thinking, which promotes risk-seeking. For the control group, there were no significant differences for the subjects to set the invest goals in different risk conditions after priming counterfactual thinking. The discounting effects were found where counterfactual thinking impacts on economic decision-making.

The dynamics of the factors of occupational prestige during financial and economic crisis

NAYDONOV, M. (Institute of Social and Political Psychology), NAYDONOV, M. (Institute of Social and Political Psychology), GRYGOROVSKA, L. (Institute of Social and Political Psychology), NAYDONOVA, L. (Institute of social and political psychology), KHorINA, O. (Institute of Social and Political Psychology)

Inadequate quality of the labor force becomes more and more critical for Ukraine, as well as disproportion between employment market and educational services market. The deficit of workers’ occupations is most acute. The development of entire career guidance systems for the young generation is one of the ways to solve this problem. The prestige of workers and other mass professions should be further enhanced. While choosing the research methods we made an assumption that one of the factors which has become the reason of imbalance between the employment market and educational market is public belief about occupational prestige. The questionnaire we used was compiled in line with the titles classifier currently acting in Ukraine based on ISCO-88. The monitoring of the level and psychological factors of the prestige in occupational choice had two cycles of representative across-country survey (N = 2400) to define the status level of certain occupations. Focus-group research was also carried out with a variety of target audiences was directed at discovering the causes of the choices. There is a difference of prestige conception between two group categories: adults and young people from Ukraine. The research reveals directions of change in forming the ideas about prestige among youth who did not experience Soviet ideological system influence (socialization after Soviet era collapse). Labor market reactions resulted in the changing of the rating of factors of occupational prestige, these included: social capital (helpful acquaintances became more important), weights of comfortable labor conditions, personal independence, opportunity for creativity, and carrier perspectives which decreased in adult cohorts. Personal independence and opportunity for creativity remained as important factors of the occupational prestige in crisis circumstance for teenagers. Solid prognosis was made with regard to popular amid masses occupations, which are in deficit, for the period of three to five years for the Ukrainian labor market dynamics. Both objective and subjective reasons for occupational prestige were taken into consideration. In order to verify the social transformation effect on the psychological mechanisms of occupational prestige dynamics it is necessary to consider cross-cultural frameworks to compare the research results with the latest international research data.

Keywords: career guidance, Ukraine, social transformation, occupational prestige

The effect of “victim participants” expression of emotions on the judgments of mock jurors

SHIRAIWA, Y. (University of Tokyo), KARASAWA, K. (University of Tokyo)
The Flexible Correction Model (FCM: Wegener & Petty, 1997) suggests that people can adjust their judgments toward a target if they are aware of the contextual effect which may bias their judgments. The present study examined if the jurors whose attention were attracted to the burning emotion of “victim participant” would be conscious of the possible bias in their judgments and, as a result of an overcorrection, make judgments in favor of the defendants. To make mock jurors be conscious of the possible bias in their judgments, the hypothetical victim’s mother or father was depicted to serve as the “victim participant” who expresses bald emotions in court. 131 Japanese undergraduate students participated in the study. They read a scenario depicting a mock trial and made judgments on the appropriate punishment for a homicidal defendant. The scenarios were manipulated on who the “victim participant” was (victim’s mother, father, or their lawyer) and their emotional reaction (anger, grief, or impassive). In the bias-inducing condition, the victim’s parent was depicted to express their emotion in bar. Respondents’ sentence judgments in such conditions were compared to those in the control condition where the victim’s lawyer talked unemotionally. Contrary to our assumption, the ANOVA revealed that the two manipulated factors (victim participant type and their reaction) had no significant effect on the sentences the respondents gave. In this study, overcorrection based on FCM was not observed. Moreover, whether the “victim participant” showed emotional or impassive reactions had no influences on sentence. Japanese legal experts consider the “victim’s participation” system as problematic because the judgments of citizen judges (naive lay public) would likely be influenced by the degree of emotion expressed by crime victims and their family, consequently giving overly severe penalty to the defendants. However, the empirical findings of this study showed a lack of impact of “victim participants” on sentences.

Keywords: contextual effect, judgement, victim participant, bias

The effect of different types of music on mood and verbal performance

AU, A. (James Cook University), MILLER, S. (Queensland University of Technology)

This study aimed to investigate the arousal and mood effect of different types of music on verbal performance, on the basis that: 1) there are shared neural substrates between language and music such that the brain processes language like music in terms of its auditory properties like tone and pitch; and 2) music training can improve children’s reading ability. Seventy-eight English-speaking undergraduates were selected based on their neither-type preference in the Composite Scale of Morningness to control for chronotype. They were allocated randomly to 3 different music conditions in order to induce a corresponding emotion: happy, sad and neutral (control) conditions. The different music types controlled for mood between conditions, with each group consisting of 26 participants. Positive and negative affect as measured by PANAS was taken pre- and post-music exposure. Verbal performance as measured by PPVT4 was taken after music listening. Behavioural responses as measured by finger tapping was obtained during music listening. Results showed that listening to different types of music did not induce significant changes in one’s positive and negative affect or arousal. Although participants tapped more in happy music than in sad music, there were no significant differences in verbal performance among the 3 music conditions. It was concluded that different types of music may selectively affect only certain cognitive tasks and can have differential effect on various behavioural and cognitive measures. Methodological issues and implications of the use of music in language learning are discussed.

Keywords: arousal, mood, music, verbal performance

The effect of leader-member exchange and coworker trust on safety behavior

JIANG, L. (Chinese Academy of Sciences), LI, Y. (Chinese of Academy Sciences), LIU, X. (Chinese of Academy Sciences)

In the present study, we examined leader-member exchange and coworker trust as predictors of safety behavior. Drawing on social
exchange theory and the norm of reciprocity, we proposed a mediated model predicting employee safety behavior. The model was tested using a cross-sectional survey. The participants were 232 air traffic controllers and air maintenance in China. A total of 94% of them were male. Hierarchical regression analysis showed that leader-member exchange was positively related with both safety compliance and safety participation. Affect-based coworker trust partially mediated the relationship between leader-member exchange and safety participation, while cognition-based trust did not show this trend. This study adds to the safety behavior literature that cognition- and affect-based coworker trust can play different role. Implications of these findings are discussed.

Keywords: leader-member exchange, coworker trust, safety, social exchange theory, reciprocity

The effect of personality disorders and coping styles on addict’s attitude towards addiction and selection of kinds of drugs

KOOSHKI, S. (Islamic Azad University)

The purpose of this study was to examine the effect of personality disorders types and its severity and coping styles on the attitudes towards use, and selection of drug used. 375 male adults belonging to various groups of drug users by stratified sampling completed a Personality Disorders Questionnaire (PDQ4; Hiller & et al., 1992), Coping Style (Carver & et al., 1989), Attitude on Drug Use Questionnaire (DeRight, 1998), and Demographic Characteristics Questionnaire. The findings confirmed that a meaningful relationship does exist between personality disorders, and attitude towards drug use, coping styles, and attitude towards drug use. It also become apparent that differences between coping styles and drug type used are not meaningful. Results also indicated that the role of each person’s attitude in prediction of personality disorders. The findings emphasis the necessity of prevention programs for reduction of personality disorders, coping styles for drug dependant persons and effective attitude–altering programs related to drug use.

Keywords: personality disorders, coping styles, drug use, attitudes, drug dependence

The effect of situational factors on unsafe driving behavior

LI, Y. (Chinese Academy of Sciences), JIANG, L. (Chinese Academy of Sciences), XU, Y. (Chinese Academy of Sciences)

The purpose of the current study was to explore the effects of situational factors on unsafe driving behavior. Specifically, we empirically tested the impact of time pressure, descriptive norms, as well as the base rate of accident on drivers’ violation behavior. A total of 168 drivers were recruited to read two of eight scenarios and were asked a series of questions after each scenario, respectively. Demographic questions were at the end of the survey. A 2 x 2 x 2 mixed design was used for the scenarios, with one within-subjects variable (descriptive norms) and two between-subjects variables (time pressure and safety record of local district). Hierarchical Linear Modeling (HLM) analysis showed that the demographic variables were not significantly related with the driver’s violation behavior, so they were not taken into account. HLM analysis showed descriptive norms are negatively related to driving violation behavior, and time pressure is positively related to driver’s violation behavior, while base rate of accident is not related with unsafe driving behavior. Results from this study indicate that drivers’ behavior would be significantly different under different context. The implications of these results for traffic safety research as well as traffic safety managerial practice were discussed.

Keywords: situational factors, unsafe driving behaviours, time pressure, violation behavior, accidents

The effect of the length of meditation experience on muscle relaxation

CHU, L. (Chung Shan Medical University)

Muscle tension is an automatic physical response to stress, and the literature overwhelmingly indicates that meditation is an effective treatment for it. The benefits of
meditation may be attributed to its nature. Lutz, Slagter, Dunne, and Davidson (2008) found that meditation practices’ potential regulatory functions on attention and emotional processes can cultivate such ends as well-being and emotional balance. Although the research literature has clearly provided considerable evidence that meditation practice can reduce muscle tension, few published studies have inquired into whether it is more effective for people who have lengthy meditation experience than for those just starting. The development of concentration or mindfulness through the experience of meditation would become increasingly effortless in sustaining focus or surrendering to the flow of experience without emotional disturbance (Epstein, 1990; Lutz et al., 2008). This means that its effects in terms of muscle relaxation could vary with the length of time people have been practicing meditation. This study tested whether the amount of experience that people have in practicing meditation can affect the extent and the onset time of muscle relaxation while meditating. We assigned 20 male and female graduate students at National Central University in Taiwan randomly to an experimental meditation group and a control group. The meditation group consisted of participants with different amounts of meditation experience. One had more than five years of such experience, one between three and five years, three had between one and three years, three had less than one year, and two had none. The control group consisted of only participants with no meditation experience. We defined meditation experience as having learned to practice meditation before participating in the experiment and having had a regular daily habit of practicing meditation for at least 20 minutes. We recorded the participants’ psychophysiological measure of stress as reflected by their muscle tension with an EMG, both before and after each treatment. Each participant in the experimental group took part in an eight-session meditation program, with each session lasting for 20 minutes. The control group subjects did not receive any relaxation training. The repeated measure ANOVA was used to investigate changes between baseline and post-intervention scores in the EMG measures. The results show that the meditation group had significantly reduced EMG activity on the right and left shoulders after meditation treatment ($t_{right} = 3.85; p < 0.01; t_{left} = 3.22; p < 0.05$). However, the control group experienced no significant change between the baseline and post-intervention scores in the EMG measures. In order to explore whether the length of the meditation experience benefited muscle relaxation, we not only used an analysis of one-way ANOVA tests to compare the mean differences in the EMG measures for the various meditation experiences of the meditation group, but also engaged in qualitative tests to simultaneously depict the change in the state of muscle tension during the meditation process. Scheffe’s post-hoc test showed that subjects with over three years of meditation experience experienced greater muscle relaxation than those with no meditation experience after meditation practice. We also found that the shoulder muscles of a participant who had been practicing meditation for more than five years relaxed significantly more quickly than those of one with no previous meditation experience. These findings indicate that the amount of time people have been practicing meditation affects the extent and rapidity of muscle relaxation during meditation. This study found that the amount of meditation experience people have affects the speed with which muscle relaxation during meditation occurs, with the muscles of the participant having the most experience relaxing more quickly during the meditation process than those of a participant with no previous experience. This leads to the conclusion that the ongoing practice of meditation may lead to increasingly efficacious physical relaxation. This means that those who practice meditation frequently and repeatedly can control themselves, and therefore return to a normal state of body and mind, with increasing rapidity whenever they become nervous or upset. We suggest that meditation practice could be incorporated one’s daily routine career or family.

Keywords: meditation, muscle relaxation, experience
The effect of trust in authority on cooperation: The mediator roles of distributive fairness and procedural fairness

ZHANG, Q. (Chinese Academy of Sciences), WANG, E. (Chinese Academy of Sciences)

The present research aims to explore the effects of trust in authority and fairness on people’s attitudes and cooperative behaviors across disaster and non-disaster social situations. We applied one field study in disaster situation (study 1) and one experimental study in non-disaster situation (study 2) to investigate the effect of trust in authority on people’s attitudes and willingness to cooperate, and to further examine the mediator role of fairness. In study 1, we collected 424 survey data during the reconstruction process after “5.12" Wen Chuan Earthquake in China. Trust in local government, distributive fairness, satisfaction of local government and willingness to allocate resources to communal goods were measured. In study 2, we manipulated two level of trust in authority (high vs. low) in a community scenario. 55 undergraduate students participated in the experiment. Distributive fairness, procedural fairness, satisfaction of community agent and cooperative behavior were measured. The results showed that both in disaster and non-disaster social situations, trust in authority affect people’s evaluations of authority and their cooperative behaviors. The more people trust, the more positive they evaluate the authority, and the more resources they are willing to allocate to communal goods. Furthermore, procedural fairness as well as distributive fairness partially mediates the effect of trust in authority on evaluation. While only distributive fairness mediate the effect of trust in authority on cooperation which is different from the prior research done in western culture background. Results from 2 studies in different social situations provide consistent evidence for the effects of trust in authority and fairness on people’s attitudes and cooperative behaviors. This study tries to apply social psychology approach to the field of public administration on topic of trust in authority to investigate the mediator role of fairness in the relationship between trust and cooperation, and also compare the effects of distributive fairness and procedural fairness.

Keywords: authority, distributive fairness, disasters, procedural fairness

The effect of vehicle speed and motion perception ability on elderly pedestrians’ crossing decisions

The present experiment investigated perceptual age-related factors likely to contribute to risky street-crossing decisions in elderly pedestrians. Previous research has shown that older people make many unsafe crossing decisions when vehicles approach at high speed, but miss many crossing opportunities when vehicle speed is low. It can be assumed that elderly pedestrians have trouble in analyzing vehicle motion and thus mainly use simplifying heuristics based on vehicle distance. The purpose of our experiment was to determine whether the elderly peoples’ crossing decisions are actually explained by their capacity of motion perception. 20 young (20-30 years), 20 younger-old (61-70 years) and 20 older-old (71-83 years) participants took part in the experiment. All participants carried out a street-crossing task in a virtual environment displaying an urban scene with traffic coming from one side. The time gap between the cars varied between 1 and 7 seconds. Five vehicle speeds between 30 and 70 km/h were simulated. The participants had to cross the experimental road when they judged that crossing between the approaching cars was safe. They were also submitted to a series of motion discrimination tasks. In line with earlier findings, elderly pedestrians exhibited more risky decisions when vehicles approached at high speeds and missed more opportunities to cross when vehicles approached slowly. Regression analyses indicated that in young pedestrians, neither unsafe decisions nor missed opportunities were predicted by motion discrimination tasks. In line with earlier findings, elderly pedestrians exhibited more risky decisions when vehicles approached at high speeds and missed more opportunities to cross when vehicles approached slowly. Regression analyses indicated that in young pedestrians, neither unsafe decisions nor missed opportunities were predicted by motion discrimination thresholds. In younger-old pedestrians, the capacity of speed discrimination predicted unsafe decisions at high speeds as well as missed opportunities at low speeds. In older-
old participants’, only missed opportunities were explained by motion discrimination thresholds. As a whole, these findings demonstrated that motion discrimination abilities play an important role in elderly pedestrians’ street-crossing behaviour. The decline in motion discrimination was found to explain risky decisions especially in early aging. Other factors, such as cognitive and motor declines, are likely to become predominant at later aging. More generally, our study confirmed that high vehicle speed is an important risk factor for elderly pedestrians as it is often not perceived. Traffic calming measures, especially in urban areas, can be recommended as an effective countermeasure.

Keywords: motion perception, elderly, pedestrian crossings, judgement

The effectiveness of dialectical behavior therapy for borderline personality disorder: A naturalistic investigation

HALL, M. (Deakin University), MELLOR, D. (Deakin University)

The first aim of this study was to investigate whether Dialectical Behavior Therapy (DBT) is effective with real world clients in real world settings in Australia. The second aim was to investigate whether a modified version of group-only DBT is as effective as the more comprehensive manualized version. Thirty-seven individuals with Borderline Personality Disorder (BPD) who were referred to DBT across two community mental health services were included in the study. The seven individuals who completed a modified version of DBT in one setting were compared to six individuals who completed the full version of DBT in another setting. Individuals were assessed before and after a year-long cycle of DBT with the following assessment tools: The Structured Clinical Interview for the DSM-IV I and II, the Suicidal Behaviors Questionnaire, the Beck Depression Inventory – Second Edition, the State-Trait Anxiety Inventory, the World Health Organization Quality of Life – Brief, the Ways of Coping Checklist, and the Affective Controls Scale. Results revealed that both groups showed significant reductions in the number of borderline personality disorder traits, self-reported depression, and fear of anxiety and depressed mood. The more comprehensive version of DBT was superior in reducing the number of comorbid conditions as well as state anxiety. A more cost-effective version of DBT can be successful in producing change in those with BPD. However, the more comprehensive manualized version of DBT is superior on some but not all outcomes.

Keywords: dialectical behaviour therapy, borderline personality disorder

The effects of personality, cultural context, and situation on environmental concern: Comparing zoos and universities in the U.S. and China

CLAYTON, S. (The College of Wooster), PAPE, K. (The College of Wooster)

The increasing salience of environmental problems has led to increasing interest in understanding environmental attitudes. Surveys routinely indicate less public concern about some environmental issues, for example climate change, than most experts consider appropriate. Perhaps more important, most people are not demonstrating the significant behavioral changes needed to address environmental problems. Although they may not consider the issue to be important, it is also possible that they believe responsibility for addressing the issue lies elsewhere. What predicts environmental concern and beliefs about how environmental issues should be addressed? How can environmental concern and understanding be increased? The present study was designed to examine the impact of several important factors on environmental concern. Firstly, cultural context, in which we compared two countries where environmental issues are highly salient but where the sociopolitical structure is very different: China and the U.S. To date, environmental attitudes in China have not been extensively studied; some surveys suggest a fairly low level of concern as well as knowledge about environmental problems. In order to better understand the reasons for cross-country differences, we also measured some personality variables: level of national identification, and self-construal. Finally, we wanted to explore the
The possibility that situations can be deliberately constructed to heighten environmental concern. Zoos in the U.S., and to some extent in China, try to deliver a conservation message. Thus we compared zoo and non-zoo locations. Data were collected in four locations: in a small U.S. zoo, a liberal arts college in the U.S., the Panda Research Base in Chengdu, China, which is a zoo-like facility with a strong conservation theme, and Sichuan University, also in Chengdu. At least 50 participants were surveyed in each location. Surveys included brief measures of environmental concern, national identity, and perceived responsibility to address environmental problems, as well as Singelis’s Self-Construal scale, a measure of interdependent or independent self-concept. Results are discussed in terms of cultural differences, and particularly in terms of how these variables relate to perceived responsibility for addressing environmental problems.

Keywords: environmental attitudes, climate change, cultural context, personality variables, zoo

The effects of transformational leadership on employee innovation and job performance: Explicating the mediating effects of regulatory focus

WILSON-EVERED, E. (Monash University), REITER, M. (Monash University)

This study examined the possible process through which transformational leaders influence followers’ innovation and performance levels and proposed a mediating role for regulatory focus. We hypothesized that promotion focus and prevention focus would mediate the relationship between transformational leadership and innovation and transformational leadership and job performance. In sum, in line with previous research and in light of the conceptual links discussed, the present study hypothesised that transformational leadership would explain significant variance in innovation and performance after controlling for the influence of the demographic variables and positive/negative affect. Second, promotion focus was expected to be positively related to innovation and performance, and prevention focus negatively related to the outcome variables. Third, transformational leadership was expected to be positively related to promotion focus and negatively associated with prevention focus. Fourth, promotion focus and prevention focus were predicted to mediate the relationship between transformational leadership and innovation. Finally, theoretical reasoning suggested that promotion focus and prevention focus would mediate the relationship between transformational leadership and performance. The sample included 174 employees from various organizations in Victoria who were invited to complete an anonymous on-line survey. The majority of respondents were from the private sector organizations (57%), with (48%) from organizations with more than 500 employees. Of the 174 employees in the study sample, (63%) were female and (37%) were male. The average age of participants was 36 years (SD=10.96, range = 19-64). The average length of tenure was 5 years (SD= 5.77), and the average length of time in their occupation was 9.8 years (SD= 9.7). The majority of employees (68%) were in positions that held no management responsibility. Discrete relationships within the research model were analysed using a series of hierarchical regression analyses. The effects of demographic variables such as job level and gender, as well as positive/negative affect were controlled in the hierarchical regressions. Multiple regression analyses were conducted to determine the extent to which transformational leadership, regulatory focus, positive affect, negative affect and other demographic variables explained unique variance in the criterion variables. The data from the regressions demonstrated the pattern of association among the predictors and criterion variables, innovation and job performance and were largely in support of the hypotheses. The study investigated the relationship between transformational leadership, regulatory focus and the important organisational outcomes of innovation and performance. The study contributes several important findings to the understanding of how leadership and individual motivation orientations influence employee innovation and job performance. First, the study extends regulatory focus research to contribute to the understanding of the complex nature of the mediating influences of this individual difference.
construct. Second, in delineating and supporting the linkages among transformational leadership, regulatory focus and performance outcomes, the findings inform leadership approaches to different individual motivational orientations in organisations. Third, these findings provide an empirical response to the needs for research to investigate whether situational primed participants achieve the same results as chronically predisposed participants. Fourth, this study also responds to scholars’ call for further research to determine the appropriateness of the different scales used to measure regulatory focus, to ensure they are measuring a single phenomenon. Although a number of hypotheses were not supported, these non-significant results are useful for contributing to the iterative process of theory development (Cervone et al., 2006).

The effects of vipassana meditation on well-being, mindfulness and substance use

WERTHEIM, E. (La Trobe University), SZEKERES, R. (La Trobe University), WERTHEIM, E. (La Trobe University)

This paper reports on two studies examining the effects of Vipassana meditation in a community sample. Vipassana is a meditation technique taught worldwide in 10-day residential courses. While some independent research has been conducted overseas most studies examine Vipassana in prison settings. Study 1 examined whether individuals with prior experience of Vipassana (old students) report greater well-being and mindfulness and less substance use than individuals without prior experience (new students). Study 2 examined whether students completing the Vipassana course, compared to a waitlist control group, scored higher on well being and mindfulness and lower on stress and substance use at post course. Whether changes were maintained at follow-up and due to actual meditation practice were examined. Study 1 participants were 233 adults (56.2% new students) enrolled to complete a Vipassana meditation course in NSW. Online or hardcopy questionnaires assessed demographics, meditation practice, mindfulness, well being and substance use. In Study 2, 184 participants completed measures at pre-course, 122 at post-course, and 90 at the 6 month follow-up. A waitlist control group (n=50) also completed measures at two time points before commencing the course. At baseline old students scored significantly higher (MANOVA) on mindfulness, acceptance and self-compassion and lower on stress compared to new students. Overall WHO wellbeing scores did not differ. Old students were also found to abstain significantly more from substance use during a typical use week in the preceding three months. More frequent meditation practice was associated with greater well being, mindfulness, self-compassion and abstinence from alcohol. Repeated measures ANOVAs indicated Vipassana course participants improved more than control participants from pre-course to post-course on well-being, mindfulness, stress and self-compassion, but not substance use. Six month follow-up will be reported as will associations between frequency of practice and well-being. Study 1 provided some support for the efficacy of Vipassana meditation over the long-term, particularly among those practicing the technique more frequently. However, the possibility that older students were not typical of all Vipassana students limits generalization. Study 2 will more clearly indicate the effects of the Vipassana course immediately post course and at a 6-month follow up.

Keywords: vipassana meditation, well-being, mindfulness, substance use

The empirical research on the relationship between organizational culture and organizational commitment under organizational change

CHEN, L. (Zhejiang University), WANG, S. (Zhejiang University), LIU, F. (China Gezhouba Group)

With the fierce competitions of enterprises worldwide, organization changes are launched frequently. Traditional paradigm in studying organizational change focused on macro problems, such as organizational development, strategy choice. We wanted to study
organizational change from micro perceptive and in individual level. We treated organizational change (OC) as context variable, and concentrated on organizational commitment. The purposes of our study were: (1) find the differences of organizational commitment and organizational cultures between the units with OC and units without OC; (2) explore the relationship between organizational culture and organizational commitment under the circumstance of OC; and (3) develop strategy to improve organizational commitment for companies under changes through construction of organizational culture. We used the Competing Value Framework of Organizational Culture and hypothesized: (1) OC would influence organizational commitment and organizational culture, whereby lower Organizational Commitment would be found in Units with Changes; (2) Organizational culture in the units with changes would be dominant by the value of Adhocracy and Market, otherwise the units without changes would be dominant by Clan and hierarchy value; (3) Organizational culture would be positively related to organizational commitment under the OC. Measures of OC (self-developed), Organizational Commitment (Porter Mowday, 1979), Organizational Culture (Quinn, 1991) were used. We chose China Gezhouba Group, a state-owned company with 36,000 employees, as our study sample. In last five years, the Gezhouba Group experienced a series of OC. We investigated 1000 respondents in Gezhouba China Group and obtained 546 valid responses. The statistical method used was a regression analysis and ANOVA. Our result indicated that hierarchy, adhocracy and market value of organizational culture was positively related to affective Commitment, but only Market value was positively related to Normative Commitment and Continuance Commitment. It also demonstrated that technical changes in organization would significantly influence employees’ organizational commitment negatively, but structure changes and managerial system changes had no significant impacts on organizational commitment. Employees in the units with changes would perceived lower Clan value. Our study verified that relationship between organizational culture and organizational commitment under OC. It also revealed that in Chinese background, technical changes will easily have negative impact on organizational commitment. The implication of these results was discussed and further researches were proposed.

Keywords: organisational culture, organisational commitment, organisational change

The epidemiology of non-suicidal self-injury (NSSI) in Australia

SWANELL, S. (The University of Queensland), MARTIN, G. (The University of Queensland), PAGE, A. (The University of Queensland)

The aim of the present study was to estimate the prevalence and describe the features of non-suicidal self-injury (NSSI) in the Australian population by sociodemographic and cultural variables, psychiatric morbidity, childhood trauma and substance use. 12,006 Australians aged 10+ who were randomly selected from the Australian Electronic White Pages completed a 14 minute Computer Assisted Telephone Interview (CATI). The interview included questions on demographics, NSSI, general mental distress, childhood trauma and substance use. Odds ratios and chi squares were calculated to derive measures of effect size between groups. The four week prevalence of NSSI was 1.1% (n = 129) and was slightly higher for women (1.2%) than men (0.9%). It was also higher among Indigenous respondents (2.4%; n = 4) compared to the overall sample, but the Indigenous sample size was small (n = 183) and so results should be interpreted with caution. The most common methods of self-injury were scratching (45.9%) and cutting (33.8%) for females and hitting a part of the body on a hard surface (20.4%), scratching (18.5%) and cutting (18.5%) for males. For both men and women the most common reasons for NSSI were emotional regulation (56.9%) and self-punishment (26.4%). Respondents who self-injured were 10.0 times more likely to report clinically severe mental health problems (95% CI=6.6-15.2), 4.0 times more likely to report neglect (95% CI 3.4-4.6, adults only), 4.1 times more likely to report physical abuse (95% CI 3.5-4.7, adults only), 4.0 times more likely to report sexual abuse (95% CI 3.4-4.8, adults only), 3.7 times more likely to smoke tobacco (95% CI=2.6-5.3), 5.1 times more
likely to drink to get drunk (95% CI=3.3-7.9), and more likely to use marijuana (OR=3.7, 95% CI=3.3-4.3), amphetamines (OR=3.8, 95% CI=3.3-4.5), ecstasy (OR=3.8, 95% CI=3.2-4.5), inhalants (OR=5.7, 95% CI=4.3-7.7), heroin (OR=5.6, 95% CI=4.0-7.9), cocaine (OR=3.6, 95% CI=2.9-4.4) and LSD (OR=3.5, 95% CI=2.9-4.2). The respondents who reported NSSI were, in many ways, a troubled group at higher risk of psychological morbidity than the general population. The proportion of NSSI among males and females was not very different, perhaps challenging the traditional view that NSSI is more prevalent in females.

Keywords: non-suicidal self-injury, Australia

The family and community questionnaire: A multidimensional measurement of poverty

COUGHLAN-WARD, V. (Monash University), JENVEY, V. (Monash University)

Poverty is a world-wide phenomenon that adversely affects the well-being of families. A lack of consensus on the definition and measurement of poverty hinder effective policy formulation and intervention programmes to alleviate poverty. It is argued that poverty is a multi-dimensional construct encompassing income and finances; employment; education; housing; health; and access to community services. It is proposed that the adoption of such a holistic concept of poverty, would help in identifying pathways by which poverty’s adverse effects on adults’ and children’s psychological adjustment could be attenuated. The Family and Community Questionnaire (2007) was developed by researchers to obtain demographic and descriptive information about the sample, and data on the six indices of deprivation required for calculation of an overall deprivation score (Index of Multiple Deprivation). The initial Family and Community Questionnaire has been shown to have reasonable psychometric properties (N=71). The Family and Community Questionnaire has face validity, however, no information yet exists about the content and construct validity of the questionnaire. The Family and Community Questionnaire also has good test-retest reliability and is also able to identify “poor” vs. “not poor” on the basis of participants’ IMD scores (Index of Multiple Deprivation).

Keywords: poverty, well-being, family

The high potential label and its career effects

DRIES, N. (Vrije Universiteit Brussel)

This large-scale quantitative study aimed to examine the effects of being identified as a high potential (or not) on a number of career variables, taking into account the openness of communication that is adopted by organizations with respect to their talent management procedures. A total of 711 respondents (250 high potentials versus 461 non-high potentials) from 12 organizations participated in the online survey. Half of the participating organizations had implemented, at the time of survey administration, a policy of openly disclosing which employees are on their high potential list; the other half had a policy of keeping this information hidden from their employees. We found positive main effects of being identified as a high potential, and of organizational communication openness, on job performance, career success, and commitment. Furthermore, we found interaction effects of being identified as a high potential with communication openness on salary, satisfaction with performance, and satisfaction with job security. Overall, results indicate that adopting an open communication strategy about talent management generates the most desirable outcomes. However, nuance must be applied in interpreting and generalizing these findings.

Keywords: high potential identification, openness of communication, job performance, career success, job satisfaction

The impact of biological attribution on stigma and help seeking behaviour for depression in young people

HOWARD, K. (Australian National University)
Adolescence is a high-risk period for the first onset of depression. Effective early intervention for depression is impeded by the reluctance of young people to seek help and this may significantly influence the trajectory of the condition throughout the life course. A potential barrier to help seeking is stigma. According to Weiner’s (1988; 1995) Attribution Theory, increasing biological causal attributions of depression should decrease stigma. Other researchers have reported that biological causal attributions are associated with higher levels of stigma. However, almost all of the evidence to date has been derived from cross sectional studies. The current study employed a randomised controlled trial (RCT) methodology to examine the effect on stigma and help seeking of manipulating causal attribution. A sample of 300 year 11 and 12 students were randomised to receive online information containing either: (1) biological casual attributions; (2) psychosocial causal attributions; or (3) no causal attributions (control). Scores for all conditions were examined at baseline and post-test. It was hypothesised that biological causal attributions would reduce stigma and increase help seeking intentions from both informal and formal networks. This study found significant differences in the effect of the two types of attribution information intervention. It was found that the biological attribution condition did not reduce stigma but was associated with increased help seeking intention relative to the control condition. This study is the first RCT to investigate the question of whether an intervention designed to manipulate causal attribution has an effect on stigma and/or help seeking for a mental disorder. The results have significant implications for the development and targeting of broad-based public health campaigns aimed at young people, particularly given the low level of help seeking and the burden associated with untreated depression in young people.

Keywords: adolescence, depression, attribution theory, help-seeking, stigma

The impact of compulsive cleaning on confidence in memory, attention and perception, and on confidence in cleanliness

This study aimed to examine why compulsive cleaning does not reduce fear of contamination in individuals with Obsessive Compulsive Disorder (OCD). Prior compulsive research suggests that rather than provide reassurance, repeated checking or staring counterproductively produces distrust in memory, attention and perception concerning that behaviour, thereby stimulating continued checking or staring. The current study extends previous research by examining whether the cognitive distrust that occurs following compulsive checking and staring also occurs following compulsive cleaning. This study examined the impact of repeated cleaning on confidence in memory, perception, attention, and cleanliness. Sixty undergraduate psychology students completed a practical cleaning task, a computerised experimental task, and a number of paper-and-pencil questionnaires examining cognitive confidence. Consistent with predictions, repeated cleaning was found to produce distrust in memory and attention for the cleaning behaviour; participants doubted both the accuracy of their recollections, and whether they had maintained attention throughout the cleaning trial. Importantly, the cognitive distrust that results from repeated cleaning was found to generalise to visually similar objects. Results also showed that asking participants to recall the colour of the last dish cued participants to focus on a concrete, salient dimension of the last cleaning trial. This prevented a decline in memory confidence following repeated cleaning. Inconsistent with predictions, repeated cleaning did not reduce confidence in perception or confidence in cleanliness. These findings have important implications as they enhance understanding of the cognitive processes that underlie OCD, and inform treatment practices. Ultimately, these findings are a preliminary step towards improving the quality of life for individuals with OCD.

Keywords: compulsive cleaning, Obsessive Compulsive Disorder, cognitive distrust
Abstracts of the 27th International Congress of Applied Psychology

The impact of conscious regulation of influences in traditional and project virtual teams on their creativity and effectiveness

KOZUSZNiK, B. (University of Silesia), POLLAK, A. (Silesian University of Technology)

Increase of innovativeness and creativity of polish organizations is a condition of economical growth of the country. The purpose of this research is to identify barriers and chances of intellectual capital use in work–teams – traditional ones and project virtual teams (Pauleen, 2004; Andriessen, 2003). One of the barriers is still the over-use of managers’ influence and lack of free space for individual choice and decision (Hertel, Geister, Konradt, 2005). The aim of this contribution is to show the relation between the influences tactics used by managers in traditional and virtual teams and their regulation of influences ability (deinfluentizaion - ability to reduce their influence) with some positive consequences as creativity and effectiveness (Kipnis, Schmidt, 1983, Yukl, Falbe, 1990). Do these teams require different tactics? Is influence regulation of the same importance in traditional and virtual teams? The DEI-beh Scale was used to measure regulation of influences ability (2004), and the Influence Behavior Questionnaire (IBQ) (Yukl, 1994), Team Effectiveness Scale (2004), Team Creativity Scale (2006) were used. Research was conducted in 33 traditional and 35 project virtual teams (each team about 5-10 members). It was confirmed that there is a positive relation between ability to conscious reducing of influence (deinfluentization) and effectiveness as well as creativity in traditional and virtual teams. The ability of conscious influence regulation seems more important in virtual teams. There are differences in influence tactics used in more creative and effective teams no matter traditional or virtual. More effective virtual and traditional team leaders have higher results in conscious influence regulation ability. The results confirm that there is high time to change leader behaviour toward not only flexible use of influence tactics but also towards influence regulation ability which helps in better use of intellectual capital in traditional and virtual team. Traditional and virtual teams seem no different as far as positive impact of influence regulation and ability to reduce one’s influence is concerned. This ability could be trained and developed in traditional forms and in virtual environment.

Keywords: innovation, creativity, influence tactics, effectiveness, teams

The impact of emotional sincerity on leadership effectiveness

WANG, L. (University of New South Wales), CAZA, A. (Wake Forrest University), ZHANG, G. (London Business School)

Recent research has highlighted the importance of leaders’ emotion expression in influencing followers. However, attention has focused primarily on the effects of the valence of leaders’ emotion expression. This paper extends previous research on leader emotion expression by examining how the sincerity of a leader’s emotion expression affects followers. The study used a 2 (leader emotion valence: positive vs. negative) x 2 (leader emotion sincerity: sincere vs. insincere emotion expression) between-subjects design. One hundred and twenty undergraduate students were randomly assigned to each of the four conditions. In each condition, participants took part in an online task where they worked under the supervision of an assigned leader over the Internet. In reality, the “leader” was a computer program designed to simulate the appropriate emotion expression. After the task, participants invested money they received from the experiment on their leader who was to manage an organizational leadership crisis (i.e., the more effective the leader in managing the crisis, the more money followers will receive). Lastly, participants reported their perceptions of the leader and their emotional experiences while working with the leader. The sincerity of a leader’s emotion expression significantly affected followers’ responses to the leader. Particularly, sincere emotion aroused more positive affect in followers. For example, followers experienced more excitement when their leader displayed sincere positive emotion than feigned positive emotion. In addition, sincere emotion induced greater trust in the leader among followers. Lastly, the trust
The impact of highly complex work and low job decision latitude on employees’ emotional and cognitive strain and burnout at an international airport’s hub section

MICHEL, A. (University of Heidelberg), NOEFER, K. (University of Heidelberg), TURGUT, S. (University of Heidelberg), SONNTAG, K. (University of Heidelberg)

Aim of this study was to investigate stressors that elicit stress reactions among blue-collar workers at an international airport’s hub section. Based on the transactional stress model (Lazarus & Folkman, 1986), we developed a theoretical model to explain how work complexity (stressor, respectively ‘primary appraisal’) and job decision latitude (coping strategy, respectively ‘secondary appraisal’) affect employees’ subjectively perceived emotional and cognitive strain and burnout. The following assumptions were tested: firstly, it was supposed that work complexity is positively related to latitude. Secondly, it was postulated that latitude in turn correlates negatively with perceived emotional and cognitive strain as well as burnout. Thirdly, it was hypothesized that latitude mediates the positive relationship between complexity of work and employees’ stress reactions. Stressor and coping strategy were rated in two ways. First, employees evaluated the extent of work complexity and latitude. Second, the same measures were used to rate work complexity and latitude for the investigated workplace from a team of organisational experts consisting of an executive manager, a work and organisational psychologist, an occupational physician, a member of the workers’ council and an on-the-job trainer. Because the sample-size for the self-reported measure was higher, and both measures were highly correlated, we used the self-reported data for further analyses (see Ohly, Sonnentag, & Pluntke, 2006). To test the fit of the proposed model, structural equation models were calculated using longitudinal data (N = 122). Results indicated adequate data fit to our proposed model and revealed that work complexity and latitude at time 1 were significantly positively correlated and latitude at time 1 and employees’ subjectively perceived emotional and cognitive strain and burnout at time 2 were significantly negatively correlated. In addition, the mediating effect of latitude could be confirmed. Results emphasize that latitude perceived as a possibility to cope with complex work plays an important role in relation to employees’ stress reactions. Thus, in line with the transactional stress model (Lazarus & Folkman, 1986), it is important to strengthen employees’ job decision latitude to be able to successfully cope with the highly complex work at the hub section of an international airport.

The impact of intervention on rates of recidivism from a prison based offence specific CBT programme delivered to men incarcerated for sexual offences

O’REILLY, G. (University College Dublin), MCDONALD, C. (University College Dublin)

This oral paper will present the results of a study that compared the post-release sexual, violent non-sexual, non-violent non-sexual rates of recidivism for all men in the Republic of Ireland who received an offence-specific cognitive behavioural therapy (CBT) intervention while serving a custodial sentence for a sexual crime, with a matched control group of untreated men. All men (n = 124) in the Republic of Ireland who participated in a year-long offence-specific CBT program for sexual offences during their sentence were identified through prison records. A control group of untreated men (n = 124) matched on variables of offence, victim characteristics, age, sentence length, and release were also identified. The rates of recidivism for
both groups were identified through official police records of re-conviction and official prison records of re-imprisonment. The results indicated that offence-specific CBT intervention for sexual offending men did not reduce their rates of sexual, violent non-sexual, non-violent non-sexual offending. Due to the limited provision of intervention to sexual offending men in the Republic of Ireland the current study allowed for a high quality match between treated and untreated men. The current study fits with other data from methodologically stronger studies in other jurisdictions that suggest caution is needed in the adoption of findings from large scale meta-analyses that combine data from studies of limited methodology to conclude that sexual offender intervention reduces rates of recidivism.

Keywords: sexual offences, recidivism, cognitive behavioural therapy, men, interventions

The impact of organizational structures, workplace characteristics, and climate features on employees’ affective commitment

UNTERRAINER, C. (University of Innsbruck), UNTERRAINER, C. (University of Innsbruck), WEBER, W. (University of Innsbruck), PIRCHER-VERDORFER, A. (University of Innsbruck)

Affective Commitment, which deals with employees’ emotional attachment to, identification with, and involvement in the organization, is known for its favorable organizational outcomes (e.g. job satisfaction, job performance). Thus, organizations’ benefit of affectively committed employees is obvious. Our study targets the antecedents of this construct. How can employers establish affectively committed employees in organizations? Meyer and Allen (1991) proposed that affective commitment can result from three different categories: personal characteristics, organizational structure, and work experience. Past research has focused more on workplace characteristics than on personal or structural features. Thus, relatively few studies exist concerning especially to organizations’ structural characteristics. Our study investigates the impact of organizational structures in terms of structurally anchored participation (organizational democracy), as well as the influence of workplace characteristics in the form of individually perceived participation in democratic decision-making, and the effects of a socio-moral climate on employees’ affective commitment. As regards the personal characteristics, we controlled for supervisory function, age, educational background, and tenure. We used a multi-method, cross-level design to examine the proposed interrelations. Based on a typology of democratic enterprises, we surveyed 30 enterprises with different levels of structurally anchored participation in Austria, Germany, and Italy. Using document analyses and structured expert interviews, we collected data on company features. Individually perceived participation in decision-making, the socio-moral climate, and personal characteristics were recorded by questionnaires. With a response rate of 58 per cent, we applied 402 questionnaires for analyses. By means of hierarchical linear modeling, we found support for the impact of structural and workplace characteristics and for the influence of a socio-moral climate on affective commitment. In this context, employees’ individually perceived participation in decision-making has the strongest predictive value for commitment. But also a socio-moral climate and structurally anchored participation are significant predictors for employees’ commitment. Personal characteristics did not show any predictive value. Summing up, employees are most affectively committed in companies with strong democratic structures and a high level of socio-moral climate if they individually perceive many possibilities to participate in organizational decision-making processes.

The impact of perceived organizational supports to employee job satisfaction

MANGUNDJAYA, W. (University of Indonesia, Faculty of Psychology)

Employee satisfaction and retention have always been important issues. Although there has been contradictory literature regarding this issue, in
general it has been found that satisfied employees tend to be more productive, creative and committed to their employers. Moreover, Harper et al., (2003) also stated that the more satisfied the employee the more cooperative they are. In this regard, job satisfaction can be influenced by a variety of factors, e.g., the quality of one’s relationship with their supervisor, the quality of the physical environment in which they work, degree of fulfillment in their work, etc. In this regard, the question arises whether employee satisfaction is influenced by the perception of employee about the organization (by their Perceived Organizational Support). In this regard, Perceived Organizational Support (POS) would increase employees’ felt obligation to help the organization reach its objectives. Behavioral outcomes of POS would include increases in in-role and extra-role performance and decreases in corresponding withdrawal behaviors such as absenteeism and turnover, and would also be associated with increased job satisfaction. Based on that, this paper will study the impact of POS to Employee Job Satisfaction (EJS). The benefits of this study is to find variables that have significant contribution to EJS, in order to give feedback to the management about their employee well being. The research is using a quantitative ex post field study design and correlational methods. To collect the data, this study used the modified Employee Satisfaction and Perceived Organizational Support Questionnaire which has been recently modified and validated. A total of 374 employees who worked at a coal mining company in Indonesia were asked to participate in the study. The results show that there is a positive and significant correlation between POS and job satisfaction (R 0.778, los 0.01), and POS has an impact of 60.6 per cent to Employee Job Satisfaction. In conclusion, organizations need to actively support their employees in order to achieve higher Employee Job Satisfaction.

Keywords: employee satisfaction, employee retention, perceived organisational support

The impact of persuasive health imagery on health information retention, coping and vulnerability

JOHNSON, M. (University of Newcastle), RICHARDS, J. (University of Newcastle), BEEHAG, N. (University of Newcastle), WHEATLE, J. (University of Newcastle), THORNTON, K. (University of Newcastle), JOHNSON, M. (University of Newcastle)

Fear is used in health campaigns to elicit health behaviour change. Health models have not been able to explain how individuals respond to fear appeals. There is little empirical evidence to show if health information presented via fear appeals is retained. This study investigated if health knowledge is affected by the presentation of persuasive health imagery. 175 participants from the psychology participant pool (n = 92), and the general public (n = 83) were presented with health information and allocated into either skin cancer (SC) or smoking related illness (SRI) contexts. Participants were exposed to benign, mild or persuasive imagery relating to each context. Then participants completed the Beck Anxiety Inventory, the Coping Response Inventory and measures of Vulnerability and Susceptibility. Their health knowledge was then tested. No significant difference in health knowledge was found between conditions in either context. However, in the SRI context, smokers had the least amount of health knowledge. In the SC context, those who had visited a skin cancer clinic had less health knowledge. Further, for those whom the health threat was salient perceived themselves as the least vulnerable and used a more avoidant coping repertoire. Health knowledge is not affected by the persuasiveness of imagery relating to the health context. These results suggest that fear appeals may not be the most effective means of communicating health knowledge.

Keywords: health, persuasive imagery, information retention, coping, fear

The impact of self-esteem and fear of older people on ageist attitudes towards older people

SANDERS, L. (Queensland Health), HARRISON, D. (Griffith University), WILSON, K. (Griffith University)

Ageist attitudes reflect a prejudice in society against older adults, which is considered to be a
problem within the community and workplace settings. Although research is growing, the current body of literature would benefit from further research into to predictors of ageist attitudes. Therefore, the aim of the following study was to investigate the dual impact of self-esteem and ageing anxiety (i.e. comprising of four factors being: Fear of Older People; Psychological Concerns; Physical Appearance; and Fear of Loss) on ageist attitudes towards older people. This study utilised a cross-sectional design to investigate the impact of self-esteem and ageing anxiety on ageist attitudes towards older people. A total of 321 individuals participated in this study. Two hundred and twenty six of these participants were women (70.4%) and 95 (29.6%) men. Structural equation modeling (SEM) was used to test the causal relationships of the proposed model. Goodness of fit estimates supported the hypothesised model. Investigation of the direct effects identified that low self-esteem and the ‘fear of older people’ factor of the ageing anxiety scale predicted higher levels of ageist attitudes towards older people. The implications for this study identified that individuals who have a positive self-image are less likely to have negative attitudes towards older people. This is an important finding as it suggests that negative attitudes toward the elderly may be reduced through programs aimed at increasing levels of self-esteem within the population. This study also found a significant relationship between fear of older people and ageist attitudes towards older people. This result supports the role that educational programs play in reducing ageist stereotypes within society. Future research is encouraged to identify the causes of ageing anxiety, as it is likely to provide additional insights into the predictors of ageism, and inform strategies to reduce its effect within the community and workplace settings.

Keywords: self-esteem, ageist attitudes, prejudice, ageing anxiety, older people

The impact of self-esteem, situational characterization, and gender on the propensity to initiate negotiation: Implications for lifetime earnings

BENINGER, A. (London School of Economics and Political Science)

This study analyzes the impact of self-esteem (high vs. low), situational characterization (“negotiate” vs. “ask”), and gender on the likelihood an individual initiates negotiation (n = 140). Initiating negotiations for compensation, specifically in one’s first job, has a huge impact when factored over a lifetime because an individual’s initial salary sets the trajectory for the rest of one’s career. The participants were undergraduate students enrolled in a liberal arts college in California during the Fall 2008 and Spring 2009 semesters. Participants were recruited from psychology classes and advertisements posted on campus. A total of 140 students participated in this study including 51 men and 89 women. Self-esteem was primed with a prompt and the participants were told they could either “negotiate” or “ask” for more money after completing two tasks. All participants were offered $1 and then given the opportunity to initiate a negotiation for up to a maximum of $5. A main effect of situational characterization was found such that negotiation was more likely in the “negotiate” condition. Neither self-esteem nor gender produced significant results. A significant interaction showed that men were more likely to negotiate in the “ask” condition, but there were no gender differences in the “negotiate” condition. Finally, gender differences in anticipated future earnings were found. Men held considerably higher expectations for average annual salary 5 years after graduating from college than women. Initiating negotiation is a difficult task for most people. Only 36% of participants were willing to request more money, even though they were all explicitly told it was acceptable. Initiating salary negotiations has substantial long-term career ramifications and the results of this study have important implications for training students and workers to negotiate for the salaries they deserve.

Keywords: self-esteem, situational characterization, gender differences, negotiation

The impact of work complexity on the relationships between positive and negative affective appraisal and recovery experiences

TURGUT, S. (University of Heidelberg), MICHEL, A. (University of Heidelberg), SCHRAUB, E. (University...
The present study sought to investigate the relationship between affective appraisal in the morning and recovery experiences in the evening among blue-collar workers at an international airport’s hub section. Based on the transactional stress model (Lazarus & Folkman, 1986) and the demand-control model (Karasek, 1979), we hypothesized the following assumptions: Firstly, it was assumed that positive affective appraisal is positively related to recovery in the evening. Conversely, we hypothesized that negative affective appraisal in the morning is negatively related to recovery after work. Finally, we assumed that both relationships are moderated by work complexity. Thus, we postulate that employees with negative or positive affective appraisal in the morning experiencing high levels of work complexity show lower levels of recovery after work in comparison to employees experiencing low levels of work complexity. To test these assumptions we conducted a diary study (N=45). We assessed employees’ perceived work complexity and the control variables age, position and shift system on a person level. Affective appraisal in the morning and recovery experiences in the evening were rated by the participants on 12 consecutive days (N=406). We used multilevel analyses (HLM 6, Raudenbush, Bryk, Cheong, Congdon & Du Toit, 2004) to accurately fit the hierarchical data structure. The assumed relationships between positive and negative affective appraisal in the morning and recovery in the evening were confirmed. By applying the described cross-level interaction design, we could also confirm the moderating effect of work complexity on both relationships. As research has shown that recovery fades out quickly after vacations, everyday recovery seems to be crucial for employees’ well-being (Westman & Eden, 1997; Zijlstra & Sonntag, 2006; Rook & Zijlstra, 2006; Sonntag & Fritz, 2007). The present study highlights the importance to examine how employees affectively appraise the upcoming day in the morning and perceive work complexity regarding their recovery after work. Concluding from this study, we recommend that organizations should support their employees’ recovery by either reducing the complexity of the employees’ work or by providing training and coaching to help their employees to successfully cope with their perceived work complexity.

The implications of systematic training for the validity of online ability testing

Fluid intelligence is critical for a wide variety of cognitive tasks, and it is considered one of the most important factors in learning. Hence, fluid intelligence is a vital construct in aptitude testing. There is a long history of the assumption that fluid intelligence must be simply genetically determined. However, recent studies (see Jeaggi, Buschkuehl, Jonides & Perrig, 2008) have indicated that fluid intelligence can be improved with training. If training improves fluid intelligence, it needs a measure for current psychometric fitness level to determine the true potential of a candidate in aptitude testing. Cognitive training data of participants (N=12,548) of a long-term online study is used to identify cognitive aspects that are subject to improvement by training and to aptitude testing. The results indicate that taking into account the cognitive training level is a vital element of test fairness for aptitude testing in general and for online pre-screening in particular.

The importance of anxiety sensitivity as a predictor of anxiety symptomatology in primary school children

JONES, B. (Australian Catholic University)

A key factor to be considered when providing intervention for anxious children is anxiety sensitivity. Anxiety sensitivity is essentially the fear of anxiety-related sensations. There is ongoing debate in the research literature as to
whether anxiety sensitivity and the more traditionally recognized trait anxiety are distinct constructs or not. The aim of the present study was to screen a large number of children in the general population for anxiety sensitivity and trait anxiety, and to evaluate anxiety sensitivity as a distinct construct from trait anxiety in predicting anxiety symptoms. Participants included 455 primary school children (241 boys and 214 girls) with a mean age of 9.68 years (SD = 1.23). The children completed the Childhood Anxiety Sensitivity Index (CASI); the A-Trait scale of State-Trait Anxiety Inventory for Children (STAIC) and the Anxiety Symptoms Checklist for Children (ASCC). Results indicated that anxiety sensitivity and trait anxiety are similar constructs and that anxiety sensitivity is not easily distinguished from trait anxiety. However, some distinction between the two constructs became apparent as anxiety sensitivity was found to be a reliable predictor of cognitive processes associated with anxiety. Evidence to date may provide some insight into the importance of anxiety sensitivity as a distinct and important factor when examining anxiety in children. The findings of the present study may also have important implications for psychological intervention, and for parents and educators involved in the overall development and well being of anxious children.

The importance of perceived workplace difficulties in those with multiple sclerosis in determining work outcomes

Employment in people with Multiple Sclerosis (PwMS) is of increasing concern. Whilst some previous studies have identified various demographic and disease-related factors that may be involved in determining work outcomes, few have quantitatively examined the potentially important contribution of difficulties experienced by PwMS in the workplace itself. Even if these difficulties have been examined, the inclusion of cognitive difficulties has typically not been satisfactory. This research seeks to more comprehensively examine workplace difficulties in PwMS and its relationship with employment outcomes and expectations. Participants were 170 PwMS (74% female) of working age (M=49 years) who were currently in or no longer in paid employment. Various self-report measures were completed including 123 workplace difficulty items developed through an extensive literature search and expert review. The items were factor analyzed forming the MS Work Difficulties Questionnaire – MSWDQ. A subset of this sample (N=103) also completed a short battery of cognitive tests measuring processing speed, immediate and long-term memory, working memory, prospective memory, abstract and verbal reasoning, and planning. Exploratory principal components analysis of the work difficulty items yielded several components with good to excellent internal consistency reliabilities. These included difficulties related to cognition, physical limitations, career progression, support in the workplace, workplace accessibility, home responsibilities, finance, and personal interactions. Using logistic regression analyses, variance accounted for by this model in current employment status and reduced working hours since diagnosis was 22% and 37%, respectively. Variance accounted for in future expectations about withdrawing from work entirely, reducing work hours, and changing type of work was 37%, 32%, and 47%, respectively. Perceived cognitive difficulties accounted for more variance in work outcomes than objective cognitive measures. Perceived workplace difficulties are strong predictors of employment outcomes in people with MS. Since many PwMS leave work within only a few years of being diagnosed, these findings are especially pertinent for the provision of effective vocational and rehabilitation programs.

The indirect effect of perceived school climate on adolescents’ intergroup attitudes through student relations

SCHACHNER, M. (Friedrich Schiller University Jena), NOACK, P. (Friedrich Schiller University Jena), VAN DE VIJVER, F. (Tilburg University), LESSENICH, S. (Friedrich Schiller University Jena)
Past research has shown that the way students perceive the school climate does have an effect on their intergroup attitudes (Gniewosz & Noack, 2008; Gniewosz, Noack, Wentura & Funke, 2008; Bovier & Boehnke, 1999; Aboud & Fenwick, 1999). In particular, perceived pressure to perform has been associated with elevated levels of prejudice amongst students whereas the perception of transparency and justice has been associated with higher levels of tolerance. Apart from replicating those relationships, the present study explores how perceptions of the school climate indirectly affect students' attitudes through improving peer relations within the class. A total of 1312 students attending 6th, 8th and 10th grade took part in a questionnaire study measuring their perceptions of different aspects of the school climate and the relationship between students as well as a number of background variables and their attitudes towards foreigners. Data were collected at Thuringian secondary schools in several annual waves over the course of five years. Initial cross-sectional analyses of the data collected at the first measurement point suggests that when age and school track are controlled, the effect of pressure to perform on prejudice against foreigners is mediated by student relations. However, this was only found for students with a relatively low level of identification with the school, whereas for highly identified students the quality of student relations did not significantly affect their level of prejudice. Further analyses will be conducted with regards to other indicators of perceived school climate and potential third variables reflecting student relations within the class room. The direction of causality will be established through the computation of cross-lagged effects across measurement points. The study sheds more light on the relationship between perceived school climate and intergroup attitudes. In particular, it is explored how the school climate affects another important socialization agent, namely peer relationships within the class room. Implications for interventions at the school level will be discussed.

Keywords: school climate, intergroup attitudes, prejudice, transparency, justice

The influence of achievement goals and perceptions of learning environment on students’ approaches to learning in a university in Hong Kong.

TAI, H. (University of Hong Kong)

Deep learning has been shown to enhance better understanding and conceptions of academic materials as well as greater development of generic skills in the higher education. This study aimed at examining how achievement goals and perceptions of learning environment influence students’ approaches to learning (deep/surface). With the understanding of the relationships among these three factors, deep learning and favorable learning outcomes can be better enhanced among university students in a Hong Kong Chinese context. In addition, the three factors examined in this study are constructs from two perspectives in the literature: 1) achievement goals (AG) and 2) students’ approaches to learning (SAL) perspectives. This study explored the relationships among the constructs from these two perspectives as very limited research has been conducted in this area of integrating models and perspectives in understanding student learning. A survey was conducted to measure achievement goals (Achievement Goals Questionnaire; Elliot & Church, 1997), perceptions of learning environment (Student Course Experience Questionnaire; Ginns, Prosser, & Barrie, 2007) and approaches to learning (Revised Study Process Questionnaire; Biggs, Kember, & Leung, 2001) of 770 university students. A correlation and regression analysis was conducted to investigate the relationships among these three factors. Results show that achievement goals, perceptions of learning environment and approaches to learning were related to one another. Mastery goals, performance-approach goals, perceptions of good teaching and clear goals and standards in the learning environment were positively associated with deep approaches to learning. Performance-avoidance goals were positively associated with surface approaches to learning whereas perceptions of appropriate assessment and appropriate workload in the learning environment were negatively associated with surface approaches to learning. Achievement goals from the AG perspective and perceptions
of learning environment from the SAL perspectives were related to one another. Both achievement goals and perceptions of learning environment influence university students’ adoptions of deep and surface approaches to learning. The relationships found between achievement goals and perceptions of learning environment contribute to research and theoretical models in both AG and SAL perspectives in which researchers may consider integrating constructs from both perspectives in understanding and enhancing university student learning in the Chinese context.

The influence of cultural values on mental health: The mediating effect of attitudes towards emotional expression

CHU, L. (Chung Shan Medical University)

Although in the past there have been studies that have discussed the connection between individualist or collectivist cultural values and an individual’s mental health, very few studies have attempted to understand whether the individual’s attitudes towards his emotional expression can play a mediating role in this relationship. For this reason, the main topics to be discussed in this paper include: 1. From the individual’s inclination toward certain cultural values, in accordance with how modern the individual is, cultural values can be classified into four types - namely, vertical/horizontal individualism or vertical/horizontal collectivism - in order to validate the effect of such cultural values on the individual’s attitudes towards emotional expression. 2. The influence of the individual’s attitudes towards emotional expression upon negative mental health. 3. Whether or not the influence of the individual’s cultural values (vertical/horizontal individualism or collectivism) on his mental health is achieved through his attitudes towards emotional expression serving as the mediating effect. This study adopts a two-stage survey involving full-time working adults employed by private enterprises in Taiwan. A total of 300 questionnaires were distributed. At Time 1 (T1), participants were asked to evaluate their vertical/horizontal individualism and collectivism, and any negative attitudes towards emotional expression. One month later (T2), employees who had completed the first-wave questionnaire were asked to rate their mental health. As a result, we had a final usable sample of 159 working adults, which represented a valid return rate of 53%. These participants consisted of 99 females and 60 males, with a mean age of 36.42 years (SD: 7.99), employed in such industry sectors as hi-tech, finance and insurance, business and professional services, traditional manufacturing, medical and government. From the regression analysis, it was discovered that vertical/horizontal collectivism was positively associated with negative attitudes towards emotional expression (b=-.26, p < .01; b=.16, p < .05). In addition, horizontal individualism was negatively associated with negative attitudes towards emotional expression (b=.20, p=.01). Furthermore, this study confirmed that negative attitudes towards emotional expression were positively associated with negative mental health (i.e. somatic symptoms, anxiety and insomnia, social dysfunction and severe depression) (b=.29, p<.01; b =.33, p < .01; b =.26, p < .01; b =.27, p < .01). Finally, this study showed that under horizontal individualism and vertical collectivism the predictors of negative mental health (i.e., somatic symptoms, anxiety and insomnia, social dysfunction and/or severe depression) were partially and almost completely achieved through the mediating effect of the negative attitudes towards emotional expression. The results showed that individual’s cultural values could be used to predict their mental health indirectly through their attitudes towards emotional expression processes. Within the collective cultural environment of the Chinese peoples, the overall atmosphere is one where people are not encouraged to express their emotions, especially where those emotions are negative. The burden of emotional pressure built up over the long run is actually not favorable to the development of physical and mental health. The road to improvement, apart from the nurturing of individualistic cultural values, requires the development of another set of coping strategies that are suitable for the enhancement of the physical and mental health of social groups among the Chinese.
Keywords: cultural values, attitudes, emotional expression, Chinese

The influence of internalization of emotional regulation on mental health: The moderating effect of leader-member exchange

CHU, L. (Chung Shan Medical University), HSIEH, C.F. (Chung Shan Medical University), XU, C.Y (Chung Shan Medical University)

King and Emmons (1990) proposed that ambivalence regarding withholding the expression of emotion, rather than inexpressiveness per se, is what fosters ill-being, and Katz and Campbell (1994) and King and Emmons (1990) found that ambivalence to be positively associated with self-reported physical symptoms, the number of visits to health-care providers, and depression. This study explores whether self-regulation by withholding negative emotions (SRWNE) affects mental health, and examines further whether Leader-Member Exchange (LMX) can moderate the relationship between such self-regulation and employee mental health. This study adopts a two-stage survey whose participants were full-time working adults employed by private enterprises in Taiwan. A total of 400 questionnaires were distributed. At Time 1 (T1), participants were asked to evaluate their self-regulation by withholding negative emotions (SRWNE), LMX, and demographic variables. One month later (T2), employees who had completed the first-wave questionnaire were asked to rate their mental health. The final usable sample was 284 working adults, representing a valid return rate of 71%. These participants consisted of 163 females and 121 males, with a mean age of 37.22 years (SD: 9.69), employed in such industry sectors as hi-tech, finance and insurance, business and professional services, traditional manufacturing, medical and government. External regulation of SRWNE was significantly associated positively with somatic symptoms (β = .29; p < .01), anxiety and insomnia (β = .29; p < .01), and social dysfunction (β = .22; p < .01), whereas introjected regulation of SRWNE was significantly associated positively with somatic symptoms (β = .12; p < .05) and severe depression (β = .15; p < .05). In addition, identified regulation of SRWNE was significantly associated negatively with anxiety and insomnia (β = -.17; p < .01) and social dysfunction (β = -.23; p < .01), whereas integrated regulation of SRWNE with anxiety and insomnia (β = -.16; p < .01). This means that subordinates who used controlled SRWNE had poorer mental health than subordinates who used autonomous SRWNE. This study also found that LMX may moderate the relationship between such self-regulation and employee mental health. External regulation times the LMX’s interaction was significantly associated with anxiety and insomnia (β = -.13; p < .05), whereas identified regulation times the LMX’s interaction was significantly associated with social symptoms (β = -.19; p < .01). In addition, integrated regulation times the LMX’s interaction was significantly associated with anxiety and insomnia (β = .13; p < .05), social symptoms (β = -.20; p < .01). The results support our hypotheses that not only external and introjected SRWNE are significantly associated positively with negative mental health, in line with Kim et al.’s (2002) findings that controlled SRWNE is significantly correlated positively with such psychosomatics as anxiety, somatic symptoms, depression, negative affect and immune dysfunction, but also that identified and integrated SRWNE are significantly associated positively with negative mental health. Therefore, ambivalence about not expressing emotion, rather than inexpressiveness per se, is what fosters ill-being. This assertion is not only supported by Western studies (Katz & Campbell, 1994; King & Emmons, 1990; Kim, et al. 2002), but is also by this study based on a Chinese sample, leading to the conclusion that the extent of the internalization of emotional regulation has universal value for both mental and physical health. However, this study showed that LMX could moderate the relationship between the autonomous and controlled extent of subordinates’ emotional regulation and the mental health.

Keywords: emotions, ambivalence, self-regulation, leader-member exchange, mental health
The influence of LMX on subordinate’s job satisfaction, organizational citizenship behavior, and counterproductive work behavior: The moderating effect of person-supervisor fit

CHU, L.C. (Chung Shan Medical University), XU, C.Y. (Chung Shan Medical University), HSIEH, C.F. (Chung Shan Medical University)

Although in the past there have been studies that have discussed the connection between Leader-Member Exchange (LMX) and subordinate’s job satisfaction, organizational citizenship behavior (OCB) and counterproductive work behavior (CWB), very few studies have attempted to understand whether the person-supervisor fit can play a moderating role in this relationship. This study adopts a two-stage survey whose participants were full-time working adults employed by private enterprises in Taiwan. A total of 450 questionnaires were distributed. At Time 1 (T1), participants were asked to evaluate their LMX, person-supervisor fit, and demographic variables. One month later (T2), employees who had completed the first-wave questionnaire were asked to rate their job satisfaction, OCB, and CWB. As a result, we had a final usable sample of 287 working adults, which represented a valid return rate of 64%. These participants consisted of 313 females and 74 males (mean age: 37.05 years; SD: 9.44) employed in such industry sectors as hi-tech, finance and insurance, business and professional services, traditional manufacturing, medical and government. We tested hypotheses through the use of hierarchical multiple regression. The results showed that LMX was significantly associated positively with job satisfaction (b = .42, p < .01) and OCB (b = .38, p < .01, and significantly associated negatively with CWB (b = -.37, p < .01). The study also found that person-supervisor fit may moderate the positive relationship between LMX and OCB (b = .18, p < .01), and the negative relationship between LMX and CWB (b = -.13, p < .01). As we know, supervisors choose those they like or view as strong performances into the “in-group” and those they dislike or view as weak performances into the “out-group”. People in “in-group” are able to utilize more resources, enabling them to do the task better and gain a sense of accomplishment and obtain more support and trust. According to Pool’s (1997) research, he defined job satisfaction as an attitude that individuals maintain about their job which is developed from their perceptions of their job. The quality of the LMX relationship between subordinates and the supervisor will determine job satisfaction of subordinates. Our results are consistent with previous studies on LMX and Job Satisfaction (Ekin & Terri, 2006). In addition, subordinates experiencing high quality LMX with their leader were found to have better attitudes and felt constructive for the organization, finding supervisors to be supportive. In turn, these subordinates respond with more extra-role behaviors, showing more OCB. Further, a negative relationship was found between LMX and CWB, whereby subordinates experiencing high quality of LMX received better resource and more trust from their leader than the “out-group” member, and felt that they were important in his or her organization. Therefore, they will not to damage their organization. In addition, we showed that person-supervisor fit can moderate the positive relationship between LMX and OCB, where this relationship was stronger among subordinates who had higher person-supervisor fit than among those who had less person-supervisor fit. We also found that person-supervisor fit can moderate the negative relationship between LMX and CWB, where the relationship was stronger among subordinates who had higher person-supervisor fit than among those who had less person-supervisor fit. In sum, if organizations wish to enhance the employees’ OCB or reduce their CWB in the future, we suggest that they select job applicants who share the values and visions of the supervisors.

Keywords: leader-member exchange, job satisfaction, organizational citizenship behavior, counterproductive work behaviour, person-supervisor fit

The influence of organisational attitudes on Australian airline pilot decision choices

WINDLE, K. (Deakin University), HOLGATE, A.
The decisions commercial airline pilots make have far-reaching implications for the safety of many people. Organisational attitudes have been shown to correlate with riskiness in decision making. However, the nature of this relationship remains to be fully explored. This paper aims to investigate the relationship between organisational attitudes, cue saliency within situational awareness, and resulting decision choices in Australian commercial airline pilots. It was hypothesized that pilot decision choices would change depending on the situational cues to which pilots paid most attention when making a decision. Further, it was hypothesized that this situational cue saliency would be informed by the pilot’s organisational attitudes. One hundred and sixteen commercial airline pilots from three different airlines in Australia completed a purpose-designed questionnaire. The questionnaire presented a number of in-flight scenarios; pilots were asked what they would do in the situation and then asked to assess the riskiness of their decision and provide information on the key factors informing their decision choice. A series of regression analyses were conducted and support found for a relationship between attitudes towards management and situational cue saliency ($\beta = -.247, p = .010$), and for a relationship between situational cue saliency and riskiness of a decision choice ($\beta = -.271, p = .006$). No significant relationship existed directly between attitudes towards management and riskiness of decision choice. These findings indicate that, consistent with hypotheses, organisational attitudes influenced decision choice via the mechanism of cue saliency within situational awareness. Attitudes are a powerful motivational contributor to decision choices. Pilots, airlines, and air safety regulators should be alert to the influence that organisational attitudes may have on a pilot’s situational awareness, cues attended to, and the resulting decisions made concerning both safety and commercial operations.

Keywords: commercial airline pilots, risky decision-making, situational cues, organisational attitudes

The influence of perceived organisational support, autonomy and empowering leadership on affective organisational commitment: The mediating role of engagement

FOSTER, K. (SACS Consulting), ALBRECHT, S. (Monash University)

The aim of this research was to assess the influence of perceived organisation support (POS), autonomy and empowering leadership on affective organisational commitment and to assess the possible mediating effects of engagement on these relationships. Participants ($N = 115$) were recruited from a large government organization. Participants voluntarily responded to an online survey. Results from a multiple hierarchical regression analysis suggested that perceived organisational support, autonomy and engagement had direct associations with affective commitment, however not so for empowering leadership. Engagement was found to partially mediate the influence of perceived organisational support and autonomy on commitment. Furthermore, perceived organisational support and autonomy were found to mediate the influence of empowering leadership on engagement. The results from this study corroborate previous research suggesting that affective commitment is likely to have a significant association with POS, autonomy and engagement. While demographic and dispositional variables did not impact the relationship in a significant way, they should still be considered in future research. The results extend existing research by recognising the mediating influence of POS and autonomy on the relationship between empowering leadership and affective commitment. Moreover, they provide more evidence for the mediating influence of engagement on the influence of POS and autonomy on affective commitment. As such, results suggest that those who perceive support from their organisation, who have self determination about how they complete their work, who experience empowering leadership and who are engaged in their role are likely to be more affectively committed to their organisation. This commitment has benefits for both the employee and the employer and remains an area worthy of on-going research.

The influence of social environment on the resilience of children

LUO, J. (Institute of Psychology, CAS), GAO, W. (Chinese Academy of Sciences), ZHANG, J. (Chinese Academy of Sciences), LUO, J. (Chinese Academy of Sciences)

In China, a greater number of peasants have migrated from the countryside to the urban areas in search of better-paid jobs to support their families since the 1990s. Some take their children with them, while others leave their children behind. As a result, two special groups come into being, called “the rural left-behind children” and “the city of floating children” (because their parents often move to other cities). They have already displayed high-risk behavior and exerted adverse impact on themselves and the society. Helping them to develop their talent and strength can be an effective intervention. Under the circumstances, this paper focuses primarily on the resilience of these children. There is a sample of 1577 students aged 10-18 (13.26±2.06) years old from Sichuan province and Beijing, including 902 the rural left-behind children (SS1) and 675 the city floating children (SS2). Scale (California Healthy Kids Survey Resilience Assessment Module), interview and nomination by teachers as well as classmates for SS’ interpersonal relationship and behavior in class are used. Controlling such factors as SES, parental relationship and education attainment, the results show that SS2 have lower resilience than that of SS1 on both external assets ($t=7.26, p=0.000$) and internal assets ($t=6.51, p=0.000$). Furthermore, both the male ($t=5.38, p=0.000$) and female ($t=5.36, p=0.000$) of SS2 have lower scores on resilience. In addition, findings from our interview and nomination (analyzed by Bootstrap method) show that SS1 have more harmonious relationship with their teachers and classmates than SS2 ($\chi^2=9.56, p=0.002$; $\chi^2=4.28, p=0.038$), and SS2 have more chance to be nominated for bad behavior in class by teachers ($\chi^2=4.37, p=0.036$). Results of the regression analysis show that such factors as emotion, self, coping and personality all contribute to the resilience of children ($\Delta R^2=0.35$). (1) the external environment (especially, being discriminated against and moving frequently) has more powerful influence on the children’s resilience than family factors, which means that the resilience is probably neither in one’s personality nor acquired by inheritance; (2) there are many common factors, in particularly, the anxiety, sensitivity, self-esteem, positive coping, and extroversion, which impose on both the external and internal resilience; (3) the girls present the higher resilience than boys on both SS1 and SS2.

The influence of teacher efficacy, work motivation, and mood on teaching innovation

WANG, Z. (Shaanxi Normal University), WANG, K. (Shaanxi Normal University), YOU, X. (Shaanxi Normal University)

What contributes to teaching innovation? Many studies suggested that teacher efficacy, work motivation, and emotion or mood were critical teachers’ personality factors to influence teaching and learning. Teacher efficacy includes two components: general teaching efficacy and personal teaching efficacy. Work motivation also has two aspects: intrinsic motivation and extrinsic motivation. Mood includes positive mood and negative moods. Studies showed that all of aspects of teacher efficacy, motivation, and mood were related to creativity and innovation. But what different influences these personality factors have on teaching innovation remains unclear, due to limited research. Therefore, this study aims to explore this question. The teaching innovation questionnaire, the teacher efficacy questionnaire, work motivation questionnaire, and mood scale were administered to 322 teachers of middle school. There were 123 male teachers, and 199 female teachers, with length of teaching history ranging from 2 to 33 years. The results of this study indicate that personal teaching efficacy, intrinsic motivation, and positive mood correlated with teaching innovation positively. The regression effect of personal teaching efficacy and positive mood to teaching innovation were significant. The
regression effect of intrinsic motivation and positive mood to personal teaching efficacy were significant. The path analysis showed that the personal teaching efficacy influenced the teaching innovation directly, where the path coefficient of personal teaching efficacy to teaching innovation was significant. Intrinsic motivation and positive mood influenced the personal teaching efficacy directly, where the path coefficient of intrinsic motivation and positive mood to the personal teaching efficacy was significant. The results suggested personal teaching efficacy, intrinsic motivation, and positive mood were all critical factors that influenced teaching innovation. Personal teaching efficacy influenced the teaching innovation directly; intrinsic motivation and positive mood indirectly influenced the teaching innovation by influencing personal teaching efficacy directly.

The influences of basic needs, social support and migration on mental health in South Sudan: Implications for humanitarian practice in post-conflict settings

SCHAFER, A. (Swinburne University of Technology), CRITCHLEY, C. (Swinburne University of Technology)

The project explored the influences of basic needs, like shelter, access to food, water and employment, social support and migration on mental health amongst the southern Sudanese. It investigated mental health differences between gender and two groups: A “host” group representing people who never left south Sudan during its 21-year war; and a group of “returnees” who lived in asylum but had recently returned. The project also explored cultural perceptions of mental illness. Participants comprised 53 adults living in South Sudan. Interviews with host (n=26) and returnee groups (n=27) were conducted in local language. Measures included demographic data for basic needs, the Perceived Social Support Scale (Procidano & Heller, 1983), the Harvard Trauma Questionnaire and the Hopkins Symptom Checklist-25 (Mollica et al., 2004). An interview schedule based on the DSM-IV-TR Cultural Formulation was used to collect qualitative data. Returnees reported better access to basic needs and higher education compared to the host group, but this did not equate to greater employment. There were no significant differences for symptoms of PTSD, depression or anxiety between the host and returnee groups. Higher age and social support were significant protectors against mental illness, as was longer periods of time living in asylum. Returnee group data revealed that the longer they had resettled in their homeland, the higher symptoms of mental illness were reported. Women experienced significantly more symptoms of mental illness than men. Qualitative themes indicated that basic needs and social support were directly linked to cultural views about mental illness. Research implications suggest humanitarian practice needs to continue focusing on gender specific programming. Social support programs, in addition to provision of basic needs, appear to be vital in protecting mental health. Humanitarian activities would benefit returnees more by undertaking longer term resettlement programs. The results also provide empirical data supporting classic theories, like Maslow’s well-being needs, and the recently published IASC Guidelines on Mental Health and Psychosocial Support in Emergency Settings, which advocates for humanitarians and mental health services to shift away from its emphasis on trauma in post-conflict settings.

Keywords: basic needs, social support, migration, South Sudan, mental health

The internal structure of counterproductive work behaviors: A meta-analysis

HASTINGS, S. (University of Western Ontario), TAYLOR, O. (The University of Western Ontario), STURM, A. (Fernuniversität in Hagen)

The overall objective of this research is to comprehensively and quantitatively integrate, by means of structural meta-analysis, existing empirical evidence on all types of Counterproductive Work Behaviors (CWB). This should contribute to a better understanding of
the appropriate level of parsimony in explanations of CWB as well as to clarify the number and content of facets of CWB. The present project employs structural meta-analysis, a combination of psychometric meta-analysis with structural equation modeling. A comprehensive literature search was conducted to identify relevant published articles, conference presentations, and unpublished papers from researchers in the field. One hundred and sixty-seven codable papers were obtained and each was coded twice in order to ensure accuracy. Correlations obtained were corrected for unreliability and weighted by sample size in accordance with Hunter and Schmidt’s (2004) recommendations. Subsequently, a confirmatory factor analysis (CFA) was conducted based on this correlation table following Viswesvaran and Ones’s (1995) methodology. We first analyzed the data within the Gruys and Sackett (2003) CWB framework and found positive correlations between all forms of deviance (e.g., \( \rho = 0.40 \) for theft and drug use, \( k = 8 \); \( \rho = 0.54 \) for inappropriate verbal actions and misuse of time and resources, \( k = 8 \)). Second, we tested alternative models of the internal structure of CWB (e.g., Bennett & Robinson, 2000; Spector et al., 2006) by means of CFA. These results, along with moderator analyses, will be discussed in detail at the conference. CWB has received substantial empirical attention by researchers in various fields. Unfortunately, because these researchers typically work independently in building and testing theory, an integrative and comprehensive understanding of this phenomenon has yet to be obtained. Our results suggest that the widely available models of CWB may be inadequate for classifying behavior. Modifications to existing models will be offered at the conference.

Keywords: counterproductive work behaviour

Within working memory research a great deal of attention has been devoted to one well-known phenomenon referred to as the Irrelevant Sound Effect (Beam and Jones, 1997). Basically the phenomenon is best described as a significant impairment of verbal short-term memory performance during presentation of even low-intensity background noise - usually speech. The phenomenon is considered to be of great practical importance since extraneous speech and noise are known to be amongst the most often-mentioned sources of disturbance in open-plan offices (e.g. Banbury & Berry, 2005; Bradley, 2003; Rashid & Zimring, 2008; Sundstrom, Town, Rice, Osborn & Brill, 1994). It is assumed that measures of improvement within open-plan offices can be derived from the knowledge about factors the Irrelevant Sound Effect depends on and that the productivity of companies can be improved by applying these measures. However, types of cognitive activities in offices vary depending upon the specific demands of the job. The relevance of the Irrelevant Sound Effect to real life office tasks may be questioned since the phenomenon has mostly been tested using the immediate serial recall paradigm exclusively. The aim of the reported experiments is therefore to investigate whether the Irrelevant Sound Effect generalizes beyond serial recall performance. A series of laboratory experiments investigates whether the Irrelevant Sound Effect can be generalized to tasks operationalizing text comprehension or paired associate learning. Tasks operationalizing text comprehension prove to be sensitive towards impairment by background sound but only if background sound is semantically meaningful. Long term paired associate learning also tends to be impaired only if background sound is semantically meaningful. The reported experiments prove that the Irrelevant Sound Effect cannot be easily extended to tasks that go beyond serial recall. The pattern of results depends on the experimental task at hand. The results are clearly contradictory to the findings on the Irrelevant Sound Effect as semantic content is not considered important for the phenomenon to arise. The implications of these results for theoretical modelling and the practical relevance of the Irrelevant Sound Effect must be discussed.
**Keywords:** irrelevant sound effect, serial recall performance, semantically meaningful

**The limitations of psychological predictors of xenophobia in South Africa**

FINCHILESCU, G. (University of the Witwatersrand), LAHER, H. (University of South Africa)

Xenophobic attacks against African non-nationals have occurred for many years in South Africa. However, the scale and viciousness of the outbreak of violence in May 2008 was exceptional. This violence left scores dead, hundreds wounded and thousands displaced. An important question is why did the attacks occur at this time and in those particular locations? Integrated Theory (ITT) (Stephan & Stephan, 2000) is the social psychological theory that has most commonly been used to understand xenophobia. It proposes certain threat factors (realistic and symbolic threats, negative stereotypy, intergroup anxiety and interaction experiences with the target group) are primary in explaining negative feelings and attitudes towards foreigners. This paper reports a study applying ITT in South Africa in the year prior to these attacks. Using these results, the paper will question whether the emerging factors provide an insight into the igniting factors of the May attacks. A sample of 345 South African respondents completed a questionnaire which measured the variables proposed by ITT. The sample consisted of black, white, coloured and Indian South Africans. The socio-economic levels and living circumstances of these groups still reflect the inequities of South Africa’s apartheid past. Two measures of prejudice towards African immigrants were used – affective prejudice which measured aversive feelings, and social distance, which measured the desire to avoid contact. These measures were separately regressed on the threat variables. The ITT model explained a significant amount of the variability of both prejudice measures. Realistic threats emerged as the strongest determinant of negative attitudes. This suggests that changes in the material circumstances in the country should have been the major igniting factor. However, the detailed analysis of the 2008 attacks produced for the International Organization for Migration (Misago, Landau & Monson, 2009) indicates that this hypothesis is not fully supported. The psychological variables proposed by ITT may help understand the backdrop of xenophobia, but the factors that lead from attitudes and perceptions to action are more complex.

**The longer they stay, the less talented they perceive they are: A profile of perceptions of talent in one Victorian secondary girls school**

BOWLES, T. (Ballarat University Australia)

Gardner’s theory of multiple intelligences suggests a possible nine talents emerge by or during secondary school age. To date little research has effectively measured multiple intelligences or talents of Australian adolescents. The first aim of this research was to apply a recently developed measure of talent based on various approaches to learning and engaging in talents. The second aim of this study was to investigate female student’s perceptions of their talents from a developmental perspective. A cohort of female adolescents from 11 to 18 years of age (n = 325) completed a questionnaire used to measure talent. Each respondent self-reported on a measure of nine talents. Each talent was rated on seven approaches to learning and engagement. Students’ talents scores were profiled using a cluster procedure and two distinct and significantly different groups emerged: a less talented and a highly talented group. The low talent group (n = 169) was significantly lower rating than the high group (n = 156) although the magnitude of the difference was small. There was no difference by age for language and communication and social and leadership talents. Older students (11-14 years; n = 174) rated themselves higher on self-awareness. On the other six talents, significant and weak effects were found showing that older students (15-18 years; n = 151) rated themselves lower than younger students. The findings are discussed in reference to the theory of multiple intelligence and the secondary school experience of females.
The lost individual: On the structure of personality at the within- and between-person level of analysis

BECKMANN, N. (UNSW), MINBASHIAN, A. (Accelerated Learning Laboratory, University of New South Wales), WOOD, R. (University of Melbourne)

There is a strong reliance in organisational psychology on between-person analyses; however, between-person analyses provide surprisingly little insight into the psychological functioning of the individual (Borsboom, Mellenbergh, & Heerden, 2003). Taking a within-person perspective on personality in the work place this paper investigates whether the negative neuroticism-conscientiousness relationship observed in between-person studies is purely a description of differences between individuals, or whether it also characterises the internal psychological structure that individuals possess. Employing an experience sampling methodology, over several weeks 115 mid-level managers from large Australian companies were assessed multiple times a day. Within- and between-person variation in personality indicators was analysed using hierarchical linear modeling. Findings indicate that analysing personality as a within-person phenomenon reveals information not captured by the trait approach. While conscientiousness and neuroticism were negatively correlated at the between-person level, this relationship was reversed at the within-person level. Results are discussed in terms of the distinctness of the within- and between-person structure of personality. Applications for the field of organisational psychology are considered, with a focus on the adaptiveness of neuroticism and conscientiousness.

Keywords: between-person analyses, between-person studies, personality, conscientiousness, neuroticism

The mechanisms of mindfulness

RODGERS, N. (University of Canterbury)

An increasing number of therapeutic modalities including CBT, DBT and ACT have moved to embrace and incorporate mindfulness-based practices into their treatment regimes. Whilst Mindfulness and meditation may well be of benefit to the therapist, possibly strengthening their allegiance to their therapeutic modality and thereby contributing indirectly to the therapeutic alliance, are they in and of themselves directly efficacious as therapeutic practices? Is mindfulness a state of being or a way of doing (non-doing) and what implication does this have for practice? Whilst there is now a considerable body of evidence suggesting that the therapeutic use of mindfulness leads to positive client outcomes, far less has been written on how this works. What are the specific mechanisms, processes and procedures of mindfulness that have been shown to be effective? Do psychologists, counsellors and psychotherapists need to practice and therefore embody mindfulness in order to use it effectively or can it be applied as a therapeutic technique? Further, are there particular client populations or issues that have been shown to benefit from mindfulness-based interventions? What are the risks and contra-indications for mindfulness-based practices? This paper attempts to answer these questions by undertaking an integrative meta-synthesis of the literature on relevant therapeutic outcome studies, proposes a model explaining the mechanisms of mindfulness and concludes by discussing the practical implications for psychologists, counsellors and psychotherapists interested in incorporating mindfulness into their practice.

The mediating effect of employee engagement on organizational support, communication, job satisfaction and productivity

SISON, C. (De La Salle-College of Saint Benilde)

This mediation study aimed to gain further understanding employee engagement, looking into organizational factors such as organizational support and communication as antecedents and how it affects employee performance as reflected on job satisfaction and productivity.
With 285 permanent employees from various organizations, a multiple survey questionnaire was administered which measure job and organizational engagement as well as antecedents (i.e., organizational communication and perceived organizational support) and consequences of employee engagement (i.e., job satisfaction and perceived employee productivity). Data were analyzed using structural equation modeling. The proposed model suggests an acceptable fit based on GFI (.922), CFI (.923), and TLI (.808). Although chi-square (65.56, df=6, p=.000), AGFI (.727), and RMSEA (.190) says otherwise. This implies that the model may still be improved through the inclusion of other variables related to employee engagement. Results further revealed that employee engagement fully mediates the relationship of organizational communication and perceived organizational support with job satisfaction and perceived employee productivity. This result implies the ability of both job and organizational engagement to influence employee’s job satisfaction and perceived employee productivity. It further points out the critical role of the organization through communication and support in influencing employee engagement, thus promote positive employee performance.

Keywords: mediation, employee engagement, organizational support, job satisfaction, productivity

The mediating mechanism of women entrepreneurs’ self-efficacy on entrepreneurial decision-making in China

YANG, J. (Zhejiang University), WANG, Z. (Zhejiang University), YANG, J. (Zhejiang University), LI, K. (Zhejiang University)

The purpose of this study was to explore the mediating mechanism of women entrepreneurs’ self-efficacy on entrepreneurial decision-making in China. In a longitudinal field experiment (approximately 5 months), the study found that the positive impact of entrepreneurial self-efficacy was enhanced by women entrepreneurship development training and significantly related to entrepreneurial decision-making. The sample included 100 women entrepreneurs in China. Results indicated that women entrepreneurial self-efficacy played a positive mediating role on entrepreneurial decision-making. It is expected that (1) Higher levels of women entrepreneurial self-efficacy (WSE) will result in higher levels of entrepreneurial decision-making; (2) WSE will be moderated in its impact on women entrepreneur emergence and entrepreneurial decision-making by the extent to which the WSE matches the demands of the task and the context in which the women entrepreneur is embedded; (3) Higher levels of women entrepreneurial thought efficacy are expected to result in higher levels of entrepreneur development, emergence and efficient entrepreneurial decision-making. The authors discuss practical implications on women entrepreneur development and directions for future research.

Keywords: women entrepreneurs, self-efficacy, decision making, training

The Mental Health Professionals Network workshops: State and learnings

NICHOLAS, A. (Mental Health Professionals Network (MHPN))

The Mental Health Professionals Network is a national project funded by the Department of Health and Ageing. The project aims to improve patient outcomes in primary mental health care by fostering improved interdisciplinary collaboration. This paper will report on the state of the project at the time of writing, and what MHPN has learned about fostering interdisciplinary collaboration throughout the project. The project was funded to achieve its aim of fostering interdisciplinary collaboration by running 1200 interdisciplinary workshops over a two year period. These facilitated workshops target psychologists, psychiatrists, general practitioners, mental health nurses, mental health social workers, pediatricians and mental health occupational therapists and aim to be the starting point for an ongoing, sustainable interdisciplinary mental health clinical networks. The workshops include time for interdisciplinary networking, case study
discussion, and an opportunity to discuss whether the group would like to continue to meet as an interdisciplinary mental health network and to make initial arrangements for the subsequent meeting. The workshops are administered by four MHPN project teams responsible for the workshops in two states. This paper will report on the number of MHPN workshops that have been run in all states and territories of Australia, the number of attendances by each profession, as well as a profile of MHPN facilitators. The challenges that have been met in running this interdisciplinary project will also be reported. MHPN has been operating since September 2008 and will continue to operate until October of 2010. In this time the project has run hundreds of workshops in all states and territories of Australia involving thousands of participants from a number of mental health professions. The project has encountered a number of challenges in moving towards its aim of improving patient outcomes in primary mental health care by fostering improved interdisciplinary collaborative care. The learnings of this project can make a valuable contribution to other interdisciplinary programs.

Keywords: Mental Health Professionals Network, interdisciplinary collaboration, primary care providers

The Mental Health Professionals Network: Creating sustainable interdisciplinary mental health networks

NICHOLAS, A. (Mental Health Professionals Network (MHPN))

The Mental Health Professionals Network (MHPN) aims to improve patient outcomes in the primary mental health care sector through the promotion of interdisciplinary collaborative care. This national, Department of Health and Ageing funded project, is funded to deliver 1200 interdisciplinary workshops over a two year period, with the long term aim of creating interdisciplinary mental health networks across Australia. This paper will report on the processes used to create these sustainable networks, the number and geographical distribution of these networks, and provide some vignettes on the types of networks created and their activities. MHPN’s four project teams create interdisciplinary mental health workshops that aim to bring together psychologists, psychiatrists, general practitioners, mental health nurses, mental health social workers, pediatricians and mental health occupational therapists who work in a similar geographical area, or specialty clinical field. These workshops offer the opportunity for interdisciplinary networking, case study discussion with a focus on collaborative care, and provide a forum to discuss the creation of an ongoing interdisciplinary mental health network. MHPN can provide administrative support and $500 of funding to each ongoing network. MHPN interdisciplinary mental health networks have been created in all states and territories of Australia. These networks vary in their membership, purpose and activities. This paper will report on the number and geographical spread of these networks, the professions that make up their membership, and the activities undertaken in the network meetings. Vignettes of a small number of networks that outline the process of their formation, their overarching purpose, and their activities will be reported. MHPN aims to create sustained interdisciplinary mental health networks that allow mental health professionals a forum in which they can discuss various facets of collaborative mental health care. This is done through the creation of initial, fully-resourced interdisciplinary workshops that provide an opportunity for the participants to continue to meet as an ongoing network, and ongoing administrative and minimal financial support. MHPN has encountered many challenges and learned much about the process of created these sustained networks that may be useful to communicate to other mental health care projects and services.

Keywords: Mental Health Professionals Network, interdisciplinary collaboration, mental health care

The mental representation of rearward traffic in visuo-spatial working memory during lane changing

HENNING, M. (Chemnitz University of Technology), KREMS, J. (Chemnitz University of Technology)
The goal of the study is to examine processes involved in holding information about rearward traffic in working memory. It was proposed that rearward traffic information (rather spatial) should interfere most with spatial tasks. The more dynamic rearward traffic is in terms of higher speed, the more dynamic the mental representation of rearward traffic should be, and the more it should interfere with the dynamic version of secondary tasks. A driving simulator study was conducted where 30 participants carried out lane changes with rearward traffic in the target lane. Before lane change preparation, participants memorized one of five secondary tasks (visual-static, visual-dynamic, spatial-static, or spatial-dynamic, phonological). After lane change execution, they were asked to recall the memorized material. Dependent variables were driving task performance, percentage of correct secondary tasks, and glance behavior to the left outside mirror. All secondary tasks were calibrated in a pilot study with 22 participants to be similar in difficulty. All visuo-spatial secondary tasks interfere with the preparation to a certain extent. This was measurable in the secondary task performance and in the glance behavior, but not in the driving-task’s parameters. In contrast to the hypotheses, results indicate that information about rearward traffic interfered most with visual tasks. Nevertheless, the more dynamic version of the visual task (visual-dynamic) interfered more in the condition with the faster rearward traffic, in contrast to the spatial-dynamic task. A possible explanation for the contradictory results could be that the driving scenario was too easy and predictable so that participants memorized information about rearward traffic more in terms of a picture (car vs. no car) and not a dynamic object in space. However, the dynamic of the rearward traffic is reflected in the results. Follow up studies should work with a more dynamic and less predictable driving scenario.

Keywords: working memory, rearward traffic information, visuo-spatial tasks, mental representation, performance

The passport problem: Trying to improve the ability of experienced operators to determine whether the image in a photo-ID document is of the bearer

KEMP, R. (University of New South Wales), WHITE, D. (University of New South Wales), BURTON, M. (University of Glasgow), JENKINS, R. (University of Glasgow)

It is critical to national security that we can determine the identity of people crossing national borders. This is usually achieved by comparing the traveler to the appearance of a photograph contained in a photo-ID document such as a passport. However, previous research has shown that the task of deciding whether two images are of the same unfamiliar person is more difficult and error prone than usually realized. We call this the passport problem. We are investigating methods to increase the accuracy with which human operators can match images of unfamiliar faces and have developed several new image formats which improve performance in the laboratory. In this study we present the results of a first attempt to test one of these formats in a more realistic setting with expert operators. A total of 30 people participated, all of whom worked in positions which required them to check the validity of passports by comparing the photograph to the appearance of the bearer. The participants completed a standard test of face matching (The Glasgow Face Matching Test; GFMT). Each participant then sat at a desk and was approached by a series of “customers”. The participants were required to determine whether the customer was the person shown on a computer screen in front of them. Decision accuracy and latency were recorded for an average of 54 trails per participant. In about half the trails the photograph was of the customer while in the other trails it was of another person. Half of the trails involved a comparison to a conventional photograph and half to a modified image which presented an average of several different images of the subject. In laboratory testing these average images result in slightly improved recognition compared to normal photographs. Despite the limited number of customers and photographs available for use in the study, and the level of experience of the participants, many errors were recorded. On average participants made errors on about 10% of trails when comparing a photograph to a live target. Performance on the GFMT was comparable to other populations, and showed large individual differences but was not
correlated with performance on the photo-to-live comparison task. Performance was not enhanced by the use of average images compared to standard photographs. The study demonstrates that the passport problem is not eliminated by experience or simple training: performance in this realistic task was surprisingly error prone. Contrary to our expectations, the use of average images did not improve performance. Possible reasons for this finding will be discussed. These results emphasize the need for further research in this field in order to maximize the ability of security staff to detect identity fraud.

The positive and negative consequences of emotion regulation in nursing

HAYWARD, R. (University of South Australia), TUCKEY, M. (University of South Australia), BOYD, C. (University of South Australia)

As indicated in a prior qualitative study, embedded within the work role of nurses is the chronic need to regulate one’s emotions when interacting with patients and their families. Given the problems in attracting and retaining nurses, it is important to develop our understanding of the intricate emotional processes involved in performing this work so as to create a work environment conducive to promoting the health, well-being and development of nurses. The aim of this study was to examine the relationships between different emotion regulation strategies and resultant levels of exhaustion, fatigue and recovery on a day to day basis. 30 nurses from a range of specialties completed a ‘tick box’ diary after six individual shifts indicating: details of a specific patient interaction; specific emotion regulation strategies employed in relation to the interaction; levels of emotional exhaustion and subjective fatigue; and finally how well they recovered after their shift. A multi level analysis was conducted to examine the specific relationships between emotion regulation strategies and how well they predicted emotional exhaustion, subjective fatigue and recovery at the end of each day. Results indicated a pattern of adaptive emotion regulation strategies that lead to lower levels of exhaustion and fatigue and to better recovery each day. Additionally maladaptive strategies were identified that were linked to higher daily levels of exhaustion, fatigue and poor recovery; potentially impacting on the individual’s functioning in future shifts. Baseline measures of perceived psychosocial safety culture were also associated with the use of specific emotion regulation strategies. These finding are discussed in terms of the potential for the training and professional development of nurses with regard to establishing a repertoire of adaptive emotion regulation strategies to engage when interacting with patients and their families. Stress management initiatives may also aim at reducing a reliance on maladaptive strategies and promote the development and use of more adaptive strategies. Finally, the importance of developing and maintaining a strong psychosocial safety culture within an organisation is highlighted in terms of encouraging nurses to adopt emotion regulation strategies that promote and protect their own health and well-being.

Keywords: nurses, emotion regulation, emotional exhaustion, subjective fatigue, recovery

The prediction of non-suicidal self-injury (NSSI)

SWANNELL, S. (The University of Queensland), MARTIN, G. (The University of Queensland), PAGE, A. (The University of Queensland), HASKING, P. (Monash University)

The aim of the current study was to explore the associations between non-suicidal self-injury (NSSI) and psychiatric morbidity, psychological/cognitive functioning and childhood trauma and develop an accumulative risk model to assist in the prediction of NSSI. 12,006 Australians aged 10+ randomly selected from the Australian Electronic White Pages completed a 14 minute Computer Assisted Telephone Interview (CATI). The interview included questions on demographics, NSSI, psychiatric morbidity, psychological and cognitive functioning and childhood trauma. Univariate associations between risk factors and NSSI were compared using odds ratios.
Predictive models were explored with sequential logistic regression. A model containing multiple factors and taking into account a range of mediating and moderating variables was evaluated using structural equation modeling. People who self-injured in the four weeks prior to the survey were 10.0 times more likely to report severe mental health problems (95% CI 6.6-15.2), 3.3 times more likely to lose their temper (95% CI 2.2 – 4.9), 4.5 times more likely to have trouble regulating emotion using cognitive reappraisal (95% CI 2.2-9.1), 2.9 times more likely to have trouble finding the right words to describe their feelings (95% CI 2.1-4.2), 8.5 times more likely to blame themselves when feeling stressed (95% CI 5.8-12.3), 2.7 times more likely not to turn to their family for support in times of stress (95% CI 1.8-3.9), 29.8 times more likely to experience derealisation (95% CI 21.2-41.9), 4.9 times more likely to experience depersonalisation, 4.0 times more likely to report neglect (95% CI 3.4-4.6, adults only), 4.1 times more likely to report physical abuse (95% CI 3.5-4.7, adults only), and 4.0 times more likely to report sexual abuse (95% CI 3.4-4.8, adults only). Results of sequential logistic regression and structural equation modelling are forthcoming.

Keywords: non-suicidal self-injury, psychiatric morbidity, cognitive functioning, childhood trauma, risk

The prevalence and correlates of depressive symptoms in Chinese old population

LJ, J. (Chinese Academy of Sciences), YU, J. (Chinese Academy of Sciences), WU, S. (Chinese Academy of Sciences), WU, Z. (Institute of Psych, Chinese Academy of Sciences)

Lower depression prevalence rate in Chinese elderly compared to the Westerners has been reported in a number of locally sampled studies. Explanatory factors for the low prevalence, such as higher level of social support, lower level of urbanization, stigma on mental illness, and filial culture have changed significantly during the rapid socioeconomic transition of China in the last two decades. Therefore, the aim of the present study is to explore the depression prevalence in Chinese elderly population with a nation-wide sample, taking into account the rapid economy development along with the consequential social changing condition. A cross-sectional survey was conducted with a nation-wide representative Chinese sample of 4945 old (60+ years) and pre-old (55-59 years) adults. The Center for Epidemiologic Depression Scale (CES-D) was used as the measurement tool for depressive symptoms. Demographic and four self-reported possible protective factors (Family support, Economy status, Health status, and Activities participation) were taken into consideration. The sampling was stratified with geographical region, age, sex and educational level, and convenient sampling was applied within each stratum. The study found that the prevalence of self-reported depressive symptoms (CES-D≥16) in the total study population was 39.86% (pre-old: 39.95%, young-old: 39.84%, old-old: 39.65%, oldest-old: 45.19%), and the CES-D score was significantly higher in the oldest-old than the three younger groups. Furthermore, multiple regression analysis indicated that age itself was not an effective predictor for depressive symptoms, whereas family support and health status explained most part of the variations of the depression. Family support and health status were the most significant protective factors for Chinese elderly depression. The Chinese traditional culture which values family has changed significantly, which may be an important factor for the increased prevalence found. In addition, the increased depressive symptoms with age were more likely attributed to age-related confounding variables rather than age by itself.

The process of engaging with the Nyoongar community from a Wadjallah perspective

PRANDL, K. (Curtin University of Technology), ROONEY, R. (Curtin University of Technology), BISHOP, B. (Curtin University of Technology), DAVIS, M. (Curtin University of Technology)

Aboriginal women are five times more likely than their non-indigenous counterparts to die during or soon after childbirth and are more
likely to have a baby born prematurely or to be of low birth weight. Aboriginal women are faced with the significant burden of generational stress, poverty, loss of cultural identity and support which suggests that addressing stress during the pregnancies of Aboriginal women is vital. There has been a long history of psychological research conducted with Aboriginal communities that has not provided any long term solutions and has sometimes exacerbated the situation. In order to protect the survival and cultural integrity of the Indigenous Peoples of Australia research needs to be conducted within a collaborative and culturally secure framework but most importantly be driven by the Aboriginal community. The author will be conducting research which will address these deficiencies by exploring how Aboriginal women conceptualize stress and depression during pregnancy (Study 1) which will provide the background for developing a culturally sensitive measure (Study 2). AIMS: The aim of the current paper is to describe the process by which the research aims have been developed. In general, a qualitative approach has been utilized in the current study, namely interpretive phenomenology. The context of the study has been set up through a process of incidentally engaging with the community and the development of trust. This research topic was conceived through discussions with Aboriginal women during antenatal midwifery appointments, yarning in the office and impromptu community meetings with Grandmothers and Aunties. The process of consultation began in women’s homes over the last three years when Aboriginal women identified that stress was the issue that was impacting their health. This highlights the importance of long-term commitment by researchers who are interested in engaging with Indigenous people to undertake research that is meaningful and relevant to the community. This presentation will describe the journey taken when a “Wadjallah” researcher engages with women from within the Nyoongar culture. The challenges and processes of adopting a truly collaborative approach to psychological research will be discussed, from the early negotiations with the community to the establishment of the Nyoongar Women’s Reference Group.

Keywords: Aboriginal/Indigenous women, cultural identity, pregnancy, stress

The psychological distress of the young novice driver

SCOTT-PARKER, B. (Centre for Accident Research and Road Safety, Queensland (CARRS-Q), Queensland University of Technology (QUT)), WATSON, B. (Centre for Accident Research and Road Safety, Queensland (CARRS-Q), Queensland University of Technology (QUT)), KING, M. (Centre for Accident Research and Road Safety - Qld / QUT)

Around the world young novice drivers are at significantly greater risk of being injured or killed in road crashes than older, more experienced drivers. These drivers are also traversing the developmental milestone of adolescence, a period in which risky behaviour is normative. Adolescence is also frequently associated with psychological distress, with prevalence estimates of between 12% and 28.5% for adolescent depression (Di Clemente, Santelli, & Crosby, 2009). Road safety researchers have begun to consider the influence of the young driver’s mental health upon their behaviour. Whilst correlation analyses have revealed that the young driver’s mental health is associated with their risky behaviour, the extent of this influence remains unknown. Therefore this study was designed to explore the role of psychological distress in the risky behaviour of young drivers. Seven hundred and sixty-one young drivers (523 females, 238 males) aged 17-24 years (M= 19 years, SD= 1.56) with a provisional driving license (282 P1 license, 479 P2 license) completed an online survey. Participants self-reported their sociodemographic characteristics, their psychological distress as measured by Kessler’s Psychological Distress Scale (K10), and 44 risky driving behaviour items. Correlation analyses revealed that greater psychological distress was associated with more risky driving behaviour (r= .29, p< .001). Regression analyses revealed that the combination of sociodemographic variables (age, gender, license, university, and marital, study and employment status) and psychological distress explained 10% of the variance in risky behaviour of the young driver. Psychological distress uniquely explained 8.2% of this variance. Separate regression analyses revealed that
psychological distress uniquely explained 6.2% of male and 9.3% of female; and 5% of P1 and 10.4% of P2 risky driving behaviour. The research findings have implications for mental health professionals and road safety researchers alike. Whilst insufficient as a stand-alone measure, research into young novice driver risky behaviour should incorporate a measure of their psychological distress. Moreover, it appears that adolescents who are experiencing psychological distress place themselves at greater risk of harm by undertaking risky driving behaviour. Accordingly adolescent mental health interventions may also reduce the young driver’s risk of injury due to a car crash.

Keywords: novice drivers, risky behaviours, adolescence, psychological distress

The public perception of psychologists: confusion with other professions and GP perceptions

DEMPSEY, S. (Queensland Health)

The provision of accessible and effective mental health services has become an increasing priority in Australia over the last decade. In November 2006, various levels of government in Australia responded to lobbying from the Australian Psychological Society (APS), reports from parliamentary inquiries, and independent reviews acknowledging the need for an increased level of participation by psychologists in mental health care, which ultimately resulted in the provision of some mental health care services on Medicare (Moulding et al., 2007; Perkins et al., 2007, van Gool, 2007). The aim of this presentation is to present the findings from two published studies which suggest that the public image of psychologists is an integral factor in this allocation of funding (in the form of a Medicare rebate), and remains so with regard to the allocation of referrals (from General Practitioners (GPs) and psychiatrists). A thematic analysis (Braun & Clarke, 2006) was used to explore the issues that emerged across interviews from two separate published studies. The inherent flexibility of a thematic analysis, its ability to provide a comprehensive and systematic description of the data, and the opportunity it provides to focus on and illuminate specific aspects of the data, allow for the clear analysis of a qualitative data set. Results from the two studies suggest that the public perception of psychologists is easily confused with other health professionals (particularly psychiatrists), and that GPs do not have a clear understanding of the role of psychologists or the type and amount of training which they undertake. A range of recommendations are made to distinguish (and protect) the specific role of psychologists from other mental health professionals. Recommendations are also provided to assist the profession of psychology in clearly articulating its public image particularly with regard to GPs and in light of the recent Medicare changes.

Keywords: mental health services, public image, Medicare funding

The relationship between cognitive development and attachment style

WELLISCH, M. (Macquarie University), BROWN, J. (Macquarie University)

Research indicates that securely attached children have advanced language skills and are well adjusted, whereas insecurely attached children often have ongoing problems that include learning disabilities, and psychological and behavioural problems (Prior & Glaser, 2006). Interestingly, some researchers have claimed that gifted children are well balanced, whereas others have found the opposite to be true, especially during the teenage years (Winner, 2000). However the literature on gifted children views socio-emotional problems and uneven development in terms of a by-product of giftedness (Silverman, 1997). Therefore, the current study was designed to test the hypothesis that cognitive development, socio-emotional adjustment and learning disabilities are all related to attachment style, regardless of giftedness. Participating 7-10 year old children with an already completed WISC-IV IQ assessment (currently n = 47) and their parents have been recruited. Participants have been drawn from a New Zealand psychology clinic specializing in gifted children, the Macquarie University Rod Power Psychology Clinic, the New
South Wales Association for Gifted and Talented Children, and Catholic Education Office primary schools from the Parramatta Diocese. Data collection includes a general background questionnaire, the Experience in Close Relationships Scale (Brennan, Clark, & Shaver, 1998), the Attachment Style Classification Questionnaire for Latency Age Children (ASCQ) (Finzi et al., 1996), and the Child Behavior Checklist (Achenbach, 2001). Qualitative interviews with mothers have also been collected and analyzed. Preliminary findings indicate a positive trend correlating higher IQ with secure attachment. Additionally, children were more likely to have avoidant attachment styles where the Perceptual Reasoning Index scores were higher than Verbal Comprehension Index scores. These findings are related to the current model of giftedness used in Australian schools and implications will be presented.

Keywords: cognitive development, attachment style, gifted children

The relationship between subjective well-being and satisfaction with daily travel

SUZUKI, H. (Kyoto University), FUJII, S. (Kyoto University), KITAGAWA, N. (Kyoto University), NAKAI, S. (Kyoto University), GÄRLING, T. (University of Gothenburg), FRIMAN, M. (Karlstad University), OLSSON, L. (Karlstad University), ERIKSSON, L. (Karlstad University), ETTEMA, D. (Utrecht University)

Affective/Cognitive evaluations of daily travel are hypothesized to affect subjective well-being (SWB) (cf. Ettema et al 2009). Since global SWB is known to be causally related to domain-specific SWB (e.g., Oishi et al 1999), improvement of travel satisfaction and affective status during travel (travel-specific SWB) should contribute to global SWB. This should be one important reason for transport policy measures aiming at improving evaluations of travel. Hard measures such as travel time improvement, however, has typically attracted transport policy makers’ attention and measures of affective and non-instrumental factors have not. However, as a recent study shows (Diener et al, 2008), accumulation of affective and cognitive responses to specific experiences, caused by non-instrumental factors, would have an effect on travel-specific SWB. Thus, further understandings for travel-specific SWB may contribute to improve evaluation of such travel policy. The present research explores the determinants of affective/cognitive travel-specific SWB while focusing on the differences between the different legs of daily trips. Thus, a whole trip (called a linked trip) consists of trip legs classified by their travel mode. Each trip leg with ‘hard’ (e.g. travel time) and more qualitative (e.g. crowdedness, visibility of scenery) attributes may affect mood and therefore increase travel-specific SWB. Measurements of satisfaction with trip legs would enable us to understand determinants of travel specific SWB more clearly. To examine the effect on travel-specific SWB of satisfaction with trip legs of daily trips, we conducted a survey among 120 Japanese university students. In a questionnaire format we asked respondents to consider four different daily trips and for each to list their trip legs. The respondents were also asked to rate attributes (for each linked trip; travel purpose, for each trip legs; travel mode, activity during travel, crowdedness and visibility/preference of scenery they can see during the trip), their affective evaluation and degree of satisfaction during each trip. The relationships between attributes of trips and trip legs, affective and cognitive travel-specific SWB and global SWB were examined. Overall the results confirmed the expected directions of the relationships. Results show people rate high SWB for trip which they can see and prefer scenery during the trip. The effect of other activities and crowdedness vary according to travel mode and travel purpose.

The restorative value of different landscape types

DEGENHARDT, B. (Swiss Federal Research Institute for Forest, Snow and Landscape WSL), BUCHECKER, M. (Swiss Federal Research Institute for Forest, Snow and Landscape Research)

Nearby outdoor recreation areas provide important opportunities for the public to recover from the demands of their daily life. But the
need for these areas conflict with the current landscape development in peri-urban areas in Western Europe. There, competing forms of land use, such as settlement, and road construction, increase the pressure on nearby outdoor recreation areas. It can be expected that spaces for recreation will further decrease so it is all the more important to design the remaining recreation areas so that they are of high quality. To this end, we examined which landscape elements of a nearby recreation area are preferred by residents when seeking to fulfill their restoration needs. A total of 542 inhabitants of a Swiss peri-urban town returned a postal questionnaire in which they indicated their preference for each of 20 landscape elements on their routes within the nearby recreation area. Further data were collected on how often they used the area on workdays and which of 28 cognitive, emotional, physical, social restorative and ego-related goals motivated visitation. Initial factor analysis yielded 7 landscape “types” which we labelled savannah, mountain, open country, water, semi-private outdoors, and light & space. Ordinal correlations between landscape type and restoration goals showed specific patterns of landscape types combining with use goals. These relationships were found to be more complex for social and ego-related use goals than for cognitive, emotional, and physical goals. The results indicate that the type of landscape matters when attempting to encourage or impede specific restorative effects.

The role of age as a moderator of the PEFit—performance association

KORFF, J. (Jacobs University), BIEMANN, T. (Wirtschafts- und Sozialwissenschaftliche Fakultaet; Universitaet zu Koeln), VOELPEL, S. (Jacobs University Bremen)

As workforces of highly developed societies are rapidly aging it becomes increasingly important to understand the role of employees’ development and age-related changes. It has been argued that developmental dynamics pertaining to cognitive abilities and personality can result in declined person-environment (P-E) fit (e.g., Kanfer and Ackerman 2004). Although effects of developmental dynamics have been addressed theoretically, empirical data is widely lacking. This paper contributes to close this gap by providing results of an empirical examination of the moderating impact of employees’ age on the relationship between P-E fit and individual performance. A multilevel study comprising 1,526 employees (lower level) and 586 supervisor ratings (lower level) in 74 German and Austrian business units (higher level) focused on the role of chronological age, job, and organization tenure as well as time perspective for P-E fit (demands-abilities and needs-supplies), and supervisor-rated individual performance (i.e. in-role behavior and organizational citizenship behavior). Multilevel data analyses provide evidence for the associations between P-E fit and individual performance, i.e. between needs-supplies fit and in-role behavior and organizational citizenship behavior (individuals) as well as between demands-abilities fit and in-role behavior and organizational citizenship behavior (organization). Chronological age of the employees is moderating the associations between demands-abilities fit and in-role behavior as well as between needs-supplies fit and in-role behavior such that the relationship becomes stronger with increasing age. Furthermore, the association between needs-supplies fit and organizational citizenship behavior (organization) exhibits an inverted U-shaped curvilinear development with increasing age, first strengthening and later weakening the relationship. In line with expectations derived from lifespan theory age turns out to be a relevant moderator for HR management. As workforces age it becomes more important to consider and incorporate developmental dynamics in HR management with regards to the alignment of person and job characteristics contingent of employees’ age.

Keywords: age-related changes, cognitive ability, personality, developmental dynamics, individual performance
The role of anger in obsessive compulsive checking

JONES, M. (The University of Sydney), MADIWALE, S. (The University of Sydney), VACCARO, L. (The University of Sydney)

Anecdotal, case study and empirical evidence has indicated that anger may play a salient role in the presentation of Obsessive Compulsive Disorder (OCD). However the extant literature on the relationship between anger and OCD is inconsistent and compromised by numerous methodological limitations. The present study aimed to overcome previous limitations and provide new findings about the role of anger in OCD checking subtype. The sample comprised 34 OCD patients who had checking as their primary symptom, with age and gender matched non-OCD controls. All patients met DSM-IV-TR criteria for OCD. Participants completed the Trait Anger Expression Inventory-2 (STAXI-2; Spielberger, 1999), Vancouver Obsessional Compulsive Inventory (VOCI; Thordarson, 2004) and the Beck Depression Inventory (BDI; Beck, et al. 1996). Controls were additionally screened using the Padua Inventory-Washington State University Revision (PI-WSUR; Burns, et al, 1996) to ensure that did not have OCD. Compared to the age and gender matched controls, the OCD group scored higher on trait anger, anger expression and anger suppression, but lower on anger control-in. Trait anger remained significantly higher in the OCD group after controlling for depression. Moreover, severity of checking compulsions was found to significantly predict trait anger, above and beyond the effects of depression. These findings demonstrate that anger may play an important role in OCD. As expected, overall anger expression scores were found to be higher in OCD patients, indicating that these individuals are more likely to experience anger than normal controls. The theoretical and clinical implications of the results are discussed. In particular, we suggest that the data provides support for an integrated model based on Wells (1997) and Berkowitz’s (2003) models of OCD and anger, respectively. The findings from the present study will also be compared with those from recent empirical work in this area.

Keywords: obsessive compulsive disorder, anger, traits

The role of attachment style and interpersonal processes in shaping organisational citizenship behaviour

DE SANCTIS, M. (Deakin University), KARANTZAS, G. (Deakin University)

It has recently been suggested that organisational citizenship behaviour (OCB), is in part, predicted by an individual’s ability to build bonds and communicate effectively with co-workers and maintain a positive sense of self-worth. However, little research has investigated the relationships between these interpersonal factors and OCB using a theoretical framework grounded in relationship processes. Attachment theory, an interpersonal theory of personality development, can provide a framework in which to investigate the role of relationship processes in predicting OCB. The aim of the study was to examine the relationship between attachment style, interpersonal communication competence, self-esteem and OCB. A total of 131 participants (58 males, 71 females, 2 not recorded, $M = 44.79$ years, $SD = 9.09$ years) completed an online questionnaire comprising measures of attachment, communication competence, self-esteem and OCB. The questionnaire took approximately 15 minutes to complete. Using path analysis, a double mediation model was tested and demonstrated excellent fit $X^2(3, N = 131) = 3.318, p > .01$, $CFI = .998; RMSEA = .029$. Communication competence and self-esteem significantly mediated the association between attachment anxiety and OCB, whereby, anxiety was negatively associated with communication, which in turn, was positively associated with OCB. The relationship between attachment avoidance and OCB was only mediated by communication competence, whereby avoidance was negatively associated with communication, which in turn, was positively associated with OCB. Communication competence mediated the association between self-esteem and OCB with positive associations found between these pathways in the model. The present findings demonstrate that attachment plays a key role in explaining an individual’s propensity to engage in OCB through their ability to communicate.
with colleagues and the extent to which they feel positive about themselves. This is the first study to develop such an integrative model and highlights the importance of considering relationship processes in employees’ demonstration of OCB.

Keywords: attachment style, organisational citizenship behaviour, interpersonal factors, self-esteem

The role of climate for transfer of training and intrinsic benefits in explaining employees’ motivation to attend voluntary professional development activities

SANKEY, K. (University of Southern Queensland), MACHIN, T. (University of Southern Queensland)

Attendance at organisationally provided internal training and development activities (T&D), is often non-mandatory and therefore, to some degree, contingent on employees’ motivation to attend. Organisational climate for the transfer of training (transfer climate) includes work environment factors that influence the use of skills and knowledge gained during training when back in the workplace. We expected that transfer climate would be a strong determinant of employees’ intention to participate in training activities. Based on Self-Determination Theory (SDT) which describes motivation on a self-determination continuum involving various degrees of controlled (external) and autonomous (more intrinsic) motivation, we predicted that both transfer climate and perceived intrinsic benefits from attendance at T&D would be linked to more autonomous types of motivation. Results showed that transfer climate factors differentially influenced the four types of motivation. Intrinsic benefits was a strong positive predictor of more autonomous types of motivation and a strong negative predictor of more controlled motivation and amotivation. Analysis of mediational models also showed that the relationship between transfer climate factors and type of motivation was partially mediated by intrinsic benefits. Employers should focus on strategies that generate more autonomous motivation to attend non-mandatory T&D among employees. These strategies should include promoting a positive transfer climate using positive reinforcement of the intrinsic benefits of T&D.

Keywords: organisational training and development, motivation, Organisational climate, transfer climate, self determination theory

The role of filial piety in the career commitment process among Chinese postgraduates

JIN, L. (The University of Hong Kong)

The current study extended the research line regarding the relationship between family of origin and adaptive career decision making. More specifically, it examined the unique impact of filial piety in predicting Chinese postgraduates’ career decision self-efficacy, vocational commitment, and their tendency to foreclose on their choices after controlling for the Big Five personality traits. The sample consisted of 796 postgraduates recruited from 5 universities in Beijing. Of these, 468 were males and 328 females, coming from the first year (337, 42.3%), second year (207, 26.0%), and third year (243, 30.5%). Nine students (1.1%) did not complete this item. Five measures were used. The Career-Related Filial Piety Scale (Jin, 2009), The NEO-Five Factor Inventory (Costa & McCrae, 1992), Career Decision Self-Efficacy Scale-Short Form (Betz, Klein, & Taylor, 1996), and the Commitment to Career Choices Scale (Blustein, Ellis & Devenis, 1989) assessed the key constructs, reciprocal or authoritarian filial piety, career decision self-efficacy, vocational
commitment, and the tendency to foreclose, respectively. All these measures showed acceptable internal consistency reliability with the current sample, ranging from .66 (Openness) to .91 (career decision self-efficacy). A demographic questionnaire was used to collect participants’ gender and academic year. The zero-order correlations showed that reciprocal filial piety was associated positively with self-efficacy and vocational commitment, while authoritarian filial piety was correlated negatively with vocational commitment but positively with the tendency to foreclose (p < .01). The hierarchical multiple regression analyses further revealed that reciprocal filial piety uniquely accounted for 3% (p < .001) of the variance in career decision self-efficacy, while authoritarian filial piety uniquely accounted for 5% (p < .001) of the variance in the tendency to foreclose, after controlling for the Big Five personality traits, gender, and academic year. This study applied the dual model of filial piety to understanding Chinese postgraduates’ career commitment process. The findings partially supported the unique contribution of filial piety to the prediction of career decision self-efficacy and career choice commitment beyond and above personality traits. The theoretical and practical implications of the results are discussed.

Keywords: family of origin, decision making, filial piety, self-efficacy, vocational commitment

The role of hope in promoting posttraumatic growth after experiencing bullying in school

LEUNG, B. (University of Hong Kong), HO, S. (University of Hong Kong)

Accumulating evidence has shown that people reported positive changes after experiencing stressful life events. Tedeschi and Calhoun (2004) used the term posttraumatic growth (PTG) to refer to such self-perceived positive changes. However, not all individuals reported PTG after undergoing stressful life events. Thus, identifying factors that facilitate PTG is crucial because these factors can promote better adjustment in the face of adversity. In this study, the role of hope, an adaptive cognitive style, in promoting PTG beyond and above other personal and emotional factors, after experiencing bullying in schools was examined. Seven hundred and four participants were recruited from 7 different local secondary schools in Hong Kong. Among them, 169 participants (88 boys and 81 girls, mean age 13.4 yrs) have reported experiencing being bullied in school in the last several months. They have also completed the Posttraumatic Growth Inventory, Children Hope Scale and other measures assessing their level of happiness, depression and self-esteem. Correlation analysis revealed that PTG was significantly and positively associated with happiness, self-esteem and hope (r = .44, .33 & .50, p <.01 respectively) and negatively associated with frequency of bullying and depression (r = -.33 & -.47, p <.01 respectively). In order to test the predictive power of hope on PTG beyond and above the other emotional and personal factors, a stepwise hierarchical regression analysis was performed with demographic variables were entered into the first model followed by happiness, depression and self-esteem in the second model and hope was entered lastly into the third model. Results revealed that gender, frequency of bullying experienced and depression were significant predictors of PTG. More importantly, hope was found be a significant predictor of PTG even after controlling all the other factors. The unique and total variance of PTG explained by hope and the final model was about 10% and 41% respectively. This study provided evidence that hope contributed unique facilitative effects on PTG even after controlling the effects of other important factors. Further research investigates and compares the effects of different cognitive factors such as expectancy model of optimism, explanatory style and hope will reveal a more comprehensive picture of the underlying cognitive and psychological mechanism of PTG.

Keywords: stressful life events, posttraumatic growth, positive changes, hope, bullying

The role of predicted, on-line and remembered satisfaction in current travel mode choice

FRIMAN, M. (National Institute of Occupational Health), PEDERSEN, T. (National Institute of
Previous research has revealed that measures of predicted and remembered satisfaction are biased, as compared to the more accurate online measures of experienced satisfaction. The aim of this study was to investigate whether (a) predicted satisfaction, (b) experienced satisfaction or (c) remembered satisfaction with public transport, is the best predictor for car users’ (i) current travel mode choice and (ii) their future intentions to travel by public transport.

The study used a longitudinal, quasi-experimental design in which 106 car users received a one-month free public transport travel card. Prior to the trial period they predicted what their satisfaction with public transport would be, both overall and on several satisfaction-attributes. During and following the period they reported their online experienced satisfaction. Two years later, they were asked to recall their satisfaction with the public transport service at the time of the trial period. In addition, they were asked to report their current frequency of public transport usage. Finally, they were asked to estimate their intention to use public transport in the future. Repeated measures’ MANOVAs showed that predicted satisfaction is biased, as compared to reports of online experienced satisfaction. Data on remembered satisfaction, current frequency of public transport usage, and future intentions of whether or not to use public transport were analyzed and reported. The analyses revealed whether anticipated, online or remembered satisfaction predicted car users’ current travel behavior and their future intentions to use public transport. Car users’ make mistakes when trying to forecast their satisfaction with public transport. Our research showed that car users’ predictions are biased as compared to online experienced satisfaction. In this study, conclusions were also made of car users’ remembered satisfaction with public transport two years after a completed trial period. These results show whether online measures or retrospective measures are superior to predict car users’ current travel mode choice and future intention to use public transport.

Keywords: predicted satisfaction, experienced satisfaction, remembered satisfaction, public transport

The role of Primary Motor Cortex in abstract and concrete sentences comprehension

SCOROLLI, C., SCOROLLI, C. (University of Bologna), JACQUET, P. (University of Bologna), BINKOFSKI, F. (University of Bologna), NICOLETTI, R. (University of Bologna), TESSARI, A. (University of Bologna), BORGHI, A. (University of Bologna)

One of the main challenges of embodied theories is to explain the comprehension of abstract sentences. In a recent work Scorolli, et al. (submitted) used a new paradigm that allows to study the dimension abstract-concrete in a continuum. They examined quadruples of sentences where they combined the same Concrete Verb with a Concrete Noun and with an Abstract Noun, and the same Abstract Verb with the nouns previously used. Using the same paradigm we performed a Transcranial Magnetic Stimulation (TMS) study, to replicate their results and to explore the role of the left primary motor cortex during the processing of motor and non-motor verbs, combined with nouns of graspable and non-graspable objects. Participants were required to judge the sensibility of 48 quadruples built by combining a Concrete Verb with a Concrete Noun or an Abstract Noun and by combining an Abstract Verb with the same nouns previously used. Participants received a single TMS pulse 250ms after the presentation of the noun or of the verb. Compatible combinations were processed faster than mixed combinations. Specifically concerning the effects of TMS on the portion of M1 where is represented the hand, with sentences containing Abstract Verbs, participants were equally fast both for the stimulation on the first and on the second word. When the combinations contained Concrete Verbs, participants where faster when the pulse was given on the first than on the second word. The advantage of the compatible combinations replicates that one obtained by Scorolli et al. (submitted) and it’s in line with the idea that abstract and concrete words are processed in parallel systems. The stimulation of M1 after the presentation of the first but not the second
word leads to faster RTs with sentences containing Concrete Verbs. An amodal theory doesn't predict a specific modulation of the stimulation depending on the kind of verb; a modal theory predicts a specific modulation regardless of the kind of verb. Both the predictions are disconfirmed by the data that seem to be in favor of theories based on multiple types of representation (Dove, 2009; Barsalou, et al., 2008; Borghi e Cimatti, 2009).

The role of religiosity in mediating biopsychosocial outcomes in homosexuals and heterosexuals with HIV: a structural-equation-modeling comparison study

VANCE, D. (University of Alabama at Birmingham), ANTIA, L., SMITH, B., BLANSHAN, S., BODNER, E., ACKERMANN, M., HIERS, K.

Religiosity has been shown to be a resource for many adults with HIV, but may be expressed differently according to sexual orientation. The purpose of this study was to examine how homosexuals and heterosexuals with HIV benefit from religiosity. In a state-wide survey (Alabama, USA), 395 adults with HIV were assessed on a variety of medical and psychosocial measures. Factors were extracted for age, health status, disease duration, education, social support, mood, and religiosity and were specified in a structural equation model for two groups (i.e., homosexuals and heterosexuals), where religiosity mediated the effects of age, education, and chronicity on the biopsychosocial outcomes of health, social support, and mood. All of the trimmed models fit the data well (GFI > .90; RMSEA < .10). For heterosexuals (n = 230), those who were older had higher levels of religiosity but religiosity did not mediate any of the biopsychosocial outcomes. For homosexuals (n = 165), religiosity was positively related to social support. Results from this structural-equation-modeling comparison study suggest that religiosity may facilitate certain positive biopsychosocial outcomes but is expressed differently by sexual orientation.

Keywords: HIV, religiosity, sexual orientation

The role of safety discussions in improving speeding in the work vehicle

NEWNAM, S. (Centre for Accident Research and Road Safety - Queensland), LEWIS, I. (CARRSQ)

Work-related driving crashes are the most common cause of work-related injury, death, and absence from work in Australia and overseas. Surprisingly however, limited attention has been given to initiatives designed to improve safety outcomes in the work-related driving setting. This research paper will present preliminary findings from a research project designed to examine the effects of increasing work-related driving safety discussions on the relationship between drivers and their supervisors and motivations to drive safely. The research project was conducted within a community nursing population, where 112 drivers were matched with 23 supervisors. To establish discussions between supervisors and drivers, safety sessions were conducted on a monthly basis with supervisors of the drivers. At these sessions, the researcher presented context specific, audio-based anti-speeding messages. Throughout the course of the intervention and following each of these safety sessions, supervisors were instructed to ensure that all drivers within their workgroup listened to each particular anti-speeding message at least once a fortnight. In addition to the message, supervisors were also encouraged to frequently promote the anti-speeding message through any contact they had with their drivers (i.e., face to face, email, SMS text, and/or paper based contact). Fortnightly discussions were subsequently held with drivers, whereby the researchers ascertained the number and type of discussions supervisors engaged in with their drivers. These discussions also assessed drivers’ perceptions of the group safety climate. In addition to the fortnightly discussion, drivers completed a daily speed reporting form which assessed the proportion of their driving day spent knowingly over the speed limit. As predicted, the results found that if supervisors reported a good safety climate prior to the intervention, increasing the number of safety discussions resulted in drivers reporting a high quality relationship (i.e., leader-member-
Abstracts of the 27th International Congress of Applied Psychology

exchange) with their supervisor post intervention. In addition, if drivers reported a good safety climate, increasing the number of discussions resulted in increased motivation to drive safely post intervention. Motivations to drive safely prior to the intervention also predicted self-reported speeding over the subsequent three months of reporting. These results suggest safety discussions play an important role in improving the exchange between supervisors and their drivers and drivers’ subsequent motivation to drive safely and, in turn, self reported speeding.

The roles of mother’s and father’s caregiving characteristics in the development of adult attachment orientations among Filipino young adults

PARCON, A. (University of the Philippines Diliman)

The study aims to know which of the parental caregiving characteristics best predicts adult attachment orientations. A survey was distributed among 179 single Filipino young adult professionals ages 21-31. To measure the Attachment Orientations of the participants, the study used the Experience in Close Relationships-Revised (ECR-R) Adult Attachment Questionnaire by Fraley, Waller and Brennan (2000). To assess the parental caregiving characteristics, the participants were asked to separately rate their mother and father base on the three caregiving styles which were warm, inconsistent and rejecting. Regression analysis was done to analyze which of the caregiving characteristics (i.e., mother’s warmth, inconsistency and rejection; father’s warmth, inconsistency and rejection) best predicts attachment-related anxiety and avoidance. Furthermore, an interview was done to further explore the parent-child relationship histories. Result showed that mother’s warmth and father’s inconsistency best predicts one’s attachment-related anxiety while mother’s warmth and father’s rejection best predicts one’s attachment-related avoidance. The warmth and responsiveness of the mother was seen to lessen both attachment-related anxiety and avoidance, however, the difference lies with the caregiving characteristics of the father. If the father is seen to be inconsistent, it is most likely that one would develop higher attachment-related anxiety. On the other hand, it is the father’s rejection which most likely leads to higher attachment-related avoidance. This was further substantiated in the interviews done thereafter. Mothers of those with lower anxiety and avoidance were reported to be more affectionate, attentive, available and supportive. Fathers of those with lower anxiety were reported to be indifferent and inconsistent while fathers of those with lower avoidance were described to be absentee, distant and demanding. This study further validates the importance of parent’s roles especially in the formative years of the child as it may have repercussions on one’s later development of relationships. Further, it also showed that not only mother’s caregiving characteristics influences one’s development, the father’s role is also seen as crucial in influencing one’s adult attachment orientations. The findings of this study may be helpful in relationships and family counseling.

Keywords: parental caregiving, adult attachment, attachment-related anxiety, attachment-related avoidance, parent-child relationship

The search for HMAS Sydney II: Locating a lost ship through the integration of survivor reports

DUNN, J. (University of Adelaide), KIRSNER, K. (University of Western Australia)

The aim of the current study was to describe the unique application of cognitive psychology to the successful search for HMAS Sydney II which was located off the coast of Western Australia in March 2008, after having been lost for nearly 67 years. This had created an enduring mystery concerning the circumstances of its loss and the fate of over 600 Australian Navy personnel who had perished. In order to locate Sydney, it was first necessary to locate HSK Kormoran, the German raider that ultimately sank her and was then scuttled by its crew. While there were no survivors from Sydney, there existed a database
of reports of interviews of the German survivors. While these reports all suggested a general area, they were highly variable and no one report could be safely assumed to be reliable. We addressed this problem by drawing an analogy to Bartlett’s famous War of Ghosts study. Each report could be considered as a degraded version of one of a small number of original source statements. By identifying these statements, we had a set of independent constraints that any potential location needed to satisfy. After combining the source statements with two additional pieces of physical evidence, we identified an area of high probability centred on the point, 26° 07´S 111° 02´E, approximately 300km south-west of the Western Australia town of Carnarvon. In February 2008, the search for Kormoran was initiated by David Mearns on behalf of the Finding Sydney Foundation which had raised the necessary funds. Using side scan sonar, Kormoran was discovered at 26° 05´ 49˝S 111° 04´ 27˝E – less than 5 km from the point that we had identified. Sydney was discovered a few days later and announced to the public by the Prime Minister. Our analysis of this problem was based on an innovative and, as far as we are aware, unique application of cognitive psychology based on the following principles: (1) The ability to account for variability in human data in a systematic manner; (2) a model of information integration as a basis for decision making; (3) commitment to a quantitative approach. We envisage that our analysis may be extended to future searches involving the use of disparate, fragmentary, and contradictory information.

Keywords: HMAS Sydney II, survivor reports, cognitive psychology, decision making, quantitative approach

The structure of perceptions of counterproductive work behaviour (CWB)

MUHAMMAD HAFIDZ, S. (National University of Malaysia, Malaysia), BELL, R. (The University of Melbourne)

The aim of this research was to examine individuals’ perception of counterproductive work behaviour (CWB). An important issue to consider in understanding CWB is the community perception as to what constitutes CWB, since counterproductive behaviours that are not perceived as serious may be more common. Previous research focused on identifying dimensionality and antecedents of CWB in people actually engaging in such behaviour. This study examines how people more generally perceive these behaviours, and examines competing models from the participant research in order to derive a model of perceived counterproductive work behaviours. 266 undergraduates (over 90% of them with part-time work experience of a median duration of 36 months) completed a survey where they rated the seriousness of 84 counterproductive work behaviours. Results showed that people have a complex structure of perceived counterproductive work behaviours, as a fifteen factor model was required to model that data. A second order factor model gave two factors: one focused on factors that are related to the company or others such as, ‘Give away goods or services for free without authorization’ or ‘Verbally abuse a supervisor’. The other second order factor focused on personally advantageous behaviours such as ‘Misuse of business expense account’ or ‘Conduct personal business during work time’. While an average of 99% of the group rated behaviours from the first factor as unacceptable, 30% rated items from the second factor as either acceptable or neither acceptable or unacceptable. The perception of counterproductive work behaviours follows a complex structure and attempts to change organizational climates or to screen future employees with respect to this, particularly with respect to relatively undetectable behaviours needs to take this complexity into account.

Keywords: counterproductive work behaviour, perceptions

The study of relationships between expatriates’ psychological contract and employees’ work outcomes: The mediating effects of organizational commitment

CHEN, H. (Chien-Kuo Technology University), LIU, H.Y. (Chien-Kuo Technology University)
During the trend of globalization, expatriates have become an important workforce in multinational corporations. In general, the average cost of expatriates was over three times higher than other employees. However, many expatriates unable to complete their overseas assignments. These failures will cause a tremendous expend for multinational companies. Past research argued that the psychological contract is not only helpful for building employees’ organizational commitments, but also could bring benefits for the organizational outcomes. This field study extended previous research to examine the mediating role of organizational commitment between expatriates’ psychological contract and employees’ task performance and organizational citizenship behavior. Samples consisted of 309 expatriates with at least six month overseas experience from 22 multinational companies headquartered in Taiwan. To test the proposed hypotheses, this study was analyzed by Structural Equation Model (SEM) that used the maximum likelihood estimation to estimate all of the parameters. The results partially supported hypotheses. Therefore, the expatriates’ organizational commitment had a partially mediating effect between psychological contract and task performance. However, expatriates’ organizational commitment had a fully mediating effect between psychological contract and organizational citizenship behavior. The findings from this study has provided contributions to both theory and field study of multinational company and psychological contract. Moreover, it helped to clarify the mechanisms between psychological contract and organizational commitment and organizational citizenship behavior. The results suggested that psychological contract may directly or indirectly influence expatriates’ task performance through arousing their organizational commitment. In additional, the psychological contract could indirectly motivate expatriates to demonstrate high organizational citizenship behavior by organizational commitment.

Keywords: organizational citizenship behavior, expatriate, organisational commitment, organisational outcomes, task performance

The subjective perception of benefits from cognitive fitness interventions in older women remains domain specific

KLUSMANN, V. (Charité Universitätsmedizin Berlin), EVERS, A. (Charité Universitätsmedizin Berlin CBF), SCHWARZER, R. (Freie Universität Berlin), HEUSER, I. (Charité Universitätsmedizin Berlin CBF)

In a randomized controlled trial we showed that a mental and a physical activity intervention were effective to enhance or maintain cognitive fitness, i.e., episodic memory and working memory. A positive perception of one’s own cognitive fitness is an important condition for high self-efficacy beliefs and, thus, can sustain independence in old age. Here, we pose the question whether objective cognitive benefits are reflected in subjective perceptions of memory and concentration. This would underscore the practical relevance of these kinds of interventions. Healthy women (N = 259), aged 70 to 93 years, were randomly assigned to participate in either a mentally challenging computer course or in a demanding physical exercise course or in a control group. Each intervention course lasted six months with 90-minute sessions three times per week. In addition to pre-post-tests of episodic memory and executive function, subjective evaluations of the perceived change in memory and concentration were captured at baseline, at four months and six months and at a ten-month follow-up. Multilevel linear modelling was used to compare trends over time in the three groups. Despite comparable objective cognitive benefits from both the mental and the physical interventions (in contrast to the control group), only the women in the computer course had perceived benefits in memory, $F(2, 707.9) = 4.31, p = .01$, and concentration, $F(2, 714.2) = 4.75, p = .009$. The exercise group, in contrast, rated only their physical health as having improved, $F(2, 562.0) = 4.63, p = .01$. These effects were seen during the intervention period, i.e., at four months and again at six months, but did not persist up to the ten-month follow-up. The perception of cognitive benefits seems to be biased towards the obvious intervention domain, i.e., gains are perceived in the corresponding activity domain only. A sensitization for transfer effects could not only enhance motivation and satisfaction with the
outcomes in participants of intervention programs but may also be beneficial in terms of practical relevance.

Keywords: cognitive fitness, episodic memory, working memory, self-efficacy, executive function

The support for patients at risk of suicide and self-harm component of the access to allied psychological services (ATAPS) projects

FLETCHER, J. (University of Melbourne)

The Access to Allied Psychological Services (ATAPS) projects have been operating as a component of the Better Outcomes in Mental Health Care program (BOiMHC) since 2001. This component has enabled GPs, through Divisions of General Practice, to refer consumers to allied health professionals for up to twelve (or 18 in exceptional circumstances) sessions of evidence-based mental health care (i.e., Cognitive Behavioural Therapy). Until mid-2008, the ATAPS projects have targeted people with high prevalence mental disorders. In late 2008, the Support for Patients at Risk of Suicide and Self-harm demonstration project, funded jointly under the Australian National Suicide Prevention Strategy and the ATAPS component of the BOiMHC program, provided additional targeted funding to 19 Divisions of General Practice to offer a more intensive, prioritised service for people who are at risk of suicide, who may or may not have a mental disorder. The Centre for Health Policy, Programs and Economics at the University of Melbourne is currently evaluating this project. Data sources include a web-based minimum data and purpose designed interviews with project officers and providers. This presentation will report data related to the uptake of the demonstration project by consumers, GPs and allied health professionals, as well as the outcomes of qualitative surveys of stakeholders. The experiences of Divisions in implementing the project, GPs and Emergency Departments making referrals, and allied health professionals delivering services will be reported. Divisions were enthusiastic about the project but reported a need to re-evaluate their existing models of service delivery in order to meet the requirements of the demonstration project and engage GPs and allied health professionals in the care of these consumers.

Keywords: access to allied psychological services, suicide, self-harm

The transitional stress and adjustment model (TSA)

ISRAELASHVILI, M. (Tel Aviv University)

The Transitional Stress and Adjustment (TSA) model advocates the idea that there are several universal phases that every person who is undergoing a process of transition may experience in the course of approaching a state of (re-)adjustment. Furthermore, the TSA model suggests that the six suggested phases (e.g., exploration of situational lawfulness) should also function as the components assessed to evaluate the extent to which the environment (e.g., workplace, marriage, school) supports the individual in his pursuit of resolution regarding these phases. Thus, a comprehensive understanding of the process of transitional stress and adjustment would be achieved through an exploration of the fit between the person and the environment with regard to the TSA phases. The TSA Model emerged from a cross-situational analysis of the components that have been suggested by various stage-models of adjustment to a new situation in the literature. Though the TSA model incorporates mostly cognitive components, it is argued that emotional liability is an unavoidable characteristic of any adjustment process, due to the person’s dialectical shifts – backward and forward - in exploration of P-E fit in each of the phases. In light of the prominent number of people who seek counseling in times of transition and adjustment, the TSA model can serve as a conceptual framework for better understanding the antecedents and processes of positive adjustment to life transitions. Moreover, it can also serve as a practical guide for counseling psychologists who are dealing with people in transitions. An example of that would be demonstrated with regard to counseling new immigrants who are troubled with relocation and adjustment to the new land.
Keywords: transitional stress and adjustment (TSA) model, environment, counselling

The type of chronic childhood trauma and parental behavior

WIDER A WYSOCZANSKA, A. (University of Wroclaw)

The goal of this study was to learn about parental behaviors in families with a specific type of abuse. This is part of a larger study on the risk factors which contribute to the inception and, especially, the maintenance of a given type of abuse in the family. Studied were 704 randomly selected persons with a mean age of 35 years (450 women and 254 men) and with secondary education or higher. The qualitative interviews "Family Childhood Abuse Map" and structured qualitative questionnaire "Intimate Situations Questionnaire" were used to determine the type of childhood abuse experienced by the investigated persons. The structured interview "Retrospective Perception of Parental Attitudes", with a Cronbach's alpha of 0.94, was used to identify the person's retrospective and subjective perception of their parents' parental attitudes. 88 percent of the study group had experienced emotional abuse, 60% physical abuse, 38% sexual abuse with touching, 58% alcoholism of the father, and 28% alcoholism of the mother. The statistical analysis was based on Spearman's correlation coefficient and cluster analysis. The results showed which behaviors of the mothers and fathers of the families with a specific type of abuse appear significantly more frequently or more rarely compared with mothers and fathers of the families with other types of abuse. They fall into six dimensions: care and support vs. neglect and blaming; the quality of satisfying the child's needs; the quality of abiding to boundaries, rules, and roles in the family; the quality of self-confidence as a mother; and partnership in child rearing. This study is intended to help in preparing preventative and therapeutic programs for children and adults from dysfunctional families and parents.

Keywords: parental behaviors, childhood abuse, risk factors, therapeutic practice, dysfunctional families

The underlying processes involved in the development of anxiety in adolescence: Test of a conceptual framework

PAPANDREA, K. (The University of Adelaide)

Research indicates associations between specific parenting styles and negative developmental problems in adolescents. However, the underlying processes regarding how such parenting dimensions contribute to such outcomes have not yet been clarified. By employing a theory-driven conceptual framework, the present study reports on the first wave of a two-year longitudinal study examining the relationships among maternal and paternal psychological control and responsiveness, and characteristics of adolescents, such as self-esteem, and a range of negative developmental outcomes, such as anxiety and depression. A community sample of 509 adolescents (14-15 years of age) attending fifteen high schools from rural and metropolitan areas in South Australia completed a battery of self-reported measures online, and are due for a followed-up in March, 2010. Structural Equation Modeling (SEM) will be employed to test the proposed conceptual framework. Results concurrently demonstrated that both maternal and paternal psychological control directly and indirectly predicted social anxiety through impacting on the healthy development of the adolescent's self-esteem. The findings highlight that parental attempts to psychologically control the behaviour of adolescents through such methods as love withdrawal, guilt induction, and invalidation of feelings, contribute to the development of anxiety, in particular social anxiety in adolescents. Moreover, such parenting techniques may do so through promoting thoughts and feelings of inadequacy associated with a negative sense of self, which is often an inherent feature of anxiety. Thus, the developing sense of self may be viewed as an underlying process of the relationship between parental psychological control and social anxiety. It is anticipated that a better understanding of the etiological pathways of social anxiety disorder (SAD) in adolescence may not only enhance existing knowledge but may facilitate research-based intervention and prevention programs at both the parental and adolescent levels and ultimately reduce the incidence and
consequences of this under-recognised, yet potentially debilitating disorder.

The use of learning support assistants in inclusive education, in ACT public primary schools

D’CRUZ, R. (University of Canberra)

This study aimed to examine the role, effectiveness and alternate methods of deployment of Learning Support Assistants (LSAs) in ACT public primary schools. This qualitative study used the semi-structured interview format for data collection and the Thematic Analysis Technique (TAT) (Boyatzis, 1998; Braun & Clarke, 2006; Ely, Vinz, Downing, & Anzul, 1997; Silverman, 2004) for data analysis. In keeping with the principle of Triangulation (Patton, 1990) four different stakeholder groups were interviewed comprising three school principals, three learning support assistants, three special education teachers, and three parents who had children with a disability. Four sets of interview questions, adapted from a similar questionnaire by Giangreco, Broer, and Edelman (2002), asked each participant for their views on the role, effectiveness and alternate ways of deploying LSAs. Overall, common thematic findings were that the role of LSAs is not uniformly understood across the board. For example, LSAs are briefed and consulted about Individual Learning Plans only in some schools. However, LSA input at the time of reporting is sought by most special education teachers. LSA autonomy appears to depend on the teacher-LSA relationship. Further, LSAs are generally seen to be quite effective, though there are concerns that Students with Disabilities (SWDs) can become dependent on the support LSAs provide. Concerns were also articulated that the close proximity of the LSA to the SWD could inhibit the SWD’s peer and teacher relations, and delay the SWD from commencing to work independently. Rostering LSAs so they get to work with different SWDs was suggested as a way of reducing SWD attachment to particular LSAs. It was also seen as a way of managing LSA absences. Qualifications in Disability Studies and ongoing professional learning were suggested as ways to enhance professionalism in the LSA workforce. This study has highlighted the need for greater clarity around LSA roles and methods of deployment.

Keywords: learning support assistants (LSAs), primary school, thematic analysis, students

The use of restraint and seclusion on people with intellectual disability: A population study with implications for the reform of clinical practice

MCVILLY, K. (Deakin University), WEBBER, L. (Department of Human Services)

The aim of the current study was to investigate the topography and prevalence of restrictive interventions in use with people with intellectual disability who exhibit behaviors of concern to community-based service providers; and also to develop a jurisdictional-wide strategy to promote the use of non-aversive evidence-based psychological alternatives, consistent with the UN Convention on the Rights of Persons with Disability and a Positive Behaviour Support (PBS) approach to intervention. A population database, established under the provisions of the Disability Act (2006) for the reporting of restrictive interventions (chemical and mechanical restraint and seclusion) by disability service providers, was analysed. A base-line measure of restrictive interventions was established. A literature review of alternative interventions was conducted and subsequently a range of practice alternatives established and disseminated. On-going monitoring of the population database was conducted over a two year period to ascertain the impact of the reform process. At base-line, the majority of people who were subjected to restraint and seclusion were subjected to chemical restraint (96%). Time sampling indicated, regardless of restraint type, the use of restraint was routine rather than a strategy of last resort. Consistent with findings in the U.K and U.S.A., those subjected to restrictive interventions were more likely to be young males who were reported to have multiple disabilities, including Autism. The up-take and effect of the alternative strategies is
currently being assessed at the time of submitting this abstract, with data on these findings available over the next few months. Restrictive interventions, inconsistent with internationally accepted human rights and contemporary evidence-based practice, are currently used routinely to control people’s behaviour. Systemic policy and procedural developments are needed to address these issues, together with a longitudinal study to evaluate the effectiveness, on a population level, of alternative, non-restrictive strategies. Population databases are useful, but have some limitations that need to be addressed to maximize their utility.

Keywords: intellectual disability, restrictive interventions, Positive Behaviour Support (PBS)

The work-family conflict and work ability relationship for an ageing demographic: examining the indirect effects of job satisfaction, family satisfaction and wellbeing

APPANNAH, A. (Deakin University), DEY, D. (Deakin University), PALERMO,

The aim of this study was to investigate the effects of work-family conflict (defined as when the demands of one domain of either work or family interfere with the demands of the other) on work ability (defined as one’s subjective and objective assessment of ability to work). Both work interfering with family demands (WIF) and family interfering with work demands (FIW) were measured to determine work-family conflict. The indirect effects of job satisfaction, family satisfaction and wellbeing on the work-family conflict and work ability relationship were also examined. A total of 128 participants were recruited for this study. The sample consisted of fulltime and part time workers from a public health organisation and corporate industries in Australia. Participants were required to complete a survey, either online or on paper. The results demonstrated that the Work Interfering with Family Life domain of work-family conflict was significantly related to lower levels of job satisfaction and wellbeing. Furthermore, personal wellbeing was a significant predictor of work ability. Finally, a significant negative relationship was found between work interfering with family life and work ability, with wellbeing playing a partially mediating role in this relationship. The implications of these findings are in recommending strategies for promoting work ability for all workers. These findings can be used as part of a long term strategy to delay early retirement and retain ageing workers in the workforce. Implementing policies that reduce work-family conflict in organisations can help sustain economies by enabling ageing workers to continue working for longer periods of time.

Keywords: work-family conflict, work, job satisfaction, family satisfaction, well-being

The Young Learners Project: Associations between cognitive ability and aspects of early literacy knowledge and skills

CARE, E. (University of Melbourne), CARE, E. (University of Melbourne), CHAN, E. (University of Melbourne)

The Young Learners Project is designed to investigate links between child and family characteristics, teacher effectiveness and early literacy knowledge in 4-5 year old children. In this study associations between children’s early literacy understandings, as measured by a tool developed within the project, the Early Literacy Knowledge and Skills (ELKS), and intelligence, as measured by the Naglieri Nonverbal Ability Test (NNAT), are reported. Over a two-year period, 385 children completed the NNAT, administered by psychologists and supervised probationary psychologists, and the ELKS. These tests were administered on a one-to-one basis within the normal hours of the early learning and day care centres. Based on the early literacy developmental stages proposed by Ferreiro and Teberosky’s (1982), item scores from the ELKS were analysed using item response modelling. Children were then grouped based on their developmental level in early literacy. One-way analysis of variance across four levels showed significant differences in NNAT standard scores between children who were at a lower level of early literacy development compared with those at a higher level, in both skills and knowledge areas. Consistent with previous research,
findings from the study suggest a relationship between cognitive ability and understanding of early literacy concepts in young children. Children who were more cognitively advanced appear to show greater knowledge and understanding of literacy concepts and print conventions. The findings provide support for individualised teaching in literacy for children with different cognitive abilities.

Keywords: The Young Learners' Project, teacher effectiveness, early literacy knowledge, Naglieri Nonverbal Ability Test, children

Theory of planned behavior (TPB), implementation intentions (IMIs) from unwanted inner states, study intentions and behaviors, and academic performance: An integrative model

BROONEN, J. (University of Liège)

Intention is considered as a key determinant of behaviour in goal theories and theories of attitude-behaviour relations (e.g., Theory of Planned Behaviour (TPB)). However, the intention-behavior relation is relatively weak, largely a consequence of people having good intentions but failing to act on them. A distinction must be made between forming an intention, a motivational process, and implementing it, a volitional one. Volition addresses the regulation of behavior after the intention has been formed. Problems of goal implementation involve action initiation or ongoing goal striving from getting derailed. Implementation Intentions (IMIs) are a specific volitional tool which consists of specifying an anticipated cue (‘if’ component) as a condition for initiating or protecting goal-directed responses (‘then’ component). These kinds of intentions lead to more frequent goal attainment compared to setting mere goal intentions. In the health domain, IMIs were specifically proved to increase the likelihood of realizing intentions when shielding ongoing goal pursuits from disruptive inner states. In the present field of research, it was investigated in the academic domain whether some inner states, which could impair study, could be specified in the ‘if’ component of IMIs and linked to an effective shielding response in the ‘then’ part. These intentions were also assumed to trigger not only motivational control actions, but also intentions of learning behaviours and to mediate the effects of the classical variables of the TPB on academic performance. 207 freshmen students completed longitudinal questionnaires and Structural Equation Modelling was employed (Lisrel; Robust Maximum Likelihood Method). IMIs geared at controlling interfering motivational inner states enhanced the rate of actions protecting goal-striving and triggered intentions of learning strategies, which were positive antecedents of study behaviors. IMIs totally mediated the effect of classical variables of TPB. The whole model increased the amount of explained variance of academic performance above the contribution of the constructs of the TPB ($R^2 = .35$). In the academic domain, use of unwanted motivational inner states as initiators of goal-shielding responses through IMIs maximizes the effects of simple intentions to make good marks. IMIs are also a self-regulating tool capable of inducing intentions and behaviors of applying learning strategies, which are positive antecedents of academic performance.

Keywords: theory of planned behaviour, implementation intentions (IMIs), goal theory, academic performance

Thinking is advisable. Especially when dealing with complex problems

GUTERMAN, Y. (Tel-Hai Academic College), BAR-ON, M. (The Hebrew University of Jerusalem)

Recent findings have led to the claim that non-conscious processing is superior to conscious deliberation in complex decision-making (Dijksterhuis, A., Bos, M. W., Nordgren, L. F., & Van Baaren, R. B. (2006). We dispute this claim and argue (a) that in that study (Exp. 1 & 2) no genuine non-conscious condition existed and (b) that the participants were forming attitudes rather than solving a problem and (c) that the task that meant to be more complex, was in fact no more complex than the other task. Participants were exposed to attributes of choice alternatives, for a duration long enough for encoding, but not for analyzing the information. After initial attributes exposure,
half of the participants engaged in conscious deliberation and half were distracted with an anagram task. In Exp. 1 half of the participants evaluated cars from a subjective perspective (attitude formation), and the others evaluated them from the perspective of another person’s preferences (problem solving). In Exp. 2 participants evaluated vacation packages from the point of view of a travel agent doing work for a customer. For half of the participants, the parameters underlying the customer’s preferences were additive (simple problem), whereas for the other half they interacted (complex problem). In Experiment 1 we found that participants who were given four minutes post-exposure to consciously deliberate made better criteria-fitting decisions than those who were given a distracting task. We also found that participants engaged in attitude formation were less accurate than those solving an impersonal problem. Importantly, increasing the number of attributes hampered performance in the problem solving but not in the attitude formation task. In Experiment 2 participants consciously deliberating after exposure solved impersonal problems better than the distracted participants and this effect was pronounced in the more complex task. We suggest that in problem solving tasks, conscious processing is superior to non-conscious processing, particularly in complex problems, where optimal allocation of resources is essential.

Keywords: information processing, complex decision-making, problem-solving

Time elapsing since last use of cannabis: Implications for measures of IQ

MURPHY, P. (Edge Hill University), ERWIN, P. (Edge Hill University), FISK, J. (University of Central Lancashire), MACIVER, L. (Edge Hill University), YANULEVITCH, K. (Edge Hill University), KEANE, E. (Edge Hill University), LARKIN, D. (Edge Hill University), MONTGOMERY, C. (Liverpool John Moores University), WAREING, M. (Liverpool John Moores University)

Over the past decade evidence has emerged concerning impaired cognitive performance related to the use of cannabis, and of a withdrawal syndrome arising from the cessation of its use. However, little is known about any long-term effects on cognitive abilities which may be related to cannabis use. The neurotoxic properties of cannabis make this an important question. This paper examines the relationship between time since cessation of cannabis use and performance on the Ravens Progressive Matrices IQ test. Ravens Matrices Set E scores were obtained from 59 cannabis users (mean age = 23.0 years, SD = 3.8 years), with a median lifetime use of 72 joints (1st quartile = 15, 3rd quartile = 760 joints). Participants had been abstinent from cannabis for at least seven days, with a median of 66.5 days (1st quartile = 14.3, 3rd quartile = 615.5 days) since last use. Measures of substance use history, mood, and demographics were also obtained. Tertile groups were based upon time since last cannabis use, with cut offs at 22.3 and 269.3 days. Mean Set E scores progressively declined across tertiles. One-way ANOVA with simple contrasts showed a significant difference between the first and third tertile. Using multiple linear regression analysis, 21.2% of variability in Set E scores was explained by a highly significant predictive model containing self-reported arousal scores, transformed measures of time since last cannabis use, and onset age for cannabis use, respectively. Only time since last use was inversely related to Set E scores, and explained the largest respective portion of variability in these scores (10.6%) for the three predictors. In separate analyses, Set E scores were uncorrelated with estimates of cannabis and ecstasy consumption, but approached significance in their negative correlation with time since last ecstasy use. Improvements in cognitive functioning should not be assumed when cannabis use is ceased. There is mixed evidence from relatively few studies regarding the course of cognitive functioning following cessation, so that a need for longitudinal and prospective studies is indicated. Potential causal mechanisms for changes in performance levels also require further investigation.

Keywords: cannabis use, impaired cognitive performance, withdrawal syndrome
To conserve or not to conserve? Determinants of household water use in South East Queensland

FIELDING, K. (The University of Queensland), SPINKS, A. (Sustainable Ecosystems / The Commonwealth Scientific and Industrial Research Organisation), RUSSELL, S. (Griffith University), MANKAD, A. (Sustainable Ecosystems / The Commonwealth Scientific and Industrial Research Organisation)

The current paper encompasses a review of the psychological literature on household water conservation and an empirical study of the social and psychological determinants of household water efficiency (i.e. installing water efficient appliances) and curtailment (everyday water conservation practices) behaviours. The empirical study draws on an expanded theory of planned behaviour (TPB) model that incorporates aspects of social identity theory (household identity) and norm focus theory (descriptive and injunctive norms). A review of empirical psychological literature on water conservation identified key predictors of household water conservation and limitations of current methodologies. As part of the empirical study, 1750 households in South East Queensland completed a survey (either online or via the post) measuring variables of the expanded TPB model and self-reported water efficiency and curtailment behaviours. Additionally, for consenting households, actual water use records were obtained from the relevant city council. Where possible, multiple adults in a household responded to the survey (n=195). A sub-sample (n=320) of the larger sample also agreed to installation of high resolution meters in their home so that survey responses could be linked to specific water use around the home. The review of existing literature suggests the importance of demographic factors, water use habits and environmental knowledge and priorities as determinants of actual household water use. It is clear, however, that much of the past research has measured intentions rather than actual water use and that the research has tended to rely on individual data despite the reality that water use is often a collective activity. Drawing on the survey data, key predictors of water use intentions and actual water use will be discussed (including multi-level analysis of data from households with multiple respondents). In light of the vulnerability of freshwater resources for urban populations and the likelihood that existing pressure will be exacerbated by climate change, managing urban water demand is an important strategy for water policy-makers. By drawing on established psychological theories to identify the key psychological and social drivers of household water use, and ensuring objective measurement of household water use, the current research can provide valuable information to ensure the development of effective policy in this area.

Keywords: household water conservation, efficiency, curtailment, theory of planned behaviour, psychological determinants

Trade-off in object versus spatial visualization abilities: Restriction in the development of visual processing resources

KOZHEVNIKOV, M. (George Mason University), BLAZHENKOVA, O. (George Mason University)

Previous research indicates relative independence between the ventral and dorsal visual pathways, associated with object and spatial visual processing, respectively. The aim of the current research is to investigate the relationship between Object Visualization Ability (the ability to process visual information about objects or scenes in terms of color or shape) and Spatial Visualization Ability (the ability to process information about spatial relations between objects and perform spatial transformations). We investigated the relationship between the object and spatial visualization abilities of five different age groups of participants whose ages corresponded to their amount of specialized training, ranging from none or very little to extensive. The first and second groups of participants consisted of younger children (ages 10-13) gifted in visual arts, sciences, or humanities that had not yet received area-specific training and older children (ages 14-17) who had begun to receive such training. The third and fourth groups consisted of undergraduate and graduate college students, all of whom majored in visual art, science, or...
humanities. The fifth group consisted of members of different professions. All the participants were administered a number of object and spatial visualization ability tests. Across five different age groups with different professional specializations, participants with above-average object visualization abilities (artists) had below average spatial visualization abilities, and the inverse was true for those with above-average spatial visualization abilities (scientists). No groups showed both above-average object and above-average spatial visualization abilities. Furthermore, while total object and spatial visualization resources increase with age and experience, the trade-off relationship between object and spatial visualization abilities does not. These results suggest the existence of a trade-off between object and spatial visualization abilities and that the trade-off originates through a bottleneck, which restricts the development of overall visualization resources, rather than through experience in one type of visualization.

Keywords: object visualization ability, spatial visualization ability, age

Training empathy: A review and meta-analysis of empirical studies

OBERLECHNER, T. (Webster University), BERGHOFER, G. (Webster University; PSD Wien), GONJA, T. (University of Vienna)

In counselling and psychotherapy, the concept of empathy is widely regarded as one, if not the most important, quality of effective therapists. However, the possibility to develop empathic abilities in training programs is also highly relevant outside therapy and has led to a substantial number of studies measuring the effectiveness of empathy training. This meta-analytic study aims at evaluating how effective training in empathy is. Based on a comprehensive literature review and relevant literature databases (PsycArticles, PsycInfo, SocIndex, ERIC, Medline, CINAHL), this contribution presents results of a meta-analysis of over 100 controlled studies on the effectiveness of empathy training programs. Only studies fulfilling high scientific criteria were included and comprehensively coded. Studies on empathy training were conducted with such diverse groups as students, health professionals, school and preschool children, couples, parents, older persons, and persons in the forensic field. The meta-analysis shows that empathy training has a stable and medium-size effect on increasing empathy of participants. We analyze and discuss possible influences on the effectiveness of empathy trainings. Limitations of these trainings are discussed which future practitioners and researchers of empathy trainings should consider.

Keywords: empathy, training programs, psychotherapy, counselling

Trajectories to delinquency: The significance of reputational orientations to primary, high school and incarcerated adolescent loners and non loners

HOUGHTON, S. (The University of Western Australia), CARROLL, A. (The University of Queensland)

The present study aims were to (i) establish the nature of delinquent activities and reputational orientations among loners who reportedly commit delinquent acts without an audience being present; (ii) compare the delinquent and reputational orientations of loners with non loners; and (iii) establish the applicability of reputation enhancement theory with loners. Two scales the Adapted Self-Report Delinquency Scale (ASDS) and the Reputation Enhancement Scale (RES) were administered to 886 primary and 965 secondary school students and 108 incarcerated participants. Participants were classified as loners or non loners using the sociability scale of the RES. The ASDS and RES were also administered to 98 secondary school loners who were then age and gender matched with non loners to conduct a more stringent investigation. Multivariate analyses of variance revealed no significant main effect of delinquency in the large sample according to loner status. There was, however, a main effect for reputational orientations. The more stringent examination using a closely matched sample of 98 pairs of loners and non loners revealed that loners reported significantly higher levels of involvement in physical aggression, stealing...
Abstracts of the 27th International Congress of Applied Psychology

Individual Oral Presentations

offences, and vehicle-related offences than the matched non loners. For reputation, overall, loners were less likely to perceive themselves as socially conforming and did not wish to be seen as socially conforming by others. Furthermore, they were less likely to describe themselves in terms of positive activity and power attributes, and did not want to be perceived by peers as possessing positive attributes. Moreover, loners were less willing to communicate their prosocial behaviour to friends, parents, and/or other adults. Social visibility and the committing of delinquent acts in the company of others (i.e., an audience) are NOT key elements on which loners build their reputations. Loners hold discrepancies about their actual and ideal selves than do non loners and this may offer opportunities for positive peer interaction based intervention strategies.

Keywords: delinquents, reputational orientations, loners

Translating health research into practice: It’s not just a matter of “communication”

YOUNG, D. (Cancer Council, Victoria)

To investigate differences in the ways health researchers and practitioners engage with the world and the implications for research translation. Analytic study based on some observations emerging from Individual and group interviews with an interlinked set of behavioural science researchers and practitioners, including practicing psychologists. Actor-Network theory (ANT) was employed to theoretically integrate the interview data. The original purpose of the study was to identify barriers to research translation, and this paper concentrates on an important, but less obvious barrier. One difference, in particular, was striking. When talking about their work, researchers and practitioners used different “practical ontologies”, making them sound as if they operate in two different realities. Researchers talked about protocol design, reliability and validity, conceptual rigour and, especially, about the robustness of the causal relationships either assumed, or hypothesized. Personal and interpersonal processes (e.g. getting grants, managing surveys) were seen as enabling or supporting their engagement with a predominantly conceptual reality. On the other hand, practitioners talked about specific people, what they did, why they did it and when they did it. Causal processes were unambiguously personal and interpersonal. Knowledge, concepts (e.g. models of cessation) and evidence (e.g. survey results) were seen as supporting their engagement with a predominantly interpersonal reality. Such ontologies emerge, not because of differences between the individuals involved, but because researchers and practitioners are engaged in two very different work processes, and as a consequence they are enmeshed in different worlds. It is not simply a matter of stylistic, personal or epistemological preferences. Unless we are sensitive to these differences our attempts to translate health research into practice will be less effective than they could be. While the focus of this inquiry was to inform tobacco control interventions, we believe these results can be generalised to other intervention related research.

Treating arson offenders – challenges, pitfalls and joys

DOLEY, R. (Bond University)

With heightened community focus on the issue of arson prevention and management in our community, work has commenced on developing a best practice approach to the treatment of convicted arson offenders. This paper will present the results of an extensive enquiry into current practice internationally and domestically which has culminated in an intervention approach designed for treatment of adult arsonists in institutional settings. Reference will also be made to the modifications and specific treatment targets indicated for community based interventions with this population. Currently in Australia there is no standardised treatment modality designed specifically to address the unique demands of intervention with adult deliberate firesetters. A proposed model for best practice treatment and
management for this population will be presented based on the evidence available currently.

Keywords: arson offenders, treatment, prevention, community based interventions

Trialing organisational integration between UK health and social care services in the context of whole system working: A quick fix or an enduring challenge?

CHRYSANTHAKI, T. (Imperial College Business School), HENDY, J. (Imperial College Business School), BARLOW, J. (Imperial College Business School)

Irrespective of its theoretical and empirical infancy, the whole system working concept has managed to become already an international health policy imperative and an ethos proclaiming benefits in the ‘joining’ up of individual parts of system(s) in organisations that traditionally have worked in separatist or even competitive ways. In the case of UK health and social care organisations, the idea that service delivery should be redesigned under a whole system approach has been largely supported by the fact that patient groups rarely fit neatly within one set of professional groups and organisational boundaries (Hudson, 2006). Focusing on findings from a DoH change programme, the present paper discusses the pragmatic challenges in the deployment of assistive technologies within the current separatist organisational climate. The paper does not focus on the study of this innovation as a technological artefact but as an organisational one (e.g. tensions experienced at the managerial and service provider levels). Semi-structured interviews (N= 90) were carried out with stakeholders in health and social services who participated in the programme. The results corroborate that implementing remote care services in a whole system context is a complex endeavor. Successful implementation requires collaborative thinking, inter-organisational communication, the re-evaluation of organisational approaches in the delivery of care, and personal and organisational flexibility to new opportunities. The aims of the programme and its visions were framed within a patient centred discourse which in most instances was perceived by the multiple stakeholders as a mean of dealing with or silencing conflict. Issues of asymmetrical power amongst the organisations were also apparent. The study will increase our understanding of how whole system working concept is perceived and enacted and how complex organisational innovations across health and social care can be successfully implemented and managed.

Tripartite security system of attachment, self-esteem and worldview and the threat of terrorist attack

KEEN, A. (CQUUniversity), KONDO, R. (CQUUniversity)

To provide a better understanding of the way people develop and cope with fear and trauma, this study examines the relationship between mortality salience, worldview anxiety salience as perceived threats and subsequent attachment-related anxiety and attachment related avoidance associated with threat of terrorist attack. 232 individuals (primarily university students) were allocated randomly to one of the three conditions of writing a paragraph regarding their feelings associated with experiencing a terrorist attack, keeping a pet or facing their own death. The participants responded to a series of questionnaires that tapped into the following variables: desire of close relationship, self-enhancement regarding independent and interdependent traits, feelings towards members of other cultures. Results of this study partially supported the prediction of integration of the defence mechanisms in the tripartite security system model and the role of attachment style on defence mechanisms. This research showed that people that are affected by a stressful event activate their tripartite security system and their attachment style determines which defence mechanism is enhanced or suppressed. The results also showed that to cope with an unavoidable stressful event, establishing and maintaining secure attachment style may be an appropriate strategy. The study found that people’s
attachment styles enhance or suppress activation of defence mechanisms regardless of them experiencing fear or trauma. The study challenges Hart, Shaver and Goldenberg’s (2005) tripartite security system model.

Keywords: fear, trauma, terrorism, anxiety, attachment

Undergraduate psychology training and workplace needs: Student perspectives on the extent to which their education prepares them for their chosen career

STOYLES, G. (University of Wollongong), CAPUTI, P. (University of Wollongong), BYRNE, M. (University of Wollongong), CROWE, T. (University of Wollongong)

The current study surveyed 195 first to fourth year psychology students at a regional university in New South Wales about the amount of applied content in undergraduate psychology training and post-graduate opportunities for employment as a psychologist. Eighty-nine percent of students believed that the level of applied psychological training was either non-existent or inadequate, and therefore did not equip them for finding work as a psychologist. Ninety-six percent of students who wished to become intern psychologists believed that opportunities for working as intern generalist psychologists were either non-existent or insufficient. Concerns around employment and registration opportunities reflected this group’s disillusionment with undergraduate training. Availability of work-place supervision and associated worry about paying for alternative private supervision was also evident. Recommendations for further investigation of the ‘goodness of fit’ between undergraduate psychology training and the ability of students to be competitive in the workplace following graduation will be articulated.

Keywords: students, undergraduate psychology, employment, supervision

Understanding client perceptions of the therapeutic relationship: A phenomenological investigation

DI MATTIA, M. (Monash University)

The aim of this paper is to present the results of an empirical research study exploring client perceptions of the relationship with their therapist, within the first five sessions of therapy. The presenter will explore the rationale for this study, including the significance of investigating clients’ perspective on the therapeutic relationship in the early stages of therapy. The major results of this study and the implications in understanding the therapeutic relationship will be discussed. This study utilized a qualitative methodology to closely explore client perceptions of the therapeutic relationship, with the aim of identifying those aspects of the relationship clients find helpful and unhelpful. Three participants were interviewed on two occasions about their experiences of the relationship with a therapist. The data was analyzed using an empirical phenomenological approach and the researcher utilised a third party verifier to enhance the validity of the analysis. Themes were derived for each participant that reflected an aspect of their perception of helpful and unhelpful characteristics of the relationship with their therapist. The major results that emerged from this study, common to all participants was an interest in the personal life of the therapist, linked to participants’ awareness of the boundaries of the relationship. Each participant expressed hesitation and uncertainty about what the boundaries of the relationship with a therapist are. An awareness of the role of the therapist and the importance of perceived trust and understanding were also major findings from this study. This study highlighted clients interest in the personal life of their therapists and it is suggested that future research is required to explore what it is clients’ want to know about their therapist and clients’ understandings of what the boundaries of the relationship are. Further research is also required to explore what it is clients see the role of a therapist and how this is connected to the quality of the relationship and perceived experience of a therapist.

Keywords: therapeutic relationship, boundary, trust
Understanding driver anger and aggression: Attributional theory in the driving environment

WICKENS, C. (Centre for Addiction and Mental Health), WIESENTHAL, D. (York University), FLORA, D. (York University), FLETT, G. (York University)

Much of the aggressive driving displayed on our roads and highways is the result of driver anger and retaliation for a perceived driving offence. Theories of attribution depict the general process by which individuals explain the events around them, and may provide some insight regarding aspects of driver behaviour or the roadway environment that elicit aggression. The current two studies tested the applicability of Weiner’s (1995, 1996) attributional model of social conduct to the roadway environment. Study 1 employed written scenarios where participants were asked to imagine themselves driving on a major highway. The vignette described another driver who cut in front of the participant causing him or her to brake suddenly. The degree of Controllability and Intentionality of the driving act was experimentally manipulated by altering the specific event-related details provided to the participants. Study 2 involved participants completing on-line driving diaries every two days, identifying their most negative/upsetting encounter with another motorist. After completing four diaries, the most anger-provoking event from the diary entries was selected and participants were asked to respond to a questionnaire similar to that used in Study 1. Path analyses in both studies generally demonstrated the hypothesized relationships proposed by Weiner’s model and confirmed the model fit. Specifically, perceived Controllability, Intentionality, and Locus of Causality were associated with judging the offending driver as responsible for the negative driving event. Judgments of Responsibility were associated with more anger and with less sympathy (in Study 2 only). Anger was associated with aggressive behaviour in response to the offensive act, whereas sympathy was associated with prosocial behaviour. Recommendations will be offered for improved driver safety including the development of attributional retraining programs, teaching novice drivers about both formal and informal roadway communication, and the promotion of forgiveness in the driving environment.

Keywords: attribution theory, driving behaviour, anger, aggression

Understanding knowledge sharing in organizations

CASTANEDA, D. (Catholic University of Colombia), FERNANDEZ, M. (Universidad Autonoma Madrid)

The purpose of this paper was to empirically study the influence of four psychosocial variables and four organizational conditions of knowledge sharing behavior. The psychosocial variables are: attitude, subjective norms, self-efficacy and perceived value of knowledge. The organizational conditions are: organizational learning culture, training, strategic clarity and organizational support. Quantitative data were obtained from 1057 participants, 55.7% female and 44.3% male, all of them knowledge workers. An instrument of 50 items was designed and validated using Rasch’s model. The items of the instrument were answered by research participants using a Likert scale of seven levels of response. The data showed a relationship between the studied psychosocial variables and organizational conditions and knowledge sharing behavior. A model was proposed using structural equation modeling. Knowledge sharing is the spine of organizational learning and knowledge management. This research contributes to the understanding of the human side of knowledge management. A new concept called perceived value of knowledge sharing is proposed and discussed. A study of the relationship between the perceived value of knowledge and knowledge sharing is suggested.

Keywords: psychosocial variables, knowledge sharing behavior, subjective norms, organisational learning, support

Understanding moves in task conflict: A framework integrating self salience and opponent’s stance

AU, A. (National University of Singapore), LAM, S. (University of Hong Kong)
A framework based on a dual party approach is proposed to understand interpersonal task conflict. It integrates both personal and opponent factors in understanding moves of a conflict party. Drawing from the literature in conflict and self salience, we posit that both self-enhancing and complementary mechanisms could explain conflict moves. The former mechanism is associated with personal self salience whereas the latter with relational self salience. The exact direction of conflict moves, however, depends on the interaction between the self salience of an individual and the stance of his/her opponent. Two studies were conducted to test the proposed framework. In Study 1, 165 participants completed a scenario questionnaire describing a conflict situation. Stance of the opponent was manipulated in the scenario whereas participants’ trait self salience was measured. In Study two, 94 participants engaged in a discussion task with another participant on the computer. The task was in fact an experimentally induced conflict situation in which the opponent’s responses were programmed. Both of participants’ self salience and stance of the opponent were manipulated whereas trait self salience was also measured. In Study one, participants’ perceived dominance in the conflict scenario was found a function of trait self salience and opponent’s stance. When participants’ personal self was salient, their perceived dominance remained high regardless of the opponent’s stance. When participants’ relational self was salient, their perceived dominance in conflict was high when facing a submissive opponent but was low facing a dominant opponent. In Study two, an interaction between trait and primed self salience was found. Primed self salience produced the hypothesized pattern in behavioral conflict moves as in Study one, but only among participants whose trait personal self salience was low. The results echo with recent findings regarding self priming and social behavior. Results of the two studies supported the notion of using self-enhancing as well as complementary mechanisms to understand moves in task conflict. The present framework treats interpersonal conflict as a dynamic system such that a conflict party’s actions should be an interaction between factors from the two parties involved. The framework also provides an alternative to existing theories of conflict processes that mostly adopt a single party approach in explaining conflict processes.

**Unraveling the role of different forms of autonomy and demands for creativity and health at work**

GLASER, J. (Ludwig-Maximilians-University), HERBIG, B. (Ludwig-Maximilians-University), ANGERER, P. (Ludwig-Maximilians-University)

Innovation and creativity are competitive factors in a globalized economy. However, pressure to innovate leads to detrimental working conditions and a growing rate of mental-health problems. Review of literature and pilot studies showed that well-known health-promoting working conditions – namely, autonomy and variety of job demands – may also have a beneficial effect on creativity. The aim of the study is to get a more differentiated understanding of the role of autonomy, with its theoretically-derived facets of decision-, action-, and design latitudes, and job demands on employees’ health and creativity as performance indicator. 228 employees from companies with high demands on creativity answered questionnaires on different facets of autonomy, job demands and job stressors. Health indicators were assessed according to a threshold model of ‘mild’ (psychological) to manifest (psychosomatic) disorders. Creativity was examined by self-rating and – for a subsample of 160 employees – validated by supervisor assessments. Structural equation modelling was used to analyze the differential impact of forms of autonomy and job demands on health and performance outcomes. A second ongoing survey (currently, 194 employees, 4 companies) is used for cross-validation. Although the different facets of autonomy are interlinked, especially design latitudes show a strong relation to higher creativity and lesser irritation. Moreover, job demands have a clear impact on creativity. Irritation can be seen as an early indicator of health impairment and the starting point of a chain of progressively severe health problems. Structural relationships are cross-validated by means of the second survey sample.
Results show the relevance of a differentiated analyses of work (e.g., discerning facets of autonomy) and health (according to a graded threshold model). They pinpoint specific implications for work design that promotes both health and creativity of employees.

Keywords: innovation, creativity, autonomy, job demands

Urban vs. rural differences in attitudes affecting dangerous driving behavior: An application of structural equation modeling

Death rates from highway accidents for rural populations are markedly higher than similar rates for more urbanized populations. The question is raised concerning a possible “culture of bad driving attitudes” on the part of the rural population. The paper seeks to explore differences between urban and rural populations in terms of the relationship among factors representing component elements which are known to affect the propensity to drive in a dangerous manner. The research applied a series of methods which included principal component analysis, confirmatory factor analysis, and structural equation modeling to build a model of the interaction among five latent factors for the full sample (n=1040) drawn from three adjacent states in the USA. The five latent factors were derived from 18 directly observed manifest variables. The model was applied on a multi-sample basis for a subsample of rural respondents (n = 483) and a subsample of urban/suburban respondents (n = 557.) The survey instrument was designed to reveal patterns such as sensation seeking, denial of risk (reflecting optimism bias); social norm, objective norm and acceptance of the efficacy of speed, among other hypothesized factors. A factor representing dangerous driving was derived from five self-reported behaviors, drawn from the Driver Behaviour Questionnaire. The model produced an adequate level of fit to the data; (RMSEA=.026, CFI=.97 TLI=.96.) The hypothesis of a possible “culture of bad driving attitudes” on the part of rural drivers was not supported by the research. A comparison of the parameters (beta coefficients) calculated for the two samples suggests that, for the rural sample, the factor representing denial of risk is significantly more important in predicting dangerous behavior than the factor representing sensation seeking, while denial of risk is somewhat less important than sensation seeking for the urban sample. Factors representing the role of social norm and desirability of speed did not vary between the two sub-samples. The observed difference in roles of sensation seeking and denial of risk became more pronounced when additional segmentation was undertaken to reveal differences between rural males under age 30 and their urban counterparts. No differences in the role of the two factors were attributable to gender. The possibility that bad driving behavior in rural populations is associated with problematic attitude factors different from those in urban populations should be examined further, with a database based on a wider geographic area. If the pattern is confirmed in further research, the implications of the differences between attitude factors should be examined for possible integration into the development of context specific strategies to improve driving behavior.

Use of an extended protection motivation theory (PMT) to examine change in walking episodes and saturated fat consumption in patients treated with percutaneous coronary intervention

HIGGINS, R. (Heart Research Centre), HARDIE, E. (Swinburne University of Technology), MURPHY, B. (University of Melbourne), WORCESTER, M. (University of Melbourne), BROWN, S. (Heart Research Centre)

The present study aimed to examine the utility of the Protection Motivation theory-plus (PMTplus) model in predicting change over six months in health behaviours in patients who had undergone a first Percutaneous Coronary Intervention (PCI). In total 218 patients consecutively admitted for first PCI were
included in the study. Walking and saturated fat consumption and PMT scales along with a 'future distress' scale to enable investigation of the PMTplus model were administered via telephone shortly after discharge and again six months later. Results indicated that walking episodes increased significantly over time, while saturated fat consumption remained stable over time. Significant main effects for time were evident for all PMTplus measures with the exception of exercise self efficacy. Future distress was the only PMTplus component that decreased over time. The addition of 'future distress' significantly improved the predictive power of the PMT model. In total the PMTplus walking model explained 21.7% of the variance, while the PMTplus dietary model explained 16.5% of the variance. Age group, change in exercise self-efficacy and change in future distress made significant unique contributions to the prediction of change in walking episodes after PCI. Dietary vulnerability and change in future distress made significant unique contributions to the prediction of change in saturated fat intake. Overall these findings point to the PCI patients undergoing a process of adaptation to their CHD over time. The PMTplus model provides a useful model of cognitive and emotional appraisal. Findings point to the importance of providing psychological support to patients alongside advice regarding behaviour change.

Keywords: protection motivation theory, percutaneous coronary intervention, exercise, future distress

Using a novel method of measuring knowledge acquisition and bias to evaluate the effectiveness of ‘active learning’

CATHERWOOD, D. (University of Gloucestershire), EDGAR, G. (University of Gloucestershire), GROVER, R. (University of Gloucestershire), NIKOLLA, D. (University of Gloucestershire)

This study had two aims: 1) to compare the effectiveness of ‘active’ and ‘passive’ learning in undergraduate students, and 2) to evaluate a new assessment technique that uses signal detection theory to give an indication of not only how much students know but also their tendency to accept or reject information that they hold (bias). Two different psychology practical sessions investigating visual illusions were prepared in either an active or passive format. In the active session students worked in groups and were given free use of the web; although with certain suggested websites. They were given the illusions to explore and the aim of the session was to discover the answer to certain general questions. In the passive sessions the students worked individually and did not have access to the web or the actual illusions - although they were given printouts of all material from the suggested websites, thus providing all the information needed to answer the questions posed. Each group of students did one active and one passive session. The order of presentation of the active and passive sessions was counterbalanced across groups. After the students had completed both sessions, they were tested on the material using a series of true/false statements. The data were then analysed using an assessment technique based on signal detection theory to give a score for how much each student knew and also a measure of their bias (see above). 2 x 2 mixed ANOVAs with active or passive session as the within participants variable and session topic as the between participants variable, were conducted on the knowledge and bias scores. For the knowledge scores there was a significant main effect of which topic was the active one ($p = 0.012$). For the bias scores there was a significant interaction between session topic and the effect of active Vs passive learning ($p = 0.002$). Considering only the knowledge scores, it appeared that passive learning was more effective, but was heavily task dependent. Consideration of the bias scores, however, suggested that the high knowledge score was at the expense of a lax bias representing a tendency to accept false information as true. Overall, it appeared that active learning was less affected by the task, and participants in the active conditions appeared better ‘calibrated’ (less bias). An interesting finding was that, over all the participants, there was almost no correlation ($r = 0.004$) between their scores in the active and passive conditions suggesting that different participants performed better in active or passive learning situations suggesting that different learning types may suit different people.
Using latent trait modeling to inform the DSM-V classification of Generalized Anxiety Disorder

HOBBS, M. (University of New South Wales)

DSM-IV identifies discrete diagnoses. Lists of observable indices are used to assess latent disorder processes, but can DSM be a valid classification if it measures largely unobservable phenomena? There are no laboratory tests for most psychiatric disorders. There is no gold standard to measure the classification against. DSM has thus depended on reliability rather than validity to justify the parceling out of categorical diagnoses. The revision of DSM-IV is underway. The retention of a predominantly categorical classification is one of the greatest challenges to the validity of DSM-V. The alternative to such a classification is one that includes or wholly replaces this binary system with some form of dimensional assessment. A paradigm shift towards a more dimensionally based classification would increase the validity of DSM by reflecting the latent structure of disorders in the organization of diagnoses. Robust support for including dimensional measurement in DSM-V on this premise does not exist for all DSM-IV diagnoses. Evidence for incorporating diagnosis-specific dimensional assessment is limited particularly for Generalized Anxiety Disorder (GAD). This is the first study to investigate whether DSM-IV GAD criteria are graded markers of latent dimension(s) of pathology. The lifetime experience of DSM-IV GAD symptoms was assessed in 1,632 community respondents of the 2007 Australian National Survey of Mental Health and Well Being. Respondents who had experienced sub-threshold and threshold GAD symptoms were included in the sample to examine the relationship between DSM-IV diagnostic criteria and the latent structure of the disorder. The comparative model fit of unidimensional and multidimensional latent trait models was tested. These dimensions were then externally validated. It was found that a third of the sample reported threshold criteria for GAD. Based on the full information factor analyses, increasingly multidimensional solutions provided superior fit to a unidimensional conceptualization of the disorder. The DSM-IV criteria are graded markers of the interaction of these dimensions. Therefore, this study supports considering the inclusion of diagnosis-specific dimensional assessment of GAD in DSM-V. How these results could be used to establish categorical and dimensional diagnostic thresholds will be discussed.

Keywords: generalised anxiety disorder, latent trait modeling, classification

Using mixed distribution models to test the construct validity of the physical self-description questionnaire

STRAUSS, B. (University of Muenster), TIETJENS, M. (University of Muenster), BÜSCH, D. (IAT Leipzig), FREUND, A. (University of Muenster)

The Physical Self Description Questionnaire (PSDQ) (Marsh et al, 1994) is an internationally established instrument to measure the physical self. To test the psychometric quality of the PSDQ, confirmatory factor analyses (CFA) and multi-trait multi-method (MTMM) analyses have been conducted as well as item response theory (IRT) models (e.g. the Samejima-model). Probabilistic mixture distribution models such as the Mixed-Rasch-Model (MRM, Rost, 1990) have not been used so far. They allow us to identify different groups of people (latent classes) which the Rasch model holds, but with different item parameters. The MRM is an IRT model which combines the properties of latent class models with the Rasch model (as latent trait model). The PSDQ consists of 70 items which measure eleven subscales. Subjects respond on a six-point scale. The sample of this study constituted N = 568 students (mean age = 27.06; male n = 236). The results indicated acceptable goodness of fit indices for the 11 factor solution (χ²/df [1585.87/505] = 3.14, TLI = .93, CFI = .94, RMSEA = .06, SRMR = .05). The inter-correlations varied between r = 0 -.75. To test the unidimensionality of the 11 scales, 11 separate confirmatory factor analyses were conducted. CFAs for each single scale almost always produced an inadequate model fit. Analyses of each of the 11 scales using the Mixed-Rasch-Model (MRM) confirmed this lack of unidimensionality, showing that the
best fit indices were almost always for a two-class solution. Approximately 30% of respondents did not complete the scales according to the given ordinal response format. As a result, their data has to be interpreted in terms of response tendencies and not in terms of content. The other 70% of respondents generally revealed unidimensionality in the sense of the specific construct. These detailed MRM analyses reveal the reason for the frequently observed lack of unidimensionality in the single scales: The PSDQ is inappropriate for assessing the specific assumed underlying dimension in a relatively large proportion of persons (approx. 30%).

Keywords: construct validity, physical self description questionnaire, latent class models

Using negative and positive social feedback from a robotic agent to save energy, the moderating roles of feedback relevance and multiple goal activation

MIDDEN, C. (Eindhoven University of Technology), HAM, J. (Eindhoven University of Technology)

Sustainable living is to a large extent the outcome of how consumers use the technology surrounding them. Seen from this perspective the rather strict separation of technological and behavioral solution is not only artificial but also detrimental to finding real sustainable solutions. Persuasive technology aims to intervene in these user-system interactions by using intelligent agents to change human attitudes and behavior. In the present paper, we explore the persuasive effects of social feedback, as provided by a robotic agent, on behavioral change. In two recent studies we showed that robotic agents are capable of exerting social influence on the behavior of users of household appliances by providing positive and negative social feedback (approval vs. disapproval). In the present paper we focus on the self-regulatory role of negative social feedback and demonstrate the effects of feedback-task relevance and multiple vs. single goal activation as moderating factors on the effects of both types of feedback. Two lab experiments will be presented that analyze the effects of task relevance of the feedback and the role of single vs. multiple goal activation. The experimental setup was largely based on the appliance simulation paradigm, which was developed and validated in a series of prior experiments on the topic. In this setup subjects make task decisions while engaged in the use of certain appliances, for example programming a washing machine. This setup makes it possible to study feedback processes and behavioral effects in a well-controlled lab environment. MANOVA analysis showed that social feedback by smart agents was more powerful than non-social factual feedback as provided through the user interfaces of appliances. In addition we showed that negative social feedback could produce more behavioral change than positive social feedback. Finally, we found that this valence effect was moderated by task relevance of the feedback and by single vs. multiple goal activation. The paper concludes that smart agents embodied by a robotic system are capable of persuading human users through mechanisms of social influence. Apparently humans are sensitive for social feedback even if this originates from a non-human source. Negative feedback is effective in achieving behavioral change suggesting the importance of negative feedback in self-regulation. The moderating effects of task relevance and multiple goal activation further strengthen the self-regulation explanation of feedback valence. Finally theoretical and practical implications of the findings will be discussed.

Validity of cognitive workload indexes: An analysis of eye movements during interruption handling

VELICHKOFSKY, B. (Moscow State University)

The aim of the current was to conduct an exploratory study of the sensitivity of eye movements-based cognitive workload indexes to cognitive load manipulations in the context of interruption handling. 65 subjects (aged 18-23, mostly female) took part in an experiment simulating interruptions during computerized office work. The complexity of interrupted and interrupting tasks was manipulated within subjects. The presence of an interruption lag
(which is a factor shown to decrease the cognitive complexity of interruption handling) was manipulated between randomly selected halves of the sample. Various eye movements-based indexes of cognitive workload were registered during different phases of interruption handling. As expected, most of the workload indexes were sensitive to the interruption lag presence (ps between 0.023 and 0.186, ps below 0.2 were considered significant according to the exploratory nature of the study). Two notable exceptions were blink rate and pupil dilation. The interactions of the complexity factors with the interruption lag factor were also assessed because the presence of the interruption lag allows for the employment of special cognitive-behavioral interruption handling strategies. Such strategies may decrease the cognitive load associated with the complexity factors and thus their employment should be reflected in a valid index of cognitive workload. The interactions were systematically found for fixation duration (ps between 0.061 and 0.179). Complexity factors had no effects on fixation duration in conditions with interruption lag, but there were clear complexity effects in conditions with no interruption lag (there was an increase in mean fixation duration in more complex interruption episodes). This is the first study to assess the validity of cognitive workload indexes related to eye activity in the context of interruption handling. Increase in fixation duration was shown to be the most sensitive index of cognitive workload. The use of pupil dilation as an index of cognitive workload in ecologically valid setting should be avoided.

Keywords: cognitive workload indexes, interruption handling, eye movement, validity, cognitive complexity

Value orientations, perceived risks and benefits, and acceptability of nuclear energy

DE GROOT, J. (Bournemouth University), STEG, L. (University of Groningen)

Acceptability of an increase in the supply and use of nuclear energy is most likely not based on purely objective risks such as expected morbidity. Subjective aspects of risks, such as specific beliefs on costs and benefits of nuclear energy, play an important role in supporting or opposing an increase in the supply and use of nuclear energy. These beliefs are rooted in values. Therefore, this study focuses on which values and beliefs can explain the acceptability of an increase in the supply and use of nuclear energy. Respondents completed questions on egoistic, altruistic and biospheric values, perceived risks and benefits of nuclear energy, and the acceptability of an increase in the supply and use of nuclear energy in the Netherlands (N=123). We examined the relationships between these constructs by means of a series of regression analyses. Perceived risks were negatively related to acceptability of nuclear energy, and perceived risks partly mediated the relationship between egoistic value orientations and acceptability. Perceived benefits were positively related to acceptability of nuclear energy and partly mediated the relationship between egoistic values and acceptability as well. Both perceived risks and benefits of nuclear energy did not mediate the relationships between the altruistic and biospheric value orientations and acceptability. Our results indicate that values are mainly indirectly related to acceptability, but are sometimes still directly related to acceptability as well, although weaker. The findings largely confirm that the relatively stable general value orientations affect perceptions of risks and benefits of nuclear energy and often indirectly influence acceptability via these specific beliefs.

Keywords: nuclear energy, risks, egoistic values, altruism, biospheric values

Value-related information processing: An experimental study on waste prevention

VON BORGSTEDE, C. (University of Gothenburg), ANDERSSON, M. (University of Gothenburg)

Excessive solid waste production is becoming both an environmental and economic burden in society. Even though people are increasingly engaged in recycle programs the waste mountain is continuously growing. Therefore, concurrently waste prevention has gained increased attention. On an individual level,
waste prevention is mainly about reducing consumption. People’s motivation and ability to reduce personal consumption vary to a large extent. The aim of the present research is to explore how information can be designed in order to increase motivation. Internal motivation is operationalized as value orientation. It is hypothesized that information can be framed to match people’s value orientations, thereby increasing message processing. We address this experimentally. Before reading the persuasive message the participants completed a value orientation questionnaire. Equal numbers of participants with sex and age balanced were then randomly assigned to a 2 (Source: Reliable vs. Unreliable) by 2 (Argument frame: Economic vs. Environmental) mixed factorial design. After completing a value orientation questionnaire, participants read messages on waste prevention where the source was framed as either reliable or unreliable. Dependent variables were favourability of cognitive responses and post-message attitudes. As predicted, factor analysis identified two distinct groups with either egoistic or altruistic value orientation. Participants with egoistic value orientation had more positive attitudes towards the economic arguments and processed them more thoroughly than did participants with altruistic value orientation. In current practice, provided information about waste management is most commonly homogenous even though the target groups are dissimilar in many ways. Since the present research suggests that information about waste prevention with economic framing is unlikely to reach individuals with altruistic value orientation, a suggestion is to adjust information.

Keywords: information processing, waste prevention, value orientation

Victim responses to interpersonal deviance: Motivators and deterrents to response strategy selection and evidence that even EVLN – R is not enough

MICHALAK, R. (University of Queensland)

The two dimensional, (active/passive and positive/negative) exit, voice, loyalty and neglect framework (EVLN - Withey and Cooper, 1989) was originally developed to study individual responses to dissatisfying workplace situations. Recently, the framework was theoretically expanded to include retaliation (R - active and negative) where the perpetrated individual becomes a perpetrator. Aims of this study were to determine if the EVLN–R framework is applicable to the interpersonal deviance domain in reference to victim response strategies; what factors motivate or deter response strategy selection, and whether victims also use other, non EVLN-R response strategies. The national sample spanning a range of industries consisted of 19 employees, 25 - 64 years, (M = 39), 16 females, recruited using snowball and convenience sampling methods. Semi-structured in-depth interviews commencing with a critical incident technique explored victims self-reported experiences of perpetration at work by other employees. Digital recordings were independently transcribed by a professional service blind to the aims of the study and a random selection of interviews were checked for transcription accuracy (99%+). The data were content analyzed in NVivo using a combination of both a priori thematic and data reduction techniques. The results also suggest that while victims use response strategies that resemble the expanded EVLN – R framework, they also use a number of other strategies, both behavioral (e.g. ignoring, managing/befriending the perpetrator and avoidance) and cognitive (e.g. minimization and denial). The results suggest that response strategy selection is influenced by individual (e.g. need for confirmation, justice or social support and motivation to protect others) and situational factors (e.g. fear of negative consequences including victimization, a culture of silence, perceptions of HR as “for management” and absence of results/positive results). It is evident that, whilst useful, the EVLN–R framework does not adequately capture the wide range of responses that victims use, and specifically it excludes any cognitive response strategies. Practical implications of this research are relevant to organizations, HR practitioners and individuals, and the study makes a worthwhile contribution to the sparse literature on victims, including what responses are used and why.
Violence at school: A challenge for educational psychologists. Beyond focus on individual towards socio-cultural perspective

ERAUSQUIN, C. (Facultad de Psicologia universidad de Buenos Aires)

The current study analyses mental models of activity displayed by Psychologists who work at educational contexts through narrations about their practice facing problems of violence at school. The research studies what kind of problems they name “violence”, where they are located and if they can search the history and analyse the variety of perspectives. On the other hand the study also looks at how agents have acted, who decided what actions for what, if there has been a chance to investigate or to help, towards whom intervention was directed, which instruments were used and results obtained. Categories of socio-cultural framework (Leontiev-Engestrom theory of activity) are linked to contextualist perspective of “mental models” (Rodrigo). Questionnaires about Situation-Problems of Violence in Professional Intervention at Educational Contexts were administered to sixty psycho-educational professionals that work at different schools in two main cities of Argentine, in the frame of specific postgraduate courses. Data were analysed with Multidimensional Matrix for Psychologists Professionalisation. Strengths, tensions and critical knots were related to: psychologists’ career, historic role of schooling and human development in impoverished and turbulent social contexts. Work points were: the relationship between violence and challenges for inclusive education; the importance of “emotionally holding” environments for education through meaningful learning; social justice and equality worth for exchanging experiences and knowledge with multivocality; the problem of educating diversity of people with one method, one direction and rhythm and the same goals for everybody; how psychologists can collaborate with teachers in inclusive solutions for behavior-and-learning problems; the former role of Educational Psychologists linked with assessment of special educational needs children by using IQ tests; and the “splitting” between cognition and emotion, learning and life, reducing interpersonal/institutional problems into individual mind questions since the origins of modern Psychology. To analyse their “models of activity” into social networks is a useful tool to re-conceptualize agents’ experience “from”, “in” and “for” action (Schon). It allows psychologists to deconstruct implicit conceptions that support practice.

Keywords: retaliation, victim response strategies, dissatisfying workplace situations

Violence, trauma, and suicidality: Multifactorial analyses of abuse, sexual violation, and perturbation across gender and sexual orientation

STEWART, A. (RMIT University), SMITH, D. (RMIT University)

Violence directed toward the self and others continues to manifest as a profound human problem, despite concerted amelioration efforts. Effective redress is hampered by taboos and underreporting, particularly in relation to sexual and familial violence and mental illness. The major objectives of this study were to: devise an inclusive, nonthreatening methodology to facilitate disclosure and circumvent previous research shortcomings, to achieve representation from under-researched and marginalized cohorts; to derive comprehensive data to measure abuse impact and sequelae; and to determine whether past suicidality differentiates individuals on current wellbeing. Quantitative and qualitative data were derived from 2503 Australian males and females, aged 16-83 years, using a nationwide online survey. Extensive analyses were conducted to differentiate victims and non-victims of child and adult sexual abuse; and non-suicidal individuals from those reporting past suicidality. Comparative examination encompassed domains such as gender, sexual orientation (SO), urban/rural location, psychosocial wellbeing, trauma symptomology, cognitions, substance use, and risk-taking. Procedures included factor analysis, regression, and multivariate analyses to identify perpetrator modus operandi; offence typology and impact; victim reactions; and
suicidal ideation and behaviour predictors. Current psychopathology was strongly associated with sexual abuse and suicidality histories. Heightened perturbation and suicidality were associated with childhood abuse and adulthood revictimisation. Males exhibited greater nondisclosure and help-seeking reticence than females, yet both have similar post-abuse psychopathology. Victims experienced multiple reporting barriers and frequent suboptimal reactions upon disclosure. Few perpetrators were reported. Perturbation, substance use, suicidality, and risk-taking varied across SO groups, evidencing vulnerability gradients such that bisexuality conferred greatest vulnerability, followed by homosexuality and heterosexuality. Rural location, contagion effects, and SO-related uncertainty and distress heightened vulnerability. Suicidality history and other variables were identified as useful vulnerability markers. Sociopolitical, judicial, clinical, and social change implications are discussed emphasizing needs for deconstructing silence, fostering help-seeking, nonthreatening methodologies, primary prevention initiatives, and strengthened responses toward substance use, mental illness, and victims and perpetrators of violence. Importance of including SO as a basic demographic variable in human research and fostering broader social acceptance, inclusive practices, and strengths-based initiatives to address minority group stress are also discussed.

Keywords: violence, trauma, Suicidal behaviour, abuse, sexual violation

Visual fixations in the weapon focus effect

PARK, K. (Chung-Ang University), LEE, J. (Chung-Ang University)

The Weapon Focus Effect (WFE) states that crimes involving weapons cause attention to be focused on central details (weapon), leaving little attention to be spent elsewhere. This causes memory impairment for peripheral details, such as the perpetrator’s external features or the surrounding environment. The purpose of this study is to determine whether eyewitnesses actually fixate on peripheral details, but fail to remember what they saw, or whether they spend all their attentional resources fixating only on central details. A slide show depicting a man (Target) entering a store, approaching the counter, and interacting with the clerk (6 slides) is presented on a computer monitor. The 3rd slide shows the Target reaching into his pocket, followed by the 4th slide (critical slide) which shows the Target a) handing over a check (Control condition), or b) pointing a knife (WFE condition). Half of the participants in each condition will view the critical slide containing an unusual-peripheral detail (UPD) in the top-left corner (Probe condition), and half without the probe (No-probe condition). After viewing a slide show, participants will complete a memory test regarding the central detail (money or knife) as well as peripheral details (e.g., Target appearance, environment). A 2(WFE vs. Control) x 2(Probe vs. No-probe) ANOVA will be used for data analysis. As the study is currently in progress, we predict that the WFE conditions will spend more time fixating on the central detail, compared to the Control conditions, leading to increased memory for the central detail and decreased memory for peripheral details. In contrast, the Control conditions will spend less time fixating on the central detail, resulting in better memory for peripheral details compared to the WFE conditions, and will also show better memory for the Probe. Until now, researchers have only been able to show through research that the WFE causes memory impairment for peripheral details. The present study may be able to demonstrate whether this because witnesses fixate only on central details, or actually see peripheral details but simply don’t remember. This information could help investigators interview eyewitnesses of crimes involving weapons more effectively.

Keywords: weapon focus effect (WFE), visual fixation, eyewitness accounts, memory, peripheral details

Vocational development and expectations of transition to college or/and to work of high school seniors

SANTOS, E. (University of Coimbra), FERREIRA, J. (University of Coimbra), ANDRADE, R. (University of Coimbra)
The purpose of the present study was to analyze the influence of a set of variables: sociological-contextual (age, gender, parental socio-economic status-SES), academic (typology of training in high school, school retentions), social-cognitive (career decision self-efficacy, vocational identity) and affective (dispositional optimism) in satisfaction, and outcome expectations of transitional pathways after high school: 1. to college; 2. to work; 3. to college (study) and work. The sample includes 622 high school seniors (12th graders), 376 females and 246 males, with ages ranging from 16 to 23 years old, attending both regular and vocational training schools, in the Madeira Autonomous Region, Portugal. The study design is non-experimental, with one moment of evaluation. To the study of predictor variables of transition pathways we used logistic regression. Results of the empirical study have shown that different variables are related with the anticipation of different pathways after high school; satisfaction and success outcome expectations. High scores in social-cognitive factors (career decision self-efficacy and vocational identity) are negatively related to school-to-work anticipation, satisfaction and positively associated to success outcome expectations to university transitions. Parental SES and vocational/technological training in high school are the major predictors to school-to-work transitions. Age and dispositional optimism are the major predictors to anticipate to study and work after high school. Implications of the results for career counseling interventions, and career services delivery are addressed. Finally, will be put forward suggestions for future research in the area of transitions, specifically dealing with school to work or/and school to college.

Keywords: vocational development, transition, vocational identity, satisfaction, self-efficacy

Waste and recycling behaviours – do positive attitudes towards the environment and education have an impact on people’s behaviour? Do they raise awareness and cause best practice?

FEMIA, V. (VAFEMIA Consulting), O’CONNOR, P. (The University of Notre Dame Sydney)

This study aims to show how positive attitudes towards the environment and targeted education programs have had a positive impact on people's behaviour with regards to the disposal and recycling of waste. Tenants from two Sydney CBD buildings, whose buildings had implemented effective recycling programs, were targeted. Their facility manager notified the tenants about the survey via the company server. They were invited to complete the 145-question spreadsheet on the web and were given four days to complete it. It is not known how many people saw this message, however, 195 people completed the questionnaire. For the main building this represented about 10% of the tenants. The questionnaire was structured so as to explore a number of key constructs. A cross-sectional survey analysis was completed on the number of variables. The variables included items that tried to tease out the impact of domestic and commercial recycling education programs. Other items attempted to identify the people’s recycling and disposal behaviour and their attitudes towards these. Some items attempted to see whether their company’s green strategies sat comfortably with them. The frequency of responses on items in the recycling education section that referred to waste and recycling education that was provided by the people’s local council showed that the majority thought the education was self explanatory and well written. These two items had a significant correlation with the item were the people said they created more recycling than waste on a weekly basis. There was also significant association in the following: if the people received education on the building recycling program, they did not create more waste than recycling on a weekly basis, and if they received information from the local council for the residential recycling program they tended to not create more waste than recycling on a weekly basis. The study has shown that there was significant support for the notion that Waste and Recycling education programs tend to raise awareness and cause best practice. The significant correlations between the questions specific to the education programs and certain key variables show a high level of understanding of key constructs that would be a part of any waste and recycling education program.
Keywords: Waste recycling strategies, positive attitudes, education, green strategies, awareness

What a difference a group makes: A comparison of individual and multilevel explanations of occupational stress

BARBOUR, J. (Griffith University), BROUGH, P. (Griffith University), BIGGS, A. (Griffith University)

Occupational stress research has been slow to incorporate multilevel analyses. Consequently, the exact role and influence of workgroup climate in occupational stress processes remains unclear. In this study, the job demands-control (JDC) model was employed as a theoretical basis for investigating the moderating effects of workgroup perceptions of cohesion and management on employees’ well-being, turnover intentions and job performance. A survey containing measures of job demands, job control, emotional dissonance, workgroup cohesion, work-related affect, psychological strain, turnover intentions and job performance was distributed to police officers from one Australian police service. Survey responses were obtained from 2,200 operational police officers nested within 248 workgroups. Comparison to organizational reports indicated the sample was representative of gender and rank distribution. Both individual-level and multilevel structural models of the data were analyzed in Mplus. Prior to aggregation of data at the workgroup-level, a three step procedure was used to check the appropriateness of data for multilevel analyses. ICC values > .05 were obtained for perceptions of cohesion and management, but also for job demands, work-related affect and psychological strain, indicating significant workgroup-level variance in these measures. Multilevel exploratory and confirmatory factor analyses indicated some differences between individual and workgroup levels in the factor structure of the measures. Both structural models of the hypothesized relationships demonstrated acceptable fit to the data. Perceptions of management moderated between job control, emotional dissonance and work-related affect. The use of multilevel factor analyses as a preliminary step to aggregation of individual data to the group level was strongly supported. Workgroup climate, and in particular, perceptions of management (‘management climate’) was found to moderate between job characteristics and strain. Results suggest that organizational efforts to ameliorate or exacerbate the harmful/protective effects of the psychosocial work environment on employees need to more fully consider the influence of workgroup processes and perceptions on these efforts. In the case of police officers, it seems that workgroup perceptions of management in particular can either buffer or exacerbate stressor-strain associations. Implications for future research and practice in occupational health psychology are discussed.

Keywords: occupational stress, job demands-control (JDC) model, workgroup climate, management

What about me? Perceptions of power, explanations for being targeted and self-reported outcomes for victims of interpersonal deviance

MICHALAK, R. (University of Queensland)

Despite a recent emphasis on legislated psychological safety, rising concern regarding mental health issues (e.g. depression, stress and anxiety) and potential links to organizational behavior phenomena, studies on ‘who, why and what does it lead to’ are sparse. The aim of this study was to begin bridging this gap by exploring the role of power, victim explanations for being targeted and the self-reported outcomes of interpersonal deviance. The national sample spanning a range of industries consisted of 19 employees, 25 - 64 years, (M = 39), 16 females, recruited using snowball and convenience sampling methods. Semi-structured in-depth interviews commencing with a critical incident technique explored victims self reported experiences of perpetration at work by other employees. Digital recordings were independently transcribed by a professional service blind to the aims of the study and a random selection of interviews were checked for transcription accuracy (99%+). The data were content analyzed in NVivo using a combination of both a priori thematic and data reduction techniques. The results suggest that both absolute and perceived perpetrator relative
power influence why an individual is targeted. Victims described perpetrators as ‘control freaks’, suffering ‘little person syndrome’, with a perceived tendency to target individuals who present any sort of threat to them. Outcomes were influenced by victim response strategies and the type/duration of interpersonal deviance experienced, and included slight to severe physical and psychological wellbeing issues, decreases in job satisfaction and commitment, and notably the withdrawal of citizenship behavior. Learning, both over the process and from prior experiences, was also reported. Interestingly, similar prior experiences at school and other workplaces were reported by a proportion of cases, suggesting that some victims may somehow incite perpetration. It is evident that experiencing interpersonal deviance leads to negative outcomes for individuals and their organizations, with power playing a critical role in target selection. Implications of this research apply to organizations, HR practitioners, individuals and society overall. The study makes a worthwhile contribution to victim literature and provides support for further research on how interpersonal deviance can be prevented and managed more effectively.

Keywords: psychological safety, power, interpersonal factors

What can an organisation’s history tell us about strategic leadership?

WILLIAMS, A. (City University London)

This paper aims to draw attention to the value of organizational histories in the process of understanding aspects of leadership in times of change. There is an extensive literature relating to: the development of strategy; the assessment of individuals in order to predict their likely leadership potential; the internal (e.g. personal power) and external (e.g. international competition) forces underlying organisational change. Knowledge associated with these three concepts of ‘strategy’, ‘leadership’ and ‘forces’ for change needs to be synthesised by psychologists/consultants advising their clients (e.g., in the selection and development of Chief Executive Officers). This paper will attempt to show that an organisation’s history can provide further insights, and clarifications, when formulating the requirements for effective strategic leadership. The historical or longitudinal case study described in this paper covers the period 1966 to 2009 of a UK university. Data collection methods used involved the examination of documents and the interviewing of senior staff. A version of the critical incident approach was used in the semi-structured interviews: respondents were invited to identify key individuals, working parties, events and institutions that had an influence on the development of the university. The case study illustrates four components of strategic leadership: (1) Managing strategic choices (i.e. developing Organisation-Environment fit strategies); (2) Managing internal stakeholders (i.e. implementing chosen strategies); (3) Managing external stakeholders (i.e. protecting and enhancing organisational interests); (4) Managing CEO transitions (i.e. enhancing O/E fit through the appointment of a new CEO). Historical research of this nature can help academics and consultants understand why current strategies, structures and decision making processes have evolved into their present form. It also helps us to understand the role of the CEO, and his or her team, in manipulating the forces for change in pursuance of strategic objectives. The paper should be of interest to practitioners involved in the process of selecting and developing CEOs/Vice-Chancellors, and to academics involved in conducting more quantitative research into this complex area of strategic leadership.

Keywords: leadership, organisational change, strategy, forces

What can the N170 tell us about face processing in schizotypy?

BATTY, R. (MAPrc & RMIT University), BATTY, R. (RMIT University), ROSSELL, S. (MAPrc), FRANCIS, A. (RMIT University)

Deficits in facial affect discrimination in schizophrenia may reflect inadequate configural processing. It has been proposed that the event-related potential (ERP) known as the N170 reflects the process of encoding facial information to form a structural representation.
We investigated whether configural processing was behaviourally and/or neurophysiologically different in persons with high schizotypy. Healthy individuals (N = 28) were assigned to either high or low schizotypy extremes as defined by the Oxford Liverpool Inventory of Feelings and Experiences (O:LIFE; Mason, Claridge & Jackson, 1995). Two stimulus types were presented in both an upright and inverted orientation: Mooney stimuli (configural information only), and photographic stimuli (both featural and configural). These were compared with non-face stimuli and participants were required to make face/non-face judgements. N170 latency and amplitude were submitted to separate repeated measures analysis of variance with the following within subject factors; orientation (two levels, upright and inverted), hemisphere (two levels, left and right), and electrode (three levels, P7/P8, PO7/PO8, C81/C82). Group sizes were too small to detect differences. Correlations of the O-LIFE scores with amplitudes for each electrode were then run. Accuracy and reaction times did not differentiate the schizotypy groups, however O-LIFE scores correlated significantly with N170 amplitudes (p < .05). Assessment of group waveforms revealed that high schizotypy showed a trend for reduced N170 amplitudes to both face orientations relative to the low group. Reduced amplitudes in high schizotypy indicate impoverished facial information during face processing. Face processing impairment in schizophrenia may instead be attributable to a global reduction in the quality and/or quantity of fine detailed information. Determining the aetiology of face processing deficits will have a significant impact on the management of social distress experienced in schizophrenia, and subsequent treatments may help to reduce delusions of a social/persecutory nature.

Keywords: schizophrenia, facial affect discrimination, event-related potential, schizotypy, face processing

What makes or breaks creative performance: How the achievement motive affects the evaluation of ideas

URBACH, T. (University of Potsdam), FAY, D. (University of Potsdam), LAUCHE, K. (Delft University of Technology)

One crucial step regarding the implementation of a creative suggestion is the line manager’s decision whether to support the idea or not. This study seeks to contribute to our understanding of the factors that enhance the likelihood of a decision-maker sponsoring an idea by exploring the effect of the decision-makers’ achievement motive and characteristics of the idea and idea presenter. We conducted two experiments with student participants. Participants’ trait achievement motive (AM) was assessed. Then, participants were presented written scenarios that depicted a situation in which a fellow student had come forward with an innovative idea. Participants’ reaction to the idea was then obtained. Experiment 1 (2x2 design, N = 83) manipulated whether or not the innovative idea permitted satisfaction of the achievement motive. An interaction effect with participants’ AM was assumed: Individuals high on AM should rate the idea serving the motive more favourably than the other idea, while the reverse should apply for participants low on AM. In Experiment 2 (2x2x2 design, N = 174), we additionally manipulated the AM of the person voicing the idea (high vs. low). Participants were expected to evaluate an idea more positive when they perceived the AM of the suggesting person corresponding to their own. Thus, we proposed a three-way-interaction. Dependent variables were idea appraisal, intentions (e.g., probability of supporting the idea), affective reactions, and the imputed intentions of the idea presenter. Hypotheses were partially supported. Interactions were as predicted: Participants low on AM rated the idea that did not fit their motive less positive than the idea that did fit. Hypotheses regarding imputed intentions were not confirmed. Besides replicating previous results, corresponding effects occurred for affective reactions and behavioural intentions. The interaction of the suggesting person’s and participant’s motive had an impact on participants’ negative affective reactions, general appraisal and probability of approval; other effects were less strong. Results suggest that whether an employees’ idea will be sponsored by their line manager will not solely depend on the utility of the idea (as implicitly assumed) but might be also influenced by the idea’s implications for the motives of the beholder.
What the Hell is Employee Presenteeism?!

KARIMI, L. (La Trobe University), GILBREATH, B. (Colorado State University - Pueblo)

Presenteeism occurs when employees are physically present but mentally absent. We investigated the extent to which supervisor behavior is associated with employees’ presenteeism. We also investigated the efficacy of a measure of job-stress-related presenteeism. Australian employees (N=154) from organizations completed a questionnaire asking how often they experience job-stress-related presenteeism and about their supervisor’s behavior. Results from hierarchical multiple regression analyses were supportive of our hypothesis that supervisor behavior will be associated with employees’ presenteeism. Negative supervisor behaviors were more strongly correlated with presenteeism than positive supervisor behaviors. Our results suggest presenteeism is another factor subject to supervisor influence, and they provide additional evidence for the important effects supervisors can have on employees. In addition, our results indicate that the measure of job-stress-related presenteeism pilot-tested in this study has good internal-consistency reliability and merits further tests of its utility and validity.

Keywords: presenteeism, supervisor, job-related stress

What theoretical basis for intervention with very young children?

LÉCUYER, R. (Université Paris Descartes)

The prevailing theory concerning the first months of cognitive development is the nativism, that is, the infant would be born equipped with knowledge independently of any interaction with the environment. It follows from this view that no environmental influence can change the basic conceptions of the world. Another conception can be based on the construction of early representations. This second approach would leave the possibility for both cognitive disturbances and actions for compensation. Adopting this latter view presupposes that we are able to describe the genesis of these representations. The purpose of this presentation is to describe the acquisition of knowledge from the end of fetal life until the age of three months, where a number of knowledge has been evidenced, and to propose a representational system that can account for this development of knowledge through interactions with the environment.

Keywords: cognitive development, nativism, cognitive disturbances, representations

What works? The impact of educational and development project in elderly care

WESTERBERG, K., HAUER, E. (Umeå University)

In an intervention project, “Steps for skill”, which took place between 2005-2008, the aim was to build an infrastructure for learning in a public elderly care organization with 1800 employees. The project contained education and development activities for individuals, work groups, and leaders. In addition two, occupationally mixed, teams were formed and these teams worked with work group development and transfer of specialist competence to the work groups. Before, during, and after the intervention period data has been collected. The design is basically a case study but contains also comparison groups that have not been subject to intervention. In all, the questionnaires (including learning climate, group climate, psychosocial work environment, health, stress, motivation, attitudes to workplace learning) have been completed by 320 participants. There is a substantial amount of interview material, observation data, and documents collected within the same period of time. The preliminary results showed that on an individual level there were no differences between the intervention and the comparison groups before and after the intervention. But there were differences between workplaces and different types of work organizations. Those who had been subject to other organizational changes during the project period seemed not able to benefit from the intervention. Those who
worked in home help services had the lowest learning climate scores before the intervention improved during the project period. The leaders gained in the social factors but not in their experience of competence. It is argued that the sustainable effects of the intervention are mainly related to the teams and organizational learning processes. In conclusion, to target organizational processes and consider the effects of organizational changes are of vital importance when planning and implementing a learning and development project.

What’s in a meme? Internal letter transposition, word length and the eye-voice span

HENDRY, L. (University of Southern Queensland), LAX, M. (University of Southern Queensland), STUBBERFIELD, T. (University of Southern Queensland)

To investigate if internal letter transposition (ILT) decreased reading performance and memory output in a rehearsal-free memory task using the eye-voice span (EVS) as the measure. The major source was an internet meme (a rumour, urban legend or concept propagated via email) suggesting that ILT did not affect reading performance, provided the initial and final letters in words remained unchanged. An Interrupted Reading Task (IRT) tested the concept of the original meme. Reading speed, number of words output and output duration were measured by analysing sound files recorded from the IRT. The IRT presented text passages on a computer screen to participants, who immediately began reading them aloud, until a predetermined point at which the experimenter caused the text to disappear from view, replacing it with a random pattern mask, while participants continued reading aloud for as long as they could. Text passages were designed so that the words following the interruption were either mostly long (3 or more syllables) or short (one syllable). Additionally, passages were either presented as unmodified text or as ILT stimuli, where the internal letters were randomised whilst leaving the initial and final letters intact. Word length was manipulated within subjects, and ILT condition between subjects in a mixed ANOVA. Recorded output represents the contents of the EVS, which relates to short term memory capacity. Significant main effects obtained for both the ILT manipulation (ILT worse) and word length (long words worse) on the measures of number of words output and output duration, as well as a significant interaction showing the ILT further reduced output measures when passages contained longer words. A significant difference in reading speed was evident, with ILT passages read much slower than unmodified text. Data and analyses support both the DRC model of reading (Coltheart et al., 2001) and a global account of word recognition (Frankish & Barnes, 2008) as well as reiterating the robust and well-known Word Length Effect (WLE; as noted in Baddeley et al., 1975) – however the IRT is a rehearsal-free task and as such the results do not support rehearsal accounts of the WLE. The content of the original meme is, unsurprisingly, refuted by these data.

What’s it like to be back home?

ALLAN, A. (University of Melbourne)

This study aimed to discern the nature of psychosocial adjustment experienced by medical humanitarian aid workers after returning from deployment overseas on their first humanitarian emergency mission. 28 humanitarian aid medical doctors and nurses completed a Q-Sort on three occasions in the period 0-10 months following their return from an international emergency deployment. The Q-Sort elements comprised 38 biopsychosocial descriptors pertaining to cognitive and emotional functioning; social and vocational activity and personal, health and self-care behaviour. Participants sorted elements according to perceived salience at time of sort (-3 to +3). A total of 79 sorts were factor analyzed. A Varimax rotation of factors revealed 53 out of 79 sorts accounted for by 9 factors. The 9-factor solution catered for 69% of the variance (Eigenvalues >1 and loadings ≥ 0.42). The results of the Q-Sort revealed qualitatively...
different patterns of psychological adjustment phenomenon than typically outlined in studies describing the adjustment of corporate or student expatriate re-entry experiences. Rather than describing compartmentalized and sequential re-entry experiences as discrete phases of elation, depression, recovery and adaptation, this Q-Sort analysis suggests that the nature of adjustment is better understood by consideration of the underlying existential constructs of meaning, purpose, order, role and sense of belonging. For many humanitarian workers, their profound experiences in the realm of human suffering results in a permanent shift in their existential frame of reference. Re-entry support for humanitarian aid workers could be strengthened by an increase in qualitative understanding of the existential challenges faced upon reentry and the subsequent impact this has on the quest for adjustment. The results of this study have implications for the nature of support and timing of support that is offered to humanitarian aid workers upon their return home from deployments.

When hurt endures: The influence of degree of closeness, degree of attachment and victim attachment style on ongoing hurt feelings

BURCHELL, J. (The Australian National University), WILKINSON, R. (The Australian National University)

Hurt feelings are an important negative emotion and there are a number of complex factors that influence their development and expression. Much of the field is yet to be explored empirically. One area where research is at a preliminary stage is in understanding why hurtful events continue to cause pain long after the event has ceased to have an impact on the individual’s life. Recent studies have indicated that both the degree of closeness and the degree of attachment that the victim has to the perpetrator of the hurtful act, as well as the victim’s attachment style, influences the intensity of hurt feelings resulting from the event. The current study aimed to assess whether these factors in conjunction influence the processing of hurt over time. The current study used a self-report questionnaire with 97 adult participants (90 females, 7 males, Mage = 27.56, SDage = 6.43) from a community sample. This is a preliminary sample of the expected 200 participants. Participants recalled hurtful events from three relationships of varying closeness, and reported the intensity of hurt from each event both at the time the event occurred and at the time they completed the study. The study also measured the degree of attachment to each relational partner, as well as the attachment style of the participant. The closeness of the perpetrator to the victim significantly predicted the hurt experienced from an event, with closer relational partners causing more hurt both at the time of the hurtful event and at the time of study. The closest relational partners also met the criteria for full-blown attachment relationships. Regardless of relationship, there was a significant reduction in the level of hurt over time. Attachment anxiety and avoidance significantly interacted with the change in hurt over time, but only for hurt originating from romantic partners. This suggests that attachment style plays a role in how hurtful events are processed, but these effects only become salient in the context of an attachment relationship. These findings are explored within an evolutionary framework.

When is it ethical to breach confidentiality with adolescent clients engaged in risk behaviours? A survey of Australian psychologists

DUNCAN, R. (Murdoch Childrens Research Institute), KNOWLES, A. (Swinburne University of Technology), SAWYER, S. (University of Melbourne)

Confidentiality is a vital piece of the therapeutic puzzle in psychology. It allows clients to speak honestly about sensitive aspects of their lives and it allows psychologists to build an effective therapeutic alliance with their clients. However, psychologists describe confidentiality as the cause of their most serious ethical dilemmas. These dilemmas are further complicated when clients are adolescents, as young people differ
from adults in their emotional, social and cognitive capacities. The current study aimed to investigate: (1) when Australian psychologists believe it is appropriate to breach confidentiality with adolescents; (2) what types of considerations mediate their decisions about confidentiality with adolescents; and (3) what general philosophies they employ when making such decisions. A total of 264 Australian psychologists completed an online survey. The survey consisted of three parts. Firstly, a series of vignettes describing risk behaviours being undertaken by a 15-year-old male were presented and respondents were asked to indicate whether they would breach confidentiality in each scenario. Secondly, respondents were asked to rate the importance of 13 separate considerations for making decisions about breaching confidentiality with adolescent clients. Finally, respondents were asked to articulate their general philosophies about breaching confidentiality with adolescent clients and the types of factors that mediate their decisions. Factor analysis and thematic analysis were used to analyse the quantitative and qualitative data respectively. Australian psychologists demonstrated general consensus about the need to breach confidentiality with adolescents when a serious and immediate risk of harm was present. However, great variation existed in their opinions about less serious scenarios. When deliberating about decisions regarding confidentiality with adolescent clients, Australian psychologists consider three key areas: professional obligations; process issues; and the overall best interests of the young person. Australian psychologists also described significant challenges concerning confidentiality dilemmas with adolescent clients and articulated a desire for greater support, guidance and training in this area. The results of the current study were used to produce a model for ethical decision-making about confidentiality dilemmas with adolescent clients.

When is professional ethics education indispensable? Psychology students’ answers to professional dilemmas

PASMANIK, D. (Universidad de Santiago de Chile), INÉS WINKLER, M. (Universidad de Santiago de Chile, USACH), SABALLA, D. (Universidad de Santiago de Chile), JADUE, F. (Universidad de Santiago de Chile, USACH)

The aim of this study was to discover to what extent is the personal ethics and ethics training given during undergraduate studies sufficient for psychology students to judge the soundness of psychological interviews. This information would be the basis for assessing improvements in students’ judging abilities after training in professional ethics competencies. 50 psychology students evaluated either one interview related to school issues (a psychologist interviewing a teacher), or one related to psychotherapy (a first session). The interviews were performed by actors and filmed. Scripts included ethical mistakes and were judged by 8 and 9 experts, respectively. Four sample groups participated, with students from three public universities, two groups on courses related to school or educational psychology, and two related to psychotherapy. Ten students had never received formal ethics education, 18 had studied one ethics course and the rest had had some classes within different courses. Participants were asked to write down their judgements arguing their cases, proposing alternatives, and stating which principles were violated according to the Code of Ethics of Chilean Psychological Association and/or The Universal Declaration of Ethical Principles for Psychologists. Answers were analyzed using Content Analysis. All the students (50) identified correctly the violation of confidentiality. Evaluating the school psychologist’s interview, 22 (95.6%) students focused on the interviewee’s wellbeing. Ten (43.4%) incorporated the wellbeing of other members of the school, and/or the school itself, in their analysis. Fourteen (51.8%) clinical answers alluded to the violation of the patient’s autonomy. No one considered the others’ wellbeing involved in the patient’s problem. Students succeeded in identifying ethical faults in the one to one helping relationships, focused on the consultant’s inner world. This matched the traditional way of representing psychology work. A more sophisticated deontological background would be required when dealing in institutional contexts and having to consider the
perspectives and wellbeing of multiple participants.

When latent inhibition influences change blindness? The moderating effect of epistemic motives on perceptual style

LIOU, S. (National Cheng Kung University)

This study examines how epistemic motives moderate the effect of Latent Inhibition (LI) on change blindness. Change blindness is the striking failure to see large changes that normally would be noticed easily. Although our understanding of visual perception and awareness are fairly well established in the change-detection literature, how individual differences in knowledge, personality, or expectations influence change detection as a function of the semantic content of a scene has still been underexplored. This study proposes that reduced LI decreases change blindness, and the effect is moderated by need for cognitive closure (NFC). LI, the ability to selectively attend and respond to relevant stimuli, and to ignore irrelevant ones, is essential for adaptive behavior. Many recent studies relate selective attention to individual differences. Thus, we hypothesize that reduced LI decrease change blindness. Moreover, Individuals scoring high on NFC are likely to lead to a very narrow information search and a higher tendency to use cognitive heuristics when it comes to finding a solution to a question. Hence, we hypothesize that higher NFC will enhance the tendency to adopt default perceptual heuristic, thus expand the difference of change blindness between high and low LI. Two experiments both in laboratory and field were conducted. We used the latent inhibition paradigm (LI; Lubow, 1989) to divide into high and low LI group, and manipulate NFC both by situation (time pressure) and by disposition measure (Webster & Kruglanski, 1994). Task materials developed by Simons & Chabris (1999) were used as to measure change blindness in laboratory experiment. We also developed an interactive media on internet as field experiment. Results both from laboratory and field experiments show that individuals with reduced LI detect more change, i.e. decrease change blindness. Moreover, the difference of change blindness between high and low LI is expanded when with higher NFC thus support the hypothesis. These findings suggest that individual differences (aging, cultural differences, expertise, and practice) and their relationship to change detection and attention is an exciting new direction for the field. The implication for applying this motivated cognition in human computer interaction design is also discussed.

Keywords: epistemic motives, latent inhibition, change blindness, need for cognitive closure

Why do individuals with borderline personality disorder drop out of treatment?

HALL, M. (Deakin University), MELLOR, D. (Deakin University)

The aim of this study was to investigate whether individuals who drop out of Dialectical Behavior Therapy are different from those who complete therapy on demographic factors and pretreatment psychiatric functioning. Thirty individuals with Borderline Personality Disorder participated in a modified group-only version of Dialectical Behavior Therapy in a public mental health service in Victoria, Australia. Participants were predominantly female (93%), aged between 23 and 59, were predominantly single (83%), and were Australian born. Individuals were assessed before and after a year-long cycle of DBT with the following assessment tools: The Structured Clinical Interview for the DSM-IV I and II, the Suicidal Behaviors Questionnaire, the Beck Depression Inventory – Second Edition, the State-Trait Anxiety Inventory, the World Health Organization Quality of Life – Brief, the Ways of Coping Checklist, and the Affective Controls Scale. Of the 30 participants who were included in the study, 22 dropped out of treatment (6 dropped out before entering the skills group and 16 dropped out once the group had commenced) and 8 completed a cycle of Dialectical Behavior Therapy. Individuals who dropped out of treatment tended to be single, had a fear of abandonment, and had more Borderline Personality Disorder traits at
pretreatment than those who completed therapy. Individuals who drop out of treatment differ from those who complete therapy on a series of easy to identify pretreatment factors. These findings have implications for the treatment retention of a group of clients who are notorious for dropping out of therapy.

Willingness to pay a fair price

GEERTSHUIS, S. (University of Auckland)

The aim of this research was to build understanding of how purchase decisions are influenced. The research examines the impact of benchmark prices, conceptions of fairness, satisfaction with service and self-reported decision criteria on willingness to pay. Over 400 existing customers responded to an online survey on willingness to pay for community education courses. Respondents were asked to provide data on the price they were willing to pay in response to a series of vignettes. They were asked to rate satisfaction level so that the strength of relationships between satisfaction and willingness to pay could be assessed. The survey also obtained data on attitudes to fair price setting and subsidy and on the factors respondents felt were important in making purchasing decisions. Self reported decision making data and benchmark prices predicted willingness to pay to a limited extent. Satisfaction with service also predicted willingness to pay with satisfaction with content and the accuracy of course descriptions and the pleasure derived from learning being the areas of satisfaction which translated most consistently into a willingness to pay higher prices. Bargain price points appear to be more sensitive to satisfaction than do points at which products start to become expensive. Respondents appeared to be basing judgments of fair pricing on cost of production and the ability of the individual to pay. The results are interpreted with an exchange theory model and contribute to understanding in that they offer an insight into the relative contributions of benchmarking and satisfaction to willingness to pay. In examining the relative contribution of different aspects of satisfaction the paper provides useful insight into aspects of service and product development that may be more important than others in building revenue.

Women in academia: a cross-cultural perspective on identity and work/life balance

BENINGER, A. (London School of Economics and Political Science)

What challenges do women in academia in the United Kingdom, Australia, and the United States face in achieving work/life balance? How do cultural norms and institutional and governmental policies affect this balance? Sixty academic women, 20 each in the UK, Australia, and the US, in permanent contract positions both with and without primary care responsibilities were recruited via email to take part in this study. They came from a diverse range of fields including anthropology, psychology, business, and medicine. In-depth interviews composed of 12 open-ended questions were conducted with each participant to provide a detailed look into the challenges these women face on a daily basis balancing work and life outside work. Following the interview, each participant filled out a survey with quantitative information regarding their domestic division of labour, specifically hours spent at work, on childcare, and on household tasks. The dominant live-to-work ideology of the UK, mirrored by the US, leads individuals to prioritize work over other parts of life and limits the use of progressive European Union policies. Australian participants, by contrast, described an egalitarian culture that encourages individuals to have a life outside of work, in turn fostering more progressive institutional and governmental policies that support a more desirable work/life balance in a mutually reinforcing cycle. The more desirable work/life balance promoted by institutional and governmental policies in Australia was found to reduce stress and minimize guilt among academic women, specifically with respect to childcare, improving overall life satisfaction. The results of this
research have important policy implications and provide cross-cultural comparisons that illuminate potential solutions to shared social problems.

Work and recovery: Different behavioural strategies to recover from work complexity and work interruptions in nearby nature

DEGENHARDT, B. (Swiss Federal Research Institute for Forest, Snow and Landscape WSL)

Work stress-related illnesses and health costs are increasing in modern societies. Nearby outdoor recreation areas are important for workday recreation, but little is known about the role nearby recreation behaviour plays for people in the recovery from workloads. This study aims to answer the question of whether nearby recreation behaviour is influenced by the work situation and whether different types of cognitive workload are associated with different nearby recreation behaviours. A total of 656 inhabitants (53% women) with an average age of 48 years from the Swiss peri-urban city of Frauenfeld (22'000 inhabitants) returned a postal questionnaire on work complexity and interruptions at work, and on their workday nearby recreation behaviour. They were specifically asked to indicate the frequency with which they realize diverse cognitive, emotional, physical and social use goals on workdays. Workloads were measured with Semmer, Zapf, and Dunckel’s (1999) stress-oriented job analysis instrument (ISTA) while use goals were measured with items adopted from different leisure scales and a qualitative pilot study. Multivariate regression analysis showed that variations in cognitive workloads correspond to different nearby outdoor recreation behaviours. Thus, people recover in nearby nature with specific behavioural strategies depending on the characteristics of their particular loads at work. Organizational health management and landscape management would be well advised to take the differentiations into account when designing restorative environments.

Work motivation of employees in production innovation: An exploratory study in the Chinese furniture industry

YU, N. (Albert-Ludwigs-University), LEWARK, S. (Albert-Ludwigs-University)

Innovation is one key element of industry development. In the past decade, the concepts of lean production and mass customization were introduced to developing countries. Substantial efforts of R&D have been made. Significant success was achieved by implementing new working systems or improving the existing ones, mainly as the result of using automatic machines, advanced information technology or production process reengineering. But unfortunately, neglecting work motivation of employees resulted in limited success of implementation of new working systems in enterprises. Therefore, an exploratory study was conducted to reveal the relationship between the nature of work and the motivation potential of employees in the process of technology innovation in the Chinese furniture industry. The study was carried out in three Chinese furniture enterprises, which were all in phases of production innovation, being large, medium and small sized enterprises, respectively. The questionnaire used in the research was modified, based on the Job Diagnostic Survey (JDS) in Chinese. The resultant questionnaire survey was validated with 190 incumbents holding 45 distinct jobs and demonstrated high reliability and convergent and discriminant validity. Based on the data analysis, the results showed that growth satisfaction ($r=.54, p<.01$) and feedback from agents ($r=.53, p<.01$) were significantly related to the motivating potential score (MPS, $M=113.5, SD=57.5$), which is a score reflecting the potential of a job for eliciting positive internal work motivation on the part of employees. Based on the study, we conclude that if managers and supervisors could devote more effort to considering the desire of personal growth of employees and setting up good communication and feedback mechanisms that would be helpful to motivate their employees and to gain greater success in production innovation in the Chinese furniture industry.

Work stressors, performance, and the moderating influence of engagement of knowledge employees

LI, Y. (Remin University of China)

As a test of the 2-dimensional model of work stressors, the present study proposed differential relationships between intrinsic stressors and extrinsic stressors and performance, which were expected to be moderated by employee engagement. A sample of 625 knowledge employees was tested by Work Stressor Scale (WSS), Role-based Performance Questionnaire and Employee Engagement Scale. There was significant age-and-gender interaction in work stressors. And the author obtained a positive relationship between intrinsic stressors and role-based performance and a negative relationship between extrinsic stressors and role-based performance. In addition, employee engagement moderated the relationship between intrinsic stressors and role-based performance. This suggests that organizations would pay more attention to intrinsic stressors of knowledge employees as long as they increase employee engagement and control the stressors from job characteristics. Further implications for organizational theory and practice are discussed.
